FEATURES

High accuracy reference output voltage: 1 V ± 0.9%
Single-supply voltage operation: 2.3 V to 5.5 V
Rail-to-rail common-mode input voltage range
Low input offset voltage across VCMR: 1 mV typical
Guarantees comparator output logic low from VCC = 0.9 V to undervoltage lockout (UVLO)
Operating temperature range: −40°C to +125°C
10-lead mini small outline package (MSOP)

APPLICATIONS

Battery management/monitoring
Power supply detection
Window comparators
Threshold detectors/discriminators
Microprocessor systems

GENERAL DESCRIPTION

The ADCMP395 is a dual, rail-to-rail input, low power comparator ideal for use in general-purpose applications. The device operates from a supply voltage of 2.3 V to 5.5 V and draws a minimal amount of current. The dual ADCMP395 consumes only 37.2 μA of supply current. The low voltage and low current operation of the ADCMP395 make it ideal for battery-powered systems.

The ADCMP395 features a common-mode input voltage range of 200 mV beyond the rails, an offset voltage of 1 mV typical across the full common-mode range, and a UVLO monitor. In addition, the design of the comparator allows a defined output state upon power-up. The comparator generates a logic low output when the supply voltage is less than the UVLO threshold.

The ADCMP395 incorporates a 1 V ± 0.9% buffered reference voltage. The reference voltage output can directly connect to the comparator input to serve as the trip value for precise monitoring and detection of positive voltage. It can also act as an offset when monitoring the negative voltage.

The ADCMP395 is available in a 10-lead MSOP package, and is specified to operate over the −40°C to +125°C extended temperature range.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

THEORY OF OPERATION

BASIC COMPARATOR

In its most basic configuration, a comparator can be used to convert an analog input signal to a digital output signal (see Figure 27). The analog signal on INx+ is compared to the voltage on INx−, and the voltage at OUTx is either high or low, depending on whether INx+ is at a higher or lower potential than INx−, respectively.

![Figure 27. Basic Comparator and Input and Output Signals](image)

RAIL-TO-RAIL INPUT (RRI)

Using a CMOS nonRRI stage (that is, a single differential pair) limits the input voltage to approximately one gate-to-source voltage (VGS) away from one of the supply lines. Because VGS for normal operation is commonly more than 1 V, a single differential pair input stage comparator greatly restricts the allowable input voltage. This restriction can be quite limiting with low voltage supplies. To resolve this issue, RRI stages allow the input signal range to extend up to the supply voltage range. In the case of the ADCMP395, the inputs continue to operate 200 mV beyond the supply rails.

OPEN-DRAIN OUTPUT

The ADCMP395 has an open-drain output stage that requires an external resistor to pull up to the logic high voltage level when the output transistor is switched off. The pull-up resistor must be large enough to avoid excessive power dissipation, but small enough to switch logic levels reasonably quickly when the comparator output is connected to other digital circuitry. The rise time of the open-drain output depends on the pull-up resistor (R_{PULL-UP}) and load capacitor (C_L) used.

The rise time can be calculated by

\[ t_R = 2.2 \times R_{PULL-UP} \times C_L \]  

(1)

POWER-UP BEHAVIOR

On power-up, when VCC reaches 0.9 V, the ADCMP395 asserts an output low logic. When the voltage on the VCC pin exceeds UVLO, the comparator inputs take control.

CROSSOVER BIAS POINT

Rail-to-rail inputs of this type of architecture in both op amps and comparators, have a dual front-end design. PMOS devices are inactive near the VCC rail, and NMOS devices are inactive near GND. At some predetermined point in the common-mode range, a crossover occurs. At this point, normally 0.8 V and VCC − 0.8 V, the measured offset voltages change.

