ADSP-2184x/ADSP-SC84x SHARC-FX Processor

Preliminary Hardware Reference

Revision Revision 0.2, January 2026

Part Number
82-100163-01

,

Contents

Arm Cortex-A55 Subsystem

Cortex-A55 Features 1–2
Functional Description 1–2
Cortex-A55 Block Diagram 1–2
Instruction Fetch Unit (IFU) 1–3
Data Processing Unit (DPU) 1–3
Performance Monitor Unit (PMU) 1–3
Advanced SIMD and Floating-point support 1–4
Cryptographic Extension 1–4
Memory Management Unit (MMU) 1–4
L1 Memory System 1–6
L2 Memory System 1–7
Reliability, Availability, and Serviceability (RAS) 1–7
Generic Interrupt Controller (GIC) 1–7
A55 Core in DynamIQ Shared Unit (DSU) 1–8
System Control 1–8
Generic Timer 1–8
A55 Configurations 1–9
DynamIQ Shared Unit Interfaces 1–10
Performance Monitor Unit (PMU) 1–12

Clock Generation Unit (CGU)

CGU Features 2–1
CGU Functional Description 2–1
ADSP-2184x CGU Register List 2–2
ADSP-2184x CGU Interrupt List 2–2
ADSP-2184x CGU Trigger List 2–3

CGU Definitions 2–3
CGU PLL Block Diagram 2–4
CLKOUT Selections 2–5
CGU Operating Modes 2–6
CGU Power-up Sequence 2–7
CGU Event Control 2–7
CGU Programming Model 2–7
Configuring CGU Modes 2–7
Changing the Clock Frequencies 2–8
Changing the PLL Clock Frequency 2–8
Changing the CCLKn or SYSCLK Frequency Without Modifying the PLLCLK Frequency 2–9
Changing the OCLK Frequency 2–10
Selecting SCLK1_0 Source 2–10
Changing SCLK1_0 Frequencies 2–10
Aligning All Clocks 2–11
Valid Clock Multiplier Settings 2–11
PLL Bypass and PLL Disable 2–11
Processor Specific Information 2–12
ADSP-2184x CGU Register Descriptions 2–12
Core Clock Buffer Disable Register 2–14
Core Clock Buffer Status Register 2–15
CLKOUT Select Register 2–16
Control Register 2–18
Clocks Divisor Register 2–20
DIV Register Extension 2–23
PLL Control Register 2–24
Revision ID Register 2–26
System Clock Buffer Disable Register 2–27
System Clock Buffer Status Register 2–29
Status Register 2–31

Time Stamp Counter 32 LSB Register 2–34
Time Stamp Counter 32 MSB Register 2–35
Time Stamp Control Register 2–36
Time Stamp Counter Initial 32 LSB Value Register 2–37
Time Stamp Counter Initial MSB Value Register 2–38

Clock Distribution Unit (CDU)

CDU Features 3–1
CDU Functional Description 3–1
CDU Block Diagram 3–1
CDU Definitions 3–2
ADSP-2184x CDU Register List 3–3
CDU Clock Configuration Options 3–3
CDU Programming Model 3–4
Changing the PLL and Clock Frequency 3–4
Changing the Clock Frequency 3–5
ADSP-2184x CDU Register Descriptions 3–5
CDU Configuration 3–7
CDU Revision ID 3–8
CDU Status 3–9

Fractional PLL (Frac-N PLL)

Frac-N PLL Features 4–1
Frac-N PLL Definitions 4–2
Frac-N PLL Functional Description 4–4
Frac-N PLL Block Diagram 4–4
FPLL Detailed Block Diagram 4–4
DPLL and FPLL Block Diagram 4–6
ADSP-2184x FRACNPLL Register List 4–7
ADSP-2184x FRACNPLL Interrupt List 4–7
ADSP-2184x FRACNPLL Trigger List 4–8

Frac-N PLL Architectural Concepts 4–8
Interrupts and Triggers 4–8
Lock Interrupt-Trigger 4–8
DPLL Unlock Interrupt 4–9
TWAIT Trigger Receiver 4–9
DAI Clock Selection 4–10
Frac-N PLL CLKOUT Clock Selection 4–10
Usage of Frac-N PLL Output Clock 4–11
Frac-N PLL Operating Modes 4–14
FPLL Only Mode 4–14
DPLL Plus FPLL Mode 4–14
FIN (External Reference Clock) Sources 4–15
DPLL Plus FPLL Clock Multiplexer Configuration 4–17
Frac-N PLL Programming Model 4–17
Programming FPLL Only Mode 4–17
FPLL Only Mode TWAIT 4–18
Programming Model for DPLL Plus FPLL Mode 4–18
DPLL Plus FPLL Mode TWAIT 4–19
Programming the FIN Unlock and Re-lock DPLL 4–20
ADSP-2184x FRACNPLL Register Descriptions 4–20
Integration Control Register 4–22
DPLL Control Register 0 4–25
DPLL Control Register 1 4–26
DPLL Control Register 2 4–27
DPLL Control Register 3 4–28
DPLL Control Register 4 4–29
DPLL Control Register 5 4–30
DPLL Control Register 6 4–31
DPLL Control Register 7 4–32
DPLL Control Register 8 4–34

DPLL Control Register 9 4–35
DPLL Status Register 0 4–36
DPLL Status Register 1 4–37
DPLL Status Register 2 4–38
Fractional PLL Control Register 0 4–39
Fractional PLL Control Register 1 4–41
Integration Status Register 4–42

Dynamic Power Management (DPM)

DPM Features 5–1
DPM Functional Description 5–1
ADSP-2184x DPM Register List 5–1
DPM Definitions 5–2
DPM Operating Modes 5–2
Reset State 5–2
Full-on Mode 5–2
DPM Event Control 5–3
ADSP-2184x DPM Register Descriptions 5–3
Control Register 5–4
Peripherals Disable Register 0 5–5
Peripherals Disable Register 1 5–7
Revision ID 5–9
Status Register 5–10

Reset Control Unit (RCU)

RCU Features 6–1
RCU Functional Description 6–2
ADSP-2184x RCU Register List 6–2
ADSP-2184x RCU Trigger List 6–3
RCU Definitions 6–3
RCU Architectural Concepts 6–3

RCU Status and Error Signals 6–4
Core n Reset In 6–4
Core n Reset Out 6–5
ADSP-2184x RCU Register Descriptions 6–5
Boot Code Register 6–6
Core Reset Outputs Control Register 6–9
Core Reset Outputs Status Register 6–10
Control Register 6–11
Message Register 6–13
Message Clear Bits Register 6–16
Message Set Bits Register 6–17
System Interface Disable Register 6–18
System Interface Status Register 6–19
System Reset Request Status Register 6–20
Status Register 6–21
Software Vector Register 0 6–23
Software Vector Register 1 6–24
Software Vector Register 2 6–25
SVECT Lock Register 6–26

System Event Controller (SEC) and Generic Interrupt Controller (GIC)

SEC Features 7–1
SEC Functional Description 7–2
ADSP-2184x SEC Register List 7–2
ADSP-2184x SEC Interrupt List 7–3
ADSP-2184x SEC Trigger List 7–3
ADSP-2184x Interrupt List 7–3
SEC Definitions 7–16
SEC System Event Aggregator (SEA) 7–17
SEC Block Diagram 7–18

SEC Fault Interface (SFI) 7–18
SEC Core Interface (SCI) 7–19
SEC Source Interface (SSI) 7–20
SEC Architectural Concepts 7–20
System Interrupt Groups 7–20
System Interrupt Flow 7–20
System Interrupt Priorities 7–22
SEC Error 7–22
SEC Programming Model 7–22
Programming Concepts 7–23
Programming Examples 7–23
Fault Management Interface Programming Model 7–23
Configuring a System Source to Interrupt a Core 7–24
Core/SEC Handshake Requirements to Ensure Proper Interrupt Handling 7–25
Configuring a System Source as a Fault 7–25
Configuring the WDOG Expiry Event to Issue a System Reset 7–26
SEC Programming Restrictions 7–26
ADSP-2184x SEC Register Descriptions 7–27
SCI Active Register n 7–28
SCI Control Register n 7–29
SCI Group Mask Register n 7–31
SCI Priority Level Register n 7–33
SCI Priority Mask Register n 7–35
Core Pending Register n 7–36
SCI Source ID Register n 7–37
SCI Status Register n 7–38
Global End Register 7–40
Fault COP Period Register 7–41
Fault COP Period Current Register 7–42
Fault Control Register 7–43
Fault Delay Register 7–46

Fault Delay Current Register 7–47
Fault End Register 7–48
Fault Source ID Register 7–49
Fault System Reset Delay Register 7–50
Fault System Reset Delay Current Register 7–51
Fault Status Register 7–52
Global Control Register 7–54
Global Status Register 7–55
Global Raise Register 7–57
Source Control Register n 7–58
Source Status Register n 7–61
GIC Overview 7–62
GIC Functional Description 7–63
GIC Block Diagram 7–64
GIC Performance Monitoring Unit (GIC PMU) 7–64

Trigger Routing Unit (TRU)

TRU Features 8–1
TRU Functional Description 8–1
ADSP-2184x TRU Register List 8–2
ADSP-2184x TRU Interrupt List 8–2
ADSP-2184x Trigger List 8–3
TRU Definitions 8–16
TRU Block Diagram 8–17
TRU Architectural Concepts 8–17
TRU Programming Model 8–17
Programming Concepts 8–18
Programming Examples 8–18
Configuring a Simple Trigger Sequence 8–18
TRU Event Control 8–18

TRU Status and Error Signals 8–18
ADSP-2184x TRU Register Descriptions 8–18
Error Address Register 8–20
Global Control Register 8–21
Generator Trigger Register 8–23
Receiver Select Register 8–24
Status Information Register 8–25

L2 System Memory

L2 System Memory Features 9–1
L2 System Memory Functional Description 9–1
ADSP-2184x L2CTL Register List 9–2
ADSP-2184x L2CTL Interrupt List 9–3
ADSP-2184x L2CTL Trigger List 9–3
L2 System Memory Block Diagram 9–3
L2 System Memory Architectural Concepts 9–4
Access Characteristics 9–4
Read/Write Latency and Throughput 9–4
L2 Memory Controller Block Diagram (Instance) 9–5
Arbitration and Priority 9–5
Data Integrity 9–7
ECC Algorithm 9–7
ECC Hardware Control 9–9
ECC Error Management 9–9
Memory Refresh 9–10
Power Modes 9–10
L2 System Memory Event Control 9–11
ECC Error Interrupt 9–11
ADSP-2184x L2CTL Register Descriptions 9–11
Control Register 9–13
Error Type 0 Address Register 9–16

Error Type 1 Address Register 9–17
Error Type 2 Address Register 9–18
Error Type 3 Address Register 9–19
Error Type 4 Address Register 9–20
ECC Error Address 0 Register 9–21
ECC Error Address 1 Register 9–22
ECC Error Address 2 Register 9–23
ECC Error Address 3 Register 9–24
ECC Error Address 4 Register 9–25
ECC Error Address 5 Register 9–26
ECC Error Address 6 Register 9–27
ECC Error Address 7 Register 9–28
ECC Error Address 8 Register 9–29
Error Type 0 Register 9–30
Error Type 1 Register 9–32
Error Type 2 Register 9–33
Error Type 3 Register 9–34
Error Type 4 Register 9–35
Initialization Register 9–36
Initialization Status Register 9–38
Power Control Register 9–40
Revision ID Register 9–42
Read Priority Count Register 9–43
Read Priority Count Register 9–44
Scrub Start Address Register 9–45
Scrub Count Register 9–46
Scrub Control Register 9–47
Status Register 9–49
L2 Port Error Status Register 9–52
Write Priority Count Register 9–53

Write Priority Count Register 9–54

DDR Pre-fetch Buffer (DDRPFB)

DDRPFB Features 10–2
Smart Pre-fetch 10–2
Data Invalidation 10–2
Direct Access 10–2
Return Zero 10–2
Controller ID Based Direct Access 10–2
Range Based Pre-fetch 10–4
ADSP-2184x PFB Register List 10–5
DDRPFB Programming Model 10–6
Enabling the Pre-fetch Buffer and PFB Idle State 10–6
General Programming Guidelines 10–6
Guidelines For Achieving Maximum Performance 10–6
ADSP-2184x PFB Register Descriptions 10–7
Prefetch buffer fourth control register 10–9
Prefetch buffer third control register 10–10
Control Register 0 10–11
Control Register 1 10–13
Range Select Register 10–15
Requester ID 0 Register 10–16
Requester ID 0 Mask Register 10–17
Requester ID 1 Register 10–18
Requester ID 1 Mask Register 10–19
Requester ID 2 Register 10–20
Requester ID 2 Mask Register 10–21
Requester ID 3 Register 10–22
Requester ID 3 Mask Register 10–23
Requester ID Enable Register 10–24

Prefetch Buffer First Status Register 10–25
Return Zero End Address Register 10–26
Return Zero Start Address Register 10–27

One-Time Programmable Memory Controller (OTPC)

OTPC Features 11–1
OTPC Functional Description 11–1
ADSP-2184x OTPC Register List 11–1
ADSP-2184x OTPC Interrupt List 11–2
Error Correction 11–2
OTP Layout 11–2
OTPC Event Control 11–8
OTPC Interrupt Signals 11–8
OTPC Status and Error Signals 11–8
OTP API Overview 11–8
OTP Programming 11–9
OTP Reading 11–9
OTP Get Field 11–9
ADSP-2184x OTPC Register Descriptions 11–9
OTP Security State Register 11–11
OTP Status Register 11–12

System Memory Protection Unit (SMPU)

SMPU Features 12–1
SMPU Functional Description 12–2
ADSP-2184x SMPU Register List 12–3
SMPU Interrupts 12–4
Memory Writes 12–4
Memory Reads 12–4
ID Comparison 12–5
Memory Region 12–8

