**FEATURES**
- Quad Output Step-Down µModule® Regulator with 4A per Output
- Wide Input Voltage Range: 4V to 14V
  - 2.375V to 14V with External Bias
- 0.6V to 5.5V Output Voltage
- 4A DC, 5A Peak Output Current Each Channel
- Up to 5.5W Power Dissipation (TA = 60°C, 200 LFM, No Heat Sink)
- ±1.5% Total Output Voltage Regulation
- Current Mode Control, Fast Transient Response
- Parallelable for Higher Output Current
- Output Voltage Tracking
- Internal Temperature Sensing Diode Output
- External Frequency Synchronization
- Overvoltage, Current and Temperature Protection
- 9mm × 15mm × 5.01mm BGA Package

**APPLICATIONS**
- Multirail Point of Load Regulation
- FPGAs, DSPs and ASICs Applications

All registered trademarks and trademarks are the property of their respective owners.

**DESCRIPTION**
The LTM®4644/LTM4644-1 is a quad DC/DC step-down µModule (micromodule) regulator with 4A per output. Outputs can be paralleled in an array for up to 16A capability. Included in the package are the switching controllers, power FETs, inductors and support components. Operating over an input voltage range of 4V to 14V or 2.375V to 14V with an external bias supply, the LTM4644/LTM4644-1 supports an output voltage range of 0.6V to 5.5V. Its high efficiency design delivers 4A continuous (5A peak) output current per channel. Only bulk input and output capacitors are needed.

**APPLICATIONS**
- Multirail Point of Load Regulation
- FPGAs, DSPs and ASICs Applications

All registered trademarks and trademarks are the property of their respective owners.

ELECTRICAL CHARACTERISTICS

Note 1: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

Note 2: The LTM4644E/LTM4644-1 is tested under pulsed load conditions such that $T_J = TA$. The LTM4644E/LTM4644-1 is guaranteed to meet performance specifications over the 0°C to 125°C internal operating temperature range. Specifications over the full –40°C to 125°C internal operating temperature range are assured by design, characterization and correlation with statistical process controls. The LTM4644/1/LTM4644-1 is guaranteed to meet specifications over the full –40°C to 125°C internal operating temperature range. The LTM4644MP/LTM4644MP-1 is tested and guaranteed over full –55°C to 125°C internal operating temperature range. Note that the maximum ambient temperature consistent with these specifications is determined by specific operating conditions in conjunction with board layout, the rated package thermal resistance and other environmental factors.

Note 3: 100% tested at wafer level.

Note 4: See output current derating curves for different $V_{IN}$, $V_{OUT}$ and $T_A$.

Note 5: This IC includes overtemperature protection that is intended to protect the device during momentary overload conditions. Junction temperature will exceed 125°C when overtemperature protection is active. Continuous operation above the specified maximum operating junction temperature may impair device reliability.

PIN FUNCTIONS

\textbf{V}_{\text{OUT1}} (A1, A2, A3), \textbf{V}_{\text{OUT2}} (C1, D1, D2), \textbf{V}_{\text{OUT3}} (F1, G1, G2), \textbf{V}_{\text{OUT4}} (J1, K1, K2): Power Output Pins of Each Switching Mode Regulator Channel. Apply output load between these pins and GND pins. Recommend placing output decoupling capacitance directly between these pins and GND pins. See the Applications Information section for paralleling outputs.

\textbf{V}_{\text{IN1}} (B3, B4), \textbf{V}_{\text{IN2}} (E3, E4), \textbf{V}_{\text{IN3}} (H3, H4), \textbf{V}_{\text{IN4}} (L3, L4): Power input pins connect to the drain of the internal top MOSFET for each switching mode regulator channel. Apply input voltages between these pins and GND pins. Recommend placing input decoupling capacitance directly between each of \textbf{V}_{\text{IN}} pins and GND pins.

\textbf{PGOOD1}, \textbf{PGOOD2}, \textbf{PGOOD3}, \textbf{PGOOD4} (C4, F4, J4, K5): Internal 3.3V Regulator Output of Each Switching Mode Regulator Channel. The internal power drivers and control circuits are powered from this voltage. Each pin is internally decoupled to GND with a 1\mu F low ESR ceramic capacitor already.

\textbf{SV}_{\text{IN1}}, \textbf{SV}_{\text{IN2}}, \textbf{SV}_{\text{IN}}, \textbf{SV}_{\text{IN4}} (B5, E5, H5, L5): Signal \textbf{V}_{\text{IN}}. Filtered input voltage to the internal 3.3V regulator for the control circuitry of each Switching mode Regulator Channel. Tie this pin to the \textbf{V}_{\text{IN}} pin respectively in most applications. Connect \textbf{SV}_{\text{IN}} to an external voltage supply of at least 4V which must also be greater than \textbf{V}_{\text{OUT}}.

