FEATURERS
HDMI interface
- Supports high bandwidth digital content protection
- RGB to YCbCr 2-way color conversion
- 1.8 V/3.3 V power supply
- 100-lead, Pb-free LQFP
- RGB and YCbCr output formats
Digital video interface
- HDMI 1.1, DVI 1.0
- 150 MHz HDMI receiver
- Supports high bandwidth digital content protection (HDCP 1.1)
Digital audio interface
- HDMI 1.1-compatible audio interface
- SPDIF (IEC90658-compatible) digital audio output
- Multichannel I2S audio output (up to 8 channels)

APPLICATIONS
- Advanced TVs
- HDTVs
- Projectors
- LCD monitors

GENERAL DESCRIPTION
The AD9398 offers a high definition multimedia interface (HDMI) receiver integrated on a single chip. Also included is support for high bandwidth digital content protection (HDCP).

The AD9398 contains a HDMI 1.0-compatible receiver and supports all HDTV formats (up to 1080p) and display resolutions up to SXGA (1280 × 1024 @ 75 Hz). The receiver features an intrapair skew tolerance of up to one full clock cycle. With the inclusion of HDCP, displays can now receive encrypted video content. The AD9398 allows for authentication of a video receiver, decryption of encoded data at the receiver, and renewability of that authentication during transmission as specified by the HDCP 1.1 protocol.

Fabricated in an advanced CMOS process, the AD9398 is provided in a space-saving 100-lead, surface-mount, Pb-free, plastic LQFP and is specified over the 0°C to 70°C temperature range.

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

</tr>
</tbody>
</table>

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although this product features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

DESIGN GUIDE

GENERAL DESCRIPTION

The AD9398 is a fully integrated solution for receiving DVI/HDMI signals and is capable of decoding HDCP-encrypted signals through connections to an external EEPROM. The circuit is ideal for providing an interface for HDTV monitors or as the front end to high performance video scan converters.

Implemented in a high performance CMOS process, the interface can capture signals with pixel rates of up to 150 MHz.

The AD9398 includes all necessary circuitry for decoding TMDS signaling including those encrypted with HDCP. Included in the output formatting is a color space converter (CSC), which accommodates any input color space and can output any color space. All controls are programmable via a 2-wire serial interface. Full integration of these sensitive mixed signal functions makes system design straightforward and less sensitive to the physical and electrical environments.

DIGITAL INPUTS

The digital control inputs (I2C) on the AD9398 operate to 3.3 V CMOS levels. In addition, all digital inputs, except the TMDS (HDMI/DVI) inputs, are 5 V tolerant (applying 5 V to them does not cause damage.) The TMDS input pairs (Rx0+/Rx0−, Rx1+/Rx1−, Rx2+/Rx2−, and RxC+/RxC−) must maintain a 100 Ω differential impedance (through proper PCB layout) from the connector to the input where they are internally terminated (50 Ω to 3.3 V). If additional ESD protection is desired, use of a California Micro Devices (CMD) CM1213 (among others) series low capacitance ESD protection offers 8 kV of protection to the HDMI TMDS lines.

SERIAL CONTROL PORT

The serial control port is designed for 3.3 V logic. However, it is tolerant of 5 V logic signals.

OUTPUT SIGNAL HANDLING

The digital outputs operate from 1.8 V to 3.3 V (VDD).

POWER MANAGEMENT

The AD9398 uses the activity detect circuits, the active interface bits in the serial bus, the active interface override bits, the power-down bit, and the power-down pin to determine the correct power state. There are four power states: full power, seek mode, auto power-down, and power-down. Table 7 summarizes how the AD9398 determines the power mode to use and which circuitry is powered on/off in each of these modes. The power-down command has priority and then the automatic circuitry. The power-down pin (Pin 81—polarity set by Register 0x26[3]) can drive the chip into four power-down options. Bit 2 and Bit 1 of Register 0x26 control these four options. Bit 0 controls whether the chip is powered down or the outputs are placed in high impedance mode (with the exception of SOG). Bit 7 to Bit 4 of Register 0x26 control whether the outputs, SOG, Sony Philips digital interface (SPDIF) or Inter-IC sound bus (I’S or IIS) outputs are in high impedance mode. See the 2-Wire Serial Control Register Detail section for the details.

</tbody>
</table>

1 Power-down is controlled via Bit 0 in Serial Bus Register 0x26.
2 Sync detect is determined by OR’ing Bit 7 to Bit 2 in Serial Bus Register 0x15.
3 Auto power-down is controlled via Bit 7 in Serial Bus Register 0x27.
TIMING
The output data clock signal is created so that its rising edge always occurs between data transitions and can be used to latch the output data externally.

Figure 3 shows the timing operation of the AD9398.

VSYNC FILTER AND ODD/EVEN FIELDS
The VSYNC filter is used to eliminate spurious VSYNCs, maintain a consistent timing relationship between the VSYNC and HSYNC output signals, and generate the odd/odd field output.

The filter works by examining the placement of VSYNC with respect to HSYNC and, if necessary, slightly shifting it in time at the VSOUT output. The goal is to keep the VSYNC and HSYNC leading edges from switching at the same time, eliminating confusion as to when the first line of a frame occurs. Enabling the VSYNC filter is done with Register 0x21[5]. Use of the VSYNC filter is recommended for all cases, including interlaced video, and is required when using the HSYNC per VSYNC counter. Figure 4 and Figure 5 illustrate even/odd field determination in two situations.

