FEATURES
Input voltage range: 4.5 V to 16 V
Maximum output current: 800 mA
Low noise
1.0 µV rms total integrated noise from 100 Hz to 100 kHz
1.6 µV rms total integrated noise from 10 Hz to 100 kHz
Noise spectral density: 1.7 nV/√Hz typical from 10 kHz to 1 MHz
Power supply rejection ratio (PSRR) at 400 mA load
>90 dB from 1 kHz to 100 kHz, V_{OUT} = 5 V
>60 dB at 1 MHz, V_{OUT} = 5 V
Dropout voltage: 0.6 V at V_{OUT} = 5 V, 800 mA load
Initial voltage accuracy: ±1%
Voltage accuracy over line, load and temperature: ±2%
Quiescent current (I_{LOAD}): 4.3 mA at no load
Low shutdown current: 0.1 µA
Stable with a 10 µF ceramic output capacitor
Fixed output voltage options: 1.8 V, 2.8 V, 3.0 V, 3.3 V, 4.5 V, 4.8 V, and 5.0 V (16 outputs between 1.5 V and 5.0 V are available)
Exposed pad 8-lead LFCSP and 8-lead SOIC packages

APPLICATIONS
Regulated power noise sensitive applications
RF mixers, phase-locked loops (PLLs), voltage-controlled oscillators (VCOs), and PLLs with integrated VCOs
Communications and infrastructure
Cable digital-to-analog converter (DAC) drivers
Backhaul and microwave links

GENERAL DESCRIPTION
The ADM7150 is a low dropout (LDO) linear regulator that operates from 4.5 V to 16 V and provides up to 800 mA of output current. Using an advanced proprietary architecture, it provides high power supply rejection (>90 dB from 1 kHz to 1 MHz), ultralow output noise (<1.7 nV/√Hz), and achieves excellent line and load transient response with a 10 µF ceramic output capacitor.

The ADM7150 is available in 1.8 V, 2.8 V, 3.0 V, 3.3 V, 4.5 V, 4.8 V, and 5.0 V fixed outputs. In addition, 16 fixed output voltages between 1.5 V and 5.0 V are available upon request.

The ADM7150 regulator typical output noise is 1.0 µV rms from 100 Hz to 100 kHz for fixed output voltage options, and the noise spectral density is 1.7 nV/√Hz from 10 kHz to 1 MHz.

The ADM7150 is available in 8-lead, 3 mm × 3 mm LFCSP and 8-lead SOIC packages, making it not only a very compact solution but also providing excellent thermal performance for applications requiring up to 800 mA of output current in a small, low profile footprint. See the ADM7151 adjustable LDO to generate additional output voltages.

1 Based on an end-point calculation using 1 mA and 800 mA loads. See Figure 7, Figure 16, and Figure 22 for typical load regulation performance for loads less than 1 mA.
2 Current-limit threshold is defined as the current at which the output voltage drops to 90% of the specified typical value. For example, the current limit for a 5.0 V output voltage is defined as the current that causes the output voltage to drop to 90% of 5.0 V, or 4.5 V.
3 Dropout voltage is defined as the input-to-output voltage differential when the input voltage is set to achieve the nominal output voltage. Dropout applies only for output voltages above 4.5 V.
4 Start-up time is defined as the time between the rising edge of \(V_{EN}\) to \(V_{OUT}\), \(V_{REG}\), or \(V_{REF}\) being at 90% of its nominal value.
5 The output voltage is turned off until the \(V_{REG}\) UVLO rise threshold is crossed. The \(V_{REG}\) output is turned off until the input voltage UVLO rise threshold is crossed.

