FEATURES

4-quadrant multiplication
Low cost, 8-lead SOIC and PDIP packages
Complete—no external components required
Laser-trimmed accuracy and stability
Total error within 2% of full scale
Differential high impedance X and Y inputs
High impedance unity-gain summing input
Laser-trimmed 10 V scaling reference

APPLICATIONS

Multiplication, division, squaring
Modulation/demodulation, phase detection
Voltage-controlled amplifiers/attenuators/filters

GENERAL DESCRIPTION

The AD633 is a functionally complete, four-quadrant, analog multiplier. It includes high impedance, differential X and Y inputs, and a high impedance summing input (Z). The low impedance output voltage is a nominal 10 V full scale provided by a buried Zener. The AD633 is the first product to offer these features in modestly priced 8-lead PDIP and SOIC packages.

The AD633 is laser calibrated to a guaranteed total accuracy of 2% of full scale. Nonlinearity for the Y input is typically less than 0.1% and noise referred to the output is typically less than 100 µV rms in a 10 Hz to 10 kHz bandwidth. A 1 MHz bandwidth, 20 V/µs slew rate, and the ability to drive capacitive loads make the AD633 useful in a wide variety of applications where simplicity and cost are key concerns.

The versatility of the AD633 is not compromised by its simplicity. The Z input provides access to the output buffer amplifier, enabling the user to sum the outputs of two or more multipliers, increase the multiplier gain, convert the output voltage to a current, and configure a variety of applications. For further information, see the Multiplier Application Guide.

PRODUCT HIGHLIGHTS

1. The AD633 is a complete four-quadrant multiplier offered in low cost 8-lead SOIC and PDIP packages. The result is a product that is cost effective and easy to apply.
2. No external components or expensive user calibration are required to apply the AD633.
3. Monolithic construction and laser calibration make the device stable and reliable.
4. High (10 MΩ) input resistances make signal source loading negligible.
5. Power supply voltages can range from ±8 V to ±18 V. The internal scaling voltage is generated by a stable Zener diode; multiplier accuracy is essentially supply insensitive.

The AD633 is available in 8-lead PDIP and SOIC packages. It is specified to operate over the 0°C to 70°C commercial temperature range (J Grade) or the −40°C to +85°C industrial temperature range (A Grade).

\(^1\) For supply voltages less than ±18 V, the absolute maximum input voltage is equal to the supply voltage.

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

### Thermal Resistance

\(\theta_{JA}\) is specified for the worst-case conditions, that is, a device soldered in a circuit board for surface-mount packages.

### ESD Caution

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

FUNCTIONAL DESCRIPTION
The AD633 is a low cost multiplier comprising a translinear core, a buried Zener reference, and a unity-gain connected output amplifier with an accessible summing node. Figure 1 shows the functional block diagram. The differential X and Y inputs are converted to differential currents by voltage-to-current converters. The product of these currents is generated by the multiplying core. A buried Zener reference provides an overall scale factor of 10 V. The sum of \((X \times Y)/10 + Z\) is then applied to the output amplifier. The amplifier summing Node Z allows the user to add two or more multiplier outputs, convert the output voltage to a current, and configure various analog computational functions.

Inspection of the block diagram shows the overall transfer function is

\[
W = \frac{(X_1 - X_2)(Y_1 - Y_2)}{10V} + Z
\]  

(1)

ERROR SOURCES
Multiplier errors consist primarily of input and output offsets, scale factor error, and nonlinearity in the multiplying core. The input and output offsets can be eliminated by using the optional trim of Figure 11. This scheme reduces the net error to scale factor errors (gain error) and an irreducible nonlinearity component in the multiplying core. The X and Y nonlinearities are typically 0.4% and 0.1% of full scale, respectively. Scale factor error is typically 0.25% of full scale. The high impedance Z input should always reference the ground point of the driven system, particularly if it is remote. Likewise, the differential X and Y inputs should reference their respective grounds to realize the full accuracy of the AD633.
APPLICATIONS INFORMATION

The AD633 is well suited for such applications as modulation and demodulation, automatic gain control, power measurement, voltage-controlled amplifiers, and frequency doublers. These applications show the pin connections for the AD633JN (8-lead PDIP), which differs from the AD633JR (8-lead SOIC).