HDMI RECEIVER
The HDMI receiver section of the AD9398 allows the reception of a digital video stream, which is backward compatible with DVI and able to accommodate not only video of various formats (RGB, YCrCb 4:4:4, 4:2:2), but also up to eight channels of audio. Infoframes are transmitted carrying information about the video format, audio clocks, and many other items necessary for a monitor to use fully the information stream available.

The earlier digital visual interface (DVI) format was restricted to an RGB 24-bit color space only. Embedded in this data stream were HSYNCs, VSYNCs, and display enable (DE) signals, but no audio information. The HDMI specification allows transmission of all the DVI capabilities, but adds several YCrCb formats that make the inclusion of a programmable color space converter (CSC) a very desirable feature. With this, the scaler following the AD9398 can specify that it always wishes to receive a particular format—for instance, 4:2:2 YCrCb—regardless of the transmitted mode. If RGB is sent, the CSC can easily convert that to 4:2:2 YCrCb while relieving the scaler of this task.

In addition, the HDMI specification supports the transmission of up to eight channels of S/PDIF or I²S audio. The audio information is packetized and transmitted during the video blanking periods along with specific information about the clock frequency. Part of this audio information (audio infoframe) tells the user how many channels of audio are being transmitted, where they should be placed, information regarding the source (make, model), and other data.

DE GENERATOR
The AD9398 has an on-board generator for DE, for start of active video (SAV), and for end of active video (EAV), all of which are necessary for describing the complete data stream for a BT656-compatible output. In addition to this particular output, it is possible to generate the DE for cases in which a scaler is not used. This signal alerts the following circuitry as to which are displayable video pixels.
4:4:4 TO 4:2:2 FILTER

The AD9398 contains a filter that allows it to convert a signal from YCrCb 4:4:4 to YCrCb 4:2:2 while maintaining the maximum accuracy and fidelity of the original signal.

Input Color Space to Output Color Space

The AD9398 can accept a wide variety of input formats and either retain that format or convert to another. Input formats supported are:

- 4:4:4 YCrCb 8-bit
- 4:2:2 YCrCb 8-, 10-, and 12-bit
- RGB 8-bit

Output modes supported are:

- 4:4:4 YCrCb 8-bit
- 4:2:2 YCrCb 8-, 10-, and 12-bit
- Dual 4:2:2 YCrCb 8-bit

Color Space Conversion (CSC) Matrix

The CSC matrix in the AD9398 consists of three identical processing channels. In each channel, three input values are multiplied by three separate coefficients. Also included are an offset value for each row of the matrix and a scaling multiple for all values. Each value has a 13-bit, twos complement resolution to ensure the signal integrity is maintained. The CSC is designed to run at speeds up to 150 MHz, supporting resolutions up to 1080p at 60 Hz. With any-to-any color space support, formats such as RGB, YUV, YCbCr, and others are supported by the CSC.

The main inputs, R\(_{IN}\), G\(_{IN}\), and B\(_{IN}\) come from the 8- to 12-bit inputs from each channel. These inputs are based on the input format detailed in Table 10. The mapping of these inputs to the CSC inputs is shown in Table 8.

Table 8. CSC Port Mapping

<table>
<thead>
<tr>
<th>Input Channel</th>

<td>R(_{IN})</td>
</tr>
<tr>
<td>Gr/Y</td>
<td>G(_{IN})</td>
</tr>
<tr>
<td>B/CB</td>
<td>B(_{IN})</td>
</tr>
</tbody>
</table>

One of the three channels is represented in Figure 6. In each processing channel, the three inputs are multiplied by three separate coefficients marked a1, a2, and a3. These coefficients are divided by 4096 to obtain nominal values ranging from −0.9998 to +0.9998. The variable labeled a4 is used as an offset control. The CSC_Mode setting is the same for all three processing channels. This multiplies all coefficients and offsets by a factor of \(2^{\text{CSC\_Mode}}\).

The functional diagram for a single channel of the CSC, as shown in Figure 6, is repeated for the remaining G and B channels. The coefficients for these channels are b1, b2, b3, b4, c1, c2, c3, and c4.

A programming example and register settings for several common conversions are listed in the Color Space Converter (CSC) Common Settings section.

For a detailed functional description and more programming examples, refer to Application Note AN-795, AD9880 Color Space Converter User’s Guide.
AUDIPLL SETUP

Data contained in the audio infoframes, among other registers, define for the AD9398 HDMI receiver not only the type of audio, but the sampling frequency ($f_s$). The audio infoframe also contains information about the N and CTS values used to recreate the clock. With this information, it is possible to regenerate the audio sampling frequency. The audio clock is regenerated by dividing the 20-bit CTS value into the TMDS clock, then multiplying by the 20-bit N value. This yields a multiple of the sampling frequency of either $128 \times f_s$ or $256 \times f_s$. It is possible for this to be specified up to $1024 \times f_s$.

In order to provide the most flexibility in configuring the audio sampling clock, an additional PLL is employed. The PLL characteristics are determined by the loop filter design, the PLL charge pump current, and the VCO range setting. The loop filter design is shown in Figure 8.

![Figure 8. PLL Loop Filter Detail](image)

To fully support all audio modes for all video resolutions up to 1080p, it is necessary to adjust certain audio-related registers from their power-on default values. Table 9 describes these registers and gives the recommended settings.

1N AND CTS VALUES ARE TRANSMITTED USING THE AUDIO CLOCK REGENERATION PACKET. VIDEO CLOCK IS TRANSMITTED ON TMDS CLOCK CHANNEL.
**AUDIO BOARD LEVEL MUTING**

The audio can be muted through the infoframes or locally via the serial bus registers. This can be controlled with Register R0x57, Bits [7:4].