SMPU Definitions 12–9
SMPU Block Diagram 12–9
SMPU Architectural Concepts 12–10
SMPU Operating Modes 12–10
SMPU Interrupt Signals 12–10
SMPU Status and Error Signals 12–11
ADSP-2184x SMPU Register Descriptions 12–11
Bus Error Address Register 12–13
Bus Error Details Register 12–14
SMPU Control Register 12–15
Exclusive Access IDn Address 12–17
Exclusive Access Status 12–18
Interrupt Address Register 12–19
Interrupt Details Register 12–20
Region n Address Register 12–21
Region n Control Register 12–22
SMPU Revision ID Register 12–25
Region n ID A Register 12–26
Region n ID B Register 12–27
Region n ID Mask A Register 12–28
Region n ID Mask B Register 12–29
SMPU Control Secure Accesses Register 12–30
Region n Control Secure Accesses Register 12–32
SMPU Status Register 12–33

General-Purpose Ports (PORT)

PORT Features 13–2
PORT Functional Description 13–2
ADSP-2184x PORT Register List 13–3
ADSP-2184x PORT Trigger List 13–3

ADSP-2184x PINT Register List 13–4
ADSP-2184x PINT Interrupt List 13–4
ADSP-2184x PINT Trigger List 13–5
ADSP-2184x PADS Register List 13–5
PORT Architectural Concepts 13–7
Internal Interfaces 13–8
External Interfaces 13–8
GPIO Pin Function 13–8
Input Mode 13–8
Output Mode 13–8
Trigger Toggle Mode 13–8
Open-Drain Mode 13–9
Port Multiplexing Control 13–9
PORT Event Control 13–9
PORT Interrupt Signals 13–9
PORT Programming Model 13–11
Programmable Pull Enable and Pull Select Resistors for PORT and DAI 13–15
ADSP-2184x PORT Register Descriptions 13–16
Port x GPIO Data Register 13–17
Port x GPIO Data Clear Register 13–21
Port x GPIO Data Set Register 13–25
Port x GPIO Output Toggle Register 13–28
Port x GPIO Direction Register 13–31
Port x GPIO Direction Clear Register 13–35
Port x GPIO Direction Set Register 13–39
Port x Function Enable Register 13–42
Port x Function Enable Clear Register 13–45
Port x Function Enable Set Register 13–48
Port x GPIO Input Enable Register 13–51
Port x GPIO Input Enable Clear Register 13–54

Port x GPIO Input Enable Set Register 13–57
Port x GPIO Lock Register 13–60
Port x Multiplexer Control Register 13–62
Port x GPIO Polarity Invert Register 13–64
Port x GPIO Polarity Invert Clear Register 13–68
Port x GPIO Polarity Invert Set Register 13–71
Port x GPIO Trigger Toggle Register 13–74
ADSP-2184x PINT Register Descriptions 13–75
PINT Assign Register 13–77
PINT Edge Clear Register 13–79
PINT Edge Set Register 13–82
PINT Invert Clear Register 13–85
PINT Invert Set Register 13–88
PINT Latch Register 13–91
PINT Mask Clear Register 13–95
PINT Mask Set Register 13–98
PINT Pin State Register 13–101
PINT Request Register 13–105
ADSP-2184x PADS Register Descriptions 13–109
DAI0 Pins 1 to 8 Drive Strength Control Register 13–111
DAI0 Pins 9 to 16 Drive Strength Control Register 13–112
DAI0 Pins 17 to 20 Drive Strength Control Register 13–113
DAI0 Port Input Enable Control Register 13–114
DAI0 Pull Enable Register 13–115
DAI0 Pull Selector Register 13–117
DAI0 Slew Rate Control Register 13–119
DAI0 Strong Pull Up Control Register 13–121
DAI1 Pins 1 to 8 Drive Strength Control Register 13–123
DAI1 Pins 9 to 16 Drive Strength Control Register 13–124
DAI1 Pins 17 to 20 Drive Strength Control Register 13–125

DAI1 Port Input Enable Control Register 13–126
DAI1 Pull Enable Register 13–127
DAI1 Pull Selector Register 13–129
DAI1 Slew Rate Control Register 13–131
DAI1 Strong Pull up Control Register 13–133
Non-GPIO Control Register 13–135
Non-GPIO Drive Strength Register 13–137
EMAC Non-GPIO Drive Strength Register 13–138
OTPC Boot Status Register 13–139
Peripheral PAD Configuration 0 Register 13–140
Peripheral Configuration 1 Register 13–142
PORTA Pins 0 to 7 Drive Strength Control Register 13–143
PORTA Pins 8 to 15 Drive Strength Control Register 13–144
PORTB Pins 0 to 7 Drive Strength Control Register 13–145
PORTB Pins 8 to 15 Drive Strength Control Register 13–146
PORTC Pins 0 to 7 Drive Strength Control Register 13–147
PORTC Pins 8 to 15 Drive Strength Control Register 13–148
PORTD Pins 0 to 7 Drive Strength Control Register 13–149
PORTD Pins 8 to 15 Drive Strength Control Register 13–150
PORTE Pins 0 to 7 Drive Strength Control Register 13–151
PORTE Pins 8 to 15 Drive Strength Control Register 13–152
PORTF Pins 0 to 7 Drive Strength Control Register 13–153
PORTF Pins 8 to 15 Drive Strength Control Register 13–154
PORTG Pins 0 to 7 Drive Strength Control Register 13–155
PORTG Pins 8 to 15 Drive Strength Control Register 13–156
PORTH Pins 0 to 7 Drive Strength Control Register 13–157
PORTH Pins 8 and 9 Drive Strength Control Register 13–158
PORTA and PORTB Pull Enable Register 13–159
PORTA and PORTB Pull Selector Register 13–162
PORTA and PORTB Slew Rate Control Register 13–165

PORTA and PORTB Strong Pull Up Control Register 13–168
PORTC and PORTD Pull Enable Register 13–171
PORTC and PORTD Pull Selector Register 13–174
PORTC and PORTD Slew Rate Control Register 13–177
PORTC and PORTD Strong Pull Up Control Register 13–180
PORTE and PORTF Pull Enable Register 13–183
PORTE and PORTF Pull Selector Register 13–186
PORTE and PORTF Slew Rate Control Register 13–189
PORTE and PORTF Strong Pull Up Control Register 13–192
PORTG and PORTH Pull Enable Register 13–195
PORTG and PORTH Pull Selector Register 13–198
PORTG and PORTH Slew Rate Control Register 13–201
PORTG and PORTH Strong Pull Up Control Register 13–204
Status Register 13–207

Thermal Monitoring Unit (TMU)

TMU Features 14–1
TMU Functional Description 14–1
ADSP-2184x TMU Register List 14–1
ADSP-2184x TMU Interrupt List 14–2
ADSP-2184x TMU Trigger List 14–2
TMU Definitions 14–2
TMU Block Diagram 14–3
TMU Architectural Concepts 14–3
TMU and HADC 14–4
TMU Event Control 14–5
Status and Error Signals 14–5
TMU Programming Guidelines 14–5
Reading Temperature Data 14–6
TMU Calibration 14–6

ADSP-2184x TMU Register Descriptions 14–7
Alert High Limit Register 14–8
Alert Low Limit Register 14–9
Averaging Register 14–10
Temperature Conversion Blank Register 14–11
TMU Control Register 14–12
Fault High Limit Register 14–13
Fault Low Limit Register 14–14
Gain Value Register 14–15
Interrupt Mask Register 14–16
Offset Register 14–17
Temperature Refresh Counter 14–18
Status Register 14–19
Temperature Value Register 14–21

Housekeeping ADC (HADC)

HADC Features 15–1
HADC Functional Description 15–1
ADSP-2184x HADC Register List 15–2
ADSP-2184x HADC Interrupt List 15–2
ADSP-2184x HADC Trigger List 15–3
HADC Definitions 15–3
HADC Block Diagram 15–4
HADC Signal Descriptions 15–5
HADC Architectural Concepts 15–5
Converter Operation 15–6
Auto-Scan 15–6
Channel Sequence Programming 15–7
ADC Transfer Function 15–7
Results 15–7
HADC Operating Modes 15–7

HADC Event Control 15–8
HADC Programming Model 15–8
ADSP-2184x HADC Register Descriptions 15–9
Channel Mask Register 15–10
Control Register 15–11
Channel Data Registers 15–13
Interrupt Mask Register 15–14
Status Register 15–15

Controller Area Network Flexible Data Rate (CANFD)

CANFD Features 16–1
CANFD Functional Description 16–2
ADSP-2184x CANFD Register List 16–3
ADSP-2184x CANFD Interrupt List 16–5
ADSP-2184x CANFD Trigger List 16–5
CANFD Architectural Concepts 16–6
Block Diagram 16–6
Message Buffer (MB) 16–7
Message Buffer Memory Map 16–13
Memory Partition 16–18
Rx FIFO Structure 16–19
CANFD Processes 16–22
Transmit Process 16–22
Arbitration Process 16–23
Lowest Number Mailbox First 16–23
Highest-Priority Mailbox First 16–23
Arbitration Completion 16–24
Arbitration Start and Stop Conditions 16–25
Receive Process 16–26
Matching Process 16–27
Receive Process Pretending Network Mode 16–32

Move Process 16–35
Move-In 16–35
Move-Out 16–37
Data Coherence 16–37
Transmission Abort Mechanism 16–37
Mailbox Inactivation 16–38
Mailbox Lock Mechanism 16–39
Rx FIFO 16–40
Rx FIFO Under DMA Operation 16–41
Clear FIFO Operation 16–41
CAN Protocol Features 16–42
CAN FD Frames 16–42
Transceiver Delay Compensation 16–46
Remote Frames 16–47
Overload Frames 16–48
Time Stamp 16–48
Protocol Timing 16–49
Arbitration and Matching Timing 16–52
Tx Arbitration Start Delay 16–53
CANFD Clock Domains and Restrictions 16–56
CANFD Operating Modes 16–59
Normal Mode 16–59
Freeze Mode 16–60
Loop-Back Mode 16–60
Listen-Only Mode 16–61
CAN FD Active Mode 16–61
Module Disable Mode 16–61
Doze Mode 16–62
Stop Mode 16–63
Pretended Network Mode 16–64
CANFD Event Control 16–65

Interrupts 16–65
Bus Interface 16–66
Detection and Correction of Memory Errors 16–67
Sources of Memory Access 16–69
Error Indication 16–69
Error Reporting 16–70
Response to Errors 16–70
Error Injection 16–71
CANFD Programming Model 16–72
Initialization 16–73
Pretended Network - Doze Mode 16–75
Pretended Network - Stop Mode 16–76
ADSP-2184x CANFD Register Descriptions 16–76
Can Bit Timing Register 16–79
CRC Register 16–82
Control 1 Register 16–83
Pretended Networking Control1 Register 16–89
Control 2 Register 16–92
Pretended Networking Control2 Register 16–97
Error Counter Register 16–98
Error Injection Address Register 16–101
Error Injection Data Pattern Register 16–102
Error Injection Parity Pattern Register 16–103
Error Status Register 16–104
Error and Status 1 Register 16–107
Error and Status 2 Register 16–118

ARC4 State Structure 39–41
Configuring Operations in the PKTE 39–41
Basic Operations and Decoding 39–41
Error Code Description 39–43
Extended Error Codes 39–43
Number Format 39–46
PKTE Programming Examples 39–46
Calculating SHA in Direct Host Mode 39–46
Performing AES Decryption in Direct Host Mode 39–47
ADSP-2184x PKTE Register Descriptions 39–48
Packet Engine ARC4 State Record Address 39–51
Starting Entry of 256-byte ARC4 State Buffer 39–52
Packet Engine Buffer Pointer Register 39–53
Packet Engine Buffer Threshold Register 39–54

Packet Engine Command Descriptor Ring Base Address 39–56
Packet Engine Command Descriptor Count Register 39–57
Packet Engine Command Descriptor Count Increment Register 39–58
Packet Engine Configuration Register 39–59
PE Clock Control Register 39–62
PKTE Continue Register 39–64
Packet Engine Control Register 39–65
Starting Entry of 256-byte Data Input/Output Buffer 39–70
Packet Engine Destination Address 39–71
Packet Engine DMA Configuration Register 39–72
Packet Engine Endian Configuration Register 39–74
Packet Engine Halt Control Register 39–76
Packet Engine Halt Status Register 39–78
Interrupt Mask Disable Register 39–81
Interrupt Mask Enable Register 39–83
Interrupt Masked Status Register 39–85
Packet Engine Input Buffer Count Register 39–87
Packet Engine Input Buffer Count Increment Register 39–88
Interrupt Configuration Register 39–89
Interrupt Clear Register 39–90
Interrupt Enable Register 39–92
Interrupt Unmasked Status Register 39–94
Packet Engine Length Register 39–96
Packet Engine Output Buffer Count Register 39–98
Packet Engine Output Buffer Count Decrement Register 39–99
PE Alternative Key stat register 39–100
Packet Engine Cache Control 0 39–101
Packet Engine Cache Control 1 39–102
Packet Engine Result Descriptor Ring Base Address 39–103
Packet Engine Result Descriptor Count Registers 39–104

Packet Engine Result Descriptor Count Decrement Registers 39–105
Packet Engine Ring Configuration 39–106
Packet Engine Ring Pointer Status 39–107
Packet Engine Ring Status 39–108
Packet Engine Ring Threshold Registers 39–109
Packet Engine SA Address 39–111
ARC4 i and j Pointer Register 39–112
SA Command 0 39–113
SA Command 1 39–118
SA Inner Hash Digest Registers 39–122
SA Key Registers 39–123
SA Initialization Vector Register 39–124
SA Outer Hash Digest Registers 39–125
SA Ready Indicator 39–127
SA Sequence Number Register 39–128
SA Sequence Number Mask Registers 39–129
SA SPI Register 39–130
Packet Engine Source Address 39–131
Packet Engine Status Register 39–132
Packet Engine State Record Address 39–136
State Hash Byte Count Registers 39–137
State Inner Digest Registers 39–138
State Initialization Vector Registers 39–139
Packet Engine User ID 39–140

Public Key Accelerator (PKA)

PKA Features 40–1
PKA Functional Description 40–1
ADSP-2184x PKA Register List 40–2
PKA Definitions 40–2

