GENERAL DESCRIPTION

The AD7606C-16 is a 16-bit, simultaneous sampling, analog-to-digital data acquisition system (DAS) with eight channels. Each channel contains analog input clamp protection, a programmable gain amplifier (PGA), a low-pass filter (LPF), and a 16-bit successive approximation register (SAR), analog-to-digital converter (ADC). The AD7606C-16 also contains a flexible digital filter, a low drift, 2.5 V precision reference, and a reference buffer to drive the ADC and flexible parallel and serial interfaces.

The AD7606C-16 operates from a single 5 V supply and accommodates the following input ranges when sampling at throughput rates of 1 MSPS for all channels:

- ▶ Bipolar single-ended: ±12.5 V, ±10 V, ±6.25 V, ±5 V, and ±2.5 V
- ▶ Unipolar single-ended: 0 V to 12.5 V, 0 V to 10 V, and 0 V to 5 V
- ▶ Bipolar differential: ±20 V, ±12.5 V, ±10 V, and ±5 V

The input clamp protection tolerates voltages up to ±21 V. The single supply operation, on-chip filtering, and high input impedance eliminate the need for external driver op amps, which require bipolar supplies. For applications with lower throughput rates, the AD7606C-16 flexible digital filter can be used to improve noise performance.

In hardware mode, the AD7606C-16 is fully compatible with the AD7606 and AD7606B. In software mode, the following advanced features are available:

- Analog input range selectable per channel with added ranges available
- ▶ High bandwidth mode (220 kHz) selectable per channel
- ▶ Additional oversampling options with an oversampling ratio up to 256
- System gain, system offset, and system phase calibration per channel
- Analog input open circuit detector
- Diagnostic multiplexer
- Monitoring functions (serial peripheral interface (SPI), invalid read/write, cyclic redundancy check (CRC), busy stuck monitor, and reset detection)

Note that throughout this data sheet, multifunction pins, such as the $\overline{RD}/SCLK$ pin, are referred to either by the entire pin name or by a single function of the pin, for example, the SCLK pin, when only that function is relevant.

 $^{^{2}}$ TUE (% FSR) = TUE (LSB)/ 2^{16} × 100. For example, 32 LSBs = 0.05 % of FSR.

³ These specifications include the full temperature range variation and contribution from the reference buffer.

⁴ Input impedance variation is factory trimmed and accounted for in the System Gain Calibration section.

⁵ Not production tested. Sample tested during initial release to ensure compliance.

The ADC input is settled by the internal PGA. Therefore, the t_{ACQ} is the time between the end of the conversion and the start of the next conversion with no impact on external components.

PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

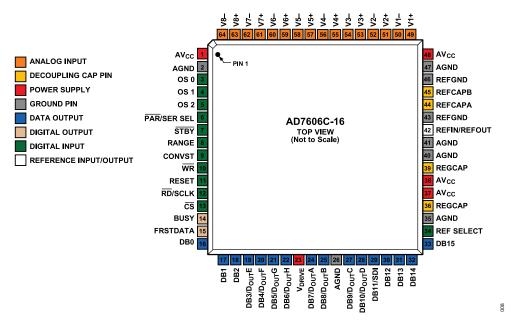

Figure 8. Pin Configuration

Table 9. Pin Function Descriptions

Pin No.	Type ¹	Mnemonic	Description	
1, 37, 38, 48	Р	AV _{CC}	Analog Supply Voltage, 4.75 V to 5.25 V. This supply voltage is applied to the internal front-end amplifiers and to the ADC core. Decouple these supply pins to AGND.	
2, 26, 35, 40, 41, 47	Р	AGND	Analog Ground. The AGND pins are the ground reference points for all analog circuitry on the AD7606C-16. All analog input signals and external reference signals must be referred to the AGND pins. All six of the AGND pins must connect to the AGND plane of a system.	
3 to 5	DI	OS0 to OS2	Oversampling Mode Pins. OS0 to OS2 select the oversampling ratio or enable software mode (see Table 14 for oversampling pin decoding). See the Digital Filter section for more details about the oversampling mode of operation.	
6	DI	PAR/SER SEL	Parallel/Serial Interface Selection Input. If the PAR/SER SEL pin is tied to a logic low, the parallel interface is selected. If the PAR/SER SEL pin is tied to a logic high, the serial interface is selected. See the Digital Interface section for more information on each interface available.	
7	DI	STBY	Standby Mode Input. In hardware mode, the \$\overline{STBY}\$ pin, in combination with the RANGE pin, places the AD7606C-16 in one of two power-down modes: standby mode or shutdown mode. In software mode, the \$\overline{STBY}\$ pin is ignored. Therefore, it is recommended to connect the \$\overline{STBY}\$ pin to logic high. See the Power-Down Modes section for more information on both hardware mode and software mode.	
8	DI	RANGE	Analog Input Range Selection Input. In hardware mode, the RANGE pin determines the input range of the analog input channels (see Table 10). If the STBY pin is at logic low, the RANGE pin determines the power-down mode (see Table 16). In software mode, the RANGE pin is ignored. However, the RANGE pin must be tied high or low.	
9	DI	CONVST	Conversion Start Input. When the CONVST pin transitions from low to high, the analog input is sampled on all eight SAR ADCs. In software mode, the CONVST pin can be configured as an external oversampling clock. Providing a low jitter external clock improves the SNR performance for large oversampling ratios. See the External Oversampling Clock section for further details.	
10	DI	WR	Parallel Write Control Input. In hardware mode, the \overline{WR} pin has no function. Therefore, the \overline{WR} pin can be tied high, tied low, or shorted to CONVST. In software mode, the \overline{WR} pin is an active low write pin for writing registers using the parallel interface. See the Parallel Interface section for more information.	
11	DI	RESET	Reset Input, Active High. Full and partial reset options are available. The type of reset is determined by the length of the reset pulse. Ensure that the device receives a full reset pulse after power-up. See the Reset Functionality section further details.	
12	DI	RD/SCLK	Parallel Data Read Control Input (RD) when the Parallel Interface is Selected. Serial Clock Input (SCLK) when the Serial Interface is Selected. See the Digital Interface section for more details.	
13	DI	CS	Chip Select. The $\overline{\text{CS}}$ pin is the active low chip select input for ADC data reads or register data reads and writes, in both serial and parallel interfaces. See the Digital Interface section for more details.

34	DI	REF SELECT	Internal/External Reference Selection Logic Input. If the REF SELECT pin is set to logic high, the internal reference is selected and enabled. If the REF SELECT pin is set to logic low, the internal reference is disabled and an external reference voltage must be applied to the REFIN/REFOUT pin.
36, 39	Р	REGCAP	Decoupling Capacitor Pin for Voltage Output from 1.9 V Internal Regulator, Analog Low Dropout (ALDO) and Digital Low Dropout (DLDO). The REGCAP output pins must be decoupled separately to AGND using a 1 µF capacitor. The voltage on the REGCAP pins is in the range of 1.875 V to 1.93 V.
42	REF	REFIN/REFOUT	Reference Input (REFIN)/Reference Output (REFOUT). The internal 2.5 V reference is available on the REFOUT pin for external use while the REF SELECT pin is set to logic high. Alternatively, by setting the REF SELECT pin to logic low, the internal reference is disabled and an external reference of 2.5 V must be applied to this input (REFIN). TERMINOLOGY

Integral Nonlinearity (INL)

INL is the maximum deviation from a straight line passing through the endpoints of the ADC transfer function. The endpoints of the transfer function are zero scale at ½ LSB below the first code transition and full scale at ½ LSB above the last code transition.

Differential Nonlinearity (DNL)

DNL is the difference between the measured and the ideal 1 LSB change between any two adjacent codes in the ADC.

Bipolar Zero Code Error

Bipolar zero code error is the deviation of the midscale transition (all 1s to all 0s) from the ideal, which is $0 \text{ V} - \frac{1}{2} \text{ LSB}$.

Bipolar Zero Code Error Matching

Bipolar zero code error match is the absolute difference in bipolar zero code error between any two input channels.

Open Circuit Code Error

Open circuit code error is the ADC output code when there is an open circuit on the analog input and a pull-down resistor (R_{PD}) connected between the analog input pair of pins. See Figure 97 for more details.

Positive Full-Scale (PFS) Error

In bipolar ranges, PFS error is the deviation of the actual last code transition from the ideal last code transition (for example, 10 V - $1\frac{1}{2}$ LSB (9.99954), 5 V - $1\frac{1}{2}$ LSB (4.99977), or 2.5 V - $1\frac{1}{2}$ LSB (2.49988)) after the bipolar zero code error is adjusted out. The PFS error includes the contribution from the reference buffer.

Positive Full-Scale (PFS) Error Matching

PFS error matching is the absolute difference in PFS error between any two input channels.

Negative Full-Scale (NFS) Error

In bipolar ranges, NFS error is the deviation of the first code transition from the ideal first code transition (for example, $-10 \text{ V} + \frac{1}{2} \text{ LSB } (-9.99984)$, $-5 \text{ V} + \frac{1}{2} \text{ LSB } (-4.99992)$, or $-2.5 \text{ V} + \frac{1}{2} \text{ LSB } (-2.49996)$) after the bipolar zero code error is adjusted out. The NFS error includes the contribution from the reference buffer.