**AVI Infoframes**

The HDMI TMDS transmission contains infoframes with specific information for the monitor such as:

- Audio information
  - 2 channels to 8 channels of audio identified
- Audio coding
- Audio sampling frequency
- Speaker placement
- N and CTS values (for reconstruction of the audio)
- Muting
- Source information
  - CD
  - SACD
  - DVD
- Video information
  - Video ID code (per CEA861B)
  - Color space
  - Aspect ratio
  - Horizontal and vertical bar information
  - MPEG frame information (I, B, or P frame)
- Vendor (transmitter source) name and product model

This information is the fundamental difference between DVI and HDMI transmissions and is located in read-only registers R0x5A to R0xEE. In addition to this information, registers are provided to indicate that new information has been received. Registers with addresses ending in 0x7 or 0xF beginning at R0x87 contain the new data flag (NDF) information. These registers contain the same information and all are reset once any of them are read. Although there is no external interrupt signal, it is very easy for the user to read any of these registers to see if there is new information to be processed.

**OUTPUT DATA FORMATS**

The AD9398 supports 4:4:4, 4:2:2, double data rate (DDR), and BT656 output formats. Register 0x25[3:0] controls the output mode. These modes and the pin mapping are listed in Table 10.

## 2-WIRE SERIAL REGISTER MAP

The AD9398 is initialized and controlled by a set of registers that determines the operating modes. An external controller is employed to write and read the control registers through the 2-wire serial interface port.

</table>
2-WIRE SERIAL CONTROL REGISTER DETAILS

CHIP IDENTIFICATION

0x00—Bits[7:0] Chip Revision
An 8-bit value that reflects the current chip revision.

0x11—Bit[7] HSYNC Source
0 = HSYNC, 1 = SOG. The power-up default is 0. These selections are ignored if Register 0x11, Bit 6 = 0.

0x11—Bit[6] HSYNC Source Override
0 = auto HSYNC source, 1 = manual HSYNC source. Manual HSYNC source is defined in Register 0x11, Bit 7. The power-up default is 0.

0x11—Bit[5] VSYNC Source
0 = VSYNC, 1 = VSYNC from SOG. The power-up default is 0. These selections are ignored if Register 0x11, Bit 4 = 0.

0x11—Bit[4] VSYNC Source Override
0 = auto VSYNC source, 1 = manual VSYNC source. Manual VSYNC source is defined in Register 0x11, Bit 5. The power-up default is 0.

0x11—Bit[3] Channel Select
0 = Channel 0, 1 = Channel 1. The power-up default is 0. These selections are ignored if Register 0x11, Bit 2 = 0.

0x11—Bit[2] Channel Select Override
0 = auto channel select, 1 = manual channel select. Manual channel select is defined in Register 0x11, Bit 3. The power-up default is 0.

0x11—Bit[1] Interface Select
0 = analog interface, 1 = digital interface. The power-up default is 0. These selections are ignored if Register 0x11, Bit 0 = 0.

0x11—Bit[0] Interface Select Override
0 = auto interface select, 1 = manual interface select. Manual interface select is defined in Register 0x11, Bit 1. The power-up default is 0.

0x12—Bit[7] Input HSYNC Polarity
0 = active low, 1 = active high. The power-up default is 1. These selections are ignored if Register 0x11, Bit 6 = 0.

0x12—Bit[6] HSYNC Polarity Override
0 = auto HSYNC polarity, 1 = manual HSYNC polarity. Manual HSYNC polarity is defined in Register 0x11, Bit 7. The power-up default is 0.

0x12—Bit[5] Input VSYNC Polarity
0 = active low, 1 = active high. The power-up default is 1. These selections are ignored if Register 0x11, Bit 4 = 0.

0x12—Bit[4] VSYNC Polarity Override
0 = auto VSYNC polarity, 1 = manual VSYNC polarity. Manual VSYNC polarity is defined in Register 0x11, Bit 5. The power-up default is 0.

0x17—Bits[3:0] HSYNCs per VSYNC MSBs
The 4 MSBs of the 12-bit counter that reports the number of HSYNCs/VSYNC on the active input. This is useful in determining the mode and aid in setting the PLL divide ratio.

0x18—Bit[7:0] HSYNCs per VSYNC LSBs
The 8 LSBs of the 12-bit counter that reports the number of HSYNCs/VSYNC on the active input.

0x21—Bit[5] VSYNC Filter Enable
The purpose of the VSYNC filter is to guarantee the position of the VSYNC edge with respect to the HSYNC edge and to generate a field signal. The filter works by examining the placement of VSYNC and regenerating a correctly placed VSYNC one line later. The VSYNC is first checked to see whether it occurs in the Field 0 position or the Field 1 position. This is done by checking the leading edge position against the sync separator threshold and the HSYNC position. The HSYNC width is divided into four quadrants with Quadrant 1 starting at the HSYNC leading edge plus a sync separator threshold. If the VSYNC leading edge occurs in Quadrant 1 or Quadrant 4, the field is set to 0 and the output VSYNC is placed coincident with the HSYNC leading edge. If the VSYNC leading edge occurs in Quadrant 2 or Quadrant 3, the field is set to 1 and the output VSYNC leading edge is placed in the center of the line. In this way, the VSYNC filter creates a predictable relative position between HSYNC and VSYNC edges at the output.

