**Typical Applications**

The HMC1010LP4E is ideal for:

- Log -> Root-Mean-Square (RMS) Conversion
- Received Signal Strength Indication (RSSI)
- Transmitter Signal Strength Indication (TSSI)
- RF Power Amplifier Efficiency Control
- Receiver Automatic Gain Control
- Transmitter Power Control

**Features**

- ±1 dB Detection Accuracy to 3.9 GHz
- Input Dynamic Range: -50 dBm to +10 dBm
- RF Signal Wave shape & Crest Factor Independent
- Digitally Programmable Integration Bandwidth
- +5V Operation from -40°C to +85°C
- Excellent Temperature Stability
- Power-Down Mode
- 24 Lead 4x4mm SMT Package: 16mm²

**General Description**

The HMC1010LP4E Power Detector is designed for RF power measurement, and control applications for frequencies up to 3.9 GHz. The detector provides an accurate RMS representation of any RF/IF input signal. The output is a temperature compensated monotonic, representation of real signal power, measured with an input sensing range of 60 dB.

The HMC1010LP4E is ideally suited to those wide bandwidth, wide dynamic range applications, requiring repeatable measurement of real signal power, especially where RF/IF wave shape and/or crest factor change with time.

The integration bandwidth of the HMC1010LP4E is digitally programmable with the use of input pins SCI1-4 with a range of more than 4 decades. This allows the user to dynamically set the operation bandwidth providing the capability of handling different types of modulations on the same platform.

The HMC1010LP4E features an internal OP-AMP at output stage, which provides for slope & intercept adjustments and enables controller application.

**Electrical Specifications, $T_A = +25\, ^\circ\mathrm{C}, Vcc = 5V$**

Evaluation PCB - Differential Configuration

The circuit board used in the application should use RF circuit design techniques. Signal lines should have 50 Ohm impedance while the package ground leads and exposed paddle should be connected directly to the ground plane similar to that shown. A sufficient number of via holes should be used to connect the top and bottom ground planes. The evaluation circuit board shown is available from Hittite upon request.

Application Information

Principle of Operation

Monolithic true-RMS detectors are in-effect analog calculators, calculating the RMS value of the input signal, unlike other types of power detectors which are designed to respond to the RF signal envelope. At the core of an RMS detector is a full-wave rectifier, log/antilog circuit, and an integrator. The RMS output signal is directly proportional to the logarithm of the time-average of $V_{IN}^2$. The bias block also contains temperature compensation circuits which stabilize output accuracy over the entire operating temperature range. The DC offset cancellation circuit actively cancels internal offsets so that even very small input signals can be measured accurately.

Configuration For The Typical Application

The RF input can be connected in differential configuration, or single-ended configuration: see “RF Input Interface” section for details on input configuration.

The RMS output signal is typically connected to VSET, through a resistive network providing a Pin -> RMSOUT transfer characteristic slope of 36.6mV/dBm (at 900 MHz), however the RMS output can be re-scaled to “magnify” a specific portion of the input sensing range, and to fully utilize the dynamic range of the RMS output. Refer to the section under the “log-slope and intercept” heading for details.

Due to part-to-part variations in log-slope and log-intercept, a system-level calibration is recommended to satisfy absolute accuracy requirements: refer to the “System Calibration” section for more details.
RF Input Interface

The IN+ and IN- pins are differential RF inputs, which can be externally configured with differential or single-ended input. Power match components are placed at these input terminals, along with DC blocking capacitors. The coupling capacitor values also set the lower spectral boundary of the input signal bandwidth.

Differential (Diff) Input Interface:

The value of R1 depends on the balun used; if the balun is 50Ω on both sides of the SE-Diff conversion, then

\[ R1 = \frac{150 \times RM}{150 - RM} \, \Omega, \]

where

\[ RM = \text{the desired power match impedance in ohms} \]

For RM = 50Ω, \( R1 = 75Ω \approx 68Ω \).

Single-Ended (SE) Input Interface:

Tuned SE-interface for signal frequency = 900 MHz

Use \( R4 = 27Ω, R11 = 82Ω, C3 = 100 \, \text{pF}, L1=6.8nH, C4=5.6\,\text{pF}, R10 = 0Ω. \) Refer to application circuit for single-ended configuration on page 11-14.

RMSOUT & Error vs. Pin Using Tuned SE-Interface: 900 ± 100 MHz

![Graph showing RMSOUT & Error vs. Pin Using Tuned SE-Interface: 900 ± 100 MHz](image)

Tuned SE-interface for signal frequency = 2100 MHz
Use R4 = 27Ω, R11 = 82Ω, C3 = 100 pF, L1=2.4nH, C4=2pF, R10 = 0Ω. Refer to application circuit for single-ended configuration on page 11-14.