\textbf{ TRACK/SS1, TRACK/SS2, TRACK/SS3, TRACK/SS4} (A6, D6, G6, K6): Output Tracking and Soft-Start Pin of Each Switching Mode Regulator Channel. Allows the user to control the rise time of the output voltage. Putting a voltage below 0.6V on this pin bypasses the internal reference input to the error amplifier, instead it serves the FB pin to match the TRACK voltage. Above 0.6V, the tracking function stops and the internal reference resumes control of the error amplifier. There’s an internal 2.5\mu A pull-up current from \textbf{INTVCC} on this pin, so putting a capacitor here provides soft-start function.

\textbf{MODE1}, \textbf{MODE2}, \textbf{MODE3}, \textbf{MODE4} (B6, E6, H6, L6): Operation Mode Select for Each Switching Mode Regulator Channel. Tie this pin to \textbf{INTVCC} to force continuous synchronous operation at all output loads. Tying it to \textbf{SGND} enables discontinuous current mode operation at light loads. Do not leave floating.

\textbf{RUN1, RUN2, RUN3, RUN4} (C6, F6, J6, K7): Run Control Input of Each Switching Mode Regulator Channel. Enable regulator operation by tying the specific RUN pin above 1.2V. Pulling it below 1.1V shuts down the respective regulator channel. Do not leave floating.

\textbf{FB1, FB2, FB3, FB4} (A7, D7, G7, J7): The Negative Input of the Error Amplifier for Each Switching Mode Regulator Channel. Internally, in LTM4644, this pin is connected to \textbf{V}_{\text{OUT}} of each channel with a 60.4k\Omega precision resistor. Different output voltages can be programmed with an additional resistor between the FB and GND pins for the LTM4644, and two resistors between the \textbf{V}_{\text{OUT}}, FB and GND pins for the LTM4644-1. In PolyPhase operation, tying the FB pins together allows for parallel operation. See the Applications Information section for details.
**PIN FUNCTIONS**

**COMP1, COMP2, COMP3, COMP4 (B7, E7, H7, L7):** Current Control Threshold and Error Amplifier Compensation Point of Each Switching Mode Regulator Channel. The internal current comparator threshold is proportional to this voltage. Tie the COMP pins together for parallel operation. The device is internally compensated.

**CLKIN (C7):** External Synchronization Input to Phase Detector of the Module. This pin is internally terminated to SGND with 20kΩ. The phase-locked loop will force the channel 1 turn-on signal to be synchronized with the rising edge of the CLKIN signal. Channel 2, channel 3 and channel 4 will also be synchronized with the rising edge of the CLKIN signal with a pre-determined phase shift. See the Applications Information section for details.

**SGND (F7):** Signal Ground Connection. SGND is connected to GND internally through single point. Use a separated SGND ground copper area for the ground of the feedback resistor and other components connected to signal pins. A second connection between the PGND plane and SGND plane is recommended on the backside of the PCB under the module.

**TEMP (F3):** Onboard Temperature Diode for Monitoring the VBE Junction Voltage Change with Temperature. See the Applications Information section.

**OPERATION**

The LTM4644 is a quad output standalone non-isolated switch mode DC/DC power supply. It has four separate regulator channels with each of them capable of delivering up to 4A continuous output current with few external input and output capacitors. Each regulator provides precisely regulated output voltage programmable from 0.6V to 5.5V via a single external resistor (two resistors for LTM4644-1) over 4V to 14V input voltage range. With an external bias voltage, this module can operate from an input voltage as low as 2.375V. The typical application schematic is shown in Figure 33.

The LTM4644 integrates four separate constant frequency controlled on-time valley current mode regulators, power MOSFETs, inductors, and other supporting discrete components. The typical switching frequency is set to 1MHz. For switching noise-sensitive applications, the µModule regulator can be externally synchronized to a clock from 700kHz to 1.3MHz. See the Applications Information section.

With current mode control and internal feedback loop compensation, the LTM4644 module has sufficient stability margins and good transient performance with a wide range of output capacitors, even with all ceramic output capacitors.

Current mode control provides the flexibility of paralleling any of the separate regulator channels with accurate current sharing. With a built-in clock interleaving between each two regulator channels, the LTM4644 could easily employ a 2+2, 3+1 or 4 channels parallel operation which is more than flexible in a multirail POL application like FPGA. Furthermore, the LTM4644 has CLKIN and CLK-OUT pins for frequency synchronization or polyphasing multiple devices which allow up to 8 phases cascaded to run simultaneously.