PKA Architectural Concepts 40–3
PKA Block Diagram 40–3
PKCP Vector Operations 40–4
Modular Exponentiation Operations 40–6
Modular Inversion 40–13
Modular Inversion with an Even Modulus 40–14
Modular Inversion with a Prime Modulus 40–14
ECC Operations 40–14
ADSP-2184x PKA Register Descriptions 40–20
PKA Vector_A Length 40–21
PKA Vector_A Address 40–22
PKA Vector_B Length 40–23
PKA Vector_B Address 40–24
PKA Compare Result 40–25
PKA Vector_C Address 40–26
PKA Most-Significant-Word of Divide Remainder 40–27
PKA Vector_D Address 40–28
PKA Function 40–29
Start of PKA RAM space 40–32
PKA Most-Significant-Word of Result Vector 40–33
PKA Bit Shift Value 40–34

Public Key Interrupt Controller (PKIC)

PKIC Functional Description 41–1
ADSP-2184x PKIC Register List 41–1
ADSP-2184x PKIC Interrupt List 41–2
PKIC Programming Model 41–2
PKIC Programming Concepts 41–2
ADSP-2184x PKIC Register Descriptions 41–3
Acknowledge Register 41–4

Enable Clear Register 41–5
Enable Control Register 41–6
Enable Set Register 41–7
Enabled Status Register 41–8
Polarity Control Register 41–9
Raw Status Register 41–10
Type Control Register 41–11

True Random Number Generator (TRNG)

TRNG Features 42–1
TRNG Functional Description 42–1
ADSP-2184x TRNG Register List 42–1
Random Number Generation 42–2
Locking Detection and Prevention 42–3
Run Testing 42–4
Monobit Testing 42–4
Poker Testing 42–5
Data for Tests 42–6
X9.31 Postprocessing 42–6
TRNG Block Diagram 42–6
TRNG Architectural Concepts 42–7

ADSP-2184x Register List

Preface

Purpose of This Manual

The ***ADSP-2184x/ADSP-SC84x SHARC-FX Processor Hardware Reference*** provides architectural information about the ADSP-2184x/SC84x processors. This hardware reference provides the main architectural information about these processors. The architectural descriptions cover functional blocks, buses, and ports, including all features and processes that they support.

For timing, electrical, and package specifications, refer to the ***ADSP-21843/844/845/846/ADSP-SC843/844/845/836 High Performance SHARC-FX DSP Core With Connectivity/Safety/Security Data Sheet***.

Intended Audience

The primary audience for this manual is a programmer who is familiar with Analog Devices products. The manual assumes the audience has a working knowledge of the appropriate product architecture and instruction set. Programmers who are unfamiliar with Analog Devices processors can use this manual, but should supplement it with other texts, such as programming reference books and data sheets, that describe their target architecture.

What's New in This Manual

This manual is the a preliminary revision (0.2) of the ADSP-2184x/SC84x SHARC-FX Processor Hardware Reference.

NOTE: Analog Devices is in the process of updating documentation to provide terminology and language that is culturally appropriate. This is a process with a wide scope and will be phased in as quickly as possible. Thank you for your patience.

Technical or Customer Support

You can reach customer and technical support for processors and peripherals from Analog Devices using the following resources:

- Post your questions in the processors and DSP support community at ***EngineerZone***®:

  http://ez.analog.com/community/dsp

- Submit your questions to technical support at ***Connect with ADI Specialists***:

  http://www.analog.com/support

- Contact your Analog Devices sales office or authorized distributor. Locate one at:

http://www.analog.com/adi-sales

Product Information

Product information can be obtained from the Analog Devices internet site.

Analog Devices Web Site

The Analog Devices Web site, http://www.analog.com, provides information about a broad range of products—analog integrated circuits, amplifiers, converters, and digital signal processors.

To access technical documentation, search the product number on the website to find the appropriate product page. The documentation on the product page includes manuals as well as data sheets and application notes. If there is an errata list, it is linked below the document listing on the product page.

Also note, MyAnalog.com is a free feature of the Analog Devices Web site that allows customization of a Web page to display only the latest information about products you are interested in. You can choose to receive weekly e-mail notifications containing updates to the Web pages that meet your interests, including documentation errata against all manuals. MyAnalog.com provides access to books, application notes, data sheets, code examples, and more.

Visit MyAnalog.com to sign up. If you are a registered user, just log on. Your user name is your e-mail address.

EngineerZone

EngineerZone is a technical support forum from Analog Devices. It allows you direct access to ADI technical support engineers. You can search FAQs and technical information to get quick answers to your design questions.

Use EngineerZone to connect with other developers who face similar design challenges. You can also use this open forum to share knowledge and collaborate with the ADI support team and your peers. Visit http://ez.analog.com to sign up.

Notation Conventions

Text conventions used in this manual are identified and described as follows. Additional conventions, which apply only to specific chapters, may appear throughout this document.

Example	Description
File > ***Close***	Titles in reference sections indicate the location of an item within the CrossCore Embedded Studio IDE's menu system (for example, the ***Close*** command appears on the ***File*** menu).
`{this | that}`	Alternative required items in syntax descriptions appear within curly brackets and separated by vertical bars; read the example as `this` or `that`. One or the other is required.
`[this | that]`	Optional items in syntax descriptions appear within brackets and separated by vertical bars; read the example as an optional `this` or `that`.

Example	Description
`[this, …]`	Optional item lists in syntax descriptions appear within brackets delimited by commas and terminated with an ellipse; read the example as an optional comma-separated list of `this`.
`.SECTION`	Commands, directives, keywords, and feature names are in text with `Letter Gothic` font.
`filename`	Non-keyword placeholders appear in text with italic style format.
NOTE:	***NOTE:*** For correct operation, ... A note provides supplementary information on a related topic. In the online version of this book, the word ***NOTE:*** appears instead of this symbol.
CAUTION:	***CAUTION:*** Incorrect device operation may result if ... ***CAUTION:*** Device damage may result if ... A caution identifies conditions or inappropriate usage of the product that could lead to undesirable results or product damage. In the online version of this book, the word ***CAUTION:*** appears instead of this symbol.
ATTENTION:	***ATTENTION:*** Injury to device users may result if ... A warning identifies conditions or inappropriate usage of the product that could lead to conditions that are potentially hazardous for devices users. In the online version of this book, the word ***ATTENTION:*** appears instead of this symbol.
Registers/Bits	All registers and bits in this manual are linked (clickable) to their respective descriptions in the "Register Descriptions" of each chapter.
Miscellaneous Conventions	Interrupt and internal signals are shown in all caps with no other formatting. For example the SPDIFn_RX or SCLK signal or the PKTE0_IRQ interrupt. An overbar denotes an active-low signal as in $\overline{\text{SYS_FAULT}}$.

Register Documentation Conventions

Register diagrams use the following conventions:

- The descriptive name of the register appears at the top with the short form of the name.
- If a bit has a short name, the short name appears first in the bit description, followed by the long name.
- The reset value appears in binary in the individual bits and in hexadecimal to the left of the register.
- Bits marked ***X*** have an unknown reset value. Consequently, the reset value of registers that contain such bits is undefined or dependent on pin values at reset.
- Shaded bits are reserved

NOTE: To ensure upward compatibility with future implementations, write back the value that is read for reserved bits in a register, unless otherwise specified.

Register description tables use the following conventions:

- Each bit's or bit field's access type appears beneath the bit number in the table in the form (read-access/write-access). The access types include:
  - R = read, RC = read clear, RS = read set, R0 = read zero, R1 = read one, Rx = read undefined
  - W = write, NW = no write, W1C = write one to clear, W1S = write one to set, W0C = write zero to clear, W0S = write zero to set, WS = write to set, WC = write to clear, W1A = write one action
- Many bit and bit field descriptions include enumerations, identifying bit values and related functionality. Unless otherwise indicated (with a prefix), these enumerations are decimal values.

1 Arm Cortex-A55 Subsystem

The ADSP-SC844/SC846 processor includes a dual Arm® Cortex-A55® core. The Cortex-A55 core is a mid-range, low-power core that implements the Armv8-A architecture with support for the Armv8.1-A extension, the Armv8.2-A extension and the reliability, availability, and serviceability (RAS) extension. Each core has a Level 1 (L1) memory system, and private Level 2 (L2) cache. The cores are implemented inside the DynamIQ Shared Unit (DSU) as a little core.

The dual Cortex-A55 sub-system in the ADSP-SC844/SC846 processor includes a data engine unit that implements the advanced SIMD and floating-point architecture support, cryptographic extension, generic interrupt controller, performance monitoring unit, and a generic timer. The Cortex-A55 also includes support for a L1-cache sub-system and a full-fledged memory management unit. The dual Cortex-A55 implements the Armv8 architecture and runs 64-bit Arm instructions in AArch64 execution state and 32-bit Arm and 32-bit Thumb instructions in AArch32 execution state.

This document describes the Arm Cortex-A55 core and memory architecture used on the ADSP-SC844/SC846 processor but does not provide detailed programming information for the Arm processor. For more information about programming the Arm processor, visit the Arm Information Center:

- ARM Documentation

The applicable documentation for programming the Arm Cortex-A55 processor include:

- Arm Cortex-A55 Core Technical Reference Manual, Revision: r2p0
- Arm Cortex-A Series Programmer's Guide for ARMv8-A, Version: 1.0
- ARM CoreLink NIC-400 Network Interconnect Technical Reference Manual
- Arm Architecture Reference Manual Armv8, for Armv8-A architecture profile
- Arm DynamIQ™ Shared Unit Technical Reference Manual, Revision: r4p1
- ARM NEON™ Programmer’s Guide
- Arm Cortex®-A55 Core Advanced SIMD and Floating-point Support Technical Reference Manual
- Arm Generic Interrupt Controller Architecture Specification GIC architecture version 3.0 and 4.0

Cortex-A55 Features

The Arm Cortex-A55 subsystem has the following features.

Core Features

- Full implementation of the Arm8.2-A A64, A32, and T32 instruction sets
- Both the AArch32 and AArch64 execution states at all exception levels (EL0 to EL3)
- In-order pipeline with direct and indirect branch prediction
- Separate L1 data and instruction side memory systems with a memory management unit (MMU)
- Support for Arm TrustZone® technology
- Data engine unit that implements the advanced SIMD and floating-point architecture support
- Cryptographic extension: This architectural extension is only available if the data engine is present
- Generic interrupt controller (GIC) CPU interface to connect to an external distributor
- Generic timers interface that support a 64-bit count input from an external system counter

Cache Features

- Unified private L2 cache
- L1 and L2 cache protection in the form of error correction code (ECC) or parity on all RAM instances
- Shared L3 cache

Debug Features

- Reliability, availability, and serviceability (RAS) extension
- Arm8.2-A debug logic
- Performance monitoring unit (PMU)
- Embedded trace macrocell (ETM) that supports instruction trace only

Functional Description

The following sections provide information on the function of the subsystem.

Cortex-A55 Block Diagram

The ***A55 Dual Core Subsystem Block Diagram*** shows the primary blocks of the dual Cortex-A55 subsystem. The cluster consists of the cores and the DynamIQ Shared Unit (DSU), which connects the cores to an external memory system.

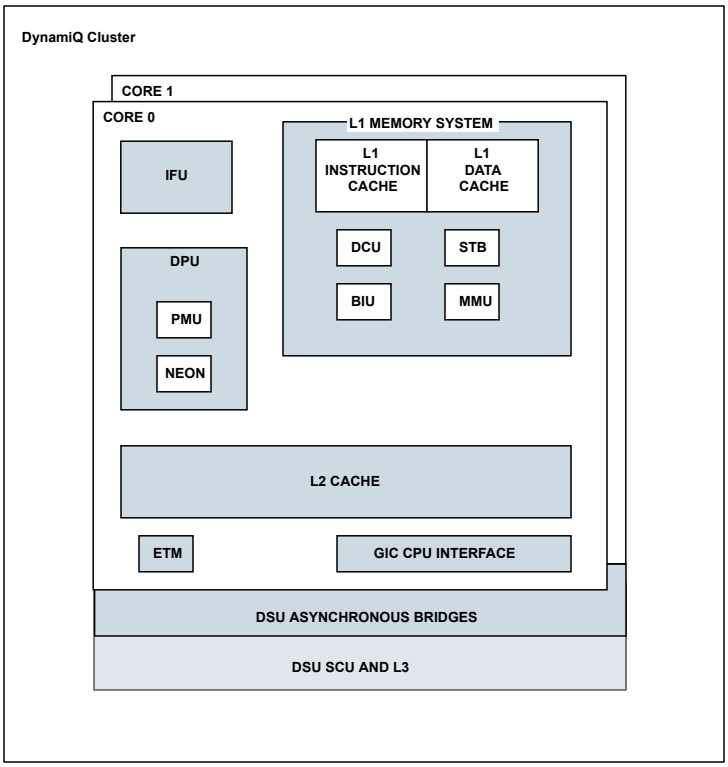

Figure 1-1: A55 Dual Core Subsystem Block Diagram

Instruction Fetch Unit (IFU)

The IFU fetches instructions from the instruction cache or from external memory and predicts the outcome of branches in the instruction stream. It passes the instructions to the Data Processing Unit (DPU) for processing.

Data Processing Unit (DPU)

The DPU decodes and executes instructions. It executes instructions that require data transfer to or from the memory system by interfacing to the Data Cache Unit (DCU). The DPU includes the PMU, the Advanced SIMD and floating-point support, and the Cryptographic Extension.

Performance Monitor Unit (PMU)

The Cortex-A55 core includes performance monitors that can be configured to gather various statistics on the operation of the core and its memory system during runtime. These provide useful information about the behavior of the code that can be used for debug and code profiling. The PMU provides six counters. Each counter can count any of the events available in the core.

See the Performance Monitor Unit (PMU) section below for details of the PMU register set and events.

Advanced SIMD and Floating-point support

Advanced SIMD is a media and signal processing architecture that adds instructions primarily for audio, video, 3D graphics, image, and speech processing. The floating-point architecture provides support for single-precision and double-precision floating-point operations.