RMSOUT & Error vs. Pin Using Tuned SE-Interface: 2100 ± 100 MHz

Please contact Hittite Customer Support for single-ended tuning for other signal frequencies.
A DC bias (Vcc-1.2V) is present on the IN+ and IN- pins, and should not be overridden

RMS Output Interface and Transient Response

The HMC1010LP4 features digital input pins (SCI1-SCI4) that control the internal integration time constant. Output transient response is determined by the digital integration controls, and output load conditions.

Shortest integration time is for SCI=0000, allowed longest integration time is for SCI=1100 (1101, 1110 and 1111 SCI settings are forbidden states).

Using larger values of SCI will narrow the operating bandwidth of the integrator, resulting in a longer averaging time-interval and a more filtered output signal; however it will also slow the power detector’s transient response. A larger SCI value favors output accuracy over speed. For the fastest possible transient settling times set SCI to 0000. This configuration will operate the integrator at its widest possible bandwidth, resulting in short averaging time-interval and an output signal with little filtering. Most applications will choose a SCI setting that maintains balance between speed and accuracy. Furthermore, error performance over modulation bandwidth is dependent on the SCI setting.

For example modulations with relatively low frequency components and high crest factors may require higher SCI (integration) settings.

[2] Input signal is 1900 MHz CW-tone switched on and off
[3] Measured from RF switching edge to 1dB (input referred) settling of RMSOUT.

Information furnished by Analog Devices is believed to be accurate and reliable. However, no responsibility is assumed by Analog Devices for its use, nor for any infringements of patents or other rights of third parties that may result from its use. RMS Power Detector Description:

Rise Time[^1] vs. SCI Setting over Input Power

- Measured from 10% to 90%
- [-40 dBm, -20 dBm, 0 dBm]

Fall Time[^3] vs. SCI Setting over Input Power

- Measured from 100% to 10%
- [-40 dBm, -20 dBm, 0 dBm]

For increased load drive capability, consider a buffer amplifier on the RMS output. Using an integrating amplifier on the RMS output allows for an alternative treatment for faster settling times. An external amplifier optimized for transient settling can also provide additional RMS filtering, when operating HMC1010LP4E with a lower SCI value.

Following figures show how the peak-to-peak ripple decreases with higher SCI settings along with the RF pulse response over different modulations.

Residual Ripple for 2.6 GHz WiMAX OFDM

- Advanced 802.16 @ SCI = 0100
- SCI = 0000
- SCI = 0100

Residual Ripple for 2.6 GHz WiMAX OFDM

- Advanced 802.16 @ SCI = 0101
- SCI = 0000
- SCI = 0101

[^1]: Measured from 10% to 90%
[^2]: Measured from RF switching edge to 1dB (input referred) settling of RMSOUT.
[^3]: Measured from 100% to 10%

**LOG-Slope and Intercept**

The HMC1010LP4 provides for an adjustment of output scale with the use of an integrated operational amplifier. Logslope and intercept can be adjusted to “magnify” a specific portion of the input sensing range, and to fully utilize the dynamic range of the RMS output.

A log-slope of 37.3 mV/dB (@1900 MHz) is set by connecting RMS Output to VSET through resistor network for $\beta = 1$ (see application schematic).

The log-slope is adjusted by applying the appropriate resistors on the RMS and VSET pins. Log-intercept is adjusted by applying a DC voltage to the VSET pin.

Optimized slope $= \beta \times \text{log-slope}$

Optimized intercept $= \text{log-intercept} - \left( \frac{R_{FBK}}{R_{SET}} \right) \times \text{VBLINE}$

\[
\beta = \frac{R_{FBK}}{R_{FBK} // R_{SHUNT} // R_{SET}}
\]

When $R_{FBK} = 0$ to set RMSOUT=VSET, then $\beta = 1/2$

If RSET is not populated, then $\beta = \frac{1}{2} \times \left( \frac{R_{FBK} / (R_{FBK} // R_{SHUNT})}{} \right)$ and intercept is at nominal value.

Example: The logarithmic slope can be simply increased by choosing appropriate RFBK and RSHUNT values while not populating the RSET resistor on the evaluation board to keep the intercept at nominal value.

