FEATURES
Ideal for driving high capacitive or low resistive loads
Wide supply range: 10 V to 40 V
High output current drive: 1 A
Wide output voltage swing: 37 V swing with 40 V supply
High slew rate: 2500 V/µs
High bandwidth: 52 MHz large signal, 70 MHz small signal
Low noise: 2.1 nV/√Hz
Quiescent current: 32.5 mA
Power down: 0.75 mA
Short-circuit protection and flag
Current limit: 1.2 A
Thermal protection

APPLICATIONS
Envelope tracking
Power FET driver
Ultrasound
Piezo drivers
PIN diode drivers
Waveform generation
Automated test equipment (ATE)
CCD panel drivers
Composite amplifiers

GENERAL DESCRIPTION
The ADA4870 is a unity gain stable, high speed current feedback amplifier capable of delivering 1 A of output current and 2500 V/µs slew rate from a 40 V supply. Manufactured using the Analog Devices, Inc., proprietary high voltage extra fast complementary bipolar (XFCB) process, the innovative architecture of the ADA4870 enables high output power, high speed signal processing solutions in applications that require driving a low impedance load.

The ADA4870 is ideal for driving high voltage power FETs, piezo transducers, PIN diodes, CCD panels, and a variety of other demanding applications that require high speed from high supply voltage at high output current.

The ADA4870 is available in a power SOIC package (PSOP_3), featuring an exposed thermal slug that provides high thermal conductivity, enabling efficient heat transfer for improved performance and reliability in demanding applications. The ADA4870 operates over the industrial temperature range (−40°C to +85°C).

Rev. 0 | Page 3 of 24
## POWER SUPPLY
- **Operating Range**: 10 to 40 V
- **Quiescent Current**
  - \( SD = V_{EE} + 5 \text{ V}, \ ON = V_{EE} \): 32.5 to 33 mA
  - \( SD = V_{EE}, \ ON = \text{not applicable} \): 0.75 to 1 mA
  - \( SD = V_{EE} + 5 \text{ V}, \ ON = V_{EE} + 5 \text{ V} \): 5.1 to 5.8 mA
- **Positive Power Supply Rejection Ratio**: 67 to 69 dB
- **Negative Power Supply Rejection Ratio**: 62 to 64 dB

### ±5 V SUPPLY
\( T_{CASE} = 25^\circ\text{C}, A_V = -5, R_f = 1.21 \text{ k}\Omega, R_G = 243 \text{ \Omega}, C_L = 300 \text{ pF}, R_S = 5 \text{ \Omega} \), unless otherwise noted.

## DYNAMIC PERFORMANCE
- **−3 dB Bandwidth**
  - \( V_{OUT} = 2 \text{ V p-p} \): 52 MHz
- **Settling Time to 0.1%**
  - \( V_{OUT} = 2 \text{ V step} \): 55 ns

## NOISE/DISTORTION PERFORMANCE
- **Harmonic Distortion, HD2/HD3**
  - \( f = 30 \text{ MHz}, V_{OUT} = 2 \text{ V p-p}, A_V = -10 \text{ dB} \)
  - \( f = 1 \text{ MHz}, V_{OUT} = 2 \text{ V p-p}, A_V = -10 \text{ dB} \)
  - \( f = 0.1 \text{ MHz}, V_{OUT} = 2 \text{ V p-p}, A_V = -10 \text{ dB} \)
  - \( f = 1 \text{ MHz}, V_{OUT} = 2 \text{ V p-p}, R_L = 25 \text{ \Omega}, A_V = -10 \text{ dB} \)
  - \( f = 0.1 \text{ MHz}, V_{OUT} = 2 \text{ V p-p}, R_L = 25 \text{ \Omega}, A_V = -10 \text{ dB} \)
- **Input Voltage Noise Density**
  - \( f = 100 \text{ kHz} \): 2.1 nV/√Hz
- **Input Current Noise Density**
  - \( f = 100 \text{ kHz} \): INP = 4.2 pA/√Hz, INN = 47 pA/√Hz