The Cortex-A55 core supports the Advanced SIMD and scalar floating-point instructions in the A64 instruction set and the Advanced SIMD and floating-point instructions in the A32 and T32 instruction sets. The A64 instruction set offers additional Advanced SIMD instructions, including double-precision floating-point vector operations.

The Cortex-A55 floating-point implementation:

- Does not generate floating-point exceptions
- Implements all scalar operations in hardware with support for all combinations of:
    - Rounding modes
    - Flush-to-zero
    - Default Not a Number (NaN) modes

The Advanced SIMD architecture, its associated implementation, and supporting software, are also referred to as NEON™ technology.

See the *Arm® Cortex®-A55 Core Advanced SIMD and Floating-point Support Technical Reference Manual* for details of the instruction and register set.

Cryptographic Extension

The Cortex-A55 core Cryptographic Extension supports the Armv8-A cryptographic extension. The cryptographic extension adds new A64, A32, and T32 instructions to advanced SIMD that accelerate:

- Advanced Encryption Standard (AES) encryption and decryption
- The Secure Hash Algorithm (SHA) functions SHA-1, SHA-224, and SHA-256
- Finite field arithmetic used in algorithms such as Galois/Counter mode and elliptic curve cryptography

See the *Arm® Architecture Reference Manual Armv8*, for Armv8-A architecture profile for details of the instruction and register set.

Memory Management Unit (MMU)

The MMU is responsible for translating addresses of code and data from the virtual view of memory to the physical addresses in the real system. The translation is carried out by the MMU hardware and is transparent to the application. In addition, the MMU controls such things as memory access permissions, memory ordering and cache policies for each region of memory.

The MMU enables tasks or applications to be written in a way that requires them to have no knowledge of the physical memory-map of the system, or about other programs that might be running simultaneously. This enables

you to use the same virtual memory address space for each program. It also lets you work with a contiguous virtual memory map, even if the physical memory is fragmented. This virtual address space is separate from the actual physical map of memory in the system. Applications are written, compiled, and linked to run in the virtual memory space. Virtual addresses are those used by you, and the compiler and linker, when placing code in memory. Physical addresses are those used by the actual hardware system.

The three main functions of the MMU are:

Page table entries support:

- Control the translation table walk hardware that accesses translation tables in main memory
- Translate virtual addresses (VAs) to physical addresses (PAs)
- Provide fine-grained memory system control through a set of virtual-to-physical address mappings and memory attributes that are held in translation tables

Each stage of address translation uses a set of address translations and associated memory properties that are held in memory-mapped tables called translation tables. Translation table entries can be cached into a Translation Lookaside Buffer (TLB). The following table describes the components included in the MMU.

Table 1-1: TLBs and TLB Caches in the MMU

Component	Description
Instruction L1 TLB	15 entries, fully associative
Data L1 TLB	16 entries, fully associative
L2 TLB	1024 entries, 4-way set associative
Walk cache RAM	64 entries, 4-way set associative
IPA cache RAM	64 entries, 4-way set associative

The Cortex-A55 core supports a 40-bit physical address range, which allows 1TB of physical memory to be addressed.

The Cortex-A55 core implements a two-level TLB structure.

L1 TLB

The first level of caching for the translation table information is an L1 TLB. It is implemented on both the instruction and data sides. The Cortex-A55 L1 instruction TLB supports 4 KB, 16 KB, 64 KB, and 2 MB pages. The Cortex-A55 L1 data TLB supports 4 KB pages only. Any other page sizes are fractured after the L2 TLB and the appropriate page size are sent to the L1 TLB. All TLB-related maintenance operations result in flushing both the instruction and data L1 TLBs.

L2 TLB

A unified L2 TLB handles the misses from the L1 instruction and data TLBs using a 4-way, set-associative, 1024-entry cache. In implementations with core cache protection, parity bits protect the TLB RAMs by detecting any single-bit error. If an error is detected, the entry is invalidated and fetched again.

IPA Cache RAM

The Intermediate Physical Address (IPA) cache RAM holds mappings between the IPAs and Physical Addresses (PAs). Only non-secure EL1 and EL0 stage 2 translations use the IPA cache. When a stage 2 translation completes, the cache is updated. The IPA cache is checked whenever a stage 2 translation is required. Like the L2 TLB, the IPA cache RAM can hold entries for different sizes.

Walk Cache RAM

The walk cache RAM holds the result of a stage 1 translation up to, but not including the last level.

NOTE: Virtual memory translation tables are typically created by operating systems and are often dynamically managed by the memory management layer. However, even a bare metal system can enable the MMU. For this, a flat mapping technique is used, where all virtual memory addresses are programmed exactly as the physical memory addresses in the system.

L1 Memory System

The dual Cortex-A55 processor L1 memory system consists of separate instruction and data caches that run at Arm core clock speed. The L1 instruction cache size is 32 KB and data cache size is 32 KB.

L1 Instruction-side Memory System

The L1 instruction-side memory system provides an instruction stream to the DPU. Its key features are:

- 64-byte instruction side cache line length
- 4-way set associative L1 instruction cache
- 128-bit read interface to the L2 memory system

The Cortex-A55 core uses extensive branch prediction to improve Instructions Per Clock (IPC) and power efficiency.

L1 Data-side Memory System

The L1 data-side memory system responds to load and store requests from the DPU. It also responds to SCU snoop requests from other cores, or external controllers. Its key features are:

- 64-byte data side cache line length
- 4-way set associative L1 data cache
- A read buffer that services both the Data Cache Unit (DCU), and the Instruction Fetch Unit (IFU)
- A 64-bit read path from the data L1 memory system to the data path
- A 128-bit write path from the data path to the L1 memory system
- Merging store buffer capability which writes to all types of memory (device, normal cacheable and normal non-cacheable)

- A data side prefetch engine that detects patterns of strides with multiple streams are allowed in parallel, capable of detecting both constant and patterns of strides

L2 Memory System

The dual Cortex-A55 L2 memory system is required to interface the Cortex-A55 cores to the L3 memory system. The main features of the L2 memory system are:

- Strictly exclusive with L1 data cache
- Pseudo-inclusive with L1 instruction cache
- Private per-core unified L2 cache
- 40-bit physical address space
- Physically indexed, physically tagged

The L2 memory subsystem consists of:

- A 4-way, set-associative L2 cache with a size of 256 KB. Cache lines have a fixed length of 64 bytes.
- Optional ECC protection for tag, data, and L2 data buffer RAM structures

The shared L3 memory system consists of:

- Unified 16-way set-associative L3 cache of 512 KB
- Partial L3 cache power-down support
- Optional cache protection in the form of error correcting code (ECC) on L3 cache
- L3 memory system operating at Arm core clock

Reliability, Availability, and Serviceability (RAS)

The Cortex-A55 core implements the RAS extension to the Armv8-A architecture which provides mechanisms for the standardized reporting of errors generated by cache protection mechanisms. When configured with core cache protection, the Cortex-A55 core can detect and correct a 1-bit error in any RAM and detect 2-bit errors in some RAMs.

See the *Arm Cortex-A55 Core Technical Reference Manual* for more information on RAS.

Generic Interrupt Controller (GIC)

The GIC-600 is an Arm architecture compliant System-on-Chip (SoC) peripheral. It is a high-performance, area-optimized interrupt controller. The GIC implements the Arm generic interrupt controller architecture. The GIC takes interrupts asserted at the system level and signals them to each connected processor as appropriate. The GIC has the following features.

- Registers for managing interrupt sources, interrupt behavior, and interrupt routing to one or more processors

- Support for the Arm architecture security extensions
- The ability to enable, disable, and generate processor interrupts from hardware (peripheral) interrupt sources
- The ability to generate software interrupts
- Support for interrupt masking and prioritization

Refer to the GIC Overview section for more information on the processor-specific configuration of the GIC.

The GIC-600 contains a performance monitoring unit (PMU) for counting key GIC events from the distributor.

Refer to the GIC Performance Monitoring Unit (GIC PMU) section for more information.

A55 Core in DynamIQ Shared Unit (DSU)

The ADSP-SC844/SC846 processor implements a dual A55 cores (LITTLE core) with L1 and L2 cache inside the DynamIQ cluster, which has a shared-L3 cache and snoop control unit (SCU) with snoop filter. Both A55 cores are configured to run synchronously with the DSU.

See the *Arm DynamIQ™ Shared Unit Technical Reference Manual* for further details on DSU.

System Control

The system registers control and provide status information for the functions that the core implements. The main functions of the system registers are:

- Overall system control and configuration
- MMU configuration and management
- Cache configuration and management
- System performance monitoring
- GIC configuration and management

The system registers are accessible in the AArch64 and AArch32 execution states.

Generic Timer

The generic timer can schedule events and trigger interrupts that are based on an incrementing counter value. It generates timer events as active-low interrupt outputs and event streams. The timer contains:

- An EL1 non-secure physical timer
- An EL2 hypervisor physical timer
- An EL3 secure physical timer
- A virtual timer
- A hypervisor virtual timer

The Cortex-A55 core does not include the system counter. This resides in the SoC. The system counter value is distributed to the core with a 64-bit bus.

See the *Arm DynamIQ Shared Unit Technical Reference Manual* and the *Arm Architecture Reference Manual Armv8*, for Armv8-A architecture profile for more information on the generic timer.

Generic Timer Interrupts

Timers can be configured to generate an interrupt. The active-low, level sensitive timer interrupt signals are routed to the GIC as a private peripheral interrupt (PPI).

A55 Configurations

The ***Core Configuration*** and ***DSU Configuration*** tables describe the Cortex A55 and processor configurations.

Table 1-2: Core Configuration

Core Feature	Comment
L1 instruction cache size	32 KB
L1 data cache size	32 KB
L2 cache	Included
L2 cache size	256 KB
ECC or parity core cache protection	Included
Advanced SIMD and floating-point support (including Dot Product instruction support)	Included
Cryptographic Extension	Included
CoreSight Embedded Logic Analyzer (ELA)	False
CoreSight ELA RAM address size	N/A
Page Based Hardware Attributes (PBHA) support	Not included

Table 1-3: DSU Configuration

Core Feature	Comment
NUM_BIG_CORES	0
NUM_LITTLE_CORES	2
NUM_OTHER_CORES	0
BIG_CORE_TYPE	N/A
LITTLE_CORE_TYPE	Ananke
OTHER_CORE_TYPE	N/A
MODULE	N/A
MODULE_DEBUG_BLOCK	N/A

Table 1-3: DSU Configuration (Continued)

Core Feature	Comment
ACE	True
REQUESTER_DATA_WIDTH	128
ACP	False
PERIPH_PORT	True
SCU_CACHE_PROTECTION	True
L3_CACHE	True

DynamIQ Shared Unit Interfaces

This section describes the DSU interface signals.

Clock and Clock Enable Signals

The ***Clock Signals*** and ***Clock Enable Signals*** tables describe the clock and clock enable signals.

Table 1-4: Clock Signals

Signal Name	Description	Connection
SCLK	Clock for the SCU/L3 and the AMBA interface	CLKO1
PCLK	Clock for the debug peripheral interface and the timers, power management, and other miscellaneous logic	SYSCLK
ATCLK	Clock for the ATB trace interface	SYSCLK
GICCLK	Clock for the GIC interface	SYSCLK

The *Default Configuration* table describe the default configuration of the dual Cortex-A55.

Table 1-5: Default Configuration

Configuration	Status
Default Execution Mode in EL3	AArch64
Endianness configuration, controls the reset value of the SCTLR_EL3/SCTLR EE bit	Little Endian
Enable Thumb exceptions, controls the reset value of the SCTLR.TE bit	Enabled
Value read in ClusterID Affinity Level-2 field, MPIDR bits [23:16]	8'h0
Value read in ClusterID Affinity Level-3 field, MPIDR bits [39:32]	8'h0
Disables the Cryptographic Extensions	False
Globally disables the CPU interface logic and routes the external interrupt signals directly to the cores	False

GIC Signals

This section describes the GIC default configuration.

Table 1-6: GIC Default Configuration (Interrupts)

Signal Name	Description	Connection
$\overline{\text{FIQ}}$	Active-low, level-sensitive fast interrupt request	Disabled
$\overline{\text{IRQ}}$	Active-low, level-sensitive interrupt request	Disabled
$\overline{\text{VFIQ}}$	Active-low, level-sensitive virtual fast interrupt request	Disabled
$\overline{\text{VIRQ}}$	Active-low, level-sensitive virtual interrupt request	Disabled
IRIT I/F	Distributor to GIC CPU Interface messages	From GIC
ICC I/F	GIC CPU Interface to distributor messages	To GIC

WFE Wakeup Event Signals

This section describes the wakeup event signals

Table 1-7: WFE Wakeup Event Signals

Signal Name	Description	TRU Requester/Completer ID
EVENTIREQ	Event input request for core wake-up from WFE state. It must remain asserted until EVENTIACK is asserted and must not be re-asserted until EVENTIACK is low.	TRU Completer 116
EVENTIACK	Event input request acknowledge. It is not asserted until EVENTIREQ is high, and then remains asserted until after EVENTIREQ goes low.	TRU Requester 69
EVENTOREQ	Event output request for core wake-up, triggered by SEV instruction. It is only asserted when EVENTOACK is low, and then remains high until after EVENTOACK goes high.	TRU Requester 70
EVENTOACK	Event output request acknowledge. It must not be asserted until EVENTOREQ is high, and then must remain asserted until after EVENTOREQ goes low.	TRU Completer 117

Error Signals

This section describes the error signals

Table 1-8: Error Signals

Signal Name	Description
$\overline{\text{ERRIRQ[0]}}$ A55_SCU_ERR (A55 SCU Error)	Active-low, level-sensitive error indicator for an ECC error that causes potential data corruption or loss of coherency in L3 and snoop filter RAMs or ACE write transactions with a write response condition. It is output from the SCLK domain.