Negative Full-Scale (NFS) Error Matching

NFS error matching is the absolute difference in NFS error between any two input channels.

Full-Scale (FS) Error

In unipolar ranges, FS error is the deviation of the actual last code transition from the ideal last code transition (for example, 10 V - 1½ LSB (9.99954), or 5 V - 1½ LSB (4.99977)) after the zero scale error is adjusted out. The FS error includes the contribution from the reference buffer.

Zero Scale (ZS) Error

In unipolar ranges, ZS error is the deviation of the first code transition from the ideal first code transition, which is $0 \text{ V} - \frac{1}{2} \text{ LSB}$.

Total Unadjusted Error (TUE)

TUE is the maximum deviation of the output code from the ideal. TUE includes INL errors, bipolar zero code and positive and negative full-scale errors, and reference errors.

Signal-to-Noise and Distortion Ratio (SINAD)

SINAD ratio is the measured ratio of signal-to-noise and distortion at the output of the ADC. The signal is the RMS amplitude of the fundamental. Noise is the sum of all nonfundamental signals up to half the sampling frequency (f_S/2, excluding DC).

The ratio depends on the number of quantization levels in the digitization process: the more levels, the smaller the quantization noise.

The theoretical SINAD for an ideal N-bit converter with a sine wave input is given by

$$SINAD = (6.02 N + 1.76) (dB)$$
 (1)

Thus, for a 16-bit converter, the SINAD is 98 dB.

Total Harmonic Distortion (THD)

THD is the ratio of the RMS sum of the harmonics to the fundamental. For the AD7606C-16, THD is defined as

$$THD(dB) = 20\log \frac{\sqrt{V_2^2 + V_3^2 + V_4^2 + V_5^2 + V_6^2 + V_7^2 + V_8^2 + V_9^2}}{V_1}$$
(2)

where:

 V_1 is the RMS amplitude of the fundamental.

 V_2 to V_9 are the RMS amplitudes of the second through ninth harmonics.

Peak Harmonic or Spurious Noise

Peak harmonic or spurious noise is the ratio of the RMS value of the next largest component in the ADC output spectrum (up to $f_{\rm S}/2$, excluding dc) to the RMS value of the fundamental. Normally, the value of this specification is determined by the largest harmonic in the spectrum, but for ADCs where the harmonics are buried in the noise floor, the value is determined by a noise peak.

Power Supply Rejection Ratio (PSRR)

Variations in power supply affect the full-scale transition but not the linearity of the converter. The power supply rejection (PSR) is the maximum change in full-scale transition point due to a change in power supply voltage from the nominal value. The PSRR is defined as the ratio of the 100 mV p-p sine wave applied to the AV $_{\rm CC}$ supplies of the ADC frequency, $f_{\rm S}$, to the power of the ADC output at that frequency, $f_{\rm S}$.

analog.com Rev. A | 29 of 80

TERMINOLOGY

 $PSRR (dB) = 20 \log (0.1/Pf_S)$

(3)

where

 Pf_S is equal to the power at frequency, f_S , coupled on the AV_{CC} supply.

Channel-to-Channel Isolation

Channel-to-channel isolation is a measure of the level of crosstalk between all input channels. It is measured by applying a full-scale sine wave signal, up to 200 kHz, to all unselected input channels and then determining the degree to which the signal attenuates in the selected channel with a 1 kHz sine wave signal applied (see Figure 69 and Figure 72).

Phase Delay

Phase delay is a measure of the absolute time delay between when an input is sampled by the converter and when the result associated with that sample is available to be read back from the ADC, including delay induced by the analog front end of the device.

Phase Delay Drift

Phase delay drift is the change in phase delay per unit temperature across the entire operating temperature of the device.

Phase Delay Matching

Phase delay matching is the maximum phase delay seen between any simultaneously sampled pair.

Box Method

The box method is represented by the following equation:

 $TCV_{OUT} =$

$$\left| \frac{max\{V_{OUT}(T_{1,}T_{2,}T_{3})\} - min\{V_{OUT}(T_{1,}T_{2,}T_{3})\}\}}{V_{OUT}(T_{2}) \times (T_{3} - T_{1})} \right|$$
 (4)

 $\times 10^6$

where:

TCV_{OUT} is expressed in ppm/°C.

 $V_{OUT}(T_X)$ is the output voltage at temperature T_X .

 $T_1 = -40^{\circ}$ C.

 T_2 = +25°C.

 $T_3 = +125^{\circ}\text{C}$

This box method ensures that TCV_{OUT} accurately portrays the maximum difference between any of the three temperatures at which the output voltage of the device is measured.

THEORY OF OPERATION

ANALOG FRONT END

The AD7606C-16 is a 16-bit, simultaneous sampling, analog-to-digital DAS with eight channels. Each channel contains analog input clamp protection, a PGA, a low-pass filter, and a 16-bit SAR ADC.

Analog Input Ranges

The AD7606C-16 can handle true bipolar differential, bipolar single-ended, and unipolar single-ended input voltages.

In software mode, it is possible to configure an individual analog input range per channel using Address 0x03 through Address 0x06. The logic level on the RANGE pin is ignored in software mode.

In hardware mode, the logic level on the RANGE pin determines either ±10 V or ±5 V single-ended as the analog input range of all analog input channels, as shown in Table 10.

A logic change on the RANGE pin has an immediate effect on the analog input range. However, there is typically a settling time of approximately 80 μ s in addition to the normal acquisition time requirement. Changing the RANGE pin during a conversion is not recommended for fast throughput rate applications.

Table 10. Analog Input Range Selection

Range (V)	Hardware Mode ¹	Software Mode ²
±10 Single- Ended	RANGE pin high	Address 0x03 through Address 0x06
±5 Single- Ended	RANGE pin low	Address 0x03 through Address 0x06
Any Other Range	Not applicable	Address 0x03 through Address 0x06

¹ The same analog input range, ±10 V or ±5 V, applies to all eight channels.

Analog Input Impedance

The analog input impedance ($R_{\rm IN}$) of the AD7606C-16 is 1 M Ω minimum. $R_{\rm IN}$ is a fixed input impedance that does not vary with the AD7606C-16 sampling frequency. This high analog input impedance eliminates the need for a driver amplifier in front of the AD7606C-16, allowing direct connection to the source or sensor. Therefore, bipolar supplies can be removed from the signal chain.

Analog Input Clamp Protection

Figure 75 shows the analog input circuitry of the AD7606C-16. Each analog input of the AD7606C-16 contains clamp protection circuitry. Despite single, 5 V supply operation, this analog input clamp protection allows an input overvoltage of up to ±21 V.

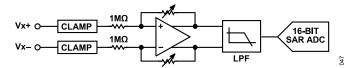

Figure 75. Analog Input Circuitry for Each Channel

Figure 76 shows the input clamp current vs. the source voltage characteristic of the clamp circuit. For input voltages of up to ±21 V, no current flows in the clamp circuit. For input voltages that are above ±21 V, the AD7606C-16 clamp circuitry turns on.

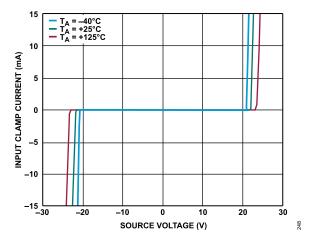

Figure 76. Input Protection Clamp Profile

It is recommended to place a series resistor on the analog input channels to limit the current to ± 10 mA for input voltages greater than ± 21 V. In an application where there is a series resistance (R) on an analog input channel, Vx+, it is recommended to match the resistance (R) with the resistance on Vx- to eliminate any offset introduced to the system, as shown in Figure 77. However, in software mode, a per channel system offset calibration removes the offset of the full system (see the System Offset Calibration section).

During normal operation, it is not recommended to leave the AD7606C-16 in a condition where the analog input is greater than the input range for extended periods of time because this condition can degrade the bipolar zero code error performance. In shutdown or standby mode, there is no such concern.

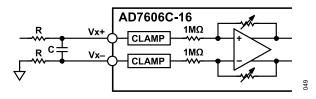

Figure 77. Input Resistance Matching on the Analog Input of the AD7606C-16 for Single-Ended Ranges (V_X- Tied to Ground)

analog.com Rev. A | 31 of 80

The analog input range is selected on a per channel basis using the memory map.

THEORY OF OPERATION

PGA

A PGA is provided at each input channel. The gain is configured depending on the analog input range selected (see Table 10) to scale the analog input signal, either bipolar differential or bipolar or unipolar single-ended, to the ADC fully differential input range.

Input impedance on each input of the PGA is accurately trimmed to maintain the overall gain error. This trimmed value is then used when the gain calibration is enabled to compensate for the gain error introduced by an external series resistor. See the System Gain Calibration section for more information on the PGA feature.

Analog Input Antialiasing Filter

An analog antialiasing filter is provided on the AD7606C-16. Figure 78 and Figure 79 show the frequency response and phase response, respectively, of the analog antialiasing filter. The -3 dB frequency is typically 25 kHz.

