FEATURES

2 A maximum output current
Low input voltage supply range
  \( V_{\text{IN}} = 1.10 \text{ V} \) to 1.98 V, no external bias supply required
Fixed output voltage range: \( V_{\text{OUT, FIXED}} = 0.9 \text{ V} \) to 1.5 V
Adjustable output voltage range: \( V_{\text{OUT, ADJ}} = 0.5 \text{ V} \) to 1.5 V
Ultralow noise: 2 \( \mu \text{V} \), rms, 100 Hz to 100 kHz
Noise spectral density
  4 nV/\( \sqrt{\text{Hz}} \) at 10 kHz
  3 nV/\( \sqrt{\text{Hz}} \) at 100 kHz
Low dropout voltage: 62 mV typical at 2 A load
Operating supply current: 4.5 mA typical at no load
\( \pm 1.5\% \) fixed output voltage accuracy over line, load, and temperature
Excellent power supply rejection ratio (PSRR) performance
  62 dB typical at 10 kHz at 2 A load
  46 dB typical at 100 kHz at 2 A load
Excellent load/line transient response
Soft start to reduce inrush current
Optimized for small 10 \( \mu \text{F} \) ceramic capacitors
Current-limit and thermal overload protection
Power-good indicator
Precision enable
16-lead, 3 mm \( \times \) 3 mm LFCSP package

APPLICATIONS

Regulation to noise sensitive applications such as radio frequency (RF) transceivers, analog-to-digital converter (ADC) and digital-to-analog converter (DAC) circuits, phase-locked loops (PLLs), voltage controlled oscillators (VCOs) and clocking integrated circuits
Field-programmable gate array (FPGA) and digital signal processor (DSP) supplies
Medical and healthcare
Industrial and instrumentation

GENERAL DESCRIPTION

The ADP1762 is a low noise, low dropout (LDO) linear regulator. It is designed to operate from a single input supply with an input voltage as low as 1.10 V, without the requirement of an external bias supply, to increase efficiency and provide up to 2 A of output current.

The low 62 mV typical dropout voltage at a 2 A load allows the ADP1762 to operate with a small headroom while maintaining regulation and providing better efficiency.

The ADP1762 is optimized for stable operation with small 10 \( \mu \text{F} \) ceramic output capacitors. The ADP1762 delivers optimal transient performance with minimal board area.

The ADP1762 is available in fixed output voltages ranging from 0.9 V to 1.5 V. The output of the adjustable output model can be set from 0.5 V to 1.5 V through an external resistor connected between VADJ and ground.

The ADP1762 has an externally programmable soft start time by connecting a capacitor to the SS pin. Short-circuit and thermal overload protection circuits prevent damage in adverse conditions.

The ADP1762 is available in a small 16-lead LFCSP package for the smallest footprint solution to meet a variety of applications.

1 Guaranteed by design and characterization; not production tested.
2 Based on an endpoint calculation using 10 mA and 2 A loads.
3 Dropout voltage is defined as the input to output voltage differential when the input voltage is set to the nominal output voltage, which applies only for output voltages above 1.1 V.
4 Start-up time is defined as the time from the rising edge of EN to VOUT being at 90% of the nominal value.
5 Current-limit threshold is defined as the current at which the output voltage drops to 90% of the specified typical value. For example, the current limit for a 1.0 V output voltage is defined as the current that causes the output voltage to drop to 90% of 1.0 V, or 0.9 V.

1 The minimum input and output capacitance must be >7.0 μF over the full range of the operating conditions. Consider the full range of the operating conditions in the application during device selection to ensure that the minimum capacitance specification is met. X7R and X5R type capacitors are recommended. Y5V and Z5U capacitors are not recommended for use with any LDO.

THERMAL DATA

Absolute maximum ratings apply only individually, not in combination. The ADP1762 can be damaged when junction temperature limits are exceeded. Monitoring ambient temperature does not guarantee that the junction temperature is within the specified temperature limits. In applications with high power dissipation and poor thermal resistance, the maximum ambient temperature can need to be derated.

In applications with moderate power dissipation and low printed circuit board (PCB) thermal resistance, the maximum ambient temperature can exceed the maximum limit as long as the junction temperature is within specification limits. The junction temperature (TJ) of the device is dependent on the ambient temperature (TA), the power dissipation of the device (PD), and the junction to ambient thermal resistance of the package (θJA). TJ is calculated using the following formula:

\[ TJ = TA + (PD \times θJA) \]

The junction to ambient thermal resistance (θJA) of the package is based on modeling and a calculation using a 4-layer board.