Table 1-8: Error Signals (Continued)

Signal Name	Description
$\overline{\text{ERRIRQ}}$[2:1] A55_L1L2_ERR (A55 L1,L2 Error)	Active-low, level-sensitive error indicator for an ECC error that causes potential data corruption or loss of coherency for the L1 and L2 caches in the respective core. The bits are output from the PERIPHCLK domain.

NOTE: The bit[1] is for core 0 and bit[2] for core 1

Debug Block APB Interface Signals (Debug)

The interface between the debug block and the DSU consists of a pair of APB interfaces, one in each direction. The following table shows the signals between the cluster APB controller and the debug block APB target.

Table 1-9: Debug Block APB Interface Signals (Debug)

Signal Name	Description
$\overline{\text{COMMIRQ}}$	Active-low, level-sensitive comms channel receive or transmit interrupt request
DBGEN	Invasive debug enable
NIDEN	Non-invasive debug enable
SPIDEN	Secure privilege invasive debug enable
SPNIDEN	Secure privilege non-invasive debug enable

Performance Monitor Unit (PMU)

The Cortex-A55 core includes performance monitors that can be configured to gather various statistics on the operation of the core and its memory system during runtime. These provide useful information about the behavior of the code that can used for debug and code profiling. The PMU provides six counters. Each counter can count any of the events available in the core.

For complete register information refer to the *Arm Cortex-A55 Core Technical Reference Manual* and the *Arm Cortex-A Series Programmer's Guide for ARMv8-A*.

Functional Description

This section describes the functionality of the PMU. The PMU includes the following interfaces and counters:

- Events from all other units from across the design are provided to the PMU
- The PMU registers can be programmed using the system registers or the external peripheral interface
- The PMU has 32-bit counters that increment when they are enabled, based on events, and a 64-bit cycle counter
- The Cortex-A55 core supports access to the performance monitor registers from the internal system register interface and a memory-mapped interface

PMU Events

The PMU event counters can gather various statistics on the operation of the core and its memory system, like cycle count, cache miss/hit, memory read/write, load and prefetch instructions. For the all the PMU events, please refer to *Arm Cortex-A55 Core Technical Reference Manual*.

PMU Interrupts

The Cortex-A55 core asserts the nPMUIRQ signal when the PMU generates an interrupt. The active-low, level sensitive PMU interrupt signal is routed to the GIC as a private peripheral interrupt.

Interrupt ID	Name	Description	Sensitivity
16	PMU_IRQ	PMU interrupt request	Level

2 Clock Generation Unit (CGU)

The Clock Generation Unit (CGU) includes the phase locked loop (PLL) and the PLL control unit (PCU). The PLL generates a requester clock that runs at a frequency that is a multiple of the CLKIN input clock frequency. The PCU divides down the requester clock to generate various system clocks and synchronization signals.

CGU Features

The CGU module supports the following features:

- Provides smooth transitions from the current clock condition to a new condition with PLL logic and executes the changes to clocks due to register programming.
- Provides PLL and clock domain status reporting for event management.
- Supports the capability to bypass the PLL for power savings.
- Software controlled dynamic power management allows control of the core clock frequency (f_{CCLK}).
- Controls clock gating of the core and system clocks.

NOTE: For more information about processor-specific CGU features, see the processor data sheet.

CGU Functional Description

The CGU generates all on-chip clocks and synchronization signals based on the programmed PLL multiplication factor and dividers. The CGU provides the following functionality.

Change the PLL Clock Frequency

The CGU allows programs to change the PLL clock frequency by writing new values to bits in the control register. Any time the PLL relocks, the CGU aligns all core and system clocks.

Change Other Clock Frequencies

The CGU allows programs to change the CCLKn, SYSCLK, SCLKn, DCLK, and OCLK frequencies by writing values to the CGU_DIV register. Any time the clock frequency is changed, the OCLK, CCLKn, SYSCLK, DCLK, and SCLKn clocks exit the frequency change sequence aligned.

Perform Clock Alignment

The CGU can align all clocks by writing to the CGU_DIV register. This function aligns all PLL-based clocks.

For more information on these functions, see the CGU Programming Model section.

ADSP-2184x CGU Register List

The clock generation unit (CGU) includes the phase locked loop (PLL) and the PLL control unit (PCU). The PLL generates a clock, running at a frequency that is a multiple of the CLKIN input clock's frequency. The CGU also generates all on-chip clocks and synchronization signals. The PCU permits application software control of the PLL's operation. A set of registers govern CGU operations. For more information on CGU functionality, see the CGU register descriptions.

Table 2-1: ADSP-2184x CGU Register List

Name	Description
CGU_CCBF_DIS	Core Clock Buffer Disable Register
CGU_CCBF_STAT	Core Clock Buffer Status Register
CGU_CLKOUTSEL	CLKOUT Select Register
CGU_CTL	Control Register
CGU_DIV	Clocks Divisor Register
CGU_DIVEX	DIV Register Extension
CGU_PLLCTL	PLL Control Register

CGU Definitions

DPM

The Dynamic Power Management module (DPM) works with the CGU to provide flexible power dissipation modes for the processor.

PCU

The PLL control unit (PCU) in the CGU controls PLL operations. The MMR registers of the CGU are implemented in the PCU.

PLL

The phase-locked loop (PLL) operates within the CGU.

RCU

The reset control unit (RCU) provides input to the CGU to manage clocks during processor reset.

CDU

The clock distribution unit distributes the clocks from the CGU to different clock domains

CGU

The clock generation unit (CGU) is comprised of the PLL and PCU. The CGU generates the clocks listed in the ***Clock Descriptions*** table.

Table 2-5: Clock Descriptions

Clock	Description
CCLK0_0	CCLK0 derived from CGU0
SYSCLK_0	SYSCLK derived from CGU0
SCLK0_0	SCLK0 derived from CGU0
SCLK1_0	SCLK1 derived from CGU0
DCLK0_0	DCLK derived from CGU0
OCLK_0	OCLK derived from CGU0
CCLK2_0	CCLK (VCO/3) derived from VCO clock of CGU0
DCLK1_0	DCLK1(VCO/3) derived from VCO clock of CGU0
CCLK0_1	CCLK0 derived from CGU1
SYSCLK_1	SYSCLK derived from CGU1
SCLK0_1	SCLK0 derived from CGU1
SCLK1_1	SCLK1 derived from CGU1
DCLK_1	DCLK derived from CGU1
OCLK_1	OCLK derived from CGU1
CCLK2_1	CCLK (VCO/3) derived from VCO clock of CGU1
DCLK1_1	DCLK1(VCO/3) derived from VCO clock of CGU1

CGU PLL Block Diagram

The ***CGU PLL Block Diagram*** provides a top-level block diagram of the phase locked loop (PLL). The main blocks of the PLL are the phase/frequency detector (PFD), the charge pump, the loop filter and the voltage controlled oscillator (VCO). The VCO multiplies the `SYS_CLKIN0` input to a higher frequency.

Additional configuration options are configured using the Clock Distribution Unit.

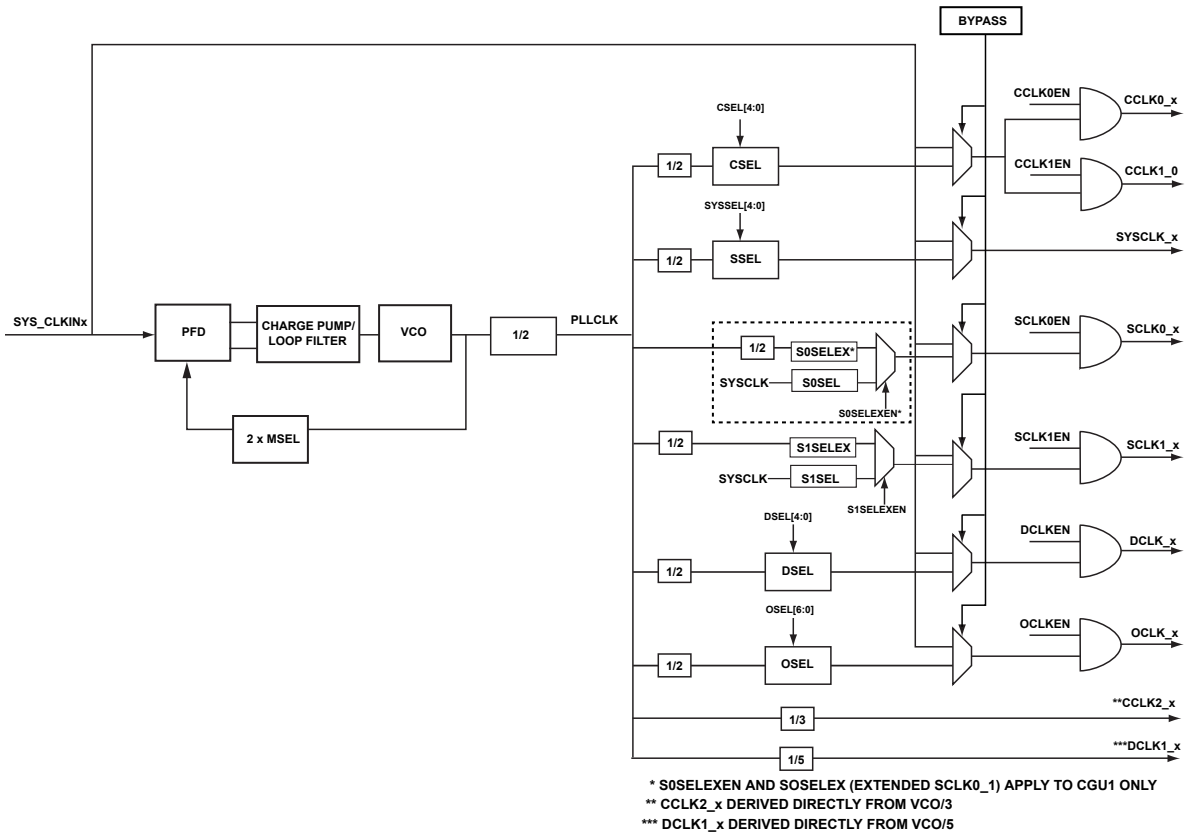

Figure 2-1: CGU PLL Block Diagram

CLKOUT Selections

The ***SYS_CLKOUT Generation*** figure is a conceptual representation of the CLKOUT module. Different clocks that originate from the CGU blocks are available on the SYS_CLKOUT output pin. The selection of the clock output on the SYS_CLKOUT pin is controlled by the `CGU_CLKOUTSEL.CLKOUTSEL` bit field. Most of the clock frequencies are divided with a fixed divider value, for example CGU0_SYSCLK0 has a fixed divider of 8 for the CLKOUT pin.

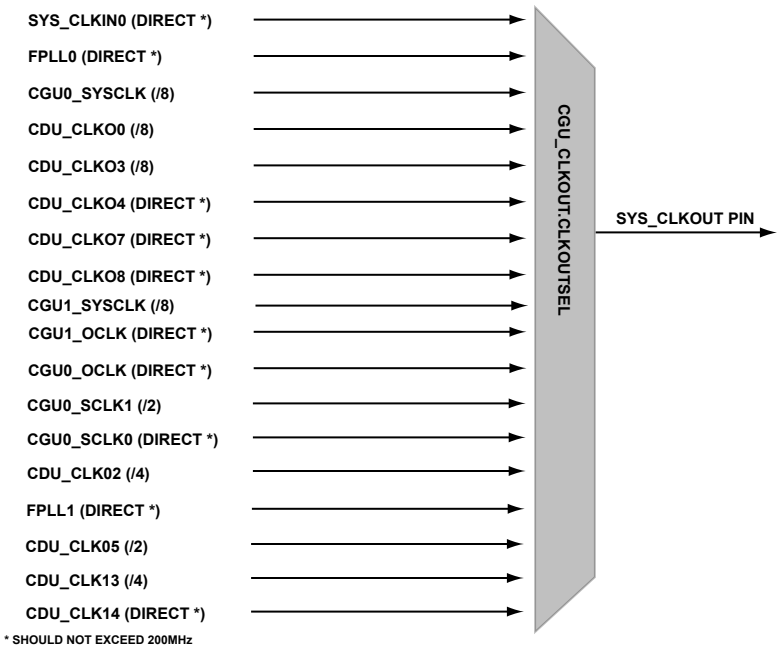

Figure 2-2: SYS_CLKOUT Generation

The BMODE pin affects the CLKOUT pins after a hardware reset is deasserted.

BMODE= 0 — When a hardware reset is deasserted, CGU0_OCLK is selected to come out of the CLKOUT pin. While programming all values of the `CGU_CLKOUTSEL.CLKOUTSEL` bit field is possible, changing it to 0 (SYS_CLKIN) is not possible until and unless a non-zero value is first programmed to the the `CGU_CLKOUTSEL.CLKOUTSEL` bit field.

BMODE = (non zero) — When a hardware reset is deasserted, SYS_CLKIN is selected by default.

CGU Operating Modes

The CGU does not have configurable operating modes, but CGU operations affect the operating modes of other modules. Some CGU operation issues that affect operation of other modules include the following:

- The PLL of the CGU operates in either normal mode (CGU clock divisors applied) or bypass mode (CGU PLL is bypassed and clock divisors ignored).
- The SCB uses the CGU for clock synchronization across clock domains. For more information, see System Crossbars (SCB).
- The DPM uses the CGU for clock management as power state transitions occur. For more information, see the Dynamic Power Management (DPM) chapter.
- The CGU uses clock gating control to obtain flexible low-power modes.

CGU Power-up Sequence

See the product data sheet for exact power-up requirements. The processor is configured to come up in clock bypass mode. The programs is required to configure full speed clocks and safety monitors. SYS_CLKIN0 and all supplies should be stable before the SYS_HWRST signal is deasserted.

CGU Event Control

The CGU generates an event or error for several different reasons. Events and errors are described in the following sections.

Events

After a frequency change, a CGU event indicates that the PLL has locked, and clocks are synchronized. If a core was idled while changing frequencies, the CGU can use an event interrupt to break the core idle. While in active mode, a CGU event indicates that the PLL has locked.

CGU Errors

A CGU error occurs under following conditions:

- A write access to the CGU_DIV/CGU_DIVEX registers trigger an alignment sequence while the PLL is locked and is still aligning the clocks.