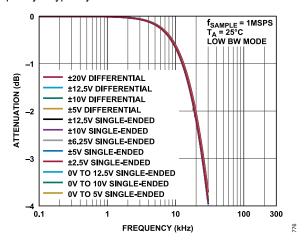

Figure 78. Analog Antialiasing Filter Frequency Response, Low Bandwidth

Mode

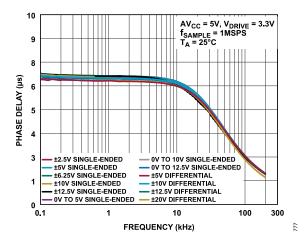

Figure 79. Analog Antialiasing Filter Phase Response, Low Bandwidtn Mode

In addition, the AD7606C-16 allows the ADC to enable the high bandwidth mode, on a per channel basis, that moves the $-3~{\rm dB}$

frequency up to 220 kHz, as shown in Figure 80 and Figure 81. This mode is dedicated for fast analog input settling applications, as shown in Figure 63 to Figure 68.

SAR ADC

The AD7606C-16 allows the ADC to accurately acquire an input signal of full-scale amplitude to 16-bit resolution. All eight SAR ADCs sample the respective inputs simultaneously on the rising edge of the CONVST signal.

The BUSY signal indicates when conversions are in progress. Therefore, when the rising edge of the CONVST signal is applied, the BUSY pin goes logic high and transitions low at the end of the entire conversion process. The end of the conversion process across all eight channels is indicated by the falling edge of the BUSY signal. When the BUSY signal edge falls, the acquisition time for the next set of conversions begins. The rising edge of the CONVST signal has no effect while the BUSY signal is high.

New data can be read from the output register through the parallel or serial interface after the BUSY output goes low. Alternatively,

analog.com Rev. A | 32 of 80

THEORY OF OPERATION

data from the previous conversion can be read while the BUSY pin is high, as explained in the Reading During Conversion section.

The AD7606C-16 contains an on-chip oscillator that performs the conversions. The conversion time for all ADC channels is t_{CONV} (see Table 3). In software mode, there is an option to apply an external clock through the CONVST pin. Providing a low jitter external clock improves SNR performance for large OSRs. See the Digital Filter section and Figure 15 to Figure 18 for further information.

Connect all unused analog input channels to AGND. The results for any unused channels are still included in the data read because all channels are always converted.

ADC Transfer Function

The output coding of the AD7606C-16 is twos complement for the bipolar analog input ranges, either single-ended or differential. In unipolar ranges, the output coding is straight binary.

The designed code transitions occur midway between successive integer LSB values, that is, 1/2 LSB and 3/2 LSB. The LSB size is FSR/65,536 for the AD7606C-16. The ideal transfer characteristics for the AD7606C-16 are shown in Figure 82. The LSB size is dependent on the analog input range selected, as shown in Table 11 and Table 12.

THEORY OF OPERATION

REFERENCE

The AD7606C-16 contains an on-chip, 2.5 V, band gap reference. The REFIN/REFOUT pin allows the following:

- ▶ Access to the internal 2.5 V reference if the REF SELECT pin is tied to logic high
- Application of an external reference of 2.5 V if the REF SELECT pin is tied to logic low

Table 13. Reference Configuration

REF SELECT Pin	Reference Selected
Logic High	Internal reference enabled
Logic Low	Internal reference disabled; an external 2.5 V reference voltage must be applied to the REFIN/REFOUT pin

The AD7606C-16 contains a reference buffer configured to amplify the reference voltage up to approximately 4.4 V, as shown in Figure 84. The 4.4 V buffered reference is the reference used by the SAR ADC, as shown in Figure 84. After a reset, the AD7606C-16 operates in the reference mode selected by the REF SELECT pin. The REFCAPA and REFCAPB pins must be shorted together externally, and a ceramic capacitor of 10 μF must be applied to the REFGND pin to ensure that the reference buffer is in closed-loop operation. A 0.1 μF ceramic capacitor is required on the REFIN/REFOUT pin.

When the AD7606C-16 is configured in external reference mode, the REFIN/REFOUT pin is a high input impedance pin.

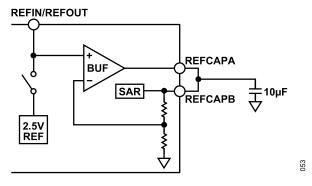

Figure 84. Reference Circuitry

Using Multiple AD7606C-16 Devices

For applications using multiple AD7606C-16 devices, the configurations in the External Reference Mode section and the Internal Reference Mode section are recommended, depending on the application requirements.

Internal Reference Mode

One AD7606C-16 device, configured to operate in internal reference mode, can drive the remaining AD7606C-16 devices, which are configured to operate in external reference mode (see Figure

85). Decouple the REFIN/REFOUT pin of the AD7606C-16, configured in internal reference mode, using a 10 μ F ceramic decoupling capacitor. The other AD7606C-16 devices, configured in external reference mode, must use at least a 100 nF decoupling capacitor on their REFIN/REFOUT pins.

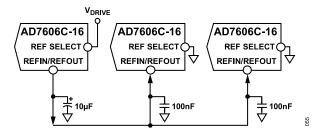

Figure 85. Internal Reference Driving Multiple AD7606C-16 REFIN/REFOUT
Pins

External Reference Mode

One external reference can drive the REFIN/REFOUT pins of all AD7606C-16 devices (see Figure 86). In this configuration, decouple each REFIN/REFOUT pin of the AD7606C-16 with at least a 100 nF decoupling capacitor.

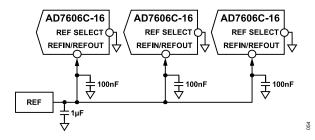

Figure 86. Single External Reference Driving Multiple AD7606C-16 REFIN/ REFOUT Pins

OPERATION MODES

The AD7606C-16 can be operated in hardware or software mode by controlling the OSx pins, described in Table 14.

In hardware mode, the AD7606C-16 is configured depending on the logic level on the RANGE, OSx, or STBY pins. The AD7606C-16 is backwards compatible to the AD7606, AD7606B, AD7608, and AD7609.

In software mode, that is, when all three OSx pins are connected to logic high level, the AD7606C-16 is configured by the corresponding registers accessed through the serial or parallel interface. Additional features are available, as described in Table 15.

The reference and the data interface is selected using the REF SELECT and PAR/SER SEL pins, in both hardware and software modes.

Reset Functionality

The AD7606C-16 has two reset modes: partial or full. The reset mode selected is dependent on the length of the reset high pulse. A partial reset requires the RESET pin to be held high between 55 ns and 2 μs . After 50 ns from the release of the RESET pin ($t_{\mbox{\scriptsize DEVICE_SETUP}}$, partial reset), the device is fully functional and a conversion can be initiated. A full reset requires the RESET pin to be held high for a minimum of 3.2 μs . After 274 μs ($t_{\mbox{\scriptsize DEVICE_SET-UP}}$, full reset) from the release of the RESET pin, the device is completely reconfigured and a conversion can be initiated.

A partial reset reinitializes the following modules:

- Digital filter
- Serial peripheral interface (SPI) and parallel, resetting to ADC read mode
- ▶ SAR ADCs
- ▶ CRC logic

After the partial reset, the RESET_DETECT bit of the status register asserts (Address 0x01, Bit 7). The current conversion result is discarded after the completion of a partial reset. The partial reset does not affect the register values programmed in software mode or the latches that store the user configuration in both hardware and software modes.

A full reset returns the device to the default power-on state, the RESET_DETECT bit of the status register asserts (Address 0x01, Bit 7), and the current conversion result is discarded. The following features, in addition to the features that reinitialized with a partial reset and listed previously, are configured when the AD7606C-16 is released from full reset:

- ▶ Hardware mode or software mode
- ► Interface type (serial or parallel)

Power-Down Modes

In hardware mode, two power-down modes are available on the AD7606C-16: standby mode and shutdown mode. The \$\overline{STBY}\$ pin controls whether the AD7606C-16 is in normal mode or in one of the two power-down modes, as shown in Table 16. If the \$\overline{STBY}\$ pin is low, the power-down mode is selected by the state of the RANGE pin.

THEORY OF OPERATION

Table 16. Power-Down Mode Selection, Hardware Mode (Continued)

Power Mode	STBY Pin	RANGE Pin
Shutdown	0	0

¹ X means don't care.

In software mode, the power-down mode is selected through the OPERATION_MODE bits on the CONFIG register (Address 0x02, Bits[1:0]) within the memory map. There is an extra power-down mode available in software mode called autostandby mode.

Table 17. Power-Down Mode Selection, Software Mode, Through CONFIG Register (Address 0x02)

Operation Mode	Address 0x02, Bit 1	Address 0x02, Bit 0
Normal	0	0
Standby	0	1
Autostandby	1	0
Shutdown	1	1

When the AD7606C-16 is placed in shutdown mode, all circuitry is powered down and the current consumption reduces to 4.5 μ A, maximum. A reset pulse is needed to exit shutdown mode. The power-up time is approximately 10 ms. When the AD7606C-16 is

powered up from shutdown mode, a full reset must be applied to the AD7606C-16 after the required power-up time elapses.

When the AD7606C-16 is placed in standby mode, all the PGAs and all the SAR ADCs enter a low power mode, such that the overall current consumption reduces to 6.5 mA, maximum. No reset is required after exiting standby mode.

When the AD7606C-16 is placed in autostandby mode, available only in software mode, the device automatically enters standby mode on the BUSY signal falling edge. The AD7606C-16 exits standby mode automatically on the CONVST signal falling edge. Therefore, the CONVST signal low pulse time is longer than $t_{WAKE\ UP}$ (standby mode) = 1 μs (see Figure 87).