If the VSYNC occurs near the HSYNC edge, this guarantees that the VSYNC edge follows the HSYNC edge. This performs filtering also in that it requires a minimum of 64 lines between VSYNCs. The VSYNC filter cleans up extraneous pulses that might occur on the VSYNC. This should be enabled whenever the HSYNC/VSYNC count is used. Setting this bit to 0 disables the VSYNC filter. Setting this bit to 1 enables the VSYNC filter. Power-up default is 0.

0x21—Bit[4] VSYNC Duration Enable
This enables the VSYNC duration block which is designed to be used with the VSYNC filter. Setting the bit to 0 leaves the VSYNC output duration unchanged; setting the bit to 1 sets the VSYNC output duration based on Register 0x22. The power-up default is 0.

0x22—Bits[7:0] VSYNC Duration
This is used to set the output duration of the VSYNC, and is designed to be used with the VSYNC filter. This is valid only if Register 0x21, Bit 4 is set to 1. Power-up default is 4.
**0x23—Bits[7:0] HSYNC Duration**

An 8-bit register that sets the duration of the HSYNC output pulse. The leading edge of the HSYNC output is triggered by the internally generated, phase-adjusted PLL feedback clock. The AD9398 then counts a number of pixel clocks equal to the value in this register. This triggers the trailing edge of the HSYNC output, which is also phase-adjusted. The power-up default is 32.

**0x24—Bit[7] HSYNC Output Polarity**

This bit sets the polarity of the HSYNC output. Setting this bit to 0 sets the HSYNC output to active low. Setting this bit to 1 sets the HSYNC output to active high. The power-up default setting is 1.

**0x24—Bit[6] VSYNC Output Polarity**

This bit sets the polarity of the VSYNC output (both DVI and analog). Setting this bit to 0 sets the VSYNC output to active low. Setting this bit to 1 sets the VSYNC output to active high. Power-up default is 1.

**0x24—Bit[5] Display Enable Output Polarity**

This bit sets the polarity of the display enable (DE) for both DVI and analog. 0 = DE output polarity is negative. 1 = DE output polarity is positive. The power-up default is 1.

**0x24—Bit[4] Field Output Polarity**

This bit sets the polarity of the field output signal on Pin 21. 0 = active low = even field; active high = odd field. 1 = active low = odd field; active high = even field. The power-up default setting is 1.

**0x24—Bit[0] Output Clock Invert**

This bit allows inversion of the output clock as specified by Register 0x25, Bit 7 to Bit 6. 0 = noninverted clock. 1 = inverted clock. The power-up default setting is 0.

**0x25—Bits[7:6] Output Clock Select**

These bits select the clock output on the DATACLK pin. They include ½× clock, a 2× clock, a 90° phase shifted clock, or the normal pixel clock. The power-up default setting is 01.

**0x25—Bits[5:4] Output Drive Strength**

These two bits select the drive strength for all the high speed digital outputs (except VSOUT, A0, and O/E FIELD). Higher drive strength results in faster rise/fall times and in general makes it easier to capture data. Lower drive strength results in slower rise/fall times and helps to reduce EMI and digitally generated power supply noise. The power-up default setting is 11.

**Table 13. Output Drive Strength**

<tr>
<td>11</td>
<td>High output drive strength</td>
</tr>
</tbody>
</table>

**0x25—Bits[3:2] Output Mode**

These bits choose between four options for the output mode, one of which is exclusive to an HDMI input. 4:4:4 mode is standard RGB; 4:2:2 mode is YCrCb, which reduces the number of active output pins from 24 to 16; 4:4:4 is double data rate (DDR) output mode; and the data is RGB mode that changes on every clock edge. The power-up default setting is 00.

**Table 14. Output Mode**

</tbody>
</table>

**0x25—Bit[1] Primary Output Enable**

This bit places the primary output in active or high impedance mode. The primary output is designated when using either 4:2:2 or DDR 4:4:4. In these modes, the data on the red and green output channels is the primary output, while the output data on the blue channel (DDR YCrCb) is the secondary output. 0 = primary output is in high impedance mode. 1 = primary output is enabled. The power-up default setting is 1.

**0x25—Bit[0] Secondary Output Enable**

This bit places the secondary output in active or high impedance mode. The secondary output is designated when using either 4:2:2 or DDR 4:4:4. In these modes, the data on the blue output channel is the secondary output, while the output data on the red and green channels is the primary output. Secondary output is always a DDR YCrCb data mode. 0 = secondary output is in high impedance mode. 1 = secondary output is enabled. The power-up default setting is 0.
0x26—Bit[7] Output Three-State
When enabled, this bit puts all outputs (except SOGOUT) in a high impedance state. 0 = normal outputs. 1 = all outputs (except SOGOUT) in high impedance mode. The power-up default setting is 0.

0x26—Bit[5] S/PDIF Three-State
When enabled, this bit places the S/PDIF audio output pins in a high impedance state. 0 = normal S/PDIF output. 1 = S/PDIF pins in high impedance mode. The power-up default setting is 0.

0x26—Bit[4] I²S Three-State
When enabled, this bit places the I²S output pins in a high impedance state. 0 = normal I²S output. 1 = I²S pins in high impedance mode. The power-up default setting is 0.

0x26—Bit[3] Power-Down Polarity
This bit defines the polarity of the input power-down pin. 0 = power-down pin is active low. 1 = power-down pin is active high. The power-up default setting is 1.