  The CGU_STAT.WDIVERR bit state indicates this error. If this error occurs, clear the CGU_STAT.WDIVERR bit and rewrite the desired values to the CGU_DIV/CGU_DIVEX registers.

- A write access to the CGU_CTL.MSEL bit field occurs while the PLL is locking.

  The CGU_STAT.WDFMSERR bit state indicates this error. If this error occurs, wait until the PLL has finished locking, cleared the error, and rewritten the desired value change.

CGU Generated Bus Errors

The CGU generates a bus error when a read or write transaction to an unused address within the CGU address range is attempted. It also generates a bus error when a misaligned access is made to a CGU register. In addition to the bus error, the CGU_STAT.ADDRERR bit is set. If a write to a write-protected CGU register is attempted, the CGU generates a bus error. In addition, the CGU_STAT.LWERR bit is set.

CGU Programming Model

The programming model for the CGU involves the various mode configuration techniques.

Configuring CGU Modes

Use the following procedures to configure the clocks and PLL.

NOTE: The program needs to clear the CGU_STAT.CLKSALGN bit before changing clocks. The following sequence is executed once, inside the application, after coming out of reset.

```
*pREG_CGU0_PLLCTL |= BITM_CGU_PLLCTL_PLLBPCL; // come out of bypass and enter
Full ON
while( (pADI_CGU0 ->STAT & 0xF) != 0x5 ) { } // poll
// now clocks are running with hardware default divisors.
// now program can change frequencies If desired the program can put the PLL
again into bypass.
```

Changing the Clock Frequencies

Applications change clock frequencies in two ways. The first way is modifying the PLL multiplication value by writing to the CGU_CTL register and the second is modifying the clock dividers by writing to the CGU_DIV register. Both actions have different implications even if the frequencies of the final clock are the same. Write accesses to change the CGU_CTL.MSEL bit field while the PLL is locking set the CGU_STAT.WDFMSERR error bit. The CGU_STAT.WDIVERR error bit is set when one of following accesses is attempted while the PLL is locked, but still aligning the clocks:

- A write access to the CGU_DIV/CGU_DIVEX to trigger an alignment sequence.
- A write access to the CGU_DIV/CGU_DIVEX to change the CGU_DIV.CSEL/, CGU_DIV.SYSSEL, CGU_DIV.S0SEL, CGU_DIV.S1SEL, or CGU_DIV.DSEL/CGU_DIVEX.S1SELEX bits.

Read-after-write accesses to these registers return the new value, even if the frequency of the clock change is still in-progress.

Modifying the PLL multiplier requires the PLL to relock. Once the PLL locks, the CGU synchronizes the clocks. Changes to the CGU_CTL.MSEL bit field result in bypassing the PLL. By setting the CGU_CTL.WFI bit, programs force the PLL to wait for the core to return to the idle or reset state before the frequency changes. If necessary, clear the CGU_DIV.UPDT bit to avoid multiple clock alignment sequences. If the CGU_DIV register is not updated, the CGU uses the current values to determine the frequencies of the clock. It is the programs responsibility to guarantee that the new CGU_CTL.MSEL and CGU_DIV/CGU_DIVEX combinations are legal.

Changing the PLL Clock Frequency

To change the phase-locked loop clock (*PLLCLK*) frequency, write new values to the CGU_CTL.MSEL field. Any time the PLL relocks, all core and system clocks are aligned.

1. Read CGU_STAT register and verify that:
    a. The CGU_STAT.PLLEN bit =1 (PLL enabled)
    b. The CGU_STAT.PLOCK bit =1 (PLL is not locking)
    c. The CGU_STAT.CLKSALGN bit =0 (clocks aligned)

2. Write the desired values to the clock divisor select fields of the CGU_DIV/CGU_DIVEX register with the CGU_DIV.UPDT bit =0.
3. Write the desired values to the CGU_CTL.MSEL field.
    a. To change the PLL frequency while the core is idle, write to the CGU_CTL register with the CGU_CTL.WFI bit =1.
    b. To change the PLL frequency while the core is active, write to the CGU_CTL register with the CGU_CTL.WFI bit =0.

This sequence performs these actions:

1. Updates the corresponding CGU registers.
2. Bypasses the PLL.
3. Makes the PLL lock to the new values in the CGU_CTL.MSEL field.
4. Changes the clock frequencies.
5. Exits the PLL bypass with all clocks aligned.

When exiting the PLL bypass state, a CGU event occurs.

The CGU_STAT register exits this sequence with the CGU_STAT.PLLEN bit =1, the CGU_STAT.PLOCK bit =1, the CGU_STAT.PLLBP bit =0, and the CGU_STAT.CLKSALGN bit =0. Poll the CGU_STAT.PLOCK bit, CGU_STAT.PLLBP bit, and CGU_STAT.CLKSALGN bit to discover when the PLL is locked and the clocks are aligned.

Changing the frequency of the PLL is allowed while the PLL is bypassed. In this case the new PLLCLK frequency is not used until the PLL is no longer bypassed.

Changing the CCLKn or SYSCLK Frequency Without Modifying the PLLCLK Frequency

To change the clock frequencies, write new values to CGU_DIV.CSEL or CGU_DIV.SYSSEL bits. The frequency change occurs only when the PLL is not bypassed. Any time the CCLKn or SYSCLK clock frequencies are changed, they exit the frequency change sequence aligned.

1. Read the CGU_STAT register to verify that the CGU_STAT.CLKSALGN bit =0 (clocks aligned).
2. Write the desired CGU_DIV.CSEL, CGU_DIV.SYSSEL, and CGU_DIV.OSEL bitfield values with the CGU_DIV.UPDT bit = 1 and/or, write to the CGU_DIVEX.S1SELEX field. This write updates the CGU_DIV register, changes the SCLKn and SYSCLK frequencies, and aligns the clocks. When the clocks are aligned, a CGU event occurs.

The CGU_STAT register exits this sequence with the CGU_STAT.CLKSALGN bit =0. Poll the CGU_STAT.CLKSALGN bit to discover when the clocks are aligned. Any write attempt to change the CGU_DIV.S0SEL or CGU_DIV.S1SEL bit fields while CGU_STAT.CLKSALGN bit =1 (clocks alignment in progress) triggers an MMR access bus error and the CGU_DIV register is not modified.

Also, any write attempt to change the CGU_DIVEX.S1SELEX field while the CGU_STAT.CLKSALGN bit =1 (clocks alignment in progress) triggers an MMR access bus error and the CGU_DIVEX register is not modified.

Programming the SYSCLK frequency to a higher value than CCLKn also triggers an MMR access bus error and the CGU_DIV/CGU_DIVEX register is not modified.

Writing to the CGU_DIV/CGU_DIVEX register is allowed while the processor is in active (PLL bypassed) mode. In this case the effect of the write is visible only after the transition to full-on (PLL not bypassed) mode.

Accessing the DDR memory while changing the SYSCLK frequency is not supported and can have unpredictable results.

Changing the OCLK Frequency

To change the OCLK clock frequency, write a new CGU_DIV.OSEL bit value. Any time the OCLK clock frequency is changed, the OCLK, CCLKn, SYSCLK, and SCLKn clocks exit the frequency change sequence aligned.

1. Read the CGU_STAT register to verify that the CGU_STAT.CLKSALGN bit =0 (clocks aligned).
2. Write the desired CGU_DIV.OSEL value with the CGU_DIV.UPDT bit =1. This write updates the CGU_DIV register, changes the OCLK frequency, and aligns all clocks except OCLK.

The CGU_STAT register exits this sequence with the CGU_STAT.CLKSALGN bit =0. Poll the CGU_STAT.CLKSALGN bit to discover when the clocks are aligned. Any write attempt to change the CGU_DIV.DSEL field while the CGU_STAT.CLKSALGN bit =1 (clock alignment in progress) triggers an MMR access bus error and the CGU_DIV/CGU_DIVEX is not modified. When the clocks are aligned, a CGU event occurs.

Writing to the CGU_DIV.OSEL bit field is allowed while the processor is in active (PLL bypassed) mode. In this case the effect of the write is visible only after the transition to full-on (PLL not bypassed) mode.

Selecting SCLK1_0 Source

SCLK1_0 sources the SPDIF receiver clock. This can be sourced from PLL clock or SYSCLK0_0. Programming the CGU_DIVEX enables PLL clock as source (bypassing SYSCLK0_0 that continues to source other peripherals). When CGU_DIVEX is enabled, the PLL clock is divided from CGU_DIVEX register value.

Changing SCLK1_0 Frequencies

Complete the following steps to change the SCLK0 or SCLK1 frequency.

1. Read the CGU_STAT register. Verify that CGU_STAT.CLKSALGN = 0 (Clocks aligned).
2. Read the CGU_CTL register. Verify that the CGU_CTL.S1SELEXEN bit is set as needed. (These bits can only be modified when the PLL is bypassed).

3. Read the CGU_STAT register. Verify that the PLL is not bypassed. (If it is bypassed, see PLL Bypass and PLL Disable topic.)
4. Read the CGU_DIV register. Verify that the CGU_DIV.UPDT bit is set.
5. Write the desired CGU_DIVEX.S1SELEX value to the CGU_DIVEX registers .

Aligning All Clocks

To align the clocks, write 1 to the CGU_DIV.ALGN bit. The frequency can also be changed, if necessary. The clocks aligned include:

- CCLKn
- SYSCLK
- SCLKn
- DCLK
- OCLK

1. Read the CGU_STAT register to verify that CGU_STAT.CLKSALGN bit =0 (clocks aligned).
2. Write 1 to the CGU_DIV.ALGN bit. All other fields can change.

   ADDITIONAL INFORMATION: This write does not alter the CGU_DIV/CGU_DIVEX register unless one of the clock-select fields is modified. When the clocks are aligned, a CGU event occurs.

The CGU_STAT register exits this sequence with the CGU_STAT.CLKSALGN bit =0. Poll the CGU_STAT.CLKSALGN bit to discover when the clocks are aligned. Any write to the CGU_DIV/CGU_DIVEX register intended to align clocks or to change a clock select field while the CGU_STAT.CLKSALGN bit =1 (clocks alignment in progress) triggers an MMR access bus error. In this case, the CGU_DIV/CGU_DIVEX register is not modified.

Writing 1 to the CGU_DIV.ALGN bit has no effect while the processor is in active (PLL bypassed) mode.

Valid Clock Multiplier Settings

Processor operations depend on valid settings in the CGU_CTL and CGU_DIV registers. These registers control the clock multiplier and divisor values. Set these registers such that the minimum and maximum clocks specified in the data sheet are not violated. All other clock specifications in the data sheet must also be adhered to for correct operation of the processor.

PLL Bypass and PLL Disable

Writing 1 to the CGU_PLLCTL.PLLBPST bit tells the PLL to apply OSC_CLKIN clock to CCLK, SYSCLK, SCLK0, SCLK1, DCLK (PLL Bypass), and OCLK outputs. Writing 1 to the CGU_PLLCTL.PLLBPCL bit

tells the PLL to exit its PLL Bypass state and make all output clocks align and transition to their programmed frequencies.

The PLL can be disabled by clearing the CGU_PLLCTL.PLLEN bit while in the bypass state. If necessary, clock buffers can be disabled.

CCLK0 clock can be disabled or enabled by writing 1 or 0 to the corresponding bit in the CGU_CCBF_DIS register.

To determine which core clock buffers were disabled since the last read, software reads the CGU_CCBF_STAT register. The SCLK0, SCLK1, DCLK and OCLK clocks can be disabled or enabled by writing 1 or 0 to the corresponding bit in the CGU_SCBF_DIS register. Software cannot disable SYSCLK.

Processor Specific Information

The processor has one system crystal oscillator and two system CGU units to provide the clocks to the system. Both of the CGUs come up in bypass mode out of reset.

CGU0 is the main CGU which provides most of the clocks including CCLK0, SYSCLK (SYSCLK_0), SCLK0 (SCLK0_0), and SCLK1 (SCKL1_0) to the system buses, infrastructure, and most of the peripherals. The DCLK source can be selected between CGU0 and CGU1, through CDU0.

For details, refer to the Clock Distribution Unit (CDU).

NOTE: The frequency ratio of the core clock to SYSCLK is 2:1.

The frequency ratios of SYSCLK to SCLK0 are 6:1, 4:1 or 2:1.

The processor does not support any other frequency ratio.

ADSP-2184x CGU Register Descriptions

Clock Generation Unit (CGU) contains the following registers.

Table 2-6: ADSP-2184x CGU Register List

Name	Description
CGU_CCBF_DIS	Core Clock Buffer Disable Register
CGU_CCBF_STAT	Core Clock Buffer Status Register
CGU_CLKOUTSEL	CLKOUT Select Register
CGU_CTL	Control Register
CGU_DIV	Clocks Divisor Register
CGU_DIVEX	DIV Register Extension
CGU_PLLCTL	PLL Control Register
CGU_REVID	Revision ID Register

Table 2-6: ADSP-2184x CGU Register List (Continued)

Name	Description
CGU_SCBF_DIS	System Clock Buffer Disable Register
CGU_SCBF_STAT	System Clock Buffer Status Register
CGU_STAT	Status Register
CGU_TSCOUNT0	Time Stamp Counter 32 LSB Register
CGU_TSCOUNT1	Time Stamp Counter 32 MSB Register
CGU_TSCTL	Time Stamp Control Register
CGU_TSVALUE0	Time Stamp Counter Initial 32 LSB Value Register
CGU_TSVALUE1	Time Stamp Counter Initial MSB Value Register

Core Clock Buffer Disable Register

The CGU_CCBF_DIS register controls each core's clock buffer to determine if the CCLK is enabled.