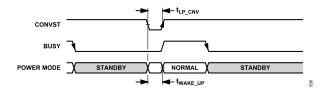

Figure 87. Autostandby Mode Operation

analog.com Rev. A | 37 of 80

DIGITAL FILTER

The AD7606C-16 contains an optional digital averaging filter that can be enabled in slower throughput rate applications that require higher SNR or dynamic range.

In hardware mode, the oversampling ratio of the digital filter is controlled using the oversampling pins, OSx, as shown in Table 14. The OSx pins are latched on the falling edge of the BUSY signal or upon a full reset.

In software mode, that is, if all OSx pins are tied to logic high, the oversampling ratio is selected through the oversampling register (Address 0x08). Two additional oversampling ratios (OS × 128 and OS × 256) are available in software mode.

In oversampling mode, the ADC takes the first sample for each channel on the rising edge of the CONVST signal. After converting the first sample, the subsequent samples are taken by the internally generated sampling signal, as shown in Figure 88. Alternatively, this sampling signal can be applied externally as described in the External Oversampling Clock section. For example, if oversampling by eight is configured, eight samples are taken, averaged, and the result is provided on the output. A CONVST signal rising edge triggers the first sample, and the remaining seven samples are taken with an internally generated sampling signal. Consequently, turning on the averaging of multiple samples leads to an improvement in SNR performance, at the expense of reducing the maximum throughput rate. When the oversampling function is turned on, the BUSY signal high time (t_{CONV}) extends, as shown in Table 3.

Table 18 and Table 19 show the trade-off in SNR vs. bandwidth and throughput for the ±10 V single-ended range, ±20 V differential range, and 0 V to 10 V single-ended range. For other ranges, check the Design Tool in Tools & Simulations section of the product page.

Figure 88 shows that the conversion time (t_{CONV}) extends when oversampling is turned on. The throughput rate ($1/t_{CYCLE}$) must be reduced to accommodate the longer conversion time and to allow the read operation to occur. To achieve the fastest throughput rate possible when oversampling is turned on, the read can be performed during the BUSY signal high time as explained in the Reading During Conversion section.

PADDING OVERSAMPLING

As shown in Figure 88, an internally generated clock triggers the samples to be averaged, and then the ADC remains idle until the following CONVST signal rising edge. In software mode, through the oversampling register (Address 0x08), the internal clock (OS clock) frequency can be changed such that idle time is minimized, that is, sampling instants are equally spaced, as shown in Figure 89. As a result, the actual oversampling clock frequency depends on the OS PAD bits configuration, as per the following equation:

$$OS_CLOCK(kHz) = \frac{1}{1000 \times \left(1 + \frac{OS_PAD}{16}\right)}$$

$$convst \int t_{CYCLE}$$

$$os_clock \int t_{CYCLE}$$

$$convert \int t_{CYCLE}$$

$$convert \int t_{CYCLE}$$

Figure 89. Oversampling by 8 Example, Oversampling Padding Enabled

EXTERNAL OVERSAMPLING CLOCK

In software mode, there is an option to apply an external clock through the CONVST pin when oversampling mode is enabled. Providing a low litter external clock improves SNR performance for large oversampling ratios. By applying an external clock, the input is sampled at regular time intervals, which is optimum for antialiasing performance.

To enable the external oversampling clock. Bit 5 in the CONFIG register (Address 0x02, Bit 5) must be set. Then, the throughput rate is the following:

That is, the sampling signal is provided externally through the CONVST pin, and every OSR number of clocks, an output is averaged and provided, as shown in Figure 91. This feature is available using either the parallel interface or the serial interface.

Simultaneous Sampling of Multiple AD7606C-16 Devices

In general, synchronizing several SAR ADCs can easily be achieved by using a common CONVST signal. However, when OS is enabled, an internal clock is used by default to trigger the subsequent samples. Any deviation between these internal clocks may impede device-to-device synchronization. This deviation can be minimized by using external OS because the CONVST signal of all the samples are managed externally.

A partial reset (t_{RESET} < 2 µs) interrupts the oversampling process and empties the data register. Therefore, if by any reason one of the AD7606C-16 devices is not in synchrony, issuing a partial reset easily resynchronizes them all, as shown in Figure 90.

SYSTEM CALIBRATION FEATURES

The following system calibration features are available in software mode by writing to corresponding registers in the memory map:

- Phase calibration
- Gain calibration
- Offset calibration
- Analog input open circuit detection

SYSTEM PHASE CALIBRATION

When using an external filter, as shown in Figure 93, any mismatch on the discrete components, or in the sensor being used, can cause phase mismatch between channels. This phase mismatch can be compensated for in software mode, on a per channel basis, by delaying the sampling instant on individual channels.

The sampling instant on any particular channel can be delayed with regard to the CONVST signal rising edge, with a resolution of 1 μ s, and up to 255 μ s, by writing to the corresponding CHx_PHASE register (Address 0x19 through Address 0x20).

For example, if the CH4_PHASE register (Address 0x1C) is written with 10 (decimal), Channel 4 is effectively sampled 10 μ s (t_{PHASE_REG}) after the CONVST signal rising edge, as shown in Figure $\overline{9}2$.

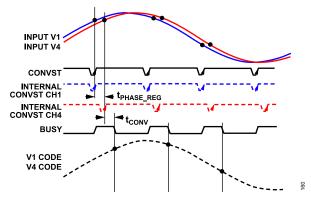

Figure 92. System Phase Calibration Functionality

Note that delaying any channel extends the BUSY signal high time, and t_{CONV} = n + 1 μ s, with n as the CH_X_PHASE register content of the most delayed channel.

In the previously explained example and Figure 92, if only the CH4_PHASE register is programmed, t_{CONV} increases by 11 μs . Therefore, this scenario must be considered when running at higher throughput rates.

SYSTEM GAIN CALIBRATION

Using an external R_{FILTER}, as shown in Figure 93, generates a system gain error. This gain error can be compensated for in software mode, on a per channel basis, by writing the series resistor value used on the corresponding register, Address 0x09 through Address 0x10. These registers can compensate up to 65 k Ω series resistors, with a resolution of 1024 Ω .

Note that system gain calibration is only available on bipolar analog input ranges, both single-ended and differential. System gain calibration is not available in unipolar single-ended ranges.

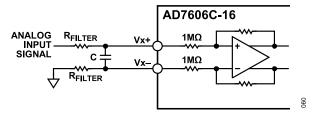

Figure 93. System Gain Error

For example, if a 27 k Ω resistor is placed in series to the analog input of Channel 5, the resistor generates a –2% positive full-scale error on the system (at ±10 V range), as shown in Figure 94. In software mode, this error is eliminated by writing 27 (decimal) to the CH5_GAIN register (Address 0x0D), which keeps the error within 0.05% of FSR, no matter the R_{FILTER} value of the series resistor, as shown in Figure 95.

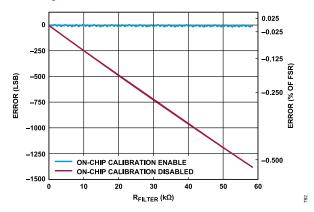

Figure 94. System Gain Calibration with and Without Calibration, ±10 V Single-Ended Range

SYSTEM CALIBRATION FEATURES

SYSTEM OFFSET CALIBRATION

A potential offset on the sensor, or any offset caused by a mismatch between the R_{FILTER} pair placed on a particular channel (as described in the Analog Front End section), can be compensated in software mode, on a per channel basis. The CHx_OFFSET registers (Address 0x11 through Address 0x18) allow the ability to add or subtract up to 128 LSBs from the ADC code automatically, with a resolution of 1 LSB, as shown in Table 20.

For example, if the signal connected to Channel 3 has a 9 mV offset, and the analog input range is set to the ± 10 V range (where LSB size = $305 \,\mu\text{V}$) to compensate for this offset, program $-30 \, \text{LSB}$ to the corresponding register. Writing 128 (decimal) -30 (decimal) = 0x80 - 0x1E = 0x62 to the CH3_OFFSET register (Address 0x13) removes such offset.

Table 20. CHx_OFFSET Register Bit Decoding

CHx_OFFSET Register	Offset Calibration (LSB)
0x00	-128
0x45	-59
0x80 (Default)	0
0x83	+3
0xFF	+127

ANALOG INPUT OPEN CIRCUIT DETECTION

The AD7606C-16 has an analog input open circuit detection feature available in software mode. To use this feature, R_{PD} must be placed as shown in Figure 96. If the analog input is disconnected, for example, if a switch opens in Figure 96, the source impedance changes from the burden resistor (R_{BURDEN}) to R_{PD} , as long as $R_{BURDEN} < R_{PD}$. It is recommended to use R_{PD} = 20 k Ω so that the AD7606C-16 can detect changes in the source impedance by internally switching the PGA common-mode voltage. Analog input open circuit detection operates in manual mode or in automatic mode.

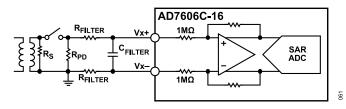

Figure 96. Analog Front End with RPD

Note that analog input open circuit detection is only available on bipolar single-ended input ranges. Analog input open circuit detection is neither available in unipolar single-ended nor in differential ranges.

