FEATURES
- Dual 8-Bit ADCs on a Single Chip
- Low Power: 400 mW Typical
- On-Chip 2.5 V Reference and Track-and-Hold
- 1 V p-p Analog Input Range
- Single 5 V Supply Operation
- 5 V or 3 V Logic Interface
- 120 MHz Analog Bandwidth
- Power-Down Mode: <12 mW

APPLICATIONS
- Digital Communications (QAM Demodulators)
- RGB and YC/Composite Video Processing
- Digital Data Storage Read Channels
- Medical Imaging
- Digital Instrumentation

PRODUCT DESCRIPTION
The AD9059 is a dual 8-bit monolithic analog-to-digital converter optimized for low cost, low power, small size, and ease of use. With a 60 MSPS encode rate capability and full-power analog bandwidth of 120 MHz typical, the component is ideal for applications requiring multiple ADCs with excellent dynamic performance.

To minimize system cost and power dissipation, the AD9059 includes an internal 2.5 V reference and dual track-and-hold circuits. The ADC requires only a 5 V power supply and an encode clock. No external reference or driver components are required for many applications.

The AD9059’s single encode input is TTL/CMOS compatible and simultaneously controls both internal ADC channels. The parallel 8-bit digital outputs can be operated from 5 V or 3 V supplies. A power-down function may be exercised to bring total consumption to <12 mW when ADC data is not required for lengthy periods of time. In power-down mode, the digital outputs are driven to a high impedance state.

Fabricated on an advanced BiCMOS process, the AD9059 is available in a space-saving 28-lead shrink small outline package (28-lead SSOP) and is specified over the industrial temperature range (−40°C to +85°C).

Customers desiring single-channel digitization may consider the AD9057, a single 8-bit, 60 MSPS monolithic based on the AD9059 ADC core. The AD9057 is available in a 20-lead shrink small outline package (20-lead SSOP) and is specified over the industrial temperature range.

**NOTES**

1. Gain error and gain temperature coefficient are based on the ADC only (with a fixed 2.5 V external reference).
2. tV and tPD are measured from the 1.5 V level of the ENCODE to the 10%/90% levels of the digital output swing. The digital output load during test is not to exceed an ac load of 10 pF or a dc current of ±40 μA.
3. SNR/harmonics based on an analog input voltage of –0.5 dBFS referenced to a 1.0 V full-scale input range.
4. Digital supply current based on VDD = 3 V output drive with <10 pF loading under dynamic test conditions.
5. Power dissipation is based on 60 MSPS encode and 10.3 MHz analog input dynamic test conditions (VDD = 3 V ± 5%, VDD = 3 V ± 5%).
6. Typical thermal impedance for the RS style (SSOP) 28-lead package: θJC = 39°C/W, θJA = 70°C/W, and θCA = 109°C/W.

Specifications subject to change without notice.

### CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD9059 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

THEORY OF OPERATION
The AD9059 combines Analog Devices’ proprietary MagAmp grey code conversion circuitry with flash converter technology to provide dual high performance 8-bit ADCs in a single low cost monolithic device. The design architecture ensures low power, high speed, and 8-bit accuracy.

The AD9059 provides two linked ADC channels that are clocked from a single ENCODE input (see Functional Block Diagram). The two ADC channels simultaneously sample the analog inputs (AINA and AINB) and provide noninterleaved parallel digital outputs (D0A–D7A and D0B–D7B). The voltage reference (VREF) is internally connected to both ADCs so channel gains and offsets will track if external reference control is desired.

The analog input signal is buffered at the input of each ADC channel and applied to a high speed track-and-hold. The track-and-hold circuit holds the analog input value during the conversion process (beginning with the rising edge of the ENCODE command). The track-and-hold’s output signal passes through the grey code and flash conversion stages to generate coarse and fine digital representations of the held analog input level. Decode logic combines the multistage data and aligns the 8-bit word for strobed outputs on the rising edge of the ENCODE command. The MagAmp/Flash architecture of the AD9059 results in three pipeline delays for the output data.

