Low Noise, Matched Dual PNP Transistor

MAT03

FEATURES
Dual Matched PNP Transistor
Low Offset Voltage: 100 µV Max
Low Noise: 1 nV/√Hz @ 1 kHz Max
High Gain: 100 Min
High Gain Bandwidth: 190 MHz Typ
Tight Gain Matching: 3% Max
Excellent Logarithmic Conformance: $r_{BE} = 0.3 \, \Omega$ typ

PIN CONNECTION
TO-78 (H Suffix)

GENERAL DESCRIPTION
The MAT03 dual monolithic PNP transistor offers excellent parametric matching and high frequency performance. Low noise characteristics (1 nV/√Hz max @ 1 kHz), high bandwidth (190 MHz typical), and low offset voltage (100 µV max), makes the MAT03 an excellent choice for demanding preamplifier applications. Tight current gain matching (3% max mismatch) and high current gain (100 min), over a wide range of collector current, makes the MAT03 an excellent choice for current mirrors. A low value of bulk resistance (typically 0.3 Ω) also makes the MAT03 an ideal component for applications requiring accurate logarithmic conformance.

Each transistor is individually tested to data sheet specifications. Device performance is guaranteed at 25°C and over the extended industrial and military temperature ranges. To ensure the long-term stability of the matching parameters, internal protection diodes across the base-emitter junction clamp any reverse base-emitter junction potential. This prevents a base-emitter breakdown condition that can result in degradation of gain and matching performance due to excessive breakdown current.

#### NOTES

<sup>1</sup>Current gain is measured at collector-base voltages (V<sub>CBO</sub>) swept from 0 to V<sub>MAX</sub> at indicated collector current. Typicals are measured at V<sub>CBO</sub> = 0 V.

<sup>2</sup>Current gain matching (Δh<sub>FE</sub>) is defined as: Δh<sub>FE</sub> = 100 (ΔI<sub>B</sub>)/h<sub>FE</sub>(min).

<sup>3</sup>Offset voltage is defined as: V<sub>OS</sub> = V<sub>BE1</sub> - V<sub>BE2</sub>, where V<sub>OS</sub> is the differential voltage for I<sub>C1</sub> = I<sub>C2</sub>; V<sub>OS</sub> = V<sub>BE1</sub> - V<sub>BE2</sub> = kT/q In (I<sub>C1</sub>/I<sub>C2</sub>).

<sup>4</sup>Sample tested. Noise tested and specified as equivalent input voltage for each transistor.

Specifications subject to change without notice.

**WARN!**

*ESD SENSITIVE DEVICE*

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the MAT03 features propriety ESD protection circuitry, permanent damage may occur on devices subjected to high-energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

APPLICATIONS INFORMATION
MAT03 MODELS
The MAT03 model (Figure 1) includes parasitic diodes $D_3$ through $D_6$. $D_1$ and $D_2$ are internal protection diodes that prevent zenering of the base-emitter junctions.

The analysis programs, SPICE and SABER, are primarily used in evaluating the functional performance of systems. The models are provided only as an aid in using these simulation programs.

MAT03 NOISE MEASUREMENT
All resistive components (Johnson noise, $e_n^2 = 4kTBR$, or $e_n = 0.13\sqrt{R/nV/Hz}$, where $R$ is in kΩ) and semiconductor junctions (shot noise, caused by current flowing through a junction, produces voltage noise in series impedances such as transistor-collector load resistors, $I_n = 0.566 \sqrt{I/pA/\sqrt{Hz}}$ where $I$ is in µA) contribute to the system input noise.

Figure 2 illustrates a technique for measuring the equivalent input noise voltage of the MAT03. 1 mA of stage current is used.
to bias each side of the differential pair. The 5 kΩ collector resistors noise contribution is insignificant compared to the voltage noise of the MAT03. Since noise in the signal path is referred back to the input, this voltage noise is attenuated by the gain of the circuit. Consequently, the noise contribution of the collector load resistors is only 0.048 nV/√Hz. This is considerably less than the typical 0.8 nV/√Hz input noise voltage of the MAT03 transistor.

The noise contribution of the OP27 gain stages is also negligible due to the gain in the signal path. The op amp stages amplify the input referred noise of the transistors to increase the signal strength to allow the noise spectral density (e\text{in} × 10000) to be measured with a spectrum analyzer. Since we assume equal noise contributions from each transistor in the MAT03, the output is divided by √2 to determine a single transistor’s input noise.

Air currents cause small temperature changes that can appear as low frequency noise. To eliminate this noise source, the measurement circuit must be thermally isolated. Effects of extraneous noise sources must also be eliminated by totally shielding the circuit.

**SUPER LOW NOISE AMPLIFIER**

The circuit in Figure 3a is a super low noise amplifier with equivalent input voltage noise of 0.32 nV/√Hz. By paralleling three MAT03 matched pairs, a further reduction of amplifier noise is attained by a reduction of the base spreading resistance by a factor of 3, and consequently the noise by √3. Additionally, the shot noise contribution is reduced by maintaining a high collector current (2 mA/device) which reduces the dynamic emitter resistance and decreases voltage noise. The voltage noise is inversely proportional to the square root of the stage current, and current noise increases proportionally to the square root of the stage current. Accordingly, this amplifier capitalizes on voltage noise reduction techniques at the expense of increasing the current noise. However, high current noise is not usually important when dealing with low impedance sources.