The junction to ambient thermal resistance is highly dependent on the application and board layout. In applications where high maximum power dissipation exists, close attention to thermal board design is required. The value of θJA can vary, depending on PCB material, layout, and environmental conditions. The specified values of θJA are based on a 4-layer, 4 in. × 3 in. circuit board. For details about board construction, refer to JEDEC JESD51-7.

ΨJB is the junction to board thermal characterization parameter with units of °C/W. ΨJB of the package is based on modeling and a calculation using a 4-layer board. The JEDEC JESD51-12 document, Guidelines for Reporting and Using Package Thermal Information, states that thermal characterization parameters are not the same as thermal resistances. ΨJB measures the component power flowing through multiple thermal paths rather than a single path, as in thermal resistance (θJA). Therefore, ΨJB thermal paths include convection from the top of the package as well as radiation from the package, factors that make ΨJB more useful in real-world applications. The maximum junction temperature (TJ) is calculated from the board temperature (TB) and power dissipation (Pd), using the following formula:

\[ TJ = TB + (PD \times ΨJB) \]

Refer to the JEDEC JESD51-8 and JESD51-12 documents for more detailed information about ΨJB.

THERMAL RESISTANCE

θJA and ΨJB are specified for the worst case conditions, that is, a device soldered in a circuit board for surface-mount packages.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.
# PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

**Table 6. Pin Function Descriptions**

<table>
<thead>
<tr>
<th>Pin No.</th>
<th>Mnemonic</th>
<th>Description</th>

THEORY OF OPERATION

The ADP1762 is an LDO, low noise linear regulator that uses an advanced proprietary architecture to achieve high efficiency regulation. It also provides high PSRR and excellent line and load transient response using a small 10 μF ceramic output capacitor. The device operates from a 1.10 V to 1.98 V input rail to provide up to 2 A of output current. Supply current in shutdown mode is 2 μA.

The ADP1762 uses the EN pin to enable and disable the VOUT pin under normal operating conditions. When EN is high, VOUT turns on. When EN is low, VOUT turns off. For automatic startup, tie EN to VIN.

SOFT START FUNCTION

For applications that require a controlled startup, the ADP1762 provides a programmable soft start function. The programmable soft start is useful for reducing inrush current upon startup and for providing voltage sequencing. To implement soft start, connect a small ceramic capacitor from SS to GND. At startup, a 10 μA current source charges this capacitor. The voltage at SS limits the ADP1762 start-up output voltage, providing a smooth ramp-up to the nominal output voltage. To calculate the start-up time for the fixed output and adjustable output, use the following equations:

\[
I_{START-UP_FIXED} = I_{DELAY} + V_{REF} \times \left( \frac{CSS}{ISS} \right)
\]

\[
I_{START-UP_ADJ} = I_{DELAY} + V_{ADJ} \times \left( \frac{CSS}{ISS} \right)
\]

where:

- \(I_{DELAY}\) is a fixed delay of 100 μs.
- \(V_{REF}\) is a 0.5 V internal reference for the fixed output model option.
- \(CSS\) is the soft start capacitance from SS to GND.
- \(ISS\) is the current sourced from SS (10 μA).
- \(V_{ADJ}\) is the voltage at the VADJ pin equal to \(R_{ADJ} \times I_{ADJ}\).

Internally, the ADP1762 consists of a reference, an error amplifier, and a pass device. The output current is delivered via the pass device, which is controlled by the error amplifier, forming a negative feedback system that ideally drives the feedback voltage to equal the reference voltage. If the feedback voltage is lower than the reference voltage, the negative feedback drives more current, increasing the output voltage. If the feedback voltage is higher than the reference voltage, the negative feedback drives less current, decreasing the output voltage.

The ADP1762 is available in output voltages ranging from 0.9 V to 1.5 V for a fixed output. Contact a local Analog Devices, Inc., sales representative for other fixed voltage options. The adjustable output option can be set from 0.5 V to 1.5 V.
ADJUSTABLE OUTPUT VOLTAGE

The output voltage of the ADP1762 can be set over a 0.5 V to 1.5 V range. Connect a resistor (RADJ) from the VADJ pin to ground to set the output voltage. To calculate the output voltage, use the following equation:

\[ V_{OUT} = A_D \times (R_{ADJ} \times I_{ADJ}) \]  

(3)

where:

- \( A_D \) is the gain factor with a typical value of 3.0 between the VADJ pin and VOUT pin.
- \( I_{ADJ} \) is the 50.0 μA constant current out of the VADJ pin.

ENABLE FEATURE

The ADP1762 uses the EN pin to enable and disable the VOUT pins under normal operating conditions. As shown in Figure 27, when a rising voltage on EN crosses the active threshold, VOUT turns on. When a falling voltage on EN crosses the inactive threshold, VOUT turns off.