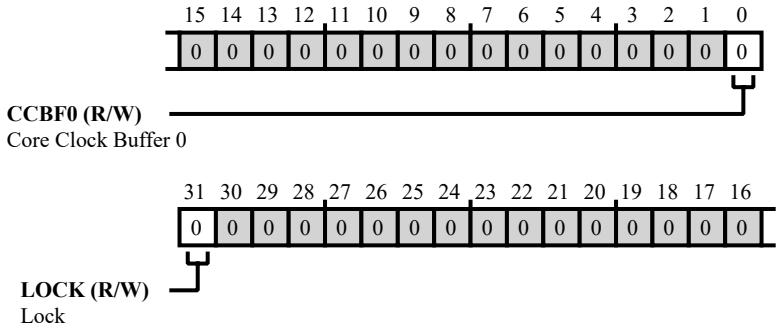

Figure 2-3: CGU_CCBF_DIS Register Diagram

Table 2-7: CGU_CCBF_DIS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If set (=1) the CGU_CCBF_DIS.LOCK bit locks the CGU_CCBF_DIS register.	
		0	Unlock register
		1	Lock register
0 (R/W)	CCBF0	Core Clock Buffer 0. The CGU_CCBF_DIS.CCBF0 bit enables (=0) or disables (=1) CCLK0s buffer.	
		0	Enable buffer
		1	Disable buffer

Core Clock Buffer Status Register

The CGU_CCBF_STAT register shows which core clock buffer(s) are disabled. For example clearing the CGU_CCBF_DIS.CCBF0 bit clears the CGU_CCBF_STAT.CCBF0 bit after a number of cycles. To guarantee that the correct value is read, this register should be read twice and the second result used.

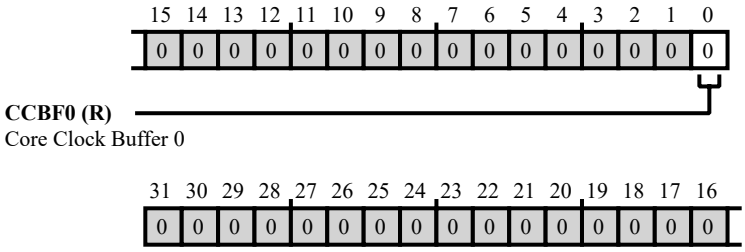

Figure 2-4: CGU_CCBF_STAT Register Diagram

Table 2-8: CGU_CCBF_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/NW)	CCBF0	Core Clock Buffer 0. The CGU_CCBF_STAT.CCBF0 bit reports the status of the CGU_CCBF_DIS.CCBF0 bit where 0 = enabled and 1 = disabled.	
		0	Enabled
		1	Disabled

CLKOUT Select Register

The CGU_CLKOUTSEL selects the signal that the CGU drives through the CLKOUT multiplexer.

Control Register

The CGU_CTL controls the clock generation divisors for SYS_CLKIN and the PLL. Read after write accesses to the CGU_CTL register returns the new value even if the clock's frequency change is still in progress.

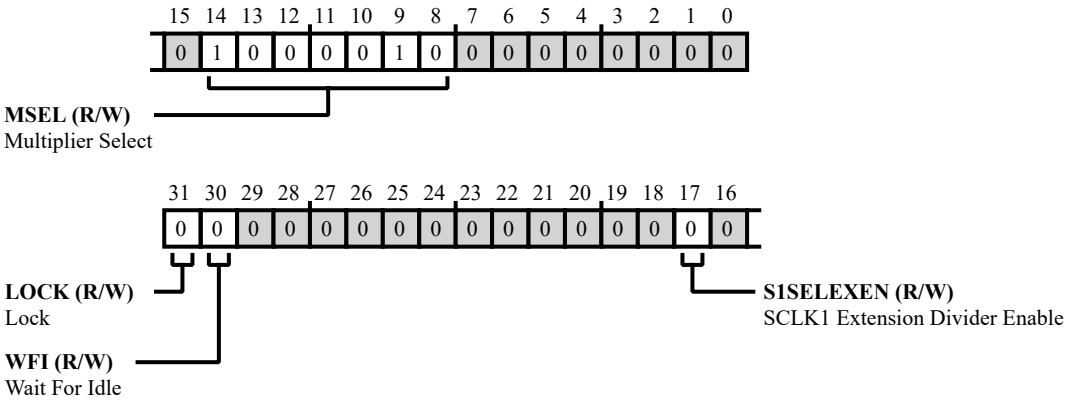

Figure 2-6: CGU_CTL Register Diagram

Table 2-10: CGU_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the CGU_CTL.LOCK bit is set, the CGU_CTL register is read only (locked).	
		0	Unlock
		1	Lock
30 (R/W)	WFI	Wait For Idle. Modifying the PLL multiplier requires the PLL to re-lock and once the PLL locks, clocks have to be synchronized. Changes to the CGU_CTL.MSEL bit values results in bypassing the PLL. The CGU_CTL.WFI bit forces the PLL to wait for all processor cores to be in an idle or reset state before changing frequencies as a result of changes to the CGU_CTL.MSEL bits. Write accesses to the CGU_CTL to change the CGU_CTL.MSEL bit values while the PLL is locking sets the CGU_STAT.WDFMSERR bit.	
		0	Update Immediately
		1	Wait for Idle

Table 2-10: CGU_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W)	S1SELEXEN	SCLK1 Extension Divider Enable. The `CGU_CTL.S1SELEXEN` directs the CGU to select S1SELEX instead of S1SEL. This bit can only be updated when the PLL is bypassed.	
		0	Selects SYSCLK to SCLK1 Divider
		1	Selects PLLCLK to SCLK1 Divider
16 (R/W)	S0SELEXEN	SCLK0 Extension Divider Enable. The `CGU_CTL.S0SELEXEN` directs the CGU to select S0SELEX instead of S0SEL. This bit can only be updated when the PLL is bypassed.	
		0	Selects SYSCLK to SCLK0 Divider
		1	Selects PLLCLK to SCLK0 Divider
14:8 (R/W)	MSEL	Multiplier Select. The `CGU_CTL.MSEL` bit field selects the multiplier in the PLLCLK equation: PLLCLK frequency = (SYS_CLKIN frequency * MSEL) Where the value of MSEL is between 1 and 127. When the processor comes out of reset, the default multiplier value is 40.	
		0	MSEL = 128
		1-127	MSEL = 1 to 127

Clocks Divisor Register

The CGU_DIV register controls clock divisors for core clocks, system clocks, external (off core) memory clocks, and output clock. Read after write accesses to the CGU_DIV register returns the new value even if the clock's frequency change is still in progress.

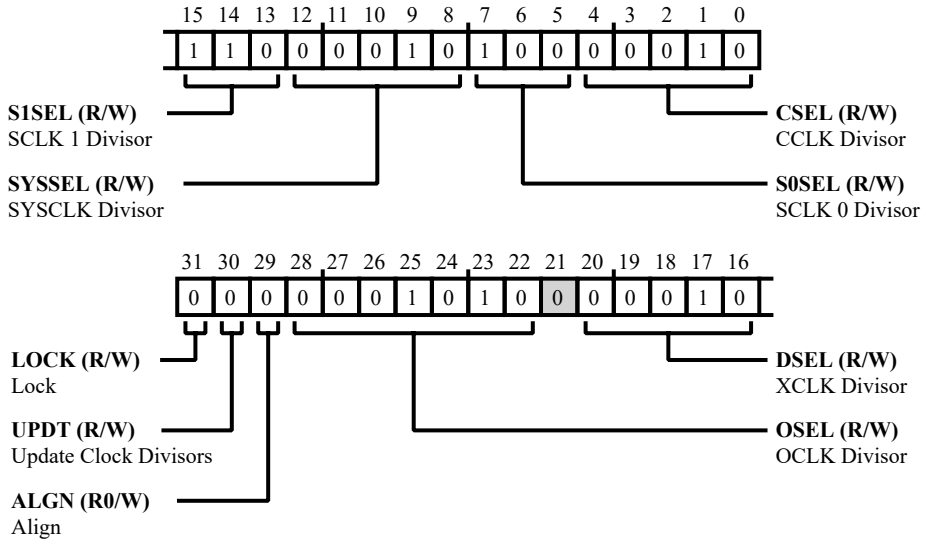

Figure 2-7: CGU_DIV Register Diagram

Table 2-11: CGU_DIV Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the CGU_DIV.LOCK bit is set, the CGU0_DIV and CGU0_DIVEX registers are read only (locked).	
		0	Unlock
		1	Lock
30 (R/W)	UPDT	Update Clock Divisors. The CGU_DIV.UPDT controls whether the CGU drives new CGU_DIV.CSEL, CGU_DIV.SYSSEL, CGU_DIV.S0SEL, CGU_DIV.S1SEL, CGU_DIV.DSEL, and CGU_DIV.OSEL values to PLL after CGU_DIV register update.	
		0	No PLL Update
		1	Drive Updated SEL Values to PLL

Table 2-11: CGU_DIV Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R0/W)	ALGN	Align. The CGU_DIV.ALGN directs the CGU to align the PLL-based clocks. The divisor selections (CGU_DIV.CSEL, CGU_DIV.SYSSEL, CGU_DIV.S0SEL, CGU_DIV.S1SEL, CGU_DIV.DSEL, and/or CGU_DIV.OSEL) do not have to change.	
		0	No Action
		1	Align PLL Clocks
28:22 (R/W)	OSEL	OCLK Divisor. The CGU_DIV.OSEL selects the divisor in the OCLK equation: OCLK frequency = (SYS_CLKIN frequency * MSEL) / (2 * CGU_DIV.OSEL) Where the value of CGU_DIV.OSEL is between 1 and 127.	
		0	OSEL = 128
		1-127	OSEL = 1 to 127
20:16 (R/W)	DSEL	XCLK Divisor. The CGU_DIV.DSEL selects the divisor in the XCLK equation: XCLK frequency = (SYS_CLKIN frequency * MSEL) / (2 * CGU_DIV.DSEL) Where the value of CGU_DIV.DSEL is between 1 and 31.	
		0	DSEL = 32
		1-31	DSEL = 1 to 31
15:13 (R/W)	S1SEL	SCLK 1 Divisor. The CGU_DIV.S1SEL selects the divisor in the SCLK1 equation: SCLK1 frequency = (SYSCLK frequency) / CGU_DIV.S1SEL Where the value of CGU_DIV.S1SEL is between 1 and 7.	
		0	S1SEL = 8
		1-7	S1SEL = 1 to 7
12:8 (R/W)	SYSSEL	SYSCLK Divisor. The CGU_DIV.SYSSEL selects the divisor in the SYSCLK equation: SYSCLK frequency = (SYS_CLKIN frequency * MSEL) / (2 * CGU_DIV.SYSSEL) Where the value of CGU_DIV.SYSSEL is between 1 and 31.	
		0	SYSSEL = 32
		1-31	SYSSEL = 1 to 31

Table 2-11: CGU_DIV Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7:5 (R/W)	S0SEL	SCLK 0 Divisor. The CGU_DIV.S0SEL selects the divisor in the SCLK0 equation: SCLK0 frequency = (SYSCLK frequency) / CGU_DIV.S0SEL Where the value of CGU_DIV.S0SEL is between 1 and 7.	
		0	S0SEL = 8
		1-7	S0SEL = 1 to 7
4:0 (R/W)	CSEL	CCLK Divisor. The CGU_DIV.CSEL bit field selects the divisor in the CCLK equation: CCLK frequency = (SYS_CLKIN frequency * MSEL) / (2 * CGU_DIV.CSEL) Where the value of CGU_DIV.CSEL is between 1 and 31. When the processor comes out of reset, the default CGU_DIV.CSEL bit field value is 2.	
		0	CSEL = 32
		1-31	CSEL= 1 to 31

DIV Register Extension

The CGU_DIVEX register contains bitfields for programming the divisor values of the system clock [SCLK0 and SCLK1] in extended divisor mode.

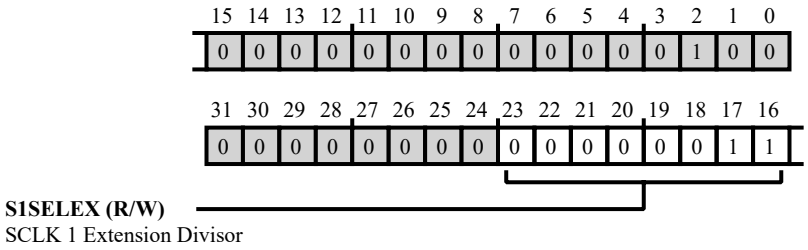

Figure 2-8: CGU_DIVEX Register Diagram

Table 2-12: CGU_DIVEX Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
23:16 (R/W)	S1SELEX	SCLK 1 Extension Divisor. The CGU_DIVEX.S1SELEX selects the divisor in the SCLK1EX equation: SCLK1EX frequency = (SYS_CLKIN frequency * MSEL) / (2 * CGU_DIVEX.S1SELEX) Where the value of CGU_DIVEX.S1SELEX is between 1 and 255.	
		0	S1SELEX = 256
		1-255	S1SELEX = 1 to 255
7:0 (R/W)	S0SELEX	SCLK 0 Extension Divisor. The CGU_DIVEX.S0SELEX selects the divisor in the SCLK0EX equation: SCLK0EX frequency = (SYS_CLKIN frequency * MSEL) / (2 * CGU_DIVEX.S0SELEX) Where the value of CGU_DIVEX.S0SELEX is between 1 and 255.	
		0	S1SELEX = 256
		1-255	S1SELEX = 1 to 255

PLL Control Register

The CGU_PLLCTL register contains bits that enable and disable the PLL as well as control its function.