0x26—Bits[2:1] Power-Down Pin Function
These bits define the different operational modes of the power-down pin. These bits are functional only when the power-down pin is active; when it is not active, the part is powered up and functioning. 0 = the chip is powered down and all outputs are in high impedance mode. 1 = the chip remains powered up, but all outputs are in high impedance mode. The power-up default setting is 00.

0x26—Bit[0] Power-Down
This bit is used to put the chip in power-down mode. In this mode, the power dissipation is reduced to a fraction of the typical power (see Table 1 for exact power dissipation). When in power-down, the HSOUT, VSOUT, DATACK, and all 30 of the data outputs are put into a high impedance state. Note that the SOGOUT output is not put into high impedance. Circuit blocks that continue to be active during power-down include the voltage references, sync processing, sync detection, and the serial register. These blocks facilitate a fast start-up from power-down. 0 = normal operation. 1 = power-down. The power-up default setting is 0.

0x27—Bit[7] Auto Power-Down Enable
This bit enables the chip to go into low power mode, or seek mode if no sync inputs are detected. 0 = auto power-down disabled. 1 = chip powers down if no sync inputs present. The power-up default setting is 1.

0x27—Bit[6] HDCP A0 Address
This bit sets the LSB of the address of the HDCP I²C. This should be set to 1 only for a second receiver in a dual-link configuration. The power-up default is 0.

0x27—Bit[5] MCLK External Enable
This bit enables the MCLK to be supplied externally. If an external MCLK is used, then it must be locked to the video clock according to the CTS and N available in the I²C. Any mismatch between the internal MCLK and the input MCLK results in dropped or repeated audio samples. 0 = use internally generated MCLK. 1 = use external MCLK input. The power-up default setting is 0.

BT656 GENERATION
0x27—Bit[4] BT656 Enable
This bit enables the output to be BT656 compatible with the defined start of active video (SAV) and the end of active video (EAV) controls to be inserted. These require specification of the number of active lines, active pixels per line, and delays to place these markers. 0 = disable BT656 video mode. 1 = enable BT656 video mode. The power-up default setting is 0.

0x27—Bit[3] Force DE Generation
This bit allows the use of the internal DE generator in DVI mode. 0 = internal DE generation disabled. 1 = force DE generation via programmed registers. The power-up default setting is 0.

0x27—Bits[2:0] Interlace Offset
These bits define the offset in HSYNCs from Field 0 to Field 1. The power-up default setting is 000.

0x28—Bits[7:2] VSYNC Delay
These bits set the delay (in lines) from the leading edge of VSYNC to active video. The power-up default setting is 24.

0x28—Bits[1:0] HSYNC Delay MSBs
Together with Register 0x29, these 10 bits set the delay (in pixels) from the HSYNC leading edge to the start of active video. The power-up default setting is 0x104.

0x29—Bits[7:0] HSYNC Delay LSBs
See the HSYNC Delay MSBs section.

0x2A—Bits[3:0] Line Width MSBs
Together with Register 0x2B, these 12 bits set the width of the active video line (in pixels). The power-up default setting is 0x500.

0x2B—Bits[7:0] Line Width LSBs
See the Line Width MSBs section.

0x2C—Bits[3:0] Screen Height MSBs
Along with the 8 bits following these 12 bits, set the height of the active screen (in lines). The power-up default setting is 0x2D0.

0x2D—Bits[7:0] Screen Height LSBs
See the Screen Heights MSBs section.
**0x2E—Bit[7] Ctrl Enable**
When set, this bit allows Ctrl [3:0] signals decoded from the DVI to be output on the I²S data pins. 0 = I²S signals on I²S lines. 1 = Ctrl[3:0] output on I²S lines. The power-up default setting is 0.

**0x2E—Bits[6:5] I²S Output Mode**
These bits select between four options for the I²S output: I²S, right-justified, left-justified, or raw IEC60958 mode. The power-up default setting is 00.

<table>
<thead>
<tr>
<th>I²S Output Mode</th>
<th>Result</th>

<tr>
<td>11</td>
<td>Raw IEC60958 mode</td>
</tr>
</tbody>
</table>

**0x2E—Bits[4:0] I²S Bit Width**
These bits set the I²S bit width for right-justified mode. The power-up default setting is 24 bits.

**0x2F—Bit[6] TMDS Sync Detect**
This read-only bit indicates the presence of a TMDS DE. 0 = no TMDS DE present. 1 = TMDS DE detected.

**0x2F—Bit[5] TMDS Active**
This read-only bit indicates the presence of a TMDS clock. 0 = no TMDS clock present. 1 = TMDS clock detected.

**0x2F—Bit[4] AV Mute**
This read-only bit indicates the presence of AV mute based on general control packets. 0 = AV not muted. 1 = AV muted.

**0x2F—Bit[3] HDCP Keys Read**
This read-only bit reports if the HDCP keys were read successfully. 0 = failure to read HDCP keys. 1 = HDCP keys read.

**0x2F—Bits[2:0] HDMI Quality**
These read-only bits indicate a level of HDMI quality based on the DE (display enable) edges. A larger number indicates a higher quality.

**0x30—Bit[6] HDMI Content Encrypted**
This read-only bit is high when HDCP decryption is in use (content is protected). The signal goes low when HDCP is not being used. Customers can use this bit to determine whether to allow copying of the content. The bit should be sampled at regular intervals because it can change on a frame-by-frame basis. 0 = HDCP not in use. 1 = HDCP decryption in use.

**0x30—Bit[5] DVI HSYNC Polarity**
This read-only bit indicates the polarity of the DVI HSYNC. 0 = DVI HSYNC polarity is low active. 1 = DVI HSYNC polarity is high active.