![Figure 27. Typical EN Pin Operation](image)

As shown in Figure 28, the EN pin has hysteresis built in. This hysteresis prevents on/off oscillations that can occur due to noise on the EN pin as it passes through the threshold points.

![Figure 28. Output Voltage vs. Typical EN Pin Voltage, VOUT = 1.3 V](image)

POWER-GOOD (PG) FEATURE

The ADP1762 provides a power-good pin (PG) to indicate the status of the output. This open-drain output requires an external pull-up resistor that can be connected to VIN or VOUT. If the device is in shutdown mode, current-limit mode, or thermal shutdown, or if it falls below 90% of the nominal output voltage, PG immediately transitions low. During soft start, the rising threshold of the power-good signal is 95% of the nominal output voltage.

The open-drain output is held low when the ADP1762 has a sufficient input voltage to turn on the internal PG transistor. An optional soft start delay can be detected. The PG transistor is terminated via a pull-up resistor to VOUT or VIN.

Power-good accuracy is 92.5% of the nominal regulator output voltage when this voltage is rising, with a 95% trip point when this voltage is falling.

Regulator input voltage brownouts or glitches trigger a power no good if VOUT falls below 92.5%.

A normal power-down triggers a power good when VOUT is at 95%.
APPLICATIONS INFORMATION

CAPACITOR SELECTION

Output Capacitor

The ADP1762 is designed for operation with small, space-saving ceramic capacitors, but it can function with most commonly used capacitors as long as care is taken with the effective series resistance (ESR) value. The ESR of the output capacitor affects the stability of the LDO control loop. A minimum of 10 µF capacitance with an ESR of 500 mΩ or less is recommended to ensure the stability of the ADP1762. Transient response to changes in load current is also affected by output capacitance. Using a larger value of output capacitance improves the transient response of the ADP1762 to large changes in load current. Figure 31 and Figure 32 show the transient responses for output capacitance values of 10 µF and 47 µF, respectively.

**Figure 31. Output Transient Response, C<sub>OUT</sub> = 10 µF**

**Figure 32. Output Transient Response, C<sub>OUT</sub> = 47 µF**

Input Bypass Capacitor

Connecting a 10 µF capacitor from the VIN pin to the GND pin to ground reduces the circuit sensitivity to the PCB layout, especially when long input traces or high source impedance are encountered. If output capacitance greater than 10 µF is required, it is recommended that the input capacitor be increased to match it.

**Input and Output Capacitor Properties**

Use any good quality ceramic capacitors with the ADP1762, as long as they meet the minimum capacitance and maximum ESR requirements. Ceramic capacitors are manufactured with a variety of dielectrics, each with different behavior over temperature and applied voltage. Capacitors must have a dielectric adequate to ensure the minimum capacitance over the necessary temperature range and dc bias conditions. X5R or X7R dielectrics with a voltage rating of 6.3 V or 10 V are recommended. Y5V and Z5U dielectrics are not recommended, due to poor temperature and dc bias characteristics.

Figure 33 shows the capacitance vs. bias voltage characteristics of an 0805 case, 10 µF, 10 V, X5R capacitor. The voltage stability of a capacitor is strongly influenced by the capacitor size and voltage rating. In general, a capacitor in a larger package or with a higher voltage rating exhibits better stability. The temperature variation of the X5R dielectric is about ±15% over the −40°C to +85°C temperature range and is not a function of package size or voltage rating.

**Figure 33. Capacitance vs. DC Bias Voltage**

Use Equation 4 to determine the worst case capacitance, accounting for capacitor variation over temperature, component tolerance, and voltage.

\[
C_{\text{EFF}} = C_{\text{OUT}} \times (1 - \text{tempco}) \times (1 - \text{TOL})
\]

where:

- \(C_{\text{EFF}}\) is the effective capacitance at the operating voltage.
- \(C_{\text{OUT}}\) is the output capacitor.
- Tempco is the worst case capacitor temperature coefficient.
- TOL is the worst case component tolerance.

In this example, the worst case temperature coefficient (tempco) over −40°C to +85°C is assumed to be 15% for an X5R dielectric. The tolerance of the capacitor (TOL) is assumed to be 10%, and \(C_{\text{OUT}} = 10 \mu\text{F}\) at 1.0 V, as shown in Figure 33.

Substituting these values in Equation 4 yields

\[
C_{\text{EFF}} = 10 \mu\text{F} \times (1 - 0.15) \times (1 - 0.1) = 7.65 \mu\text{F}
\]
Therefore, the capacitor chosen in this example meets the minimum capacitance requirement of the LDO over temperature and tolerance at the chosen output voltage.

To guarantee the performance of the ADP1762, it is imperative that the effects of dc bias, temperature, and tolerances on the behavior of the capacitors be evaluated for each application.