USING THE AD9059

Analog Inputs
The AD9059 provides independent single-ended high impedance (150 kΩ) analog inputs for the dual ADCs. Each input requires a dc bias current of 6 µA (typical) centered near 2.5 V (±10%). The dc bias may be provided by the user or may be derived from the ADC’s internal voltage reference. Figure 2 shows a low cost dc bias implementation that allows the user to capacitively couple ac signals directly into the ADC without additional active circuitry. For best dynamic performance, the VREF pin should be decoupled to ground with a 0.1 µF capacitor (to minimize modulation of the reference voltage), and the bias resistor should be approximately 1 kΩ.

Figure 2. Capacity Coupled AD9059

Voltage Reference
A stable and accurate 2.5 V voltage reference is built into the AD9059 (VREF). The reference output is used to set the ADC gain/offset and can provide dc bias for the analog input signals. The internal reference is tied to the ADC circuitry through an 800 Ω internal impedance and is capable of providing 300 µA external drive current (for dc biasing the analog input or other user circuitry).

Some applications may require greater accuracy, improved temperature performance, or gain adjustments that cannot be obtained using the internal reference. An external voltage may be applied to the VREF pin to overdrive the internal voltage reference for gain adjustment of up to ±10% (the VREF pin is internally tied directly to the ADC circuitry). ADC gain and offset will vary simultaneously with external reference adjustment with a 1:1 ratio (a 2% or 50 mV adjustment to the 2.5 V reference varies ADC gain by 2% and ADC offset by 50 mV).

Theoretical input voltage range versus reference input voltage may be calculated using the following equations.

\[ V_{\text{range}} (p-p) = V_{\text{REF}} / 2.5 \]
\[ V_{\text{midscale}} = V_{\text{REF}} \]
\[ V_{\text{top-of-range}} = V_{\text{REF}} + V_{\text{range}} / 2 \]
\[ V_{\text{bottom-of-range}} = V_{\text{REF}} - V_{\text{range}} / 2 \]

The external reference should have a 1 mA minimum sink/source current capability to ensure complete overdrive of the internal voltage reference.

Figure 3 shows typical connections for high performance dc biasing using the ADC’s internal voltage reference. All components may be powered from a single 5 V supply (analog input signals are referenced to ground).

Figure 3. DC-Coupled AD9059 (VIN Inverted)
AD9059

Digital Logic (5 V/3 V Systems)
The digital inputs and outputs of the AD9059 can easily be configured to interface directly with 3 V or 5 V logic systems. The encode and power-down (PWRDN) inputs are CMOS stages with TTL thresholds of 1.5 V, making the inputs compatible with TTL, 5 V CMOS, and 3 V CMOS logic families. As with all high speed data converters, the encode signal should be clean and jitter free to prevent degradation of ADC dynamic performance.

The AD9059’s digital outputs will also interface directly with 5 V or 3 V CMOS logic systems. The voltage supply pins (VDD) for these CMOS stages are isolated from the analog VD voltage supply. By varying the voltage on these supply pins, the digital output high levels will change for 5 V or 3 V systems. The VDD pins are internally connected on the AD9059 die. Care should be taken to isolate the VDD supply voltages from the 5 V analog supply to minimize noise coupling into the ADCs.

The AD9059 provides high impedance digital output operation when the ADC is driven into power-down mode (PWRDN, logic high). A 200 ns (minimum) power-down time should be provided before a high impedance characteristic is required. A 200 ns power-up period should be provided to ensure accurate ADC output data after reactivation (valid output data is available three clock cycles after the 200 ns delay).

Timing
The AD9059 is guaranteed to operate with conversion rates from 5 MSPS to 60 MSPS. At 60 MSPS, the ADC is designed to operate with an encode duty cycle of 50%, but performance is insensitive to moderate variations. Pulsed width variations of up to ±10% (allowing the encode signal to meet the minimum/maximum high/low specifications) will cause no degradation in ADC performance (see Figure 1).

Due to the linked ENCODE architecture of the ADCs, the AD9059 cannot be operated in a 2-channel ping-pong mode.