COMPARATOR HYSTERESIS

In noisy environments, or when the differential input amplitudes are relatively small or slow moving, adding hysteresis (V_{HYST}) to the comparator is often desirable. The transfer function for a comparator with hysteresis is shown in Figure 28. As the input voltage approaches the threshold (0 V in Figure 28) from below the threshold region in a positive direction, the comparator switches from low to high when the input crosses +V_{HYST}/2. The new switch threshold becomes −V_{HYST}/2. The comparator remains in the high state until the −V_{HYST}/2 threshold is crossed from below the threshold region in a negative direction. In this manner, noise or feedback output signals centered on the 0 V input cannot cause the comparator to switch states unless it exceeds the region bounded by ±V_{HYST}/2.

![Figure 28. Comparator Hysteresis Transfer Function](image)
TYPICAL APPLICATIONS
ADDING HYSTERESIS

To add hysteresis, see Figure 29; two resistors are used to create different switching thresholds, depending on whether the input signal is increasing or decreasing in magnitude. When the input voltage increases, the threshold is above $V_{\text{REF}}$, and when the input voltage decreases, the threshold is below $V_{\text{REF}}$.

![Noninverting Comparator Configuration with Hysteresis](image)

The upper input threshold level is given by

$$V_{\text{IN,HIGH}} = \frac{V_{\text{REF}} (R_1 + R_2)}{R_2}$$  \hspace{1cm} (2)

Assuming $R_{\text{LOAD}} \gg R_2$, $R_{\text{PULL-UP}}$.

The lower input threshold level is given by

$$V_{\text{IN,LOW}} = \frac{V_{\text{REF}} (R_1 + R_2 + R_{\text{PULL-UP}}) - V_{\text{CC}} R_1}{R_2 + R_{\text{PULL-UP}}}$$  \hspace{1cm} (3)

The hysteresis is the difference between these voltages levels.

$$V_{\text{HYST}} = \frac{V_{\text{REF}} (R_1)}{R_2} \left( \frac{R_1 (V_{\text{REF}} + V_{\text{CC}})}{R_2 + R_{\text{PULL-UP}}} \right)$$  \hspace{1cm} (4)

WINDOW COMPARATOR FOR POSITIVE VOLTAGE MONITORING

When monitoring a positive supply, the desired nominal operating voltage for monitoring is denoted by $V_M$. $I_M$ is the nominal current through the resistor divider, $V_{\text{OV}}$ is the overvoltage trip point, and $V_{\text{UV}}$ is the undervoltage trip point.

![Positive Undervoltage/Overvoltage Monitoring Configuration](image)

Figure 30 illustrates the positive voltage monitoring input connection. Three external resistors, $R_X$, $R_Y$, and $R_Z$, divide the positive voltage for monitoring ($V_M$) into the high-side voltage ($V_{\text{PH}}$) and the low-side voltage ($V_{\text{PL}}$). The high-side voltage is connected to the INA+ pin and the low-side voltage is connected to the INB− pin.

To trigger an overvoltage condition, the low-side voltage (in this case, $V_{\text{PL}}$) must exceed the $V_{\text{REF}}$ threshold on the INB+ pin. Calculate the low-side voltage, $V_{\text{PL}}$, by the following:

$$V_{\text{PL}} = V_{\text{REF}} = V_{\text{OV}} \left( \frac{R_Z}{R_X + R_Y + R_Z} \right)$$  \hspace{1cm} (5)

In addition,

$$R_X + R_Y + R_Z = V_M/I_M$$  \hspace{1cm} (6)

Therefore, $R_Z$, which sets the desired trip point for the overvoltage monitor, is calculated as

$$R_Z = \left( \frac{V_{\text{REF}} (V_M)}{V_{\text{OV}} (I_M)} \right)$$  \hspace{1cm} (7)

To trigger the undervoltage condition, the high-side voltage, $V_{\text{PH}}$, must be less than the $V_{\text{REF}}$ threshold on the INA− pin. The high-side voltage, $V_{\text{PH}}$, is calculated by

$$V_{\text{PH}} = V_{\text{REF}} = V_{\text{UV}} \left( \frac{R_Y + R_Z}{R_X + R_Y + R_Z} \right)$$  \hspace{1cm} (8)

Because $R_Z$ is already known, $R_Y$ can be expressed as

$$R_Y = \left( \frac{V_{\text{REF}} (V_M)}{V_{\text{UV}} (I_M)} \right) - R_Z$$  \hspace{1cm} (9)