**UNDERVOLTAGE LOCKOUT**

The ADP1762 has an internal undervoltage lockout circuit that disables all inputs and the output when the input voltage is less than approximately 1.06 V. The UVLO ensures that the ADP1762 inputs and the output behave in a predictable manner during power-up.

**CURRENT-LIMIT AND THERMAL OVERLOAD PROTECTION**

The ADP1762 is protected against damage due to excessive power dissipation by current-limit and thermal overload protection circuits. The ADP1762 is designed to reach the current limit when the output load reaches 3 A (typical). When the output load exceeds 3 A, the output voltage is reduced to maintain a constant current limit.

Thermal overload protection is included, which limits the junction temperature to a maximum of 150°C (typical). Under extreme conditions (that is, high ambient temperature and power dissipation) when the junction temperature begins to rise above 150°C, the output is turned off, reducing the output current to zero. When the junction temperature drops below 135°C (typical), the output is turned on again, and the output current is restored to the nominal value.

Consider the case where a hard short from VOUT to ground occurs. At first, the ADP1762 reaches the current limit so that only 3 A is conducted into the short circuit. If self heating of the junction becomes great enough to cause the temperature to rise above 150°C, thermal shutdown activates, turning off the output and reducing the output current to zero. As the junction temperature cools and drops below 135°C, the output turns on again, and the output current is restored to the nominal value.

Current-limit and thermal overload protections are intended to protect the device against accidental overload conditions. For reliable operation, limit the device power externally so that junction temperatures do not exceed 125°C.

**THERMAL CONSIDERATIONS**

To guarantee reliable operation, the junction temperature of the ADP1762 must not exceed 125°C. To ensure that the junction temperature stays below this maximum value, the user needs to be aware of the parameters that contribute to junction temperature changes. These parameters include ambient temperature, power dissipation in the power device, and thermal resistance between the junction and ambient air (θJA). The θJA value is dependent on the package assembly compounds used and the amount of copper to which the GND pin and the exposed pad (EPAD) of the package are soldered on the PCB. Table 7 shows typical θJA values for the 16-lead LFCSP for various PCB copper sizes. Table 8 shows typical ΨJB values for the 16-lead LFCSP.

</tr>
</tbody>
</table>

To calculate the junction temperature of the ADP1762, use the following equation:

\[
T_J = T_A + (P_D \times \theta_{JA}) \tag{5}
\]

where:

- \(T_A\) is the ambient temperature.
- \(P_D\) is the power dissipation in the die, given by
  \[
  P_D = (V_{IN} - V_{OUT}) \times I_{LOAD} + (V_{IN} \times I_{GND}) \tag{6}
  \]

where:

- \(V_{IN}\) and \(V_{OUT}\) are the input and output voltages, respectively.
- \(I_{LOAD}\) is the load current.
- \(I_{GND}\) is the ground current.

As shown in Equation 6, for a given ambient temperature and computed power dissipation, a minimum copper size requirement exists for the PCB to ensure that the junction temperature does not rise above 125°C.

---

Rev. A | Page 14 of 18
Figure 34 through Figure 39 show the junction temperature calculations for the different ambient temperatures, load currents, $V_{IN}$ to $V_{OUT}$ differentials, and areas of PCB copper.
In cases where the board temperature is known, the thermal characterization parameter ($\Psi_{jB}$) can be used to estimate the junction temperature rise. The maximum junction temperature ($T_J$) is calculated from the board temperature ($T_B$) and power dissipation ($P_D$) using the following formula:

$$T_J = T_B + (P_D \times \Psi_{jB})$$  \hfill (7)$$

Figure 40 through Figure 43 show the junction temperature calculations for the different board temperatures, load currents, $V_{IN}$ to $V_{OUT}$ differentials, and areas of PCB copper.
PCB LAYOUT CONSIDERATIONS

Heat dissipation from the package can be improved by increasing the amount of copper attached to the pins of the ADP1762. However, as shown in Table 8, a point of diminishing returns is eventually reached, beyond which an increase in the copper size does not yield significant heat dissipation benefits.

Use the following recommendations when designing PCBs:

- Place the input capacitor as close as possible to the VIN and GND pins.
- Place the output capacitor as close as possible to the VOUT and GND pins.
- Place the soft start capacitor (CSS) as close as possible to the SS pin.
- Place the reference capacitor (CREF) and regulator capacitor (CREG) as close as possible to the REFCAP pin and the VREG pin, respectively.
- Connect the load as close as possible to the VOUT and SENSE pins.

Use of 0603 or 0805 size capacitors and resistors achieves the smallest possible footprint solution on boards where area is limited.