Current mode control also provides cycle-by-cycle fast current monitoring. Foldback current limiting is provided in an overcurrent condition to reduce the inductor valley current to approximately 40% of the original value when $V_{FB}$ drops. An internal overvoltage and undervoltage comparators pull the open-drain PGOOD output low if the output feedback voltage exits a ±10% window around the regulation point. Continuous conduction mode (CCM) operation is forced during OV and UV conditions except during start-up when the TRACK pin is ramping up to 0.6V. Pulling the RUN pin below 1.1V forces the controller into its shutdown state, turning off both power MOSFETs and most of the internal control circuitry. At light load currents, discontinuous conduction mode (DCM) operation can be enabled to achieve higher efficiency compared to continuous conduction mode (CCM) by setting the MODE pin to SGND. The TRACK/SS pin is used for power supply tracking and soft-start programming. See the Applications Information section.

A temperature diode is included inside the module to monitor the temperature of the module. See the Applications Information section for details.
APPLICATIONS INFORMATION

The typical LTM4644 application circuit is shown in Figure 33. External component selection is primarily determined by the input voltage, the output voltage and the maximum load current. Refer to Table 7 for specific external capacitor requirements for a particular application.

V\text{IN} to V\text{OUT} Step-Down Ratios

There are restrictions in the maximum V\text{IN} and V\text{OUT} step-down ratio that can be achieved for a given input voltage due to the minimum off-time and minimum on-time limits of each regulator. The minimum off-time limit imposes a maximum duty cycle which can be calculated as:

\[ D_{\text{MAX}} = 1 - t_{\text{OFF}(\text{MIN})} \cdot f_{\text{SW}} \]

where \( t_{\text{OFF}(\text{MIN})} \) is the minimum off-time, 70ns typical for LTM4644, and \( f_{\text{SW}} \) is the switching frequency. Conversely the minimum on-time limit imposes a minimum duty cycle of the converter which can be calculated as:

\[ D_{\text{MIN}} = t_{\text{ON}(\text{MIN})} \cdot f_{\text{SW}} \]

where \( t_{\text{ON}(\text{MIN})} \) is the minimum on-time, 40ns typical for LTM4644. In the rare cases where the minimum duty cycle is surpassed, the output voltage will still remain in regulation, but the switching frequency will decrease from its programmed value. Note that additional thermal derating may be applied. See the Thermal Considerations and Output Current Derating section in this data sheet.

Output Voltage Programming (LTM4644)

The PWM controller has an internal 0.6V reference voltage. As shown in the Block Diagram, a 60.4k internal feedback resistor connects each regulator channel from V\text{OUT} pin to FB pin. Adding a resistor \( R_{\text{FB}(\text{BOT})} \) from FB pin to GND programs the output voltage:

\[ R_{\text{FB}(\text{BOT})} = \frac{60.4k}{V_{\text{OUT}} - 0.6} \]

Table 1. \( R_{\text{FB}} \) Resistor Table vs Various Output Voltages

<table>
<thead>
<tr>
<th>( V_{\text{OUT}} ) (V)</th>
<th>0.6</th>
<th>1.0</th>
<th>1.2</th>
<th>1.5</th>
<th>1.8</th>
<th>2.5</th>
<th>3.3</th>
<th>5.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>( R_{\text{FB}(\text{BOT})} ) (k)</td>
<td>Open</td>
<td>90.9</td>
<td>60.4</td>
<td>40.2</td>
<td>30.1</td>
<td>19.1</td>
<td>13.3</td>
<td>8.25</td>
</tr>
</tbody>
</table>

For parallel operation of N channels, use the following equation can be used to solve for \( R_{\text{FB}(\text{BOT})} \). Tie the V\text{OUT} and the FB and COMP pins together for each paralleled output with a single resistor to GND as determined by:

\[ R_{\text{FB}(\text{BOT})} = \left( \frac{60.4k}{N} \right) \left( \frac{V_{\text{OUT}}}{0.6} - 1 \right) \]

OUTPUT VOLTAGE PROGRAMMING (LTM4644-1)

The PWM controller has an internal 0.6V reference voltage. Adding two resistors \( R_{\text{FB}(\text{TOP})} \) from V\text{OUT} to FB pin and \( R_{\text{FB}(\text{BOT})} \) from FB pin to GND programs the output voltage:

\[ R_{\text{FB}(\text{BOT})} = \frac{R_{\text{FB}(\text{TOP})}}{V_{\text{OUT}} - 1} \]

For parallel operation of N Channels, only one set of \( R_{\text{FB}(\text{TOP})} \) and \( R_{\text{FB}(\text{BOT})} \) is needed while tying the V\text{OUT}, FB and COMP pins from different channels together. See Figure 1 for example.