Power Dissipation
The power dissipation of the AD9059 is specified to reflect a typical application setup under the following conditions: encode is 60 MSPS, analog input is –0.5 dBFS at 10.3 MHz, VD is 5 V, VDD is 3 V, and digital outputs are loaded with 7 pF typical (10 pF maximum). The actual dissipation will vary as these conditions are modified in user applications. TPC 7 shows typical power consumption for the AD9059 versus ADC encode frequency and VDD supply voltage.

A power-down function allows users to reduce power dissipation when ADC data is not required. A TTL/CMOS high signal (PWRDN) shuts down portions of the dual ADC and brings total power dissipation to less than 10 mW. The internal band gap voltage reference remains active during power-down mode to minimize ADC reactivation time. If the power-down function is not desired, Pin 3 should be tied to ground. Both ADC channels are controlled simultaneously by the PWRDN pin; they cannot be shut down or turned on independently.

Applications
The wide analog bandwidth of the AD9059 makes it attractive for a variety of high performance receiver and encoder applications. Figure 4 shows the dual ADC in a typical low cost I and Q demodulator implementation for cable, satellite, or wireless LAN modem receivers. The excellent dynamic performance of the ADC at higher analog input frequencies and encode rates empowers users to employ direct IF sampling techniques (see TPC 2). IF sampling eliminates or simplifies analog mixer and filter stages to reduce total system cost and power.
Evaluation Board

The AD9059/PCB evaluation board provides an easy-to-use analog/digital interface for the dual 8-bit, 60 MSPS ADC. The board includes typical hardware configurations for a variety of high speed digitization evaluations. On-board components include the AD9059 (in the 28-lead SSOP package), optional analog input buffer amplifiers, digital output latches, board timing drivers, and configurable jumpers for ac coupling, dc coupling, and power-down function testing. The board is configured at shipment for dc coupling using the AD9059's internal reference.

For dc-coupled analog input applications, amplifiers U3 and U4 are configured to operate as unity gain inverters with adjustable offset for the analog input signals. For full-scale ADC drive, each analog input signal should be 1 V p-p into 50 Ω referenced to ground. Each amplifier offsets its analog signal by +VREF (2.5 V typical) to center the voltage for proper ADC input drive. For dc-coupled operation, connect E7 to E9 (analog input A to R11), E14 to E13 (amplifier output to analog input A of AD9059), E4 to E5 (analog input B to R10), and E11 to E10 (amplifier output to analog input B of AD9059) using the board jumper connectors.

For ac-coupled analog input applications, amplifiers U3 and U4 are removed from the analog signal paths. The analog signals are coupled through Capacitors C11 and C12, each terminated to the VREF voltage through separate 1 kΩ resistors (providing bias current for the AD9059 analog inputs, AINA and AINB). Analog input signals to the board should be 1 V p-p into 50 Ω for full-scale ADC drive. For ac-coupled operation, connect E7 to E8 (analog input A to C12 feedthrough capacitor), E13 to E15 (C12 to R15 termination resistor for Channel A), E4 to E6 (analog input B to C11 feedthrough capacitor), and E10 to E12 (C11 to R14 termination resistor for Channel B) using the board jumper connectors.

The on-board reference voltage may be used to drive the ADC or an external reference may be applied. The standard configuration employs the internal voltage reference without any external connection requirements. An external voltage reference may be applied at board connector input REF to overdrive the limited current output of the AD9059’s internal voltage reference. The external voltage reference should be 2.5 V typical.

The power-down function of the AD9059 can be exercised through a board jumper connection. Connect E2 to E1 (5 V to PWRDN) for power-down mode operation. For normal operation, connect E3 to E1 (ground to PWRDN).

The encode signal source should be TTL/CMOS compatible and capable of driving a 50 Ω termination. The digital outputs of the AD9059 are buffered through latches on the evaluation board (U5 and U6) and are available for the user at connector Pins 30–37 and Pins 22–29. Latch timing is derived from the ADC ENCODE clock and a digital clocking signal is provided for the board user at connector Pins 2 and 21.