Manual Mode

In manual mode, enabled by writing 0x01 to OPEN_DETECT_QUEUE (Address 0x2C), each PGA common-mode voltage is controlled by the corresponding CHx_OPEN_DETECT_EN bit on the OPEN_DETECT_ENABLE register (Address 0x23). Setting this bit high shifts up the PGA common-mode voltage. If there is an open circuit on the analog input, the ADC output changes proportionally to the R_{PD} resistor, as shown in Figure 97. If there is no open circuit, any change on the PGA common-mode voltage has no effect on the ADC output.

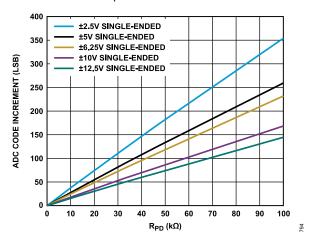

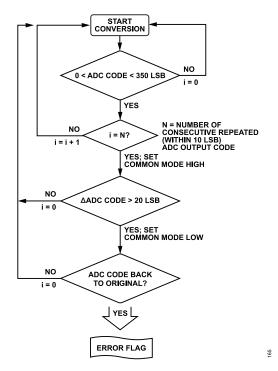

Figure 97. Open Circuit Code Error Increment, Dependent of RPD

Automatic Mode

Automatic mode is enabled by writing any value greater than 0x01 to the OPEN_DETECT_QUEUE register (Address 0x2C), as shown in Table 21. If the AD7606C-16 detects that the ADC reported a number (specified in the OPEN_DETECT_QUEUE register) of consecutive unchanged conversions, the analog input open circuit detection algorithm is performed internally and automatically. The analog input open circuit detection algorithm automatically changes the PGA common-mode voltage, checks the ADC output, and returns to the initial common-mode voltage, as shown in Figure 98. If the ADC code changes in any channel with the PGA common-mode change, this implies that there is no input signal connected to that analog input, and the corresponding flag asserts within the OPEN_DETECTED register (Address 0x24). Each channel can be individually enabled or disabled through the OPEN_DETECT_ENABLE register (Address 0x23).

SYSTEM CALIBRATION FEATURES

If no oversampling is used, the recommended minimum number of conversions to be programmed for the AD7606C-16 to automatically detect an open circuit on the analog input is

$$OPEN_DETECT_QUEUE = 10 \times f_{SAMPLE}(R_{PD} + 2 \times R_{FILTER}) \times (C_{FILTER} + 10 \text{pF})$$
(7)

However, when oversampling mode is enabled, the recommended minimum number of conversions to use is

$$OPEN_DETECT_QUEUE = 10 \times f_{SAMPLE} \times 2(R_{PD} + 2 \times R_{FILTER}) \times (C_{FILTER} + 10 \text{pF}) \times OSR$$
(8)

DIGITAL INTERFACE

The AD7606C-16 provides two interface options: a parallel interface and a high speed serial interface. The required interface mode is selected through the PAR/SER SEL pin.

Table 22. Interface Mode Selection

PAR/SER SEL	Interface Mode
0	Parallel
1	Serial

Operation of the interface modes is discussed in the Hardware Mode section and the Software Mode section.

HARDWARE MODE

In hardware mode, only ADC read mode is available. ADC data can be read from the AD7606C-16 through the parallel data bus with standard \overline{CS} and \overline{RD} signals or through the serial interface with standard \overline{CS} , SCLK, and two D_{OUT}x signals.

See the Reading Conversion Results (Parallel ADC Read Mode) section and the Reading Conversion Results (Serial ADC Read Mode) section for more details on how ADC read mode operates.

SOFTWARE MODE

In software mode, which is active only when all three OS pins are tied high, both ADC read mode and register mode are available. ADC data can be read from the AD7606C-16, and registers can also be read from and written to the AD7606C-16 through the parallel data bus with standard $\overline{\text{CS}}$, $\overline{\text{RD}}$, and $\overline{\text{WR}}$ signals or through the serial interface with standard $\overline{\text{CS}}$, SCLK, SDI, and D_{OUT}A lines.

See the Parallel Register Mode (Reading Register Data) section and the Parallel Register Mode (Writing Register Data) section for more details on how register mode operates.

Pin functions differ depending on the interface selected (parallel or serial) and the operation mode (hardware or software), as shown in Table 23.

DIGITAL INTERFACE

PARALLEL INTERFACE

To read ADC data or to read and write the register content over the parallel interface, tie the \overline{PAR}/SER SEL pin low. The rising edge of the \overline{CS} input signal moves the bus into three-state, and the falling edge of the \overline{CS} input signal takes the bus out of the high impedance state. \overline{CS} is the control signal that enables the data lines and it is the function that allows multiple AD7606C-16 devices to share the same parallel data bus.

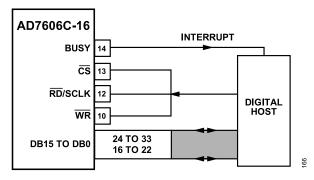

Figure 99. AD7606C-16 Interface Diagram—One AD7606C-16 Using the Parallel Bus, with $\overline{\text{CS}}$ and $\overline{\text{RD}}$ Shorted Together

Reading Conversion Results (Parallel ADC Read Mode)

The falling edge of the \overline{RD} pin reads data from the output conversion results register. Applying a sequence of \overline{RD} pulses to the \overline{RD}

pin clocks the conversion results out from each channel to the parallel bus, Bits[DB15:DB0], in ascending order, from V1 to V8, as shown in Figure 100.

The $\overline{\text{CS}}$ signal can be permanently tied low, and the $\overline{\text{RD}}$ signal can access the conversion results, as shown in Figure 3. A read operation of new data can take place after the BUSY signal goes low (see Figure 2). Alternatively, a read operation of data from the previous conversion process can take place while the BUSY pin is high.

When there is only one AD7606C-16 in a system and it does not share the parallel bus, data can be read using one control signal from the digital host. The $\overline{\text{CS}}$ and $\overline{\text{RD}}$ signals can be tied together, as shown in Figure 4. In this case, the falling edge of the $\overline{\text{CS}}$ and $\overline{\text{RD}}$ signals bring the data bus out of three-state and clocks out the

The FRSTDATA output signal indicates when the first channel, V1, is being read back, as shown in Figure 4. When the \overline{CS} input is high, the FRSTDATA output pin is in three-state. The falling edge of \overline{CS} takes the FRSTDATA pin out of three-state. The falling edge of the \overline{RD} signal corresponding to the result of V1 sets the FRSTDATA pin high, indicating that the result from V1 is available on the output data bus. The FRSTDATA pin returns to a logic low following the next falling edge of \overline{RD} .

Reading During Conversion

The data read operation from the AD7606C-16, as shown in Figure 101, can occur in the following scenarios:

- ▶ After conversion, such as when the BUSY line is low
- ▶ During conversion, such as when the BUSY line is high
- Start while the BUSY line is low and end while the following conversion, see Figure 2

Reading during conversion has little effect on the performance of the converter, and it allows a faster throughput rate to be achieved. Data can be read from the AD7606C-16 at any time other than on the falling edge of the BUSY signal because this falling edge is when the output data registers are updated with the new conversion data. Any data read while the BUSY signal is high must be completed before the falling edge of the BUSY signal.

Parallel ADC Read Mode with CRC Enabled

In software mode, the parallel interface supports reading the ADC data with the CRC appended, when enabled through the INT_CRC_ERR_EN bit (Address 0x21, Bit 2). The CRC is 16 bits, and it is clocked out after reading all eight channel conversions, as shown in Figure 102. The CRC calculation includes all data on the DBx pins: data, status (when appended), and zeros. See the Diagnostics section for more details on the CRC.

Parallel ADC Read Mode with Status Enabled

In software mode, the 8-bit status header is enabled (see Table 25) by setting STATUS_HEADER in the CONFIG register (Address 0x02, Bit 6), and each channel then takes two frames of data:

- ▶ The first frame clocks the ADC data out through DB15 to DB0.
- ► The second frame clocks out the status header of the channel on DB15 to DB8, DB15 being the MSB and DB8 being the LSB, while DB7 to DB0 clock out zeros.

This sequence is shown in Figure 100. Table 25 explains the status header content and describes each bit.

DIGITAL INTERFACE

Parallel Register Mode (Reading Register Data)

In software mode, all the registers in Table 31 can be read over the parallel interface. Bits[DB15:DB0] leave a high impedance state when both the \overline{CS} signal and \overline{RD} signal are logic low for reading register content, or when both the \overline{CS} signal and \overline{WR} signal are logic low for writing register address and/or register content.

A register read is performed through two frames: first, a read command is sent to the AD7606C-16 and second, the AD7606C-16 clocks out the register content. The format for a register read command is shown in the leading two frames of Figure 103. On the first frame, perform the following:

- ▶ Bit DB15 must be set to 1 to select a read command. The read command places the AD7606C-16 in register mode.
- ▶ Bits [DB14:DB8] must contain the register address.
- ▶ The subsequent eight bits, Bits[DB7:DB0], are ignored.

The register address is latched on the AD7606C-16 on the rising edge of the \overline{WR} signal. The register content can then be read from the latched register by bringing the \overline{RD} line low on the following frame, as follows:

- ▶ Bit DB15 is pulled to 0 by the AD7606C-16.
- ▶ Bits[DB14:DB8] provide the register address being read.
- The subsequent eight bits, Bits[DB7:DB0], provide the register content.