APPLICATIONS INFORMATION

Input Decoupling Capacitors
The LTM4644 module should be connected to a low ac-impedance DC source. For each regulator channel, a 10µF input ceramic capacitor is recommended for RMS ripple current decoupling. A bulk input capacitor is only needed when the input source impedance is compromised by long inductive leads, traces or not enough source capacitance. The bulk capacitor can be an electrolytic aluminum capacitor or polymer capacitor.

Without considering the inductor ripple current, the RMS current of the input capacitor can be estimated as:

\[ I_{\text{CIN(RMS)}} = \frac{I_{\text{OUT(MAX)}} \eta \%}{\sqrt{D \cdot (1 - D)}} \]

where \( \eta \% \) is the estimated efficiency of the power module.

Output Decoupling Capacitors
With an optimized high frequency, high bandwidth design, only single piece of low ESR output ceramic capacitor is required for each regulator channel to achieve low output voltage ripple and very good transient response. Additional output filtering may be required by the system designer, if further reduction of output ripples or dynamic transient spikes is required. Table 7 shows a matrix of different output voltages and output capacitors to minimize the voltage droop and overshoot during a 2A load step transient. Multiphase operation will reduce effective output ripple as a function of the number of phases. Application Note 77 discusses this noise reduction versus output ripple current cancellation, but the output capacitance will be more a function of stability and transient response. The LTpowerCAD™ Design Tool is available to download online for output ripple, stability and transient response analysis and calculating the output ripple reduction as the number of phases implemented increases by N times.

Discontinuous Conduction Mode (DCM)
In applications where low output ripple and high efficiency at intermediate current are desired, discontinuous conduction mode (DCM) should be used by connecting the MODE pin to SGND. At light loads the internal current comparator may remain tripped for several cycles and force the top MOSFET to stay off for several cycles, thus skipping cycles. The inductor current does not reverse in this mode.

Force Continuous Conduction Mode (CCM)
In applications where fixed frequency operation is more critical than low current efficiency, and where the lowest output ripple is desired, forced continuous conduction mode operation should be used. Forced continuous operation can be enabled by tying the MODE pin to INTVCC. In this mode, inductor current is allowed to reverse during low output loads, the COMP voltage is in control of the current comparator threshold throughout, and the top MOSFET always turns on with each oscillator pulse. During start-up, forced continuous mode is disabled and inductor current is prevented from reversing until the LTM4644’s output voltage is in regulation.

Operating Frequency
The operating frequency of the LTM4644 is optimized to achieve the compact package size and the minimum output ripple voltage while still keeping high efficiency. The default operating frequency is internally set to 1MHz. In most applications, no additional frequency adjusting is required.

If any operating frequency other than 1MHz is required by application, the µModule regulator can be externally synchronized to a clock from 700kHz to 1.3MHz.

Frequency Synchronization and Clock In
The power module has a phase-locked loop comprised of an internal voltage controlled oscillator and a phase detector. This allows all internal top MOSFET turn-on to be locked to the rising edge of the same external clock. The external clock frequency range must be within ±30% around the 1MHz set frequency. A pulse detection circuit is used to detect a clock on the CLKin pin to turn on the phase-locked loop. The pulse width of the clock has to be at least 400ns. The clock high level must be above 2V and clock low level below 0.3V. During the start-up of the regulator, the phase-locked loop function is disabled.
APPLICATIONS INFORMATION

Multichannel Parallel Operation

For loads that demand more than 4A of output current, the LTM4644 multiple regulator channels can be easily paralleled to provide more output current without increasing input and output voltage ripples. The LTM4644 has preset built-in phase shift between each two of the four regulator channels which is suitable to employ a 2+2, 3+1 or 4 channels parallel operation. Table 2 gives the phase difference between regulator channels.

Table 2. Phase Difference Between Regulator Channels

</tr>
</tbody>
</table>

Figure 2 shows a 2+2 and a 4-channels parallel concept schematic for clock phasing.

A multiphase power supply significantly reduces the amount of ripple current in both the input and output capacitors. The RMS input ripple current is reduced by, and the effective ripple frequency is multiplied by, the number of phases used (assuming that the input voltage is greater than the number of phases used times the output voltage). The output ripple amplitude is also reduced by the number of phases used when all of the outputs are tied together to achieve a single high output current design.

The LTM4644 device is an inherently current mode controlled device, so parallel modules will have very good current sharing. This will balance the thermals on the design. Please tie the RUN, TRACK/SS, FB and COMP pins of each paralleling channel together. Figure 35 and Figure 36 shows an example of parallel operation and pin connection.