![Figure 3a. Super Low Noise Amplifier](image-url)
This amplifier exhibits excellent full power ac performance, 0.08% THD into a 600 Ω load, making it suitable for exacting audio applications (see Figure 3b).

**LOW NOISE MICROPHONE PREAMPLIFIER**

Figure 4 shows a microphone preamplifier that consists of a MAT03 and a low noise op amp. The input stage operates at a relatively high quiescent current of 2 mA per side, which reduces the MAT03 transistor’s voltage noise. The $1/f$ corner is less than 1 Hz. Total harmonic distortion is under 0.005% for a 10 V p-p signal from 20 Hz to 20 kHz. The preamp gain is 100, but can be modified by varying $R_5$ or $R_6$ ($V_{OUT}/V_{IN} = R_5/R_6 + 1$).

A total input stage emitter current of 4 mA is provided by $Q_2$. The constant current in $Q_2$ is set by using the forward voltage of a GaAsP LED as a reference. The difference between this voltage and the $V_{BE}$ of a silicon transistor is predictable and constant (to a few percent) over a wide temperature range. The voltage difference, approximately 1 V, is dropped across the 250 Ω resistor which produces a temperature stabilized emitter current.

**CURRENT SOURCES**

A fundamental requirement for accurate current mirrors and active load stages is matched transistor components. Due to the excellent $V_{BE}$ matching (the voltage difference between $V_{BE}$ required to equalize collector current) and gain matching, the MAT03 can be used to implement a variety of standard current mirrors that can source current into a load such as an amplifier stage. The advantages of current loads in amplifiers versus resistors is an increase of voltage gain due to higher impedances, larger signal range, and in many applications a wider signal bandwidth.

Figure 5 illustrates a cascode current mirror consisting of two MAT03 transistor pairs.

The cascode current source has a common base transistor in series with the output which causes an increase in output impedance of the current source since $V_{CE}$ stays relatively constant. High frequency characteristics are improved due to a reduction of Miller capacitance. The small-signal output impedance can be determined by consulting “$r_{Q1}$ vs. Collector Current” typical graph. Typical output impedance levels approach the performance of a perfect current source.

Considering a typical collector current of 100 µA, we have:

$$r_{Q1} = \frac{1}{1.0 \, \mu \text{MHO}} = 1 \, \text{MΩ}$$
Q2 and Q3 are in series and operate at the same current levels so the total output impedance is:
\[ R_O = h_{FE} r_o Q_3 \@ (160)(1 \text{ M\Omega}) = 160 \text{ M\Omega}. \]

Since Q2 buffers Q3, both transistors in the MAT03, Q1 and Q3, maintain the same collector current. D2 and D3 form a Baker clamp which prevents Q2 from turning off, thereby improving the switching speed of the current mirror. The feedback serves to increase the output impedance and improves accuracy by reducing the base-width modulation which occurs with varying collector-emitter voltages. Accuracy and linearity performance of the current pump is summarized in Figure 8.

**CURRENT MATCHING**

The objective of current source or mirror design is generation of currents that are either matched or must maintain a constant ratio. However, mismatch of base emitter voltages cause output current errors. Consider the example of Figure 5. If the resistors and transistors are equal and the collector voltages are the same, the collector currents will match precisely. Investigating the current matching errors resulting from a nonzero VOS, we define \( \Delta I_c \) as the current error between the two transistors.

Graph 6b describes the relationship of current matching errors versus offset voltage for a specified average current \( I_C \). Note that since the relative error between the currents is exponentially proportional to the offset voltage, tight matching is required to design high accuracy current sources. For example, if the offset voltage is 5 mV at 100 \( \mu \)A collector current, the current matching error would be 20%. Additionally, temperature effects such as offset drift (3 \( \mu \)V/°C per mV of VOS) will degrade performance if Q1 and Q2 are not well matched.

**DIGITALLY PROGRAMMABLE BIPOLAR CURRENT PUMP**

The circuit of Figure 7 is a digitally programmable current pump. The current pump incorporates a DAC08, and a fast Wilson current source using the MAT03. Examining Figure 7, the DAC08 is set for 2 mA full-scale range so that bipolar current operation of ±2 mA is achieved. The Wilson current mirror maintains linearity within the LSB range of the 8-bit DAC08 (±2 mA/256 = 15.6 \( \mu \)A resolution) as seen in Figure 8. A negative feedback path established by Q2 regulates the collector current so that it matches the reference current programmed by the DAC08.

Collector-emitter voltages across both Q1 and Q3 are matched by D1, with Q3’s collector-emitter voltage remaining constant, independent of the voltage across the current source output.
The full-scale output of the DAC08, $I_{OUT}$, is a linear function of $I_{REF}$

$$I_{REF} = \frac{256}{256} \times I_{REF}, \quad \text{and} \quad I_{OUT} + \frac{I_{OUT}}{256} = I_{REF} \frac{256}{256}$$

The current mirror output is $I_{OUT} - \frac{I_{OUT}}{256} = 1$, so that if $I_{REF} = 2$ mA:

$$I = 2 \left( \frac{\text{Input Code}}{256} \right) (2 \text{mA}) - 1.992 \text{mA}.$$