When $R_Y$ and $R_Z$ are known, $R_X$ can be calculated by

$$R_X = (V_M/I_M) - R_Y - R_Z$$  \hspace{1cm} (10)

If $V_M$, $I_M$, $V_{\text{OV}}$, or $V_{\text{UV}}$ changes, each step must be recalculated.
WINDOW COMPARATOR FOR NEGATIVE VOLTAGE MONITORING

Figure 31 shows the circuit configuration for negative supply voltage monitoring. To monitor a negative voltage, a reference voltage is required to connect to the end node of the voltage divider circuit, in this case, REF.

Equation 7, Equation 9, and Equation 10 need some minor modifications. The reference voltage, \( V_{REF} \), is added to the overall voltage drop; therefore, it must be subtracted from \( V_M \), \( V_{UV} \), and \( V_{OV} \) before using each of them in Equation 7, Equation 9, and Equation 10.

To monitor a negative voltage level, the resistor divider circuit divides the voltage differential level between \( V_{REF} \) and the negative supply voltage into the high-side voltage, \( V_{NH} \), and the low-side voltage, \( V_{NL} \). The high-side voltage, \( V_{NH} \), is connected to INA+, and the low-side voltage, \( V_{NL} \), is connected to INB−.

To trigger an overvoltage condition, the monitored voltage must exceed the nominal voltage in terms of magnitude, and the high-side voltage (in this case, \( V_{NH} \)) on the INA+ pin must be more negative than ground. Calculate the high-side voltage, \( V_{NH} \), by using the following formula:

\[
V_{NH} = GND = \left[ (V_{REF} - V_{OV}) \left( \frac{R_x + R_y}{R_x + R_y + R_z} \right) \right] + V_{OV} \quad (11)
\]

In addition,

\[
R_x + R_y + R_z = \frac{V_M - V_{REF}}{I_M} \quad (12)
\]

Therefore, \( R_z \), which sets the desired trip point for the overvoltage monitor, is calculated by

\[
R_z = -\frac{V_{REF}(V_M - V_{REF})}{I_M(V_{OV} - V_{REF})} \quad (13)
\]

To trigger an undervoltage condition, the monitored voltage must be less than the nominal voltage in terms of magnitude, and the low-side voltage (in this case, \( V_{NL} \)) on the INB− pin must be more positive than ground. Calculate the low-side voltage, \( V_{NL} \), by the following:

\[
V_{NL} = GND = \left[ (V_{REF} - V_{UV}) \left( \frac{R_x}{R_x + R_y + R_z} \right) \right] + V_{UV} \quad (14)
\]

Because \( R_z \) is already known, \( R_y \) can be expressed as follows:

\[
R_y = -\frac{V_{REF}(V_M - V_{REF})}{I_M(V_{UV} - V_{REF})} - R_z \quad (15)
\]

When \( R_y \) and \( R_z \) are known, \( R_x \) is then calculated by

\[
R_x = \left( \frac{V_M - V_{REF}}{I_M} \right) - R_y - R_z \quad (16)
\]

PROGRAMMABLE SEQUENCING CONTROL CIRCUIT

The circuit shown in Figure 32 is used to control power supply sequencing. The delay is set by the combination of the pull-up resistor \( R_{PULL-UP} \), the load capacitor \( C_L \), and the resistor divider network.

Figure 33 shows a simple block diagram for a programmable sequencing control circuit. The application delays the enable signal, EN, of the external regulators (LDO x) in a linear order when the open-drain signal (SEQ) changes from low to high impedance.