Input RMS Ripple Current Cancellation

Application Note 77 provides a detailed explanation of multiphase operation. The input RMS ripple current cancellation mathematical derivations are presented, and a graph is displayed representing the RMS ripple current reduction as a function of the number of interleaved phases. Figure 3 shows this graph.

Soft-Start and Output Voltage Tracking

The TRACK/SS pin provides a means to either soft-start of each regulator channel or track it to a different power supply. A capacitor on the TRACK/SS pin will program the ramp rate of the output voltage. An internal 2.5µA current source will charge up the external soft-start capacitor towards the INTVCC voltage. When the TRACK/SS voltage is below 0.6V, it will take over the internal 0.6V reference voltage to control the output voltage. The total soft-start time can be calculated as:

\[ t_{SS} = 0.6 \cdot \frac{C_{SS}}{2.5 \mu A} \]

where \( C_{SS} \) is the capacitance on the TRACK/SS pin. Current foldback and forced continuous mode are disabled during the soft-start process.
Applications Information

Output voltage tracking can also be programmed externally using the TRACK/SS pin of each regulator channel. The output can be tracked up and down with another regulator. Figure 4 and Figure 5 show an example waveform and schematic of a ratiometric tracking where the slave regulator’s (VOUT2, VOUT3 and VOUT4) output slew rate is proportional to the master’s (VOUT1).

Since the slave regulator’s TRACK/SS is connected to the master’s output through a RTR(TOP)/RTR(BOT) resistor divider and its voltage used to regulate the slave output voltage when TRACK/SS voltage is below 0.6V, the slave output voltage and the master output voltage should satisfy the following equation during the start-up.

\[
\frac{V_{\text{OUT(SL)}}}{R_{\text{FB(SL)}} + 60.4k} = \frac{V_{\text{OUT(MA)}}}{R_{\text{TR(BOT)}} + R_{\text{TR(BOT)}}} + R_{\text{TR(BOT)}}
\]

Where the 60.4k is the integrated top feedback resistor and the RFB(SL) is the external bottom feedback resistor of the LTM4644. The RTR(TOP)/RTR(BOT) is the resistor divider on the TRACK/SS pin of the slave regulator, as shown in Figure 5.

Following the upper equation, the master’s output slew rate (MR) and the slave’s output slew rate (SR) in volts/time is determined by:

\[
\frac{\text{MR}}{\text{SR}} = \frac{R_{\text{FB(SL)}}}{R_{\text{TR(BOT)}} + R_{\text{TR(BOT)}}}
\]
The TRACK pins will have the 2.5µA current source on when a resistive divider is used to implement tracking on that specific channel. This will impose an offset on the TRACK pin input. Smaller value resistors with the same ratios as the resistor values calculated from the above equation can be used. For example, where the 60.4k is used then a 6.04k can be used to reduce the TRACK pin offset to a negligible value.

The coincident output tracking can be recognized as a special ratiometric output tracking which the master’s output slew rate (MR) is the same as the slave’s output slew rate (SR), as waveform shown in Figure 6.

From the equation we could easily find out that, in the coincident tracking, the slave regulator’s TRACK/SS pin resistor divider is always the same as its output voltage divider.

\[
\frac{R_{FB(SL)}}{R_{FB(SL)}+60.4k} = \frac{R_{TR(BOT)}}{R_{TR(TOP)}+R_{TR(BOT)}}
\]
Applications Information

For example, $R_{\text{TR4(TOP)}} = 60.4k$ and $R_{\text{TR4(BOT)}} = 60.4k$ is a good combination for coincident tracking for $V_{\text{OUT(MA)}} = 3.3V$ and $V_{\text{OUT(SL)}} = 1.2V$ application.

Pre-Biased Output Start-Up

There may be situations that require the power supply to start up with some charge on the output capacitors. The LTM4644 can safely power up into a pre-biased output without discharging it.

The LTM4644 accomplishes this by forcing discontinuous mode (DCM) operation until the TRACK/SS pin voltage reaches 0.6V reference voltage. This will prevent the BG from turning on during the pre-biased output start-up which would discharge the output.

Do not pre-bias LTM4644 with an output voltage higher than $\text{INTV}_{\text{CC}}$ (3.3V).

Overtemperature Protection

The internal overtemperature protection monitors the junction temperature of the module. If the junction temperature reaches approximately 160°C, both power switches will be turned off until the temperature drops about 15°C cooler.