**0x30—Bit[4] DVI VSYNC Polarity**
This read-only bit indicates the polarity of the DVI VSYNC. 0 = DVI VSYNC polarity is low active. 1 = DVI VSYNC polarity is high active.

**0x30—Bits[3:0] HDMI Pixel Repetition**
These read-only bits indicate the pixel repetition on DVI. 0 = 1×, 1 = 2×, 2 = 3×, up to a maximum repetition of 10× (0x9).

<table>

**MACROVISION**

**0x31—Bits[7:4] Macrovision Pulse Max**
These bits set the pseudo sync pulse width maximum for Macrovision detection in pixel clocks. This is functional for 13.5 MHz SDTV or 27 MHz progressive scan. Power-up default is 9.

**0x31—Bits[3:0] Macrovision Pulse Min**
These bits set the pseudo sync pulse width maximum for Macrovision detection in pixel clocks. This is functional for 13.5 MHz SDTV or 27 MHz progressive scan. Power-up default is 6.

**0x32—Bit[7] Macrovision Oversample Enable**
Tells the Macrovision detection engine whether oversampling is used. This accommodates 27 MHz sampling for SDTV and 54 MHz sampling for progressive scan and is used as a correction factor for clock counts. Power-up default is 0.

**0x32—Bit[6] Macrovision PAL Enable**
Tells the Macrovision detection engine to enter PAL mode when set to 1. Default is 0 for NTSC mode.

**0x32—Bit[5:0] Macrovision Line Count Start**
Set the start line for Macrovision detection. Along with Register 0x33, Bits [5:0], they define the region where MV pulses are expected to occur. The power-up default is Line 13.
0x33—Bit[7] Macrovision Detect Mode
0 = standard definition. 1 = progressive scan mode.

0x33—Bit[6] Macrovision Settings Override
This defines whether preset values are used for the MV line counts and pulse widths or the values stored in I2C registers.
0 = use hard-coded settings for line counts and pulse widths.
1 = use I2C values for these settings.

0x33—Bits[5:0] Macrovision Line Count End
Set the end line for Macrovision detection. Along with Register 0x32, Bits[5:0], they define the region where MV pulses are expected to occur. The power-up default is Line 21.

0x34—Bits[7:6] Macrovision Pulse Limit Select
Set the number of pulses required in the last three lines (SD mode only). If there is not at least this number of MV pulses, the engine stops. These 2 bits define the following pulse counts:
00 = 6
01 = 4
10 = 5 (default)
11 = 7

0x34—Bit[5] Low Frequency Mode
Sets whether the audio PLL is in low frequency mode or not. Low frequency mode should only be set for pixel clocks < 80 MHz.

0x34—Bit[4] Low Frequency Override
Allows the previous bit to be used to set low frequency mode rather than the internal auto-detect.

0x34—Bit[3] Up Conversion Mode
0 = repeat Cb/Cr values. 1 = interpolate Cb/Cr values.

0x34—Bit[2] CbCr Filter Enable
Enables the FIR filter for 4:2:2 CbCr output.

COLOR SPACE CONVERSION
The default power-up values for the color space converter coefficients (R0x35 through R0x4C) are set for ATSC RGB-to-YCbCr conversion. They are completely programmable for other conversions.

0x34—Bit[1] Color Space Converter Enable
This bit enables the color space converter. 0 = disable color space converter. 1 = enable color space converter. The power-up default setting is 0.

0x35—Bits[6:5] Color Space Converter Mode
These two bits set the fixed-point position of the CSC coefficients, including the A4, B4, and C4 offsets.

Table 17. CSC Fixed Point Converter Mode

0x35—Bits[4:0] Color Space Conversion Coefficient A1 MSBs
These 5 bits form the 5 MSBs of the Color Space Conversion Coefficient A1. This combined with the 8 LSBs of the following register form a 13-bit, twos complement coefficient that is user programmable. The equation takes the form of:

\[
R_{OUT} = (A1 \times R_{IN}) + (A2 \times G_{IN}) + (A3 \times B_{IN}) + A4
\]

\[
G_{OUT} = (B1 \times R_{IN}) + (B2 \times G_{IN}) + (B3 \times B_{IN}) + B4
\]

\[
B_{OUT} = (C1 \times R_{IN}) + (C2 \times G_{IN}) + (C3 \times B_{IN}) + C4
\]

The default value for the 13-bit A1 coefficient is 0x0C52.

0x36—Bits[7:0] Color Space Conversion Coefficient A1 LSBs
See the Register 0x35[4:0] section.

0x37—Bits[4:0] CSC A2 MSBs
These five bits form the 5 MSBs of the Color Space Conversion Coefficient A2. Combined with the 8 LSBs of the following register, they form a 13-bit, twos complement coefficient that is user programmable. The equation takes the form of:

\[
R_{OUT} = (A1 \times R_{IN}) + (A2 \times G_{IN}) + (A3 \times B_{IN}) + A4
\]

\[
G_{OUT} = (B1 \times R_{IN}) + (B2 \times G_{IN}) + (B3 \times B_{IN}) + B4
\]

\[
B_{OUT} = (C1 \times R_{IN}) + (C2 \times G_{IN}) + (C3 \times B_{IN}) + C4
\]

The default value for the 13-bit A2 coefficient is 0x0800.

0x38—Bits[7:0] CSC A2 LSBs
See the Register 0x37 section.

0x39—Bits[4:0] CSC A3 MSBs
The default value for the 13-bit A3 is 0x0000.