## DC PERFORMANCE
- **Input Offset Voltage**
  - \( V_{IC} = \pm 0.5 \text{ V}, \pm 3.0 \text{ V} \)
- **Input Offset Voltage Drift**
  - \( V_{IC} = \pm 0.5 \text{ V}, \pm 3.0 \text{ V} \): 14 μA/°C
- **Input Bias Current**
  - **Noninverting Input**
  - **Inverting Input**
  - **Input Bias Current Drift, Inverting Input**
  - **Open-Loop Transresistance**
  - \( R_{OM} = \pm 0.5 \text{ V}, \pm 3.0 \text{ V} \)

## INPUT CHARACTERISTICS
- **Input Resistance**
  - \( INP \): 2 MΩ
- **Input Capacitance**
  - \( INP \): 0.75 pF
- **Input Common-Mode Voltage Range (\( V_{CM} \))**
  - \( V_{CM} = \pm 0.5 \text{ V}, \pm 3.0 \text{ V} \)
- **Common-Mode Rejection Ratio**
  - \( V_{CM} = \pm 0.5 \text{ V}, \pm 3.0 \text{ V} \): 57 to 59 dB

## SD PIN (SHUTDOWN)
- **Input Voltages**
  - **High (enabled)**
  - **Low (power-down)**
- **Input Bias Current**
  - **Enabled (\( SD = V_{EE} + 5 \text{ V} \))**
  - **Power down (\( SD = V_{EE} \))**

## ON PIN (RESET AND SHORT-CIRCUIT PROTECTION)
- **Input Voltages**
  - **High (power-down)**
  - **Low (enabled)**
- **Input Bias Current**
  - **Enabled (\( ON = V_{EE} \))**
  - **Power down (\( ON = V_{EE} + 5 \text{ V} \))**

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

MAXIMUM POWER DISSIPATION

The maximum safe power dissipation in the package is limited by the associated rise in junction temperature (TJ) on the die. At approximately 150°C, which is the glass transition temperature, the plastic changes its properties. Exceeding a junction temperature of 150°C can result in changes in the silicon devices, potentially causing failure. Table 4 shows the junction to case thermal resistance (θjc) for the PSOP_3 package. For more detailed information on power dissipation and thermal management, see the Applications Information section.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

APPLICATIONS INFORMATION

ON, INITIAL POWER-UP, AND SHORT-CIRCUIT

After initial power-up, the ON pin must be pulled low to ensure that the amplifier is turned on. Subsequently, floating the ON pin enables the short-circuit protection feature while the amplifier remains on. While ON is held low, the short-circuit protection feature is disabled.

When a short-circuit condition is detected, the amplifier is disabled, the supply current drops to about 5 mA, and the TFL pin outputs a dc voltage of ~300 mV. To turn the amplifier back on after a short-circuit event, follow the sequence for initial power-up.

Pulling the ON pin high disables the amplifier and causes the supply current to drop to about 5 mA, as if a short-circuit condition had been detected.

The impedance at the ON pin is ~20 kΩ. Lay out the PCB trace leading to ON to avoid noise coupling into it and triggering a false event. A 1 nF capacitor between ON and VEE is recommended to help shunt noise away from ON.

THERMAL PROTECTION

In addition to short-circuit protection, the ADA4870 is also protected against excessive die temperatures.

During normal operation, the TFL pin outputs a dc voltage (referenced to VEE) ranging from 1.5 V to 1.9 V that is relative to die temperature. The voltage on TFL changes at approximately −3 mV/°C and can be used to indicate approximate increases in die temperature. When excessive die temperatures are detected, the amplifier switches to an off state, dropping the supply current to approximately 5 mA, and TFL continues to report a voltage relative to die temperature. When the die temperature returns to an acceptable level, the amplifier automatically resumes normal operation.

SHUTDOWN (SD)

The ADA4870 is equipped with a power saving shutdown feature. Pulling SD low places the amplifier in a shutdown state, reducing quiescent current to approximately 750 µA. When turning the amplifier back on from the shutdown state, pull the SD pin high and then pull the ON pin low. Following this sequence ensures power-on. Afterwards, the ON pin can be floated to enable short-circuit protection.

Pull SD high or low; do not leave SD floating.