Low Input Application

The LTM4644 module has a separate $SV_{\text{IN}}$ pin for each regulator channel which makes it compatible with operation from an input voltage as low as 2.375V. The $SV_{\text{IN}}$ pin is the signal input of the regulator control circuitry while the $V_{\text{IN}}$ pin is the power input which directly connected to the drain of the top MOSFET. In most application with input voltage ranges from 4V to 14V, connect the $SV_{\text{IN}}$ pin directly to the $V_{\text{IN}}$ pin of each regulator channel. An optional filter, consisting of a resistor (1Ω to 10Ω) between $SV_{\text{IN}}$ and $V_{\text{IN}}$ ground, can be placed for additional noise immunity. This filter is not necessary in most cases if good PCB layout practices are followed (see Figure 32). In a low input voltage (2.375V to 4V) application, or to reduce power dissipation by the internal bias LDO, connect $SV_{\text{IN}}$ to an external voltage higher than 4V with a 0.1µF local bypass capacitor. Figure 34 shows an example of a low input voltage application. Please note, $SV_{\text{IN}}$ voltage cannot go below $V_{\text{OUT}}$ voltage.
APPLICATIONS INFORMATION

Temperature Monitoring

A diode connected PNP transistor is used for the TEMP monitor function by monitoring its voltage over temperature. The temperature dependence of this diode voltage can be understood in the equation:

\[ V_D = nV_T \ln \left( \frac{I_D}{I_S} \right) \]

where \( V_T \) is the thermal voltage (kT/q), and \( n \), the ideality factor, is 1 for the diode connected PNP transistor being used in the LTM4644. \( I_S \) is expressed by the typical empirical equation:

\[ I_S = I_0 \exp \left( -\frac{V_{G0}}{V_T} \right) \]

where \( I_0 \) is a process and geometry dependent current, \( I_0 \) is typically around 20k orders of magnitude larger than \( I_S \) at room temperature) and \( V_{G0} \) is the band gap voltage of 1.2V extrapolated to absolute zero or –273°C.

If we take the \( I_S \) equation and substitute into the \( V_D \) equation, then we get:

\[ V_D = V_{G0} - \frac{kT}{q} \ln \left( \frac{I_0}{I_D} \right), \quad V_T = \frac{kT}{q} \]

The expression shows that the diode voltage decreases (linearly if \( I_0 \) were constant) with increasing temperature and constant diode current. Figure 6 shows a plot of \( V_D \) vs Temperature over the operating temperature range of the LTM4644.

If we take this equation and differentiate it with respect to temperature \( T \), then:

\[ \frac{dV_D}{dT} = -\frac{V_{G0} - V_D}{T} \]

This \( dV_D/dT \) term is the temperature coefficient equal to about –2mV/K or –2mV/°C. The equation is simplified for the first order derivation.

Solving for \( T \), \( T = -\frac{V_{G0} - V_D}{dV_D/dT} \) provides the temperature.

1st Example: Figure 7 for 27°C, or 300K the diode voltage is 0.598V, thus, 300K = –(1200mV – 598mV)/–2.0 mV/K

2nd Example: Figure 7 for 75°C, or 350K the diode voltage is 0.50V, thus, 350K = –(1200mV – 500mV)/–2.0mV/K

Converting the Kelvin scale to Celsius is simply taking the Kelvin temp and subtracting 273 from it.

A typical forward voltage is given in the electrical characteristics section of the data sheet, and Figure 7 is the plot of this forward voltage. Measure this forward voltage at 27°C to establish a reference point. Then using the above expression while measuring the forward voltage over temperature will provide a general temperature monitor. Connect a resistor between TEMP and \( V_{IN} \) to set the current to 100µA. See Figure 35 for an example.

![Figure 7. Diode Voltage V_D vs Temperature T(°C)](image)

Thermal Considerations and Output Current Derating

The thermal resistances reported in the Pin Configuration section of the data sheet are consistent with those parameters defined by JESD 51-12 and are intended for use with finite element analysis (FEA) software modeling tools that leverage the outcome of thermal modeling, simulation, and correlation to hardware evaluation performed on a µModule package mounted to a hardware test board: defined by JESD 51-9 (“Test Boards for Area
APPLICATIONS INFORMATION

Array Surface Mount Package Thermal Measurements”). The motivation for providing these thermal coefficients is found in JESD 51-12 (“Guidelines for Reporting and Using Electronic Package Thermal Information”).

Many designers may opt to use laboratory equipment and a test vehicle such as the demo board to predict the µModule regulator’s thermal performance in their application at various electrical and environmental operating conditions to complement any FEA activities. Without FEA software, the thermal resistances reported in the Pin Configuration section are in-and-of themselves not relevant to providing guidance of thermal performance; instead, the derating curves provided in this data sheet can be used in a manner that yields insight and guidance pertaining to one’s application-usage, and can be adapted to correlate thermal performance to one’s own application.