</tbody>
</table>

\(^1\) The minimum input, regulator, and output capacitance must be greater than 7.0 μF over the full range of operating conditions. The full range of operating conditions in the application must be considered during device selection to ensure that the minimum capacitance specification is met. X7R and X5R type capacitors are recommended; however, Y5V and Z5U capacitors are not recommended for use with any LDO.
ABSOLUTE MAXIMUM RATINGS

Table 3. Parameter | Rating
--- | ---
VIN to GND | −0.3 V to +18 V
VREG to GND | −0.3 V to VIN, or +6 V (whichever is less)
VOUT to GND | −0.3 V to VREG, or +6 V (whichever is less)
VOUT to BYP | ±0.3 V
EN to GND | −0.3 V to +18 V
BYP to GND | −0.3 V to VREG, or +6 V (whichever is less)
REF to GND | −0.3 V to VREG, or +6 V (whichever is less)
REF_SENSE to GND | −0.3 V to +6 V
Storage Temperature Range | −65°C to +150°C
Junction Temperature | 150°C
Operating Ambient Temperature Range | −40°C to +125°C
Soldering Conditions | JEDEC J-STD-020

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

THERMAL DATA

Absolute maximum ratings apply individually only, not in combination. The ADM7150 can be damaged when the junction temperature limits are exceeded. Monitoring ambient temperature does not guarantee that TJ is within the specified temperature limits. In applications with high power dissipation and poor thermal resistance, the maximum ambient temperature may have to be derated.

In applications with moderate power dissipation and low printed circuit board (PCB) thermal resistance, the maximum ambient temperature can exceed the maximum limit as long as the junction temperature is within specification limits. The junction temperature (Tj) of the device is dependent on the ambient temperature (Ta), the power dissipation of the device (Pd), and the junction to ambient thermal resistance of the package (θja).

Maximum junction temperature (Tj) is calculated from the ambient temperature (Ta) and power dissipation (Pd) using the formula

\[
T_j = T_a + (P_d \times \theta_{ja})
\]

The junction to ambient thermal resistance (θja) of the package is based on modeling and calculation using a 4-layer board. The junction to ambient thermal resistance is highly dependent on the application and board layout. In applications where high maximum power dissipation exists, close attention to thermal board design is required. The value of θja may vary, depending on PCB material, layout, and environmental conditions. The specified values of θja are based on a 4-layer, 4 in. × 3 in. circuit board. See JESD51-7 and JESD51-9 for detailed information on the board construction.

\[\Psi_{jb}\] is the junction to board thermal characterization parameter with units of °C/W. \[\Psi_{jb}\] of the package is based on modeling and the calculation using a 4-layer board. The JESD51-12, Guidelines for Reporting and Using Electronic Package Thermal Information, states that thermal characterization parameters are not the same as thermal resistances. \[\Psi_{jb}\] measures the component power flowing through multiple thermal paths rather than a single path as in thermal resistance (θjb). Therefore, \[\Psi_{jb}\] thermal paths include convection from the top of the package as well as radiation from the package, factors that make \[\Psi_{jb}\] more useful in real-world applications. Maximum junction temperature (Tj) is calculated from the board temperature (Tb) and power dissipation (Pd) using the formula

\[
T_j = T_b + (P_d \times \Psi_{jb})
\]

See JESD51-8 and JESD51-12 for more detailed information about \[\Psi_{jb}\].

THERMAL RESISTANCE

\[\theta_{ja}, \theta_{jc}\], and \[\Psi_{jb}\] are specified for the worst-case conditions, that is, a device soldered in a circuit board for surface-mount packages.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

THEORY OF OPERATION

The ADM7150 is an ultralow noise, high power supply rejection ratio (PSRR) linear regulator targeting radio frequency (RF) applications. The input voltage range is 4.5 V to 16 V, and it can deliver up to 800 mA of output current. Typical shutdown current consumption is 0.1 µA at room temperature.

Optimized for use with 10 µF ceramic capacitors, the ADM7150 provides excellent transient performance.

By heavily filtering the reference voltage, the ADM7150 is able to achieve 1.7 nV/√Hz output typical from 10 kHz to 1 MHz. Because the error amplifier is always in unity gain, the output noise is independent of the output voltage.

To maintain very high PSRR over a wide frequency range, the ADM7150 architecture uses an internal active ripple filter. This stage isolates the low output noise LDO from noise on VIN. The result is that the PSRR of the ADM7150 is significantly higher over a wider frequency range than any single stage LDO.