To revert to ADC read mode, keep all DBx pins low during one WR cycle, as shown in the Parallel Register Mode (Writing Register Data) section. No ADC data can be read while the device is in register mode.

Parallel Register Mode (Writing Register Data)

In software mode, all the R/W registers in Table 31 can be written to over the parallel interface. To write a sequence of registers, firstly exit ADC read mode (default mode) by reading any register on the memory map as explained in the Parallel Register Mode (Reading Register Data) section. A register write command is performed by a single frame, through the parallel bus (Bits[DB15:DB0]), \overline{CS} signal, and \overline{WR} signal. The format of a write command, as shown in Figure 103, is structured as follows:

- ▶ Bit DB15 must be set to 0 to select a write command.
- ▶ Bits[DB14:DB8] contain the register address.
- ► The subsequent eight bits, Bits[DB7:DB0], contain the data to be written to the selected register.

Data is latched onto the device on the rising edge of the \overline{WR} pin. To revert to ADC read mode, keep all DBx pins low during one \overline{WR} cycle. No ADC data can be read while the device is in register mode.

SERIAL INTERFACE

To read ADC data or to read/write the content of the register over the serial interface, tie the PAR/SER SEL pin high.

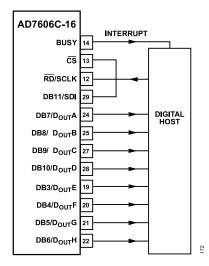

Figure 104. AD7606C-16 Interface Diagram—One AD7606C-16 Using the Serial Interface with Four D_{OUT}x Lines

Reading Conversion Results (Serial ADC Read Mode)

The AD7606C-16 has eight serial data output pins, $D_{OUT}A$ to $D_{OUT}H$. In software mode, data can be read back from the AD7606C-16 using either one (see Figure 108), two (see Figure 105), four (see Figure 106), or eight $D_{OUT}X$ lines (see Figure 107), depending on the configuration set in the CONFIG register.

2 D _{OUT} x	0	1
4 D _{OUT} x	1	0
8 D _{OUT} x	1	1

In hardware mode, only the 2 D_{OUT}x lines option is available. However, all channels can be read from D_{OUT}A by providing eight 16-bit SPI frames between two CONVST pulses.

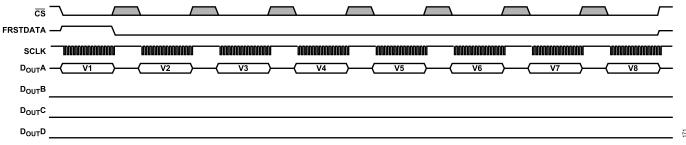

Figure 108. Serial Interface ADC Reading, One D_{OUT}x Lines

DIGITAL INTERFACE

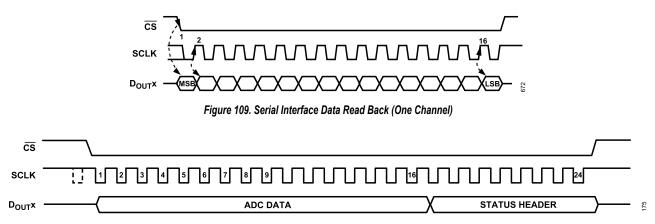

Figure 110. Serial Interface, ADC Mode

The $\overline{\text{CS}}$ falling edge takes the data output lines, D_{OUT}x, out of three-state and clocks out the MSB of the conversion result, as shown in Figure 109.

In 3-wire mode ($\overline{\text{CS}}$ tied low), instead of $\overline{\text{CS}}$ clocking out the MSB, the falling edge of the BUSY signal clocks out the MSB. The rising edge of the SCLK signal clocks all the subsequent data bits on the serial data outputs, D_{OUT}x, as shown in Figure 6. The $\overline{\text{CS}}$ input can be held low for the entire serial read operation, or it can be pulsed to frame each channel read of 16 SCLK cycles (see Figure 105). However, if $\overline{\text{CS}}$ is pulsed during a channel conversion result transmission before reaching the LSB, the channel that was interrupted retransmits on the next frame, completely starting again from the MSB.

Data can also be clocked out using only the $D_{OUT}A$ line, as shown in Figure 108. For the AD7606C-16 to access all eight conversion results on one $D_{OUT}x$ line, a total of 128 SCLK cycles is required. In hardware mode, these 128 SCLK cycles must be framed in groups of 16 SCLK cycles by the \overline{CS} signal. The disadvantage of using just one $D_{OUT}x$ line is that the throughput rate is reduced if reading occurs after conversion. Leave the unused $D_{OUT}x$ lines unconnected in serial mode.

Figure 106 shows a read of eight simultaneous conversion results using four $D_{OUT}x$ lines on the AD7606C-16, available in software mode. In this case, a 32 SCLK transfer accesses data from the AD7606C-16, and \overline{CS} is either held low to frame the entire 32 SCLK cycles or is pulsed between two 16-bit frames. This mode is only available in software mode, and it is configured using the CONFIG register (Address 0x02).

Figure 6 shows the timing diagram for reading one channel of data, framed by the \overline{CS} signal, from the AD7606C-16 in serial mode. The SCLK input signal provides the clock source for the serial read operation. The \overline{CS} signal goes low to access the data from the AD7606C-16.

The FRSTDATA output signal indicates when the first channel, V1, is being read back. When the $\overline{\text{CS}}$ input is high, the FRSTDATA output pin is in three-state. In serial mode, the falling edge of the

CS signal takes the FRSTDATA pin out of three-state and sets the FRSTDATA pin high if the BUSY line is already deasserted, indicating that the result from V1 is available on the D_{OUT}A output data line. The FRSTDATA output returns to a logic low following the 16th SCLK falling edge. If the CS pin is tied permanently low (3-wire mode), the falling edge of the BUSY line sets the FRSTDATA pin high when the result from V1 is available on D_{OUT}A.

If SDI is tied low or high, nothing is clocked to the AD7606C-16. Therefore, the device remains clocking out conversion results. When using the AD7606C-16 in 3-wire mode, keep SDI at a high level. While in ADC read mode, single-write operations can be performed, as shown in Figure 110. For writing a sequence of registers, switch to register mode, as described in the Serial Register Mode (Writing Register Data) section.

Reading During Conversion—Serial Interface

The data read operation from the AD7606C-16, as shown in Figure 101, occurs in the following scenarios:

- After conversion, such as when the BUSY line is low
- During conversion, such as when the BUSY line is high
- Starts when the BUSY line is low and ends during the following conversion, see Figure 2.

Reading during conversion has little effect on the performance of the converter, and it allows a faster throughput rate to be achieved. Data can be read from the AD7606C-16 at any time other than on the falling edge of the BUSY signal because this falling edge is when the output data registers are updated with the new conversion data. Any data read while the BUSY signal is high must be completed before the falling edge of the BUSY signal.

Serial ADC Read Mode with CRC Enabled

In software mode, the CRC can be enabled by writing to the register map. In this case, the CRC is appended on each $D_{OUT}x$ line after the last channel is clocked out, as shown in Figure 116. See the Interface CRC Checksum section for more information on how the CRC is calculated.

analog.com Rev. A | 48 of 80

DIGITAL INTERFACE

Serial ADC Read Mode with Status Enabled

In software mode, the 8-bit status header (see Table 27) can be turned on when using the serial interface so that it is appended after each 16-bit data conversion, extending the frame size to 24 bits per channel, as shown in Figure 110.

Serial Register Mode (Reading Register Data)

All the registers in Table 31 can be read over the serial interface. The format for a read command is shown in Figure 111. A read command consists of two 16-bit frames. On the first frame, perform the following:

▶ The first bit clocked in SDI must be set to 0 to enable writing the address.

- ▶ The second bit clocked in SDI must be set to 1 to select a read command.
- ▶ Bits[3:8] in SDI contain the register address to be clocked out on D_{OLIT}A on the following frame.
- ▶ The subsequent eight bits, Bits[9:16], clocked in SDI are ignored.

If the AD7606C-16 is in ADC read mode, the serial data out (SDO) keeps clocking ADC data on Bits[9:16], and then the AD7606C-16 switches to register mode.

If the AD7606C-16 is in register mode, the SDO reads back the content from the previous addressed register, no matter if the previous frame was a read or a write command. To exit register mode, keep the SDI line low for 16 SCLK cycles as shown in Figure 112

DIGITAL INTERFACE

Serial Register Mode (Writing Register Data)

In software mode, all the read/write registers in Table 31 can be written to the serial interface. To write a sequence of registers, exit ADC read mode (default mode) by reading any register on the memory map. A register write command is performed by a single 16-bit SPI access. The format for a write command is shown in Figure 113, and is structured as follows:

- ▶ The first bit clocked in SDI must be set to 0 to enable a write command.
- ▶ The second bit clocked in SDI, the R/W bit, must be cleared to 0.
- ▶ Bit ADD5 to Bit ADD0 clocked in SDI contain the register address to be written.
- ▶ The subsequent eight bits (Bits[DIN7:DIN0]) contain the data to be written to the selected register. Data is clocked in from SDI on

the falling edge of SCLK, while data is clocked out on $D_{\text{OUT}}A$ on the rising edge of SCLK.