FEEDBACK RESISTOR SELECTION

The feedback resistor value has a direct impact on the stability and closed-loop bandwidth of current feedback amplifiers. Table 6 provides a guideline for the selection of feedback resistors for some common gain configurations.

CAPACITIVE LOAD DRIVING

When driving a capacitive load (C1), the amplifier output resistance and the load capacitance form a pole in the transfer function of the amplifier. This additional pole reduces phase margin at higher frequencies and, if left uncompensated, can result in excessive peaking and instability. Placing a small series resistor (Rs) between the amplifier output and C1 (as shown in Figure 69) allows the ADA4870 to drive capacitive loads beyond 1 µF.

Figure 70 shows the series resistor value vs. capacitive load for a maximum of 1 dB peaking in the circuit of Figure 69. For large capacitive loads, Rs values of less than 0.3 Ω are not recommended.

Figure 71 shows the small signal bandwidth (SSBW) vs. CL with corresponding Rs values from Figure 70.
HEAT AND THERMAL MANAGEMENT

High output current amplifiers like the ADA4870 generate heat, instantaneous or continuous, depending on the signal being processed. Properly applied thermal management techniques move heat away from the ADA4870 die and help to maintain acceptable junction temperatures (TJ). A highly conductive thermal path from the slug of the PSOP_3 package to the ambient air is required to obtain the best performance at the lowest TJ.

POWER DISSIPATION

The first step in identifying a thermal solution is to compute the power generated in the amplifier during normal operation. The schematic in Figure 72 shows a simplified output stage of the ADA4870. The most significant heat is generated by the output stage push-pull pair, particularly when driving heavy loads.

The total power dissipation in the amplifier is the sum of the power dissipated in the output stage plus the quiescent power. The average power for an amplifier processing sine signals is computed by Equation 1. Equation 2 can be used to compute the peak power of a sine wave and can be used to compute the continuous power dissipation of dc output voltages where \( V_{\text{PEAK}} \) is the dc load voltage. These equations assume symmetrical supplies and a load referred to midsupply.

\[
P_{\text{AVG, SINE}} = (V_s \times I_q) + \left( \frac{2}{\pi} \times \frac{V_{CC} \times V_{\text{PEAK}}}{R_L} \right) - \left( \frac{V_{\text{PEAK}}^2}{2 \times R_L} \right)
\]

\[
P_{\text{PEAK}} = (V_s \times I_q) + (V_s - V_{\text{PEAK}}) \times \left( \frac{V_{\text{PEAK}}}{R_L} \right)
\]

where

- \( V_s \) is the total supply voltage (\( V_{CC} - V_{EE} \)).
- \( I_q \) is the amplifier quiescent current.

A graphical representation of the \( P_{\text{AVG, SINE}} \) and \( P_{\text{PEAK}} \) power equations is shown in Figure 73. The power curves were generated for the ADA4870 operating from ±20 V supplies and driving a 20 Ω load. The quiescent power intersects the vertical axis at ~1.3 W when \( V_{\text{OUT}} \) is at 0 V or midsupply. The graphs stop at the output swing limit of 18 V.

For dc analysis, peak power dissipation occurs at \( V_{\text{OUT}} = V_{CC}/2 \), while the maximum average power for sine wave signals occurs at \( V_{\text{OUT}} = 2V_{CC}/\pi \).
SAFE OPERATING AREA

The safe operating area (SOA) is a curve of output current vs. output stage collector-emitter voltage (V CE), under which the amplifier can operate at a safe junction temperature (T J). The area under the curves of Figure 74 shows the operational boundaries of the ADA4870 for the PCB of Figure 75 that maintains a T J ≤ 150°C. The SOA curves of Figure 74 are unique to the conditions under which they were developed, such as PCB, heat sink, and ambient temperature.

Two heat sinks (VHS-45 and VHS-95) were used in the evaluation. Both were assembled to the PCB using CT40-5 thermal interface material.

All testing was done in a still-air environment. Forced air convection in any of the test cases effectively lowers θJA and moves the corresponding curve toward the upper right, expanding the SOA. For more information on the ADA4870 evaluation board, see the ADA4870 User Guide.