The ADM7150 uses the EN pin to enable and disable the VOUT pin under normal operating conditions. When EN is high, VOUT turns on, and when EN is low, VOUT turns off. For automatic startup, EN can be tied to VIN.

The ESD protection devices are shown in the block diagram as Zener diodes (see Figure 52).
APPLICATIONS INFORMATION

CAPACITOR SELECTION

Output Capacitor

The ADM7150 is designed for operation with ceramic capacitors but functions with most commonly used capacitors as long as care is taken with regard to the effective series resistance (ESR) value. The ESR of the output capacitor affects the stability of the LDO control loop. A minimum of 10 µF capacitance with an ESR of 0.2 Ω or less is recommended to ensure the stability of the ADM7150. Output capacitance also affects transient response to changes in load current. Using a larger value of output capacitance improves the transient response of the ADM7150 to large changes in load current. Figure 53 shows the transient responses for an output capacitance value of 10 µF.

Input and VREG Capacitor

Connecting a 10 µF capacitor from VIN to GND reduces the circuit sensitivity to PCB layout, especially when long input traces or high source impedance are encountered.

To maintain the best possible stability and PSRR performance, connect a 10 µF capacitor from VREG to GND. When more than 10 µF of output capacitance is required, increase the input and VREG capacitors to match it.

REF Capacitor

The REF capacitor is necessary to stabilize the reference amplifier. Connect at least a 1 µF capacitor between REF and GND.

BYP Capacitor

The BYP capacitor is necessary to filter the reference buffer. A 1 µF capacitor is typically connected between BYP and GND. Capacitors as small as 0.1 µF can be used; however, the output noise voltage of the LDO increases as a result.

In addition, the BYP capacitor value can be increased to reduce the noise below 1 kHz at the expense of increasing the start-up time of the LDO. Very large values of CBYP significantly reduce the noise below 10 Hz. Tantalum capacitors are recommended for capacitors larger than approximately 33 µF. A 1 µF ceramic capacitor in parallel with the larger tantalum capacitor is required to retain good noise performance at higher frequencies. Solid tantalum capacitors are less prone to microphonic noise issues.

Figure 53. Output Transient Response, VOUT = 5 V, COUT = 10 µF, CH1 = Load Current, CH2 = VOUT

Figure 54. Noise Spectral Density vs. Frequency, CBYP = 1 µF to 1 mF

Figure 55. Noise Spectral Density vs. Capacitance (CBYP) for Different Frequencies
**Capacitor Properties**

Any good quality ceramic capacitors can be used with the ADM7150 as long as they meet the minimum capacitance and maximum ESR requirements. Ceramic capacitors are manufactured with a variety of dielectrics, each with different behavior over temperature and applied voltage. Capacitors must have a dielectric adequate to ensure the minimum capacitance over the necessary temperature range and dc bias conditions. X5R or X7R dielectrics with a voltage rating of 6.3 V to 50 V are recommended. However, Y5V and Z5U dielectrics are not recommended due to their poor temperature and dc bias characteristics.

Figure 56 depicts the capacitance vs. dc bias voltage of a 1206, 10 µF, 10 V, X5R capacitor. The voltage stability of a capacitor is strongly influenced by the capacitor size and voltage rating. In general, a capacitor in a larger package or higher voltage rating exhibits better stability. The temperature variation of the X5R dielectric is ~±15% over the −40°C to +85°C temperature range and is not a function of package or voltage rating.

![Graph of Capacitance vs. DC Bias Voltage](image)

Use Equation 1 to determine the worst-case capacitance accounting for capacitor variation over temperature, component tolerance, and voltage.

\[
C_{\text{eff}} = C_{\text{bias}} \times (1 - \text{TEMPCO}) \times (1 - \text{TOL}) 
\]

(1)

where:

- \(C_{\text{bias}}\) is the effective capacitance at the operating voltage.
- \(\text{TEMPCO}\) is the worst-case capacitor temperature coefficient.
- \(\text{TOL}\) is the worst-case component tolerance.