0x3A—Bits[7:0] CSC A3 LSBs
0x3B—Bits[4:0] CSC A4 MSBs
The default value for the 13-bit A4 is 0x19D7.

0x3C—Bits[7:0] CSC A4 LSBs
0x3D—Bits[4:0] CSC B1 MSBs
The default value for the 13-bit B1 is 0x1C54.

0x3E—Bits[7:0] CSC B1 LSBs
0x3F—Bits[4:0] CSC B2 MSB
The default value for the 13-bit B2 is 0x0800.
The default value for the 13-bit B3 is 0x1E89.

The default value for the 13-bit C1 is 0x0000.

The default value for the 13-bit C2 is 0x0000.

The default value for the 13-bit B4 is 0x0291.

The default value for the 13-bit C3 is 0x0E87.

The default value for the 13-bit C4 is 0x18BD.

This bit enables the use of the analog PLL.

This register indicates if a data packet in specific sections has been detected. These seven bits are updated if any specific packet has been received since last reset or loss of clock detect. Normal is 0x00.

This bit disables the inter-MDA/MCL pull-ups.

This bit allows for overriding during power down.

This bit allows normal clock termination or disconnects this.

This bit three-states the MDA/MCL lines to allow in-circuit programming of the EEPROM.

This register indicates if a data packet in specific sections has been detected. These seven bits are updated if any specific packet has been received since last reset or loss of clock detect. Normal is 0x00.

0 = DVI, 1 = HDMI.

0x84—Bits[6:0] Video ID Code

See CEA EDID short video descriptors.

0x85—Bits[3:0] Pixel Repeat

This value indicates how many times the pixel was repeated. 0x0 = no repeats, sent once, 0x8 = 8 repeats, sent 9 times, and so on.

0x86—Bits[7:0] Active Line Start LSB

Combined with the MSB in Register 0x88, these bits indicate the beginning line of active video. All lines before this comprise a top horizontal bar. This is used in letter box modes. If the 2-byte value is 0x00, there is no horizontal bar.
0x87—Bit[6:0] New Data Flags (NDF)

This register indicates whether data in specific sections has changed. In the address space from 0x80 to 0xFF, each register address ending in 0b111 (for example, 0x87, 0x8F, 0x97, 0xAF) is an NDF register. They all have the same data and all are reset upon reading any one of them.

0x88—Bits[7:0] Active Line Start MSB

See Register 0x86.

0x89—Bits[7:0] Active Line End LSB

Combined with the MSB in Register 0x8A these bits indicate the last line of active video. All lines past this comprise a lower horizontal bar. This is used in letter-box modes. If the 2-byte value is greater than the number of lines in the display, there is no lower horizontal bar.

0x8A—Bits[7:0] Active Line End MSB

See Register 0x89.

0x8B—Bits[7:0] Active Pixel Start LSB

Combined with the MSB in Register 0x8C, these bits indicate the first pixel in the display which is active video. All pixels before this comprise a left vertical bar. If the 2-byte value is 0x00, there is no left bar.

0x8C—Bits[7:0] Active Pixel Start MSB

See Register 0x8B.

0x8D—Bits[7:0] Active Pixel End LSB

Combined with the MSB in Register 0x8E, these bits indicate the last active video pixel in the display. All pixels past this comprise a right vertical bar. If the 2-byte value is greater than the number of pixels in the display, there is no vertical bar.

0x8E—Bits[7:0] Active Pixel End MSB

See Register 0x8D.

0x8F—Bits[6:0] NDF

See Register 0x87.

0x90—Bits[7:0] Audio Infoframe Version

0x91—Bits[7:4] Audio Coding Type

These bits identify the audio coding so that the receiver may process audio properly.

2-WIRE SERIAL CONTROL PORT

A 2-wire serial interface control interface is provided in the AD9398. Up to two AD9398 devices can be connected to the 2-wire serial interface, with a unique address for each device.

The 2-wire serial interface comprises a clock (SCL) and a bidirectional data (SDA) pin. The analog flat panel interface acts as a slave for receiving and transmitting data over the serial interface. When the serial interface is not active, the logic levels on SCL and SDA are pulled high by external pull-up resistors.

Data received or transmitted on the SDA line must be stable for the duration of the positive-going SCL pulse. Data on SDA must change only when SCL is low. If SDA changes state while SCL is high, the serial interface interprets that action as a start or stop sequence.

There are six components to serial bus operation:
- Start signal
- Slave address byte
- Base register address byte
- Data byte to read or write
- Stop signal
- Acknowledge (Ack)

When the serial interface is inactive (SCL and SDA are high), communications are initiated by sending a start signal. The start signal is a high-to-low transition on SDA while SCL is high. This signal alerts all slave devices that a data transfer sequence is coming.

The first 8 bits of data transferred after a start signal comprise a 7-bit slave address (the first 7 bits) and a single R/W bit (the 8th bit). The R/W bit indicates the direction of data transfer, read from (1) or write to (0) the slave device. If the transmitted slave address matches the address of the device (set by the state of the SA0 input pin as shown in Table 37), the AD9398 acknowledges by bringing SDA low on the 9th SCL pulse. If the addresses do not match, the AD9398 does not acknowledge.

DATA TRANSFER VIA SERIAL INTERFACE

For each byte of data read or written, the MSB is the first bit of the sequence.

If the AD9398 does not acknowledge the master device during a write sequence, the SDA remains high so the master can generate a stop signal. If the master device does not acknowledge the AD9398 during a read sequence, the AD9398 interprets this as the end of data. The SDA remains high, so the master can generate a stop signal.