The ADCMP395 has a defined output state during startup, which prevents any regulator from turning on if \( V_{CC} \) is still below the UVLO threshold.
When the SEQ signal changes from low to high impedance, the load capacitor, $C_L$, starts to charge. The time it takes to charge the load capacitor to the pull-up voltage (in this case, $V_{REF}$ or $V_{CC}$) is the maximum delay programmable in the circuit. It is recommended to have the threshold within 10% to 90% of the pull-up voltage. Calculate the maximum allowable delay by

$$t_{MAX} = 2.2 R_{PULL-UP} C_{LOAD}$$  \hspace{1cm} (17)

The delay of each output is changed by changing the threshold voltage, $V_1$ to $V_4$, when the comparator changes its output state. To calculate the voltage thresholds for the comparator, use the following formulas:

$$V_1 = V_{REF} \left(1 - e^{-\frac{t_1}{R_{PULL-UP} C_L}}\right)$$  \hspace{1cm} (18)

$$V_2 = V_{REF} \left(1 - e^{-\frac{t_2}{R_{PULL-UP} C_L}}\right)$$  \hspace{1cm} (19)

$$V_3 = V_{REF} \left(1 - e^{-\frac{t_3}{R_{PULL-UP} C_L}}\right)$$  \hspace{1cm} (20)

$$V_4 = V_{REF} \left(1 - e^{-\frac{t_4}{R_{PULL-UP} C_L}}\right)$$  \hspace{1cm} (21)

The threshold voltages can come from a voltage reference or a voltage divider circuit, as shown in Figure 32.

First, determine the allowable current, $I_{DIV}$, flowing through the resistor divider. After the value for $I_{DIV}$ is determined, calculate $R_1$, $R_2$, $R_3$, $R_4$, and $R_5$ using the following formulas:

$$R_{DIV} = \frac{V_{REF}}{I_{DIV}} = R_1 + R_2 + R_3 + R_4 + R_5$$  \hspace{1cm} (22)

$$R_1 = \frac{V_1 R_{DIV}}{V_{REF}}$$  \hspace{1cm} (23)

$$R_2 = \frac{V_2 R_{DIV}}{V_{REF}} - R_1$$  \hspace{1cm} (24)

$$R_3 = \frac{V_3 R_{DIV}}{V_{REF}} - R_1 - R_2$$  \hspace{1cm} (25)

$$R_4 = \frac{V_4 R_{DIV}}{V_{REF}} - R_1 - R_2 - R_3$$  \hspace{1cm} (26)

$$R_5 = R_{DIV} - R_1 - R_2 - R_3 - R_4$$  \hspace{1cm} (27)

To create a mirrored voltage sequence, add a resistor ($R_{MIRROR}$) between the pull-up resistor ($R_{PULL-UP}$) and the load capacitor ($C_L$) as shown in Figure 35.

Figure 35 shows the circuit configuration for a mirrored voltage sequencer. When SEQ changes from low to high impedance, the response is similar to Figure 34. When SEQ changes from high to low impedance, the load capacitor ($C_L$) starts to discharge at a rate set by $R_{MIRROR}$. The delay of each comparator is dependent on the threshold voltage previously set for $t_1$ to $t_4$. The result is a mirrored power-down sequence.
The timing diagram for the mirrored voltage sequencer is shown in Figure 36.

Equation 18 through Equation 21 must account for the additional resistance, \( R_{\text{MIRROR}} \), in the calculations of the voltage thresholds. To calculate these new thresholds, see Equation 28 through Equation 31.

\[
V_1 = V_{\text{REF}} \left(1 - e^{-\frac{-t_1}{R_{\text{PULL-UP}} + R_{\text{MIRROR}} C_1}}\right) 
\]

\[
V_2 = V_{\text{REF}} \left(1 - e^{-\frac{-t_2}{R_{\text{PULL-UP}} + R_{\text{MIRROR}} C_1}}\right) 
\]

\[
V_3 = V_{\text{REF}} \left(1 - e^{-\frac{-t_3}{R_{\text{PULL-UP}} + R_{\text{MIRROR}} C_1}}\right) 
\]

\[
V_4 = V_{\text{REF}} \left(1 - e^{-\frac{-t_4}{R_{\text{PULL-UP}} + R_{\text{MIRROR}} C_1}}\right) 
\]