In this example, the worst-case temperature coefficient (TEMPCO) over −40°C to +85°C is assumed to be 15% for an X5R dielectric. The tolerance of the capacitor (TOL) is assumed to be 10%, and \(C_{\text{bias}}\) is 9.72 µF at 5 V, as shown in Figure 56.

Substituting these values in Equation 1 yields

\[
C_{\text{eff}} = 9.72 \mu F \times (1 - 0.15) \times (1 - 0.1) = 7.44 \mu F
\]

Therefore, the capacitor chosen in this example meets the minimum capacitance requirement of the LDO over temperature and tolerance at the chosen output voltage.

To guarantee the performance of the ADM7150, it is imperative that the effects of dc bias, temperature, and tolerances on the behavior of the capacitors be evaluated for each application.

**ENABLE (EN) AND UNDervoltage LOCKOUT (UVLO)**

The ADM7150 uses the EN pin to enable and disable the VOUT pin under normal operating conditions. As shown in Figure 57, when a rising voltage on EN crosses the upper threshold, VOUT turns on. When a falling voltage on EN crosses the lower threshold, VOUT turns off. The hysteresis varies as a function of the input voltage. For example, the EN hysteresis is approximately 200 mV with an input voltage of 4.5 V.

![Graph of EN Response vs. Input Voltage](image)

Figure 57. Typical VOUT Response to EN Pin Operation, VOUT = 3.3 V, VIN = 5 V

![Graph of EN Rise Threshold vs. Input Voltage (VN) for Various Temperatures](image)

Figure 58. Typical EN Rise Threshold vs. Input Voltage (VN) for Various Temperatures
START-UP TIME

The ADM7150 uses an internal soft start to limit the inrush current when the output is enabled. The start-up time for a 5 V output is approximately 3 ms from the time the EN active threshold is crossed to when the output reaches 90% of its final value.

The rise time of the output voltage (10% to 90%) is approximately

\[ 0.0012 \times C_{\text{BYP}} \text{ seconds} \]

where \( C_{\text{BYP}} \) is in microfarads.

![Figure 61. Typical Start-Up Behavior with \( C_{\text{BYP}} = 1 \mu\text{F} \) to 10 \( \mu\text{F} \)]

REF, BYP, AND, VREG PINS

REF, BYP, and VREG are internally generated voltages that require external bypass capacitors for proper operation. Do not, under any circumstances, connect any loads to these pins because doing so compromises the noise and PSRR performance of the ADM7150. Using larger values of \( C_{\text{BYP}}, C_{\text{REF}}, \) and \( C_{\text{REG}} \) is acceptable but can increase the start-up time as described in the Start-Up Time section.

REV. 0 | PAGE 18 OF 24
**CURRENT-LIMIT AND THERMAL OVERLOAD PROTECTION**

The ADM7150 is protected against damage due to excessive power dissipation by current and thermal overload protection circuits. The ADM7150 is designed to current-limit when the output load reaches 1.2 A (typical). When the output load exceeds 1.2 A, the output voltage is reduced to maintain a constant current limit.

Thermal overload protection is included, which limits the junction temperature to a maximum of 155°C (typical). Under extreme conditions (that is, high ambient temperature and/or high power dissipation) when the junction temperature starts to rise above 155°C, thermal shutdown activates, turning off the output and reducing the output current to zero. When the junction temperature drops below 140°C, the output is turned on again, and output current is restored to its operating value.

Consider the case where a hard short from VOUT to GND occurs. At first, the ADM7150 current limits, so that only 1.2 A is conducted into the short. If self heating of the junction is great enough to cause its temperature to rise above 155°C, thermal shutdown activates, turning off the output and reducing the output current to zero. As the junction temperature cools and drops below 140°C, the output turns on and conducts 1.2 A into the short, again causing the junction temperature to rise above 155°C. This thermal oscillation between 140°C and 155°C causes a current oscillation between 1.2 A and 0 mA that continues as long as the short remains at the output.

