

Ultra-High-Precision, Ultra-Low-Noise, Series Voltage Reference

MAX6126

General Description

The MAX6126 is an ultra-low-noise, high-precision, low-dropout voltage reference. This family of voltage references feature curvature-correction circuitry and high-stability, laser-trimmed, thin-film resistors that result in 3ppm/°C (max) temperature coefficients and an excellent $\pm 0.02\%$ (max) initial accuracy. The proprietary low-noise reference architecture produces a low flicker noise of $1.3\mu\text{V}_{\text{P-P}}$ and wideband noise as low as $60\text{nV}/\sqrt{\text{Hz}}$ (2.048V output) without the increased supply current usually found in low-noise references. Improve wideband noise to $35\text{nV}/\sqrt{\text{Hz}}$ and AC power-supply rejection by adding a $0.1\mu\text{F}$ capacitor at the noise reduction pin. The MAX6126 series mode reference operates from a wide 2.7V to 12.6V supply voltage range and load-regulation specifications are guaranteed to be less than 0.025Ω for sink and source currents up to 10mA. These devices are available over the automotive temperature range of -40°C to $+125^\circ\text{C}$.

The MAX6126 typically draws $380\mu\text{A}$ of supply current and is available in 2.048V, 2.500V, 2.800V, 3.000V, 3.300V, 3.600V, 4.096V, and 5.000V output voltages. The MAX6126 also feature dropout voltages as low as 200mV. Unlike conventional shunt-mode (two-terminal) references that waste supply current and require an external resistor, the MAX6126 offers supply current that is virtually independent of supply voltage and does not require an external resistor. The MAX6126 is stable with $0.1\mu\text{F}$ to $10\mu\text{F}$ of load capacitance.

The MAX6126 is available in the tiny 8-pin μMAX° , as well as 8-pin SO packages.

Pin Description

PIN	NAME	FUNCTION
1	NR	Noise Reduction. Connect a 0.1μF capacitor to improve wideband noise. Leave unconnected if not used (see Figure 1).
2	IN	Positive Power-Supply Input
3	GND	Ground
4	GNDS	Ground-Sense Connection. Connect to ground connection at load.
5, 8	I.C.	Internally Connected. Do not connect anything to these pins.
6	OUTS	Voltage Reference Sense Output
7	OUTF	Voltage Reference Force Output. Short OUTF to OUTS as close to the load as possible. Bypass OUTF with a capacitor (0.1μF to 10μF) to GND.

Detailed Description

Wideband Noise Reduction

To improve wideband noise and transient power-supply noise, add a 0.1μF capacitor to NR ([Figure 1](#)). A 0.1μF NR capacitor reduces the noise from 60nV/√Hz to 35nV/√Hz for the 2.048V output. Noise in the power-supply input can affect output noise, but can be reduced by adding an optional bypass capacitor between IN and GND, as shown in the [Typical Operating Circuit](#). The 0.1Hz to 10Hz noise when measured with a 0.1μF noise reduction capacitor (NR pin) is 0.9μV_{P-P}. Using a 100μF noise reduction capacitor (NR pin) reduces the 0.1Hz to 10Hz noise to 0.6μV_{P-P}.

Output Bypassing

The MAX6126 requires an output capacitor between 0.1μF and 10μF. Locate the output capacitor as close to OUTF as possible. For applications driving switching capacitive loads or rapidly changing load currents, it is advantageous to use a 10μF capacitor in parallel with a 0.1μF capacitor. Larger capacitor values reduce transients on the reference output.

Supply Current

The quiescent supply current of the series-mode MAX6126 family is typically 380μA and is virtually independent of the supply voltage, with only a 2μA/V (max) variation with supply voltage.

When the supply voltage is below the minimum specified input voltage during turn-on, the device can draw up to 300μA beyond the nominal supply current. The input voltage source must be capable of providing this current to ensure reliable turn-on.

Figure 1. Noise-Reduction Capacitor

Thermal Hysteresis

Thermal hysteresis is the change of output voltage at $T_A = +25^\circ\text{C}$ before and after the device is cycled over its entire operating temperature range. The typical thermal hysteresis value is 20ppm (SO package).

Turn-On Time

These devices typically turn on and settle to within 0.1% of their final value in 200μs to 2ms depending on the device. The turn-on time can increase up to 4ms with the device operating at the minimum dropout voltage and the maximum load. A noise reduction capacitor of 0.1μF increases the turn-on time to 20ms.

Output Force and Sense

The MAX6126 provides independent connections for the power-circuit output (OUTF) supplying current into a load, and for the circuit input regulating the voltage applied to that load (OUTS). This configuration allows for the cancellation of the voltage drop on the lines connecting the MAX6126 and the load. When using the Kelvin connection made possible by the independent current and voltage connections, take the power connection to the load from OUTF, and bring a line from OUTS to join the line from OUTF, at the point where the voltage accuracy is needed. The MAX6126 has the same type of Kelvin connection to cancel drops in the ground return line. Connect the load to ground and bring a connection from GNDS to exactly the same point.