To write data to specific control registers of the AD9398, the 8-bit address of the control register of interest must be written after the slave address has been established. This control register address is the base address for subsequent write operations. The base address auto-increments by 1 for each byte of data written after the data byte intended for the base address. If more bytes are transferred than there are available addresses, the address does not increment and remains at its maximum value. Any base address higher than the maximum value does not produce an acknowledge signal.

Data are read from the control registers of the AD9398 in a similar manner. Reading requires two data transfer operations:
- The base address must be written with the R/W bit of the slave address byte low to set up a sequential read operation.
- Reading (the R/W bit of the slave address byte high) begins at the previously established base address. The address of the read register auto-increments after each byte is transferred.

To terminate a read/write sequence to the AD9398, a stop signal must be sent. A stop signal comprises a low-to-high transition of SDA while SCL is high.

A repeated start signal occurs when the master device driving the serial interface generates a start signal without first generating a stop signal to terminate the current communication. This is used to change the mode of communication (read, write) between the slave and master without releasing the serial interface lines.

![Figure 9. Serial Port Read/Write Timing](image-url)
SERIAL INTERFACE READ/WRITE EXAMPLES

Write to one control register:
- Start signal
- Slave address byte (R/W bit = low)
- Base address byte
- Data byte to base address
- Stop signal

Write to four consecutive control registers:
- Start signal
- Slave address byte (R/W bit = LOW)
- Base address byte
- Data byte to base address
- Data byte to (base address + 1)
- Data byte to (base address + 2)
- Data byte to (base address + 3)
- Stop signal

Read from one control register:
- Start signal
- Slave address byte (R/W bit = low)
- Base address byte
- Start signal
- Slave address byte (R/W bit = high)
- Data byte from base address
- Stop signal

Read from four consecutive control registers:
- Start signal
- Slave address byte (R/W bit = low)
- Base address byte
- Start signal
- Slave address byte (R/W bit = high)
- Data byte from base address
- Data byte from (base address + 1)
- Data byte from (base address + 2)
- Data byte from (base address + 3)
- Stop signal

Figure 10. Serial Interface—Typical Byte Transfer
PCB LAYOUT RECOMMENDATIONS

The AD9398 is a high precision, high speed digital device. To achieve the maximum performance from the part, it is important to have a well designed board. The following is a guide for designing a board using the AD9398.

POWER SUPPLY BYPASSING

It is recommended to bypass each power supply pin with a 0.1 μF capacitor. The exception is in the case where two or more supply pins are adjacent to each other. For these groupings of powers/grounds, it is only necessary to have one bypass capacitor. The fundamental idea is to have a bypass capacitor within about 0.5 cm of each power pin. Also, avoid placing the capacitor on the opposite side of the PC board from the AD9398, since that interposes resistive vias in the path.

The bypass capacitors should be physically located between the power plane and the power pin. Current should flow from the power plane to the capacitor to the power pin. Do not make the power connection between the capacitor and the power pin. Placing a via underneath the capacitor pads down to the power plane is generally the best approach.

It is particularly important to maintain low noise and good stability of PVDD (the clock generator supply). Abrupt changes in PVDD can result in similarly abrupt changes in sampling clock phase and frequency. This can be avoided by careful attention to regulation, filtering, and bypassing. It is highly desirable to provide separate regulated supplies for each of the analog circuitry groups (VDD and PVDD).

Some graphic controllers use substantially different levels of power when active (during active picture time) and when idle (during HSYNC and VSYNC periods). This can result in a measurable change in the voltage supplied to the analog supply regulator, which can in turn produce changes in the regulated analog supply voltage. This is mitigated by regulating the analog supply, or at least PVDD, from a different, cleaner power source (for example, from a 12 V supply).

It is recommended to use a single ground plane for the entire board. Experience has repeatedly shown that noise performance is the same or better with a single ground plane. Using multiple ground planes is detrimental because each separate ground plane is smaller, resulting in long ground loops.

In some cases, using separate ground planes is unavoidable; therefore, it is recommended to place a single ground plane under the AD9398. The location of the split should be at the receiver of the digital outputs. In this case, it is even more important to place components wisely because the current loops are much longer (current takes the path of least resistance). An example of a current loop is: power plane to AD9398 to digital output trace to digital data receiver to digital ground plane to analog ground plane.

OUTPUTS (BOTH DATA AND CLOCKS)

Try to minimize the trace length that the digital outputs have to drive. Longer traces have higher capacitance requiring more current that causes more internal digital noise.

Shorter traces reduce the possibility of reflections.

Adding a 50 Ω to 200 Ω series resistor suppresses reflections, reduces EMI, and reduces the current spikes inside the AD9398. If series resistors are used, place them as close as possible to the AD9398 pins (although try not to add vias or extra length to the output trace to move the resistors closer).

If possible, limit the capacitance that each of the digital outputs drives to less than 10 pF. This is easily accomplished by keeping traces short and connecting the outputs to only one device. Loading the outputs with excessive capacitance increases the current transients inside the AD9398 and creates more digital noise on its power supplies.

DIGITAL INPUTS

The digital inputs on the AD9398 are designed to work with 3.3 V signals, but tolerate 5.0 V signals. Therefore, no extra components need to be added if using 5.0 V logic.

Any noise that enters the HSYNC input trace adds jitter to the system. Therefore, minimize the trace length and do not run any digital or other high frequency traces near it.