Current-limit and thermal limit protections are intended to protect the device against accidental overload conditions. For reliable operation, device power dissipation must be externally limited so that the junction temperature does not exceed 150°C.

**THERMAL CONSIDERATIONS**

In applications with low input to output voltage differential, the ADM7150 does not dissipate much heat. However, in applications with high ambient temperature and/or high input voltage, the heat dissipated in the package may become large enough that it causes the junction temperature of the die to exceed the maximum junction temperature of 150°C.

When the junction temperature exceeds 155°C, the converter enters thermal shutdown. It recovers only after the junction temperature decreases below 140°C to prevent any permanent damage. Therefore, thermal analysis for the chosen application is important to guarantee reliable performance over all conditions.

The junction temperature of the die is the sum of the ambient temperature of the environment and the temperature rise of the package due to the power dissipation, as shown in Equation 2.

\[
T_J = T_A + (P_D \times \theta_{JA})
\]  

where:
- \(T_A\) is the ambient temperature.
- \(P_D\) is the power dissipation in the die, given by
  \[
P_D = [(V_{IN} - V_{OUT}) \times I_{LOAD}] + (V_{IN} \times I_{GND})
\]  

where:
- \(V_{IN}\) and \(V_{OUT}\) are the input and output voltages, respectively.
- \(I_{LOAD}\) is the load current.
- \(I_{GND}\) is the ground current.

Power dissipation due to ground current is quite small and can be ignored. Therefore, the junction temperature equation simplifies to the following:

\[
T_J = T_A + ([V_{IN} - V_{OUT}] \times I_{LOAD}) \times \theta_{JA}
\]  

As shown in Equation 4, for a given ambient temperature, input to output voltage differential, and continuous load current, there exists a minimum copper size requirement for the PCB to ensure that the junction temperature does not rise above 150°C.

The heat dissipation from the package can be improved by increasing the amount of copper attached to the pins and exposed pad of the ADM7150. Adding thermal planes under the package also improves thermal performance. However, as listed in Table 6, a point of diminishing returns is eventually reached, beyond which an increase in the copper area does not yield significant reduction in the junction to ambient thermal resistance.

Table 6 shows typical \(\theta_{JA}\) values of the 8-lead SOIC and 8-lead LFCSSP packages.

Table 7 shows the typical \(\Psi_{JB}\) values of the 8-lead SOIC and 8-lead LFCSSP.

The junction temperature of the ADM7150 is calculated from the following equation:

\[
T_J = T_A + (P_D \times \theta_{JA})
\]  

where:
- \(T_J\) is the ambient temperature.
- \(P_D\) is the power dissipation in the die, given by
  \[
P_D = [(V_{IN} - V_{OUT}) \times I_{LOAD}] + (V_{IN} \times I_{GND})
\]  

where:
- \(V_{IN}\) and \(V_{OUT}\) are the input and output voltages, respectively.
- \(I_{LOAD}\) is the load current.
- \(I_{GND}\) is the ground current.
Figure 63 to Figure 68 show junction temperature calculations for different ambient temperatures, power dissipation, and areas of PCB copper.
**Thermal Characterization Parameter (Ψ JB)**

When board temperature is known, use the thermal characterization parameter, Ψ JB, to estimate the junction temperature rise (see Figure 69 and Figure 70). Maximum junction temperature (T J) is calculated from the board temperature (T B) and power dissipation (P D) using the following formula:

\[
T_J = T_B + (P_D \times \Psi_{JB})
\]  

(5)

The typical value of Ψ JB is 15.1°C/W for the 8-lead LFCSP package and 17.9°C/W for the 8-lead SOIC package.

---

**PRINTED CIRCUIT BOARD LAYOUT CONSIDERATIONS**

Place the input capacitor as close as possible to the VIN and GND pins. Place the output capacitor as close as possible to the VOUT and GND pins. Place the bypass capacitors for V REG, V REF, and V BYP close to the respective pins and GND. Use of an 0805, 0603, or 0402 size capacitor achieves the smallest possible footprint solution on boards where area is limited.