When writing continuously to the device, the data that appears on $D_{OUT}A$ is from the register address that was written to on the previous frame, as shown in Figure 113. The $D_{OUT}B$, $D_{OUT}C$, and $D_{OUT}D$ lines are kept low during the transmission.

While in register mode, no ADC data is clocked out because the $D_{OUT}x$ lines are used to clock out register content. When finished writing all needed registers, a write to Address 0x00 returns the AD7606C-16 to ADC read mode, where the ADC data is again clocked out on the $D_{OUT}x$ lines, as shown in Figure 112.

In software mode, when the CRC is turned on, eight additional bits are clocked in and out on each frame. Therefore, 24-bit frames are required.

DIGITAL INTERFACE

Serial Register Mode with CRC

Registers can be written to and read from the AD7606C-16 with CRC enabled in software mode, by asserting the INT_CRC_ERR_EN bit (Address 0x21, Bit 2).

When reading a register, the AD7606C-16 provides eight additional bits on the $D_{OUT}A$ line with the CRC resultant of the data shifted out previously on the same frame. The controller can then check whether the data received is correct by applying the following polynomial:

With the CRC enabled, the SPI frames extend to 24 bits in length, as shown in Figure 114.

When writing a register, the controller must clock the data (register address plus register content) in the AD7606C-16 followed by an 8-bit CRC word, calculated from the previous 16 bits using the Equation 9. The AD7606C-16 reads the register address and the register content, calculates the corresponding 8-bit CRC word, and asserts the INT_CRC_ERR bit (Address 0x22, Bit 2) if the calculated CRC word does not match the CRC word received between the 17th and 24th bit through SDI, as shown in Figure 115.

DIAGNOSTICS

Diagnostic features are available in software mode to verify correct operation of the AD7606C-16. The list of diagnostic monitors includes reset detection, analog input open circuit detection, and digital error detection.

If an error is detected, a flag asserts on the status header, if enabled, as described in the Digital Interface section. This flag points to the registers on which the error is located, as explained in the following sections.

In addition, a diagnostic multiplexer can dedicate any channel to verify a series of internal nodes, as explained in the Diagnostics Multiplexer section.

RESET DETECTION

The RESET_DETECT bit on the status register (Address 0x01, Bit 7) asserts if either a partial reset or full reset pulse is applied to the AD7606C-16. On power-up, a full reset is required. This reset asserts the RESET_DETECT bit, indicating that the power-on reset (POR) initialized correctly on the device.

The POR monitors the REGCAP voltage and issues a full reset if the voltage drops under a certain threshold.

The RESET_DETECT bit can be used to detect an unexpected device reset or a large glitch on the RESET pin, or a voltage drop on the supplies.

The RESET_DETECT bit is only cleared by reading the status register.

DIGITAL ERROR

Both the status register and status header contain a DIGITAL_ER-ROR bit. This bit asserts when any of the following monitors trigger:

- Memory map CRC, read only memory (ROM) CRC, and digital interface CRC
- ▶ SPI invalid read or write
- ▶ BUSY stuck high

To find out which monitor triggered the DIGITAL_ERROR bit, the DIGITAL_DIAG_ERR address (Address 0x22) has a bit dedicated for each monitor, as explained in the following sections.

ROM CRC

The ROM stores the factory trimming settings for the AD7606C-16. After power-up, the ROM content is loaded to registers during device initialization. After the load, a CRC is calculated on the loaded data and verified if the result matches the CRC stored in the ROM.

The AD7606C-16 uses the following 16- bit CRC polynomial to calculate the CRC checksum value on the memory map:

$$x^{16} + x^{14} + x^{12} + x^{10} + x^8 + x^6 + x^4 + x^3 + x + 1$$
 (0xBAAD) (10)

If the calculated and stored CRC values do not match, the error checking and correction (ECC) block can detect up to 3-bit errors (hamming distance of 4). Otherwise, the ROM_CRC_ERR (Address 0x22, Bit 0) asserts. When ROM_CRC_ERR asserts after powerup, it is recommended to issue a full reset to reload all factory settings.

This ROM CRC monitoring feature is enabled by default but can be disabled by clearing the ROM_CRC_ERR_EN bit (Address 0x21, Bit 0).

Memory Map CRC

For added robustness, a CRC calculation is performed on the on-chip registers. The memory map CRC is disabled by default. After the AD7606C-16 is configured in software mode through writing the required registers, the memory map CRC can be enabled through the MM_CRC_ERR_EN bit (Address 0x21, Bit 1). When enabled, the CRC calculation is performed on the entire memory map and stored. Every time the memory map is written, the CRC is recalculated and the new value stored.

The AD7606C-16 uses the following 16-bit CRC polynomial to calculate the CRC checksum value on the memory map:

$$x^{16} + x^{14} + x^{12} + x^{10} + x^8 + x^6 + x^4 + x^3 + x + 1$$
 (0xBAAD) (11)

The ECC block can detect up to three bits of errors (hamming distance of four bits) within the memory map. Moreover, every 4 μs , the CRC on the memory map is recalculated and compared to the stored CRC value. If the calculated and the stored CRC values do not match, the memory map is corrupted and the MM_CRC_ERR bit asserts.

If the MM_CRC_ERR bit asserts, it is recommended to write to the memory map to recalculate the CRC. If the MM_CRC_ERR persists, it is recommended to issue a full reset to restore the default contents of the memory map.

Interface CRC Checksum

The AD7606C-16 has a CRC checksum mode to improve interface robustness by detecting errors in data transmission. The CRC feature is available in both ADC read modes (serial and parallel) and register mode (serial only).

The AD7606C-16 uses the following 16-bit CRC polynomial to calculate the CRC checksum value:

$$x^{16} + x^{14} + x^{12} + x^{10} + x^8 + x^6 + x^4 + x^3 + x + 1$$
 (0xBAAD) (12)

To replicate the polynomial division in the hardware, the data shifts left by 16 bits to create a number ending in 16 Logic 0s. The polynomial is aligned so that the MSB is adjacent to the leftmost Logic 1 of the data. An exclusive OR (XOR) function is applied to the data to produce a new, shorter number. The polynomial is again aligned so that the MSB is adjacent to the leftmost Logic 1 of the new result, and the procedure repeats. This process repeats until

DIAGNOSTICS

the original data is reduced to a value less than the polynomial, the 16-bit checksum.

An example of the CRC calculation for the 16-bit data is shown in Table 28. The CRC corresponding to the data 0x064E, using Equation 12, is 0x2137.

The serial interface supports the CRC when enabled via the INT_CRC_ERR_EN bit (Address 0x21, Bit 2). The CRC is a 16-bit word that is appended to the end of each $D_{OUT}x$ in use, after reading all the channels. An example using four $D_{OUT}x$ lines is shown in Figure 116.

If using two $D_{OUT}x$ lines ($D_{OUT}A$ and $D_{OUT}B$), each 16-bit CRC word is calculated using data from four channels, that is 64 bits, as shown in Figure 117. If using only one $D_{OUT}x$ line, all eight channels are clocked out through $D_{OUT}A$, followed by the 16-bit CRC word calculated using data from the eight channels, that is, 128 bits.

If using four D_{OUT}x lines, each 16-bit CRC word is calculated using data from two channels 32 bits. If using eight D_{OUT}x lines, each 16-bit CRC word is calculated using data from one channel 16 bits.

DIAGNOSTICS

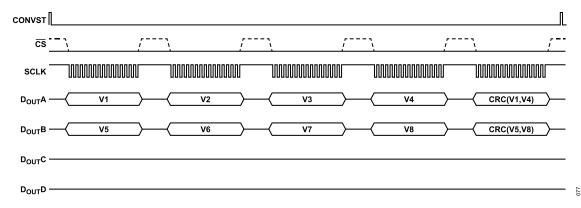

Figure 117. Serial Interface ADC Reading with CRC On, Two D_{OUT}x Lines

When the AD7606C-16 is in register mode, that is, when registers are being read or written, the CRC polynomial used is $x^8 + x^2 + x + 1$. When reading a register, and CRC is enabled, each SPI frame is 24 bits long and the CRC 8-bit word is clocked out from the 17^{th} to 24^{th} SCLK cycle. Similarly, when writing a register, a CRC word can be appended on the SDI line, as shown in Figure 113 and the AD7606C-16 checks and triggers an error, INT_CRC_ERR (Address 0x22, Bit 2), if the CRC given and the internally calculated do not match.

The parallel interface also supports CRC in ADC mode only, and it is clocked out through DB15 to DB0 after Channel 8, as shown in Figure 102. The 16-bit CRC word calculated using data from the eight channels, that is, 128 bits.

Interface Check

The integrity of the digital interface can be checked by setting the INTERFACE_CHECK_EN bit (Address 0x21, Bit 7). Selecting the interface check forces the conversion result registers to a known value, as shown in Table 29.

Verifying that the controller receives the data shown in Table 29 ensures that the interface between the AD7606C-16 and the controller operates properly. If the interface CRC is enabled because the data transmitted is known, this mode verifies that the controller performs the CRC calculation properly.

SPI Invalid Read/Write

When attempting to read back an invalid register address, the SPI_READ_ERR bit (Address 0x22, Bit 4) is set. The invalid readback address detection can be enabled by setting the SPI_READ_ERR_EN bit (Address 0x21, Bit 4). If an SPI read error is triggered, it is cleared by overwriting that bit or disabling the checker.