Setting $R_{FBK} = 4.7K\Omega$ and $R_{SHUNT} = 2.2K\Omega$ results in an optimized slope of:

Optimized Slope $= \beta \times \text{log_slope} = 1.57 \times 37.3\text{mV / dB}$

Optimized Slope $= 58\text{ mV / dB}$
Example: The logarithmic intercept can also be adjusted by choosing appropriate RFBK, RSHUNT, and RSET values. Setting RFBK = 4.7KΩ, RSHUNT = 2.2KΩ, and RSET = 24KΩ results in an optimized slope of:

Optimized Slope = \( \beta \times \log_{\text{slope}} = 1.67 \times 37.3 \text{ mV / dB} \)

Optimized Slope = 62 mV / dB

Optimized Intercept = \( \log_{\text{intercept}} - (RFBK/RSET) \times VBLINE \)

Optimized Intercept = \( \log_{\text{intercept}} - 0.196 \times VBLINE \)
DC Offset Compensation Loop

Internal DC offsets, which are input signal dependant, require continuous cancellation. Offset cancellation is a critical function needed for maintenance of measurement accuracy and sensitivity. The DC offset cancellation loop performs this function, and its response is largely defined by the capacitance (COFS) connected between COFSA, COFSB pins.

COFS sets the loop bandwidth of the DC offset compensations. Higher COFS values are required for measuring lower RF frequencies. The optimal loop bandwidth setting will allow internal offsets to be cancelled at a minimally acceptable speed.

\[ \text{Bandwidth, Hz} = \frac{1}{\pi(5000)(C_{\text{COFS}} + 20 \times 10^{-12})} \]

For example: loop bandwidth for DC cancellation with COFS = 1nF, bandwidth is ~62 kHz

Standby Mode

The ENX can be used to force the power detector into a low-power standby mode. As ENX is deactivated, power is restored to all of the circuits. There is no memory of previous conditions. Coming-out of stand-by, internal integration and COFS capacitors will require recharging, so if large SCI values have been chosen, the wake-up time will be lengthened.

Modulation Performance – Crest factor performance

The HMC1010LP4E can detect modulated signals with very high crest factors accurately. For example, up to 2.7 GHz, a modulated RF signal with a crest factor of 15 dB can be detected with 0.2 dB error.

System Calibration

Due to part-to-part variations in log-slope and log-intercept, a system-level calibration is recommended to satisfy absolute accuracy requirements. When performing this calibration, choose at least two test points: near the top end and bottom-end of the measurement range. It is best to measure the calibration points in the regions (of frequency and amplitude) where accuracy is most important. Derive the log-slope and log-intercept, and store them in non-volatile memory.

For example if the following two calibration points were measured at 2.2 GHz:

- With RMSOUT = 2.321V at Pin = -5 dBm,
- and RMSOUT = 0.809V at Pin = -45 dBm

slope calibration constant = SCC

\[ \text{SCC} = (-45+5)/(0.809-2.321) = 26.45 \text{ dB/V} \]

intercept calibration constant = ICC

\[ \text{ICC} = \text{Pin} – \text{SCC} \times \text{RMSOUT} = -5 – 26.45 \times 2.321 = -66.39 \text{ dBm} \]
Now performing a power measurement at -25 dBm:

\[ \text{RMSOUT measures 1.559V} \]
\[ \text{[Measured PIN]} = \text{[Measured RMSOUT]} \times \text{SCC} + \text{ICC} \]
\[ \text{[Measured PIN]} = 1.559 \times 26.45 - 66.39 = -25.155 \text{ dBm} \]
An error of only 0.155 dB

Factory system calibration measurements should be made using an input signal representative of the application. If the power detector will operate over a wide range of frequencies, choose a central frequency for calibration.

**Layout Considerations**

- Mount RF input coupling capacitors close to the IN+ and IN- pins.
- Solder the heat slug on the package underside to a grounded island which can draw heat away from the die with low thermal impedance. The grounded island should be at RF ground potential.
- Connect power detector ground to the RF ground plane, and mount the supply decoupling capacitors close to the supply pins.

**Definitions**

- Log-slope: slope of PIN -> RMSOUT transfer characteristic. In units of mV/dB
- Log-intercept: x-axis intercept of PIN -> RMSOUT transfer characteristic. In units of dBm.
- RMS Output Error: The difference between the measured PIN and actual PIN using a line of best fit.
\[ \text{[measured PIN]} = \frac{\text{[measured RMSOUT]}}{\text{[best-fit-slope]}} + \text{[best-fit-intercept]}, \text{ dBm} \]
- Input Dynamic Range: the range of average input power for which there is a corresponding RMS output voltage with “RMS Output Error” falling within a specific error tolerance.
- Crest Factor: Peak power to average power ratio for time-varying signals.