The Pin Configuration section typically gives four thermal coefficients explicitly defined in JESD 51-12; these coefficients are quoted or paraphrased below:

1. $\theta_{ja}$, the thermal resistance from junction to ambient, is the natural convection junction-to-ambient air thermal resistance measured in a one cubic foot sealed enclosure. This environment is sometimes referred to as “still air” although natural convection causes the air to move. This value is determined with the part mounted to a JESD 51-9 defined test board, which does not reflect an actual application or viable operating condition.

2. $\theta_{jcbottom}$, the thermal resistance from junction to the bottom of the product case, is determined with all of the component power dissipation flowing through the bottom of the page. In the typical µModule regulator, the bulk of the heat flows out the bottom of the package, but there is always heat flow out into the ambient environment. As a result, this thermal resistance value may be useful for comparing packages but the test conditions don’t generally match the user’s application.

3. $\theta_{jctop}$, the thermal resistance from junction to top of the product case, is determined with nearly all of the component power dissipation flowing through the top of the package. As the electrical connections of the typical µModule regulator are on the bottom of the package, it is rare for an application to operate such that most of the heat flows from the junction to the top of the part. As in the case of $\theta_{jcbottom}$, this value may be useful for comparing packages but the test conditions don’t generally match the user’s application.

4. $\theta_{jb}$, the thermal resistance from junction to the printed circuit board, is the junction-to-board thermal resistance where almost all of the heat flows through the bottom of the µModule regulator and into the board, and is really the sum of the $\theta_{jcbottom}$ and the thermal resistance of the bottom of the part through the solder joints and through a portion of the board. The board temperature is measured a specified distance from the package.

A graphical representation of the aforementioned thermal resistances is given in Figure 8; blue resistances are contained within the µModule regulator, whereas green resistances are external to the µModule package.

As a practical matter, it should be clear to the reader that no individual or sub-group of the four thermal resistance parameters defined by JESD 51-12 or provided in the Pin Configuration section replicates or conveys normal operating conditions of a µModule regulator. For example, in normal board-mounted applications, never does 100% of the device’s total power loss (heat) thermally conduct exclusively through the top or exclusively through bottom of the µModule package—as the standard defines for $\theta_{jctop}$ and $\theta_{jcbottom}$, respectively. In practice, power loss is thermally dissipated in both directions away from the package—granted, in the absence of a heat sink and airflow, a majority of the heat flow is into the board.

Within the LTM4644, be aware there are multiple power devices and components dissipating power, with a consequence that the thermal resistances relative to different junctions of components or die are not exactly linear with respect to total package power loss. To reconcile this complication without sacrificing modeling simplicity—but also, not ignoring practical realities—an approach has been taken using FEA software modeling along with laboratory testing in a controlled-environment chamber to reasonably define and correlate the thermal resistance values supplied in this data sheet: (1) Initially, FEA software
APPLICATIONS INFORMATION

is used to accurately build the mechanical geometry of the LTM4644 and the specified PCB with all of the correct material coefficients along with accurate power loss source definitions; (2) this model simulates a software-defined JEDEC environment consistent with JESD 51-12 to predict power loss heat flow and temperature readings at different interfaces that enable the calculation of the JEDEC-defined thermal resistance values; (3) the model and FEA software is used to evaluate the LTM4644 with heat sink and airflow; (4) having solved for and analyzed these thermal resistance values and simulated various operating conditions in the software model, a thorough laboratory evaluation replicates the simulated conditions with thermocouples within a controlled-environment chamber while operating the device at the same power loss as that which was simulated. An outcome of this process and due diligence yields the set of derating curves shown in this data sheet.

The 1V to 5V power loss curves in Figures 9 to 15 can be used in coordination with the load current derating curves in Figures 16 to 29 for calculating an approximate $\theta_{JA}$ thermal resistance for the LTM4644 with various heat sinking and airflow conditions. The power loss curves are taken at room temperature, and are increased with a multiplicative factor according to the junction temperature. This approximate factor is 1.35 for 120°C. The derating curves are plotted with the output current starting at 16A and the ambient temperature at 30°C. These are chosen to include the lower and higher output voltage ranges for correlating the thermal resistance. Thermal models are derived from several temperature measurements in a controlled temperature chamber along with thermal modeling analysis. The junction temperatures are monitored while ambient temperature is increased with and without airflow. The power loss increase with ambient temperature change is factored into the derating curves. The junctions are maintained at 120°C maximum while lowering output current or power with increasing ambient temperature. The decreased output current will decrease the internal module loss as ambient temperature is increased. The monitored junction temperature of 120°C minus the ambient operating temperature specifies how much module temperature rise can be allowed. As an example in Figure 16 the load current is derated to 9.6A at ~90°C with 400LFM of airflow and no heat sink and the power loss for the 12V to 1.0V at 9.5A output is about 3.2W. The 3.2W loss is calculated with 4 times the 0.6W room temperature loss from the 12V to 1.0V power loss curve each channel at 2.4A, and the 1.35 multiplying factor at 120°C junction. If the 90°C ambient temperature is subtracted from the 120°C junction temperature, then the difference of 30°C divided by 3.2W equals ~9.4°C/W $\theta_{JA}$ thermal resistance. Table 3 specifies a 10°C/W value which is very close. Tables 3 to 6 provide equivalent thermal resistances for the different outputs with and without airflow and heat sinking. The derived thermal resistances in Tables 3 to 6 for the various conditions can be multiplied by the calculated power loss as a function of ambient temperature to derive temperature