\( R_{\text{MIRROR}} \) provides the mirrored delay by prolonging the discharge time of the capacitor. The mirrored voltage sequencer uses the same threshold in Equation 28 to Equation 31 in a decreasing order. To calculate the exact value of the mirrored delay time, see Equation 32 through Equation 35.

\[
t_5 = -R_{\text{MIRROR}} C_1 \ln \left(\frac{V_4}{V_{\text{REF}}}\right) 
\]

\[
t_6 = -R_{\text{MIRROR}} C_1 \ln \left(\frac{V_3}{V_{\text{REF}}}\right) 
\]

\[
t_7 = -R_{\text{MIRROR}} C_1 \ln \left(\frac{V_2}{V_{\text{REF}}}\right) 
\]

\[
t_8 = -R_{\text{MIRROR}} C_1 \ln \left(\frac{V_1}{V_{\text{REF}}}\right) 
\]

**MIRRORED VOLTAGE SEQUENCER EXAMPLE**

To illustrate operation of the mirrored voltage sequencer, see Figure 33 and then consider a system that uses a \( V_{\text{REF}} \) of 1 V and requires a delay of 50 ms when SEQ changes from low to high impedance, and between each regulator when turning on. These considerations require a rise time of at least 200 ms for the pull-up resistor (\( R_{\text{PULL-UP}} \)) and the load capacitor (\( C_1 \)). The sum of the resistance of \( R_{\text{MIRROR}} \) and \( R_{\text{PULL-UP}} \) must be large enough to charge the capacitor longer than the minimum required delay. For a symmetrical mirrored power-down sequence, the value of \( R_{\text{MIRROR}} \) must be much larger than \( R_{\text{PULL-UP}} \). A 10 k\( \Omega \) \( R_{\text{PULL-UP}} \) value limits the pull-down current to 100 \( \mu \)A while giving a reasonable value for \( R_{\text{MIRROR}} \). A typical 1 \( \mu \)F capacitor together with a 150 k\( \Omega \) \( R_{\text{MIRROR}} \) value gives a value of \( t_{\text{MAX}} = 2.2((160 \times 10^3) \times (1 \times 10^{-6})) = 351 \) ms

The threshold voltage required by each comparator is set by Equation 28 to Equation 31. For example,

\[
V_1 = V_{\text{REF}} \left(1 - e^{-\frac{-50 \times 10^{-3}}{160 \times 10^3 \times 1 + 150 \times 10^3}}\right) 
\]

where \( V_1 = 268.38 \) mV.

Therefore, \( V_2 = 464.74 \) mV, \( V_3 = 608.39 \) mV, and \( V_4 = 713.5 \) mV.

Next, consider 10 \( \mu \)A as the maximum current \( (I_{\text{DIV}}) \) flowing through the resistor divider network. This current gives the total resistance of the divider network \( (R_{\text{DIV}}) \) and the individual resistor values using Equation 22 to Equation 27, resulting in the following:

- \( R_{\text{DIV}} = 100 \) k\( \Omega \)
- \( R_1 = 26.84 \) k\( \Omega \) \approx 26.7 \( \)k\( \Omega \)
- \( R_2 = 19.64 \) k\( \Omega \) \approx 19.6 \( \)k\( \Omega \)
- \( R_3 = 14.37 \) k\( \Omega \) \approx 14.3 \( \)k\( \Omega \)
- \( R_4 = 10.51 \) k\( \Omega \) \approx 10.5 \( \)k\( \Omega \)
- \( R_5 = 28.65 \) k\( \Omega \) \approx 28.7 \( \)k\( \Omega \)
Resistor values from the calculation are nonindustry standard, using industry standard resistor values result in a new $R_{DIV}$ value of 99.8 kΩ. Due to the discrepancy of the calculated resistor value to the industry standard value, the threshold of each comparator also changes. Calculate the new threshold values by using a simple voltage divider formula:

$$V_1 = \frac{V_{REF} R_1}{R_{DIV}}$$  \hspace{1cm} (37)

where $V_1 = \frac{1(26.7 \text{ kΩ})}{99.8 \text{ kΩ}} = 267.54 \text{ mV}$.