In Figure 74, the horizontal line at 1 A is the output current drive of the ADA4870. The curved section maintains a fixed power dissipation that results in a junction temperature (T J) of 150°C or less. Note that the x-axis is the output stage V CE (V CE – V OUT or V OUT – V EE) developed across the relevant output transistor of Figure 72 and ends at a maximum V CE of 20 V.

Figure 74. Safe Operating Area for Evaluation Board from Figure 75 at 25°C and 85°C Ambient Temperature With and Without Heat Sink, No Air Flow

Figure 75. Details of the ADA4870 Evaluation Board
PRINTED CIRCUIT BOARD (PCB)

All current feedback amplifiers, including the ADA4870, can be affected by stray capacitance. Paying careful attention during PCB layout can reduce parasitic capacitance and improve overall circuit performance. Minimize signal trace lengths by placing feedback and gain setting resistors as close as possible to the amplifier.

Additionally, for high output current amplifiers like the ADA4870, lay out the PCB with heat dissipation in mind. A good thermal design includes an exposed copper landing area on the top side of the board on which to solder the thermal slug of the PSOP3 package. The PCB should also provide an exposed copper area on the bottom side to accommodate a heat sink. Stitch the top and bottom layers together with an array of plated-through thermal vias to facilitate efficient heat transfer through the board. Thermal conductivity may be further improved by using widely available via fill materials.

THERMAL MODELING

Computational fluid dynamics (CFD) tools like FloTherm® can be used to create layers of materials that include PCB construction, thermal vias, thermal interface materials, and heat sinks, and can predict junction temperature and/or junction to ambient thermal resistance ($\theta_{JA}$) for a given set of conditions. Table 7 shows an example of how $\theta_{JA}$ is affected by the addition of an aluminum heat sink and forced convection. Figure 76 shows an image of the model used to establish the thermal results in Table 7.

HEAT SINK SELECTION

A heat sink increases the surface area to ambient temperature ($T_A$) and extends the power dissipation capability of the ADA4870 and PCB combination. To maximize heat transfer from the board to the heat sink, attach the heat sink to the PCB using a high conductivity thermal interface material (TIM). The heat sinks presented in the Safe Operating Area section and Figure 74 are effective up to ~10 W in still air. If lower power dissipation is anticipated and/or forced air convection is used, a smaller heat sink may be appropriate. If the thermal resistance of the chip ($\theta_{JC}$), PCB ($\theta_{CB}$), and TIM ($\theta_{TIM}$) are known, use Equation 3 to compute the thermal resistance ($\theta_{HS}$) of the required heat sink.

$$ \theta_{HS} = \frac{T_J - T_A}{P_{DISS}} - \left( \theta_{JC} + \theta_{CB} + \theta_{TIM} \right) $$ (3)

POWER SUPPLIES AND DECOUPLING

The ADA4870 can operate from a single supply or dual supplies. The total supply voltage ($V_{CC} - V_{EE}$) must be between 10 V and 40 V. Decouple each supply pin to ground using high quality, low ESR, 0.1 μF capacitors. Place decoupling capacitors as close to the supply pins as possible. Additionally, place 22 μF tantalum capacitors from each supply to ground to provide good low frequency decoupling and supply the needed current to support large, fast slewing signals at the ADA4870 output.
COMPOSITE AMPLIFIER

When dc precision and high output current are required, the ADA4870 can be combined with a precision amplifier such as the ADA4637-1 to form a composite amplifier as shown in Figure 77.

By placing the ADA4870 inside the feedback loop of the ADA4637-1, the composite amplifier provides the high output current of the ADA4870 while preserving the dc precision of the ADA4637-1.

Figure 77. Composite Amplifier

Figure 78 shows the bandwidth of the composite amplifier at a gain of 10. The offset voltage at the output is <500 μV.

The circuit can be tailored for different gains as desired. Depending on the board parasitics, the 6 pF capacitor may need to be empirically adjusted to optimize performance. Minimize PCB stray capacitance as much as possible, particularly in the feedback path.

The small signal and large signal pulse response is shown in Figure 79 and Figure 80, respectively.