![Graphical Representation of JESD 51-12 Thermal Coefficients](image-url)
Applications Information

For example, to determine the maximum ambient temperature when \( V_{OUT1} = 2.5V \) at 0.6A, \( V_{OUT2} = 3.3V \) at 3A, \( V_{OUT3} = 1.8V \) at 1A, \( V_{OUT4} = 1.2V \) at 3A, without a heat sink and 400LFM airflow, simply add up the total power loss for each channel read from Figure 9 to Figure 15 which in this example equals 2.5W, then multiply by the 1.35 coefficient for 120°C junction temperature and compare the total power loss number, 3.4W with Figure 30. Figure 30 indicates with a 3.4W total power loss, the maximum ambient temperature for this particular application is around 86°C. For reference, the actual thermal derating test in the chamber resulted in a maximum ambient temperature of 86.3°C, very close to the calculated value. Also from Figure 30, it is easy to determine with a 3.4W total power loss, the maximum ambient temperature is around 77°C with no airflow and 81°C with 200LFM airflow.

Safety Considerations

The LTM4644 modules do not provide galvanic isolation from \( V_{IN} \) to \( V_{OUT} \). There is no internal fuse. If required, a slow blow fuse with a rating twice the maximum input current needs to be provided to protect each unit from catastrophic failure. The device does support thermal shutdown and overcurrent protection.

APPLICATIONS INFORMATION

Layout Checklist/Example

The high integration of LTM4644 makes the PCB board layout very simple and easy. However, to optimize its electrical and thermal performance, some layout considerations are still necessary.

• Use large PCB copper areas for high current paths, including VIN1 to VIN4, GND, VOUT1 to VOUT4. It helps to minimize the PCB conduction loss and thermal stress.

• Place high frequency ceramic input and output capacitors next to the VIN, GND and VOUT pins to minimize high frequency noise.

• Place a dedicated power ground layer underneath the unit.

• To minimize the via conduction loss and reduce module thermal stress, use multiple vias for interconnection between top layer and other power layers.

• Do not put via directly on the pad, unless they are capped or plated over.

• Use a separated SGND ground copper area for components connected to signal pins. Connect the SGND to GND underneath the unit.

• For parallel modules, tie the VOUT, VFB, and COMP pins together. Use an internal layer to closely connect these pins together. The TRACK/SS pin can be tied a common capacitor for regulator soft-start.

• Bring out test points on the signal pins for monitoring.

Figure 32 gives a good example of the recommended layout.

BGA Package
77-Lead (9mm × 15mm × 5.01mm)
(Reference LTC DWG # 05-08-1900 Rev D)

NOTES:
1. DIMENSIONING AND TOLERANCING PER ASME Y14.5M-1994
2. ALL DIMENSIONS ARE IN MILLIMETERS
3. BALL DESIGNATION PER JESD MS-028 AND JEP95
4. DETAILS OF PIN #1 IDENTIFIER ARE OPTIONAL, BUT MUST BE LOCATED WITHIN THE ZONE INDICATED. THE PIN #1 IDENTIFIER MAY BE EITHER A MOLD OR MARKED FEATURE.
5. PRIMARY DATUM -Z- IS SEATING PLANE
6. SOLDER BALL COMPOSITION IS 96.5% Sn/3.0% Ag/0.5% Cu

SUBJECT DESCRIPTION

µModule Design and Manufacturing Resources

- Design:
  - Selector Guides
  - Demo Boards and Gerber Files
  - Free Simulation Tools

- Manufacturing:
  - Quick Start Guide
  - PCB Design, Assembly and Manufacturing Guidelines
  - Package and Board Level Reliability

µModule Regulator Products Search

1. Sort table of products by parameters and download the result as a spreadsheet.
2. Search using the Quick Power Search parametric table.

TechClip Videos
Quick videos detailing how to bench test electrical and thermal performance of µModule products.

Digital Power System Management
Linear Technology’s family of digital power supply management ICs are highly integrated solutions that offer essential functions, including power supply monitoring, supervision, margining and sequencing, and feature EEPROM for storing user configurations and fault logging.