Applications Information

Precision Current Source

Figure 2 shows a typical circuit providing a precision current source. The OUTF output provides the bias current for the bipolar transistor. OUTS and GNDS sense the voltage across the resistor and adjust the current sourced by OUTF accordingly. For even higher precision, use a MOSFET to eliminate base current errors.

The voltage range of OUTF is set by the reference output voltage (OUTS) and the $V_{BE}(BJT)$ or $V_{GS}(MOS)$ of the output external device:

$$V_{OUTF} = V_{BE} + V_{REF}$$

where:

V_{OUTF} is voltage on OUTF pin

V_{BE} is base-emitter drop across BJT

V_{REF} is the actual voltage reference output this part is supposed to provide.

It translates to supply voltage requirement for voltage reference:

$$V_{IN} \geq V_{DROP} (\text{dropout voltage}) + V_{BE\max} + V_{REF}$$

where:

V_{DROP} is dropout voltage of voltage reference

High-Resolution DAC and Reference from a Single Supply

Figure 3 shows a typical circuit providing the reference for a high-resolution, 16-bit MAX541 D/A converter.

Temperature Coefficient vs. Operating Temperature Range for a 1 LSB Maximum Error

In a data converter application, the reference voltage of the converter must stay within a certain limit to keep the error in the data converter smaller than the resolution limit through the operating temperature range. Figure 4 shows the maximum allowable reference voltage temperature coefficient to keep the conversion error to less than 1 LSB, as a function of the operating temperature range ($T_{MAX} - T_{MIN}$) with the converter resolution as a parameter. The graph assumes the reference voltage temperature coefficient as the only parameter affecting accuracy.

In reality, the absolute static accuracy of a data converter is dependent on the combination of many parameters such as integral nonlinearity, differential nonlinearity, offset error, gain error, as well as voltage reference changes

Output Shifts and LTD after Standard IR Reflow and Mechanical Stress Effects (MAX6126AASA50+)

There are many factors that contribute to a voltage reference's drift over time. These can include part soldering to a board, package stress, board stress and layout, humidity and part-to-part variation. The extreme heat of an IR reflow can also cause the output voltage to shift since the materials that make up a semiconductor device and its package, have different rates of expansion and contraction. After a device going through any IR reflow profile or

a convection soldering oven, the reference voltage output shifts. The device's expansion/contraction (due to the extreme heat/cooling process) applies stresses to the die which causes the output voltage to shift.

To better quantify the reference output shift due to die induced mechanical stress as a result of IR reflow as shown in [Figure 5](#)), Maxim has done two experiments:

Experiment 1: with 48 devices going through a 3x IR reflow process (without soldering down to a PCB)

Experiment 2: with 32 samples are undergone the same 3x IR reflow profile and soldered down to a PCB.

Figure 5. Standard IR Reflow Profile (Peak Temperature = 257°C, Ramping Rate = 0.802°C/s)

First Experiment Results:

Experimental results of the first experiment (undergone a 3x IR reflow without solder) are shown in [Figure 6](#), [7](#) and [8](#). [Figure 6a](#) shows the output voltage (V_{OUT}) accuracy before the 3x IR reflow, [Figure 6b](#) presents the V_{OUT} accuracy after the 3x IR reflow and [Figure 6c](#) shows the

shift before and after the 3x IR reflow. [Figures 7a](#), [7b](#), and [7c](#) show the Tempco Pre, Post, and the Difference (Post-Pre) 3x IR reflow for the automotive temperature range respectively. Similarly, [Figures 8a](#), [8b](#), and [8c](#) plot the Tempco for the extended temperature range.

Figure 8b. 48 Samples Tempco Post IR Reflow (ppm/°C)

Figure 8c. 48 Samples Tempco Shift (Post-Pre) IR Reflow (ppm/°C)

Second Experiment Results:

In the second experiment, Maxim has evaluated a different batch of 32 samples before and after soldering down with the same 3x IR reflow profile. In this experiment, these samples underwent the effects of both 3x IR reflow and mechanical stress from soldering. The test board was set up in a humidity-controlled oven. Conditions were set to $T_A = +35^{\circ}\text{C}$ and 40% relative humidity. Same as in experiment one, experimental data are presented in [Figures 9, 10 and 11](#).

We can observe that the MAX6126 output accuracy and temperature coefficient exhibit an additionally shift due to mechanical stress of PCB soldering compared to the first experiment where the MAX6126 was only exposed to the extreme heat of the IR reflow temperature cycle.

The above extra shift can be addressed with proper PCB design such that the mechanical stress induced by soldering is minimized.

Long Term Drift (LTD)

Besides showing the output voltage shifts due to reflows and mechanical stresses, Maxim has also collected the long-term drift of these 32 MAX6126 units in another run more than 1000 hours after the devices have gone through 3x reflow and eventually soldered down on a PCB. Similar

to the experiment above, the test board was set up in a humidity and temperature controlled oven. The conditions were set to $T_A = +35^\circ\text{C}$ and 40% relative humidity (red trace as shown in [Figure 12](#)). The LTD result as shown in [Figure 12](#).