MULTIPLIER CONNECTIONS

Figure 12 shows the basic connections for multiplication. The X and Y inputs normally have their negative nodes grounded, but they are fully differential, and in many applications, the grounded inputs may be reversed (to facilitate interfacing with signals of a particular polarity while achieving some desired output polarity), or both may be driven.

SQUARING AND FREQUENCY DOUBLING

As is shown in Figure 13, squaring of an input signal, E, is achieved simply by connecting the X and Y inputs in parallel to produce an output of $E^2/10 \text{ V}$. The input can have either polarity, but the output is positive. However, the output polarity can be reversed by interchanging the X or Y inputs. The Z input can be used to add a further signal to the output.

When the input is a sine wave $E \sin \omega t$, this squarer behaves as a frequency doubler, because

$$\frac{(E \sin \omega t)^2}{10 \text{ V}} = \frac{E^2}{20 \text{ V}} (1 - \cos 2 \omega t)$$

Equation 2 shows a dc term at the output that varies strongly with the amplitude of the input, E. This can be avoided using the connections shown in Figure 14, where an RC network is used to generate two signals whose product has no dc term. It uses the identity

$$\cos \theta \sin \theta = \frac{1}{2} (\sin 2\theta)$$

GENERATING INVERSE FUNCTIONS

Inverse functions of multiplication, such as division and square rooting, can be implemented by placing a multiplier in the feedback loop of an op amp. Figure 15 shows how to implement square rooting with the transfer function for the condition $E < 0$.

The $1N4148$ diode is required to prevent latchup, which can occur in such applications if the input were to change polarity, even momentarily.

$$W = \sqrt{-(10E)^2}$$

Equation 5
Likewise, Figure 16 shows how to implement a divider using a multiplier in a feedback loop. The transfer function for the divider is

\[ W = -10V \frac{E}{E_X} \]  

(6)

**VARIABLE SCALE FACTOR**

In some instances, it may be desirable to use a scaling voltage other than 10 V. The connections shown in Figure 17 increase the gain of the system by the ratio \((R_1 + R_2)/R_1\). This ratio is limited to 100 in practical applications. The summing input, \(S\), can be used to add an additional signal to the output, or it can be grounded.

\[ W = \frac{E}{10V} \left( \frac{X_1 - X_2}{(Y_1 - Y_2) + S} \right) \]  

Figure 17. Connections for Variable Scale Factor

**CURRENT OUTPUT**

The voltage output of the AD633 can be converted to a current output by the addition of a resistor, \(R\), between the \(W\) and \(Z\) pins of the AD633 as shown in Figure 18.

\[ I_o = \frac{1}{R} \frac{(X_1 - X_2)(Y_1 - Y_2)}{10V} \]  

(7)

**LINEAR AMplitude MODULATOR**

The AD633 can be used as a linear amplitude modulator with no external components. Figure 19 shows the circuit. The carrier and modulation inputs to the AD633 are multiplied to produce a double sideband signal. The carrier signal is fed forward to the \(Z\) input of the AD633 where it is summed with the double sideband signal to produce a double sideband with the carrier output.

**VOLTAGE-CONTROLLED, LOW-PASS AND HIGH-PASS FILTERS**

Figure 20 shows a single multiplier used to build a voltage-controlled, low-pass filter. The voltage at Output A is a result of filtering \(E_s\). The break frequency is modulated by \(E_c\), the control input. The break frequency, \(f_2\), equals

\[ f_2 = \frac{E_c}{10(2\pi RC)} \]  

(8)

and the roll-off is 6 dB per octave. This output, which is at a high impedance point, may need to be buffered.

\[ f_i = \frac{1}{2 \pi RC} \]  

(9)
For example, if $R = 8 \, \text{k}\Omega$ and $C = 0.002 \, \mu\text{F}$, then Output A has a pole at frequencies from 100 Hz to 10 kHz for $E_c$ ranging from 100 mV to 10 V. Output B has an additional 0 at 10 kHz (and can be loaded because it is the low impedance output of the multiplier). The circuit can be changed to a high-pass filter $Z$ interchanging the resistor and capacitor as shown in Figure 21.