Therefore, $V_2 = 463.93 \text{ mV}$, $V_3 = 607.21 \text{ mV}$, and $V_4 = 712.42 \text{ mV}$. Because the threshold of each comparator has changed, the time when each comparator changes its output has also changed. Calculate the new delay values for each comparator by using the following equation:

$$t_i = -C_L \left( R_{\text{FULL-UP}} + R_{\text{MIRROR}} \right) \ln \left( 1 - \frac{V_1}{V_{\text{REF}}} \right)$$  \hspace{1cm} (38)

where $t_i = -1 \mu\text{F}(10 \text{ kΩ} + 150 \text{ kΩ}) \ln \left( 1 - \frac{267.54 \text{ mV}}{1} \right) = 49.81 \text{ ms}$.

Therefore, $t_1 = 99.78 \text{ ms}$, $t_2 = 149.52 \text{ ms}$, and $t_3 = 199.4 \text{ ms}$.

To calculate $t_4$ through $t_8$, use Equation 32 to Equation 35:

$$t_5 = -R_{\text{MIRROR}} C_t \ln \left( \frac{V_4}{V_{\text{REF}}} \right)$$

where $t_5 = -150 \text{ kΩ} \times 1 \mu\text{F} \times \ln \left( \frac{712.42 \text{ mV}}{1} \right) = 50.86 \text{ ms}$.

Therefore, $t_6 = 74.83 \text{ ms}$, $t_7 = 115.2 \text{ ms}$, and $t_8 = 197.78 \text{ ms}$.

**THRESHOLD AND TIMEOUT PROGRAMMABLE VOLTAGE SUPERVISOR**

Figure 37 shows a circuit configuration for a programmable threshold and timeout circuit. The timeout, $t_{\text{RESET}}$, defines the duration that the input voltage ($V_{\text{IN}}$) must be kept above the threshold voltage to toggle the $\text{RESET}$ signal, preventing the device from operating when $V_{\text{IN}}$ is not stable. If $V_{\text{IN}}$ falls below the threshold voltage, the $\text{RESET}$ signal toggles quickly.

During startup, the ADCMP395 guarantees a low output state when $V_{\text{CC}}$ is still below the UVLO threshold, preventing the voltage supervisor from toggling.

When $V_{\text{IN}}$ reaches the threshold set by the resistor divider ($R_1$ and $R_2$) and $V_{\text{REF}}$, OUT1 changes from low to high and starts to charge the timeout capacitor ($C_t$). If $V_{\text{IN}}$ is kept above the threshold voltage and the voltage in $C_t$ reaches $V_{\text{REF}}$, OUT2 toggles. If $V_{\text{IN}}$ falls below the threshold voltage while $C_t$ is charging, the timeout capacitor quickly discharges, preventing OUT2 from toggling while $V_{\text{IN}}$ is not stable.

In the condition that $V_{\text{IN}}$ is tied to $V_{\text{CC}}$, the circuit operates when $V_{\text{CC}}$ is more than the minimum operating voltage. The threshold voltage ($V_{\text{TH}}$) is configured by changing the resistor divider or $V_{\text{REF}}$. Calculate the threshold voltage by

$$V_{\text{TH}} = V_{\text{REF}} \left( 1 + \frac{R_1}{R_2} \right)$$  \hspace{1cm} (39)

Timeout is adjusted by changing the values of the pull-up resistor or the timeout capacitor. To set the timeout value, determine the allowable current flowing through $R_{\text{FULL-UP}}$ and $I_{\text{FULL-UP}}$. When $I_{\text{FULL-UP}}$ is known, calculate $R_{\text{FULL-UP}}$ and $C_t$ by the following formulas:

$$R_{\text{FULL-UP}} = \frac{V_{\text{CC}}}{I_{\text{FULL-UP}}}$$  \hspace{1cm} (40)

$$C_t = \frac{-t_{\text{RESET}}}{R_{\text{FULL-UP}} \ln \left( 1 - \frac{V_{\text{REF}}}{V_{\text{CC}}} \right)}$$  \hspace{1cm} (41)