When attempting to write to an invalid register address or a read only register, the SPI_WRITE_ERR bit (Address 0x22, Bit 3) is set. The invalid write address detection can be enabled by setting the SPI_WRITE_ERR_EN bit (Address 0x21, Bit 3). If an SPI write error is triggered, it is cleared by overwriting that bit or disabling the checker.

BUSY Stuck High

BUSY stuck high monitoring is enabled by setting the BUSY_STUCK_HIGH_ERR_EN bit (Address 0x21, Bit 5). After this bit is enabled, the conversion time (t_{CONV} in Table 3) is monitored internally with an independent clock. If t_{CONV} exceeds 4 μ s, the AD7606C-16 automatically issues a partial reset and asserts the BUSY_STUCK_HIGH_ERR bit (Address 0x22, Bit 5). To clear this error flag, the BUSY_STUCK_HIGH_ERR bit must be overwritten with a 1.

When oversampling mode is enabled, the individual conversion time for each internal conversion is monitored.

DIAGNOSTICS

Internal Clock Counters

The AD7606C-16 uses an internal clock related to functional safety features (FS_CLK) and an internal clock for oversampling (OS_CLK). Both internal clocks run at 16 MHz. To verify the clocks are correctly operating, enable the clock counter through the CLK_FS_OS_COUNTER_EN bit in Register 0x21, Bit 6. These clock counters increment by 1 every time 64 clocks are counted. Therefore, if either the FS_CLK_COUNTER register (Address 0x2D) or the OS_CLK_COUNTER register (Address 0x2E) is read after a certain known delay that corresponds to the chosen feature, the register values must match the equivalent count for the time elapsed.

For example, if the clock counter is enabled and the FS_CLK_COUNTER register is read after 20 µs between the write and read operations, the value must equal to 0x05. The following equation calculates the FS_CLK_COUNTER value:

$$FS_CLK_COUNTER = Delay \times \frac{16 \text{ MHz}}{64}$$
 (13)

where *Delay* is the delay shown in Figure 120.

DIAGNOSTICS MULTIPLEXER

All eight input channels contain a diagnostics multiplexer in front of the PGA that allows monitoring of the internal nodes described in Table 30 to ensure the correct operation of the AD7606C-16. For accurate measurements, it is recommended to use only Channel 8, where the offset and gain for diagnostic channels have been trimmed in production. Connecting more channels to the diagnostic multiplexer simultaneously degrades the performance.

Table 30 shows the bit decoding for the diagnostic mux register on Channel 1, as an example. When an internal node is selected, the input voltage at input pins are deselected from the PGA, as shown in Figure 118.

Each diagnostic multiplexer configuration is accessed, in software mode through the corresponding register (Address 0x28 to Address 0x2B). To use the multiplexer on one channel, the ±10 V range must be selected on that channel.

Temperature Sensor

The temperature sensor can be selected through the diagnostic multiplexer and converted with the ADC, as shown in Figure 118. The temperature sensor voltage is measured and is proportional to the die temperature, as per the following equation:

DIAGNOSTICS

Reference Voltage

The reference voltage can be selected through the diagnostic multiplexer and converted with the ADC, as shown in Figure 121. The internal or external reference is selected as the input to the diagnostic multiplexer based on the REF SELECT pin. Ideally, the ADC output follows the voltage reference level ratiometrically. Therefore, if the ADC output goes beyond the expected 2.5 V, either the reference buffer or the PGA is malfunctioning.

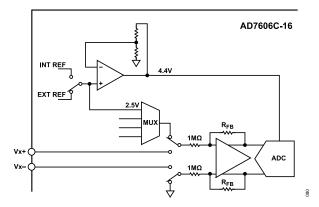

Figure 121. Reference Voltage Signal Path Through the Diagnostic
Multiplexer

Internal LDOs

The analog and digital LDO (REGCAP pins) can be selected through the diagnostic multiplexer and converted with the ADC, as shown in Figure 118. This measurement verifies that each LDO is at the correct operating voltage so that the internal circuitry is biased correctly.

Supply Voltages

 AV_{CC} , V_{DRIVE} , and AGND can be selected through the diagnostic multiplexer and converted with the ADC, as shown in Figure 118. This setup ensures the voltage and grounds are applied to the device for correct operation.

If V_{DRIVE} is below 4.3 V, the following correction factor is needed to measure AV_{CC} properly:

$$AV_{CC}(V) = ADC_{OUT}(V) - 0.5407 \times V_{DRIVE} + 2.1857(V)$$
 (15)

analog.com Rev. A | 57 of 80

TYPICAL CONNECTION DIAGRAM

There are four AV_{CC} supply pins on the device. It is recommended that each of the four pins is decoupled using a 100 nF capacitor at each supply pin and a 10 μF capacitor at the supply source. The AD7606C-16 can operate with the internal reference or an externally applied reference. When using a single AD7606C-16 device on the board, decouple the REFIN/REFOUT pin with a 100 nF capacitor. Refer to the Reference section when using an application with multiple AD7606C-16 devices. The REFCAPA and REFCAPB pins are shorted together and decoupled with a 10 μF ceramic capacitor.

The V_{DRIVE} supply is connected to the same supply as the processor. The V_{DRIVE} voltage controls the voltage value of the output logic signals. For more information on layout, decoupling, and grounding, see the Layout Guidelines section.

After supplies are applied to the AD7606C-16, apply a reset to the AD7606C-16 to ensure that it is configured for the correct mode of operation.

In Figure 122, the AD7606C-16 is configured in hardware mode and is operating with the internal reference because the REF SE-

LECT pin is set to logic high. In this example, the device also uses the parallel interface because the \overline{PAR}/SER SEL pin is tied to AGND. The analog input range for all eight channels is ±10 V, provided the RANGE pin is tied to a high level and the oversampling ratio is controlled through the OSx pins by the controller.

In Figure 123, the AD7606C-16 is configured in software mode, because all three OS2, OS1, and OS0 pins are at logic level high. The oversampling ratio, as well as each channel range, are configured through accessing the memory map. In this example, the PAR/SER SEL pin is at logic level high. Therefore, the serial interface is used for both reading the ADC data and reading and writing the memory map. The REF SELECT pin is tied to AGND. Therefore, the internal reference is disabled and an external reference is connected externally to the REFIN/REFOUT pin and decoupled through a 100 nF capacitor.

Figure 122 and Figure 123 are examples of typical connection diagrams. Other combinations of reference, data interface, and operation mode are also possible, depending on the logic levels applied to each configuration pin.

LAYOUT GUIDELINES

The following layout guidelines are recommended when designing the PCB that houses the AD7606C-16:

- ▶ If the AD7606C-16 is in a system where multiple devices require analog-to-digital ground connections, use a solid ground plane (without splitting between analog and digital grounds).
- ▶ Make stable connections to the ground plane. Avoid sharing one connection for multiple ground pins. Use individual vias or multiple vias to the ground plane for each ground pin. In the case of a split plane, join the digital and analog ground planes in only one place, preferably as close as possible to the AD7606C-16.
- ▶ Avoid running digital lines under the devices because doing so couples noise on the die. Allow the analog ground plane to run under the AD7606C-16 to avoid noise coupling.
- ▶ Shield fast switching signals like CONVST or clocks with digital ground to avoid radiating noise to other sections of the board and ensure that they never run near analog signal paths.
- Avoid crossover of digital and analog signals.
- ▶ Ensure traces on layers in close proximity on the board run at right angles to each other to reduce the effect of feedthrough through the board.
- ▶ Ensure power supply lines to the AV_{CC} and V_{DRIVE} pins on the AD7606C-16. Use as a large trace as possible to provide low impedance paths and reduce the effect of glitches on the power supply lines. Where possible, use supply planes and make stable connections between the AD7606C-16 supply pins and the power tracks on the board. Use a single via or multiple vias for each supply pin.
- ▶ Place the decoupling capacitors close to (ideally, directly against) the supply pins and their corresponding ground pins. Place the decoupling capacitors for the REFIN/REFOUT pin and the REFCAPA pin and REFCAPB pin as close as possible to their respective AD7606C-16 pins. Where possible, place the pins on the same side of the board as the AD7606C-16 device.

Figure 124 shows the recommended decoupling on the top layer of the AD7606C-16 board. Figure 125 shows the bottom layer decoupling, which is used for the four AV $_{\rm CC}$ pins and the V $_{\rm DRIVE}$ pin decoupling. Where the ceramic 100 nF caps for the AV $_{\rm CC}$ pins are placed close to their respective device pins, a single 100 nF capacitor can be shared between Pin 37 and Pin 38.

To ensure stable device-to-device performance matching in a system that contains multiple AD7606C-16 devices, a symmetrical layout between the AD7606C-16 devices is important.

Figure 126 shows a layout with two AD7606C-16 devices. The AV_{CC} supply plane runs to the right of both devices, and the V_{DRIVE} supply track runs to the left of the two devices. The reference chip is positioned between the two devices, and the reference voltage track runs north to Pin 42 of U1 and south to Pin 42 of U2. A solid ground plane is used.

These symmetrical layout principles can also be applied to a system that contains more than two AD7606C-16 devices. The

AD7606C-16 devices can be placed in a north to south direction, with the reference voltage located midway between the devices and the reference track running in the northsouth direction, similar to Figure 126.