**VOLTAGE-CONTROLLED QUADRATURE OSCILLATOR**

Figure 22 shows two multipliers being used to form integrators with controllable time constants in second-order differential equation feedback loop. $R_2$ and $R_5$ provide controlled current output operation. The currents are integrated in capacitors $C_1$ and $C_2$, and the resulting voltages at high impedance are applied to the X inputs of the next AD633. The frequency control input, $E_c$, connected to the Y inputs, varies the integrator gains with a calibration of 100 Hz/V. The accuracy is limited by the Y input offsets. The practical tuning range of this circuit is 100:1. $C_2$ (proportional to $C_1$ and $C_3$), $R_3$, and $R_4$ provide regenerative feedback to start and maintain oscillation. The diode bridge, $D_1$ through $D_4$ (1N914s), and Zener diode $D_5$ provide economical temperature stabilization and amplitude stabilization at ±8.5 V by degenerative damping. The output from the second integrator (10 V sin $\omega t$) has the lowest distortion.

**AUTOMATIC GAIN CONTROL (AGC) AMPLIFIERS**

Figure 23 shows an AGC circuit that uses an rms-to-dc converter to measure the amplitude of the output waveform. The AD633 and $A_1$, half of an AD712 dual op amp, form a voltage-controlled amplifier. The rms-to-dc converter, an AD736, measures the rms value of the output signal. Its output drives $A_2$, an integrator/comparator whose output controls the gain of the voltage-controlled amplifier. The 1N4148 diode prevents the output of $A_2$ from going negative. $R_8$, a 50 kΩ variable resistor, sets the output level of the circuit. Feedback around the loop forces the voltages at the inverting and noninverting inputs of $A_2$ to be equal, thus the AGC.
Figure 23. Connections for Use in Automatic Gain Control Circuit
MODEL RESULTS
Circuit simulation using SPICE models embedded in various application formats such as PSPICE, Multisim, and SIMetrix is a popular and efficient method of assessing the integrity of a circuit before creating the printed circuit board in which the circuits are ultimately used. Although impossible to demonstrate all of the multiplier functions in every available program, Figure 24 through Figure 41 demonstrate how the schematic and graph for simple dc, sin(x), and pulse applications appear in three popular SPICE programs. If a simulator is not shown here, a good way to progress is to start with a basic dc circuit to verify that the circuit converges and then continue with waveforms that are more complex. When analyzing nonlinear devices such as multipliers, the most common simulation issue is convergence, the iterative process by which SPICE seeks the initial dc bias condition before completely solving the circuit and displaying a graph.

Figure 24 through Figure 41 are arranged schematic first, followed by the graphic result. If the user has a problem with a simulator, the most efficient fix is to contact applications support for the program in use.

EXAMPLES OF DC, SIN, AND PULSE SOLUTIONS USING MULTISIM

EVALUATION BOARD

The evaluation board of the AD633 enables simple bench-top experimenting to be performed with easy control of the AD633. Built-in flexibility allows convenient configuration to accommodate most operating configurations. Figure 42 is a photograph of the AD633 evaluation board.

Any dual-polarity power supply capable of providing 10 mA or greater is all that is required to perform the intended tests, in addition to whatever test equipment the user wants.

Referring to the schematic in Figure 49, inputs to the multiplier are differential and dc-coupled. Three-position slide switches enhance flexibility by enabling the multiplier inputs to be connected to an active signal source, to ground, or to a test loop connected directly to the device pin for direct measurements, such as bias current. Inputs may be connected single ended or differentially, but must have a dc path to ground for bias current. If the impedance of an input source is non-zero, an equal value impedance must be connected to the opposite polarity input to avoid introducing additional offset voltage.

The AD633-EVALZ can be configured for multiplier or divider operation by switch S1. Refer to Figure 16 for divider circuit connections.

Figure 43 through Figure 46 are the signal, power, and ground-plane artworks, and Figure 47 shows the component and circuit side silkscreen. Figure 48 shows the assembly.