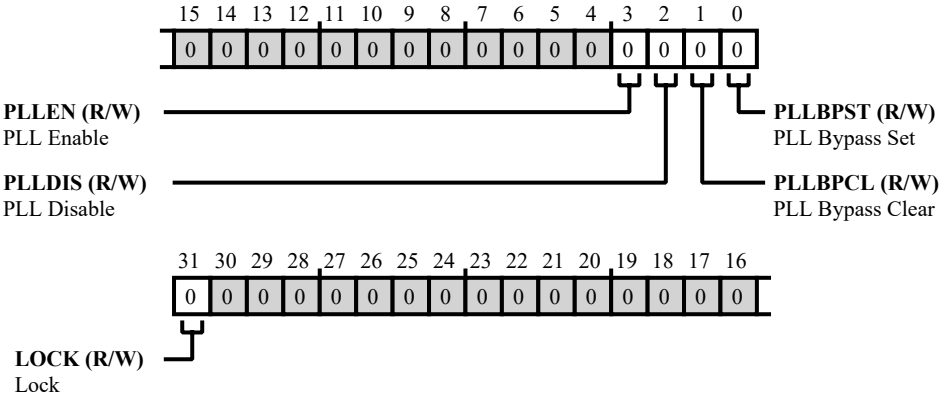

Figure 2-9: CGU_PLLCTL Register Diagram

Table 2-13: CGU_PLLCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. Setting (=1) the CGU_PLLCTL.LOCK bit locks access to the CGU_PLLCTL register.	
		0	Unlock register
		1	Lock register
3 (R/W)	PLLEN	PLL Enable. Setting (=1) the CGU_PLLCTL.PLLEN bit enables the PLL. Check the CGU_STAT.PLLEN bit to verify that the action is complete.	
		0	No action
		1	Enable PLL
2 (R/W)	PLLDIS	PLL Disable. Setting (=1) the CGU_PLLCTL.PLLDIS bit disables the PLL. Check the CGU_STAT.PLLEN bit to verify that the action is complete.	
		0	No action
		1	Disable PLL
1 (R/W)	PLLBPCL	PLL Bypass Clear. Setting (=1) the CGU_PLLCTL.PLLBPCL bit takes the PLL out of bypass mode. Check the CGU_STAT.PLLBP bit to verify that the action is complete.	
		0	No action
		1	Exit bypass mode

Table 2-13: CGU_PLLCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	PLLBPST	PLL Bypass Set. Setting (=1) the `CGU_PLLCTL.PLLBPST` bit bypasses the PLL and all the clocks run on CLKIN. Check the `CGU_STAT.PLLBP` bit to verify that the action is complete.	
		0	Use PLL
		1	Bypass PLL

Revision ID Register

The CGU_REVID register reports the version of the CGU.

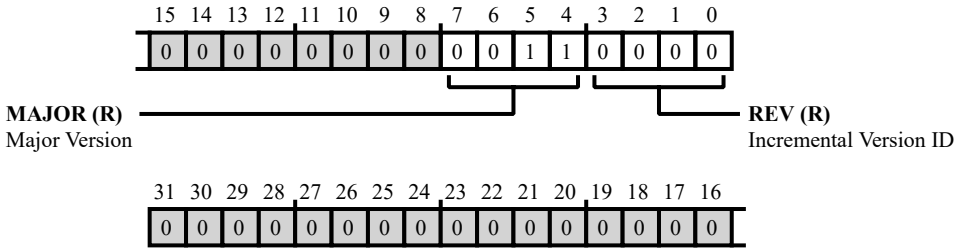

Figure 2-10: CGU_REVID Register Diagram

Table 2-14: CGU_REVID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:4 (R/NW)	MAJOR	Major Version.
3:0 (R/NW)	REV	Incremental Version ID.

System Clock Buffer Disable Register

The CGU_SCBF_DIS register controls each system's clock buffer to determine if the SCLKn buffer is enabled.

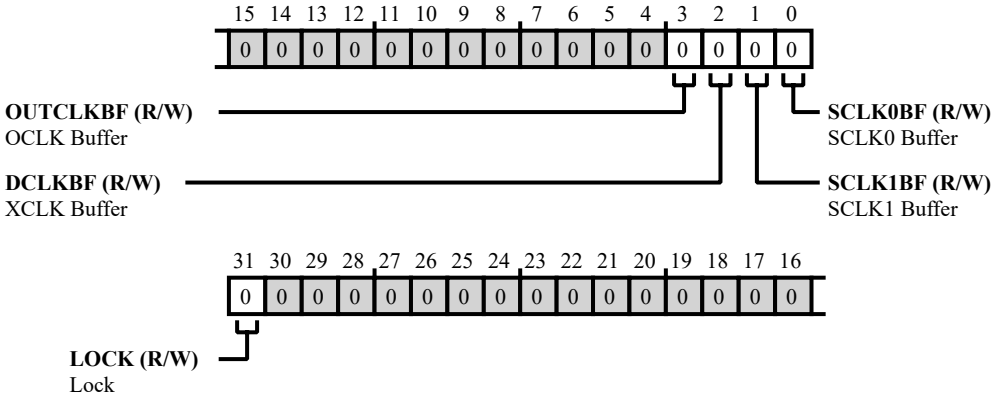

Figure 2-11: CGU_SCBF_DIS Register Diagram

Table 2-15: CGU_SCBF_DIS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. The CGU_SCBF_DIS.LOCK bit allows writes to the CGU_SCBF_DIS register when cleared (=0) or blocks writes if set (=1) and the SPU_CTL.GLCK bit is set.	
		0	Unlock register
		1	Lock register
3 (R/W)	OUTCLKBF	OCLK Buffer. The CGU_SCBF_DIS.OUTCLKBF bit enables (=0, default) or disables (=1) OCLKs buffer.	
		0	Enable buffer
		1	Disable buffer
2 (R/W)	DCLKBF	XCLK Buffer. The CGU_SCBF_DIS.DCLKBF bit enables (=0, default) or disables (=1) XCLKs buffer.	
		0	Enable buffer
		1	Disable buffer

Table 2-15: CGU_SCBF_DIS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	SCLK1BF	SCLK1 Buffer. The `CGU_SCBF_DIS.SCLK1BF` bit enables (=0, default) or disables (=1) SCLK1s buffer.	
		0	Enable buffer
		1	Disable buffer
0 (R/W)	SCLK0BF	SCLK0 Buffer. The `CGU_SCBF_DIS.SCLK0BF` bit enables (=0, default) or disables (=1) SCLK0s buffer.	
		0	Enable buffer
		1	Disable buffer

System Clock Buffer Status Register

The CGU_SCBF_STAT register shows which system clock buffer(s) are disabled. For example clearing the CGU_CCBF_DIS.CCBF0 bit clears the CGU_SCBF_STAT.SCLK0BF bit after a number of cycles. To guarantee that the correct value is read, this register should be read twice and the second result used.

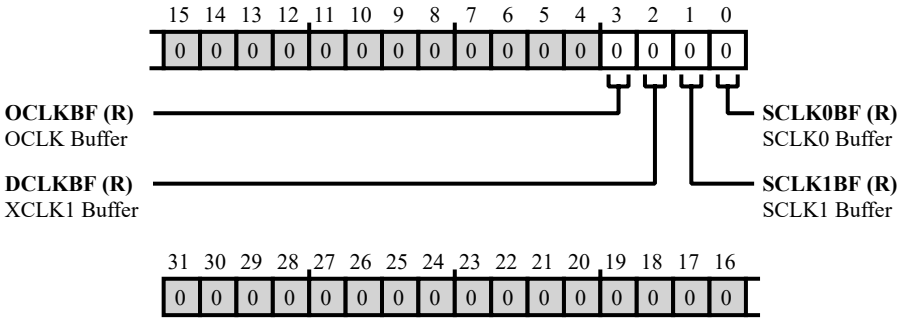

Figure 2-12: CGU_SCBF_STAT Register Diagram

Table 2-16: CGU_SCBF_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/NW)	OCLKBF	OCLK Buffer. The CGU_SCBF_STAT.OCLKBF bit reports the status of the CGU_SCBF_DIS.OUTCLKBF bit where 0 = enabled and 1 = disabled.	
		0	Enabled
		1	Disabled
2 (R/NW)	DCLKBF	XCLK1 Buffer. The CGU_SCBF_STAT.DCLKBF bit reports the status of the CGU_SCBF_DIS.DCLKBF bit where 0 = enabled and 1 = disabled.	
		0	Enabled
		1	Disabled
1 (R/NW)	SCLK1BF	SCLK1 Buffer. The CGU_SCBF_STAT.SCLK1BF bit reports the status of the CGU_SCBF_DIS.SCLK1BF bit where 0 = enabled and 1 = disabled.	
		0	Enabled
		1	Disabled

Table 2-16: CGU_SCBF_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/NW)	SCLK0BF	SCLK0 Buffer. The `CGU_SCBF_STAT.SCLK0BF` bit reports the status of the `CGU_SCBF_DIS.SCLK0BF` bit where 0 = enabled and 1 = disabled.	
		0	Enabled
		1	Disabled

Status Register

The CGU_STAT register reflects the PLL status and errors detected during the PLL configuration. This register may be cleared asynchronously by a reset signal from the RCU module. All bits---except those defined as W1C (write-1-to-clear)---are read only.

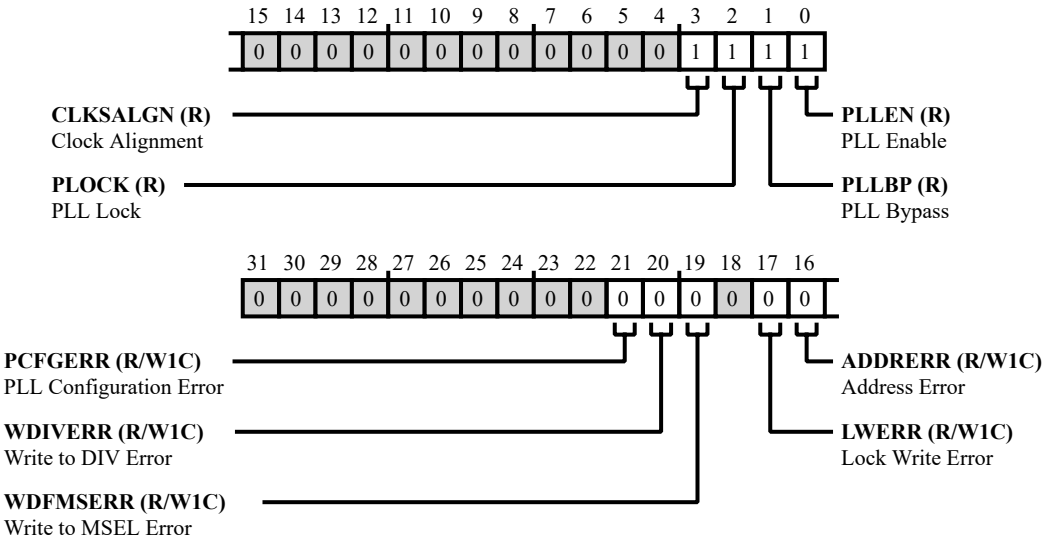

Figure 2-13: CGU_STAT Register Diagram

Table 2-17: CGU_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
21 (R/W1C)	PCFGERR	PLL Configuration Error. If the CGU_PLLCTL.PLLBPST and the CGU_PLLCTL.PLLBPCL bits are set (=1) simultaneously or the CGU_PLLCTL.PLLDIS bit was set (=1) in full-on mode or while trying to enter full-on mode (CGU_PLLCTL.PLLBPCL =1), the CGU_STAT.PCFGERR bit triggers the bus error.	
		0	No Error
		1	Configuration Error
20 (R/W1C)	WDIVERR	Write to DIV Error. The CGU_STAT.WDIVERR bit indicates a write access to the CGU_DIV register (to trigger an alignment sequence or to change the CGU_DIV.CSEL, CGU_DIV.SYSSEL, CGU_DIV.S0SEL, CGU_DIV.S1SEL, or CGU_DIV.DSEL bit values) while the PLL is locked, but still aligning the clocks. Read after write accesses to the CGU_STAT and CGU_DIV registers return the new value even if the clock frequency change is still in progress.	
		0	No Error
		1	Write DIV Error

Table 2-17: CGU_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
19 (R/W1C)	WDFMSERR	Write to MSEL Error. The CGU_STAT.WDFMSERR bit indicates a write access to the CGU_CTL register to change the CGU_CTL.MSEL bit values while the PLL is locking.	
		0	No Error
		1	Write MSEL Error
17 (R/W1C)	LWERR	Lock Write Error. The CGU_STAT.LWERR bit indicates an attempt to write to write-protected (locked) CGU registers. The CGU issues a bus error for this condition.	
		0	No Error
		1	Lock Write Error
16 (R/W1C)	ADDRERR	Address Error. The CGU_STAT.ADDRERR bit indicates an attempt to make a read or write access to unimplemented addresses or accesses are non-aligned. The CGU issues a bus error for this condition.	
		0	No Error
		1	Address Error
3 (R/NW)	CLKSALGN	Clock Alignment. The CGU_STAT.CLKSALGN bit indicates whether a clock alignment sequence is in progress. This bit is set when clocks alignment is required by changes to CGU_DIV.CSEL, CGU_DIV.S0SEL, CGU_DIV.S1SEL, CGU_DIV.DSEL, or CGU_DIV.OSEL. The CGU_STAT.CLKSALGN bit is cleared when clocks are aligned. Note that (after a PLL frequency change in active state) the CGU_STAT.CLKSALGN bit may indicate that clocks are not aligned even though the clocks are aligned (all clocks are aligned and running at CLKIN frequency).	
		0	Clocks are Aligned
		1	Clocks not Aligned (alignment in progress)
2 (R/NW)	PLOCK	PLL Lock. The CGU_STAT.PLOCK bit indicates whether the PLL is locked. This bit is set when the PLL locks (PLL lock counter end-of-count). The CGU_STAT.PLOCK bit is cleared when requested PLL frequency change (for PLL reset, PLL disable-to-enable transition, or a change to the CGU_CTL.MSEL values) is in progress.	
		0	PLL not Locked (PLL frequency change in progress)
		1	PLL Locked

Table 2-17: CGU_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/NW)	PLLBP	PLL Bypass. The `CGU_STAT.PLLBP` bit indicates whether the PLL is bypassed. The default value for the `CGU_STAT.PLLBP` bit is determined by the bypass strap pin.	
		0	PLL not Bypassed
		1	PLL Bypassed
0 (R/NW)	PLLEN	PLL Enable. The `CGU_STAT.PLLEN` bit indicates whether the PLL is enabled.	
		0	Disabled
		1	Enabled

Time Stamp Counter 32 LSB Register

The CGU_TSCOUNT0 register address is used to read the CoreSight time stamp counter LSB 32-bit (bits [31:0]) value.

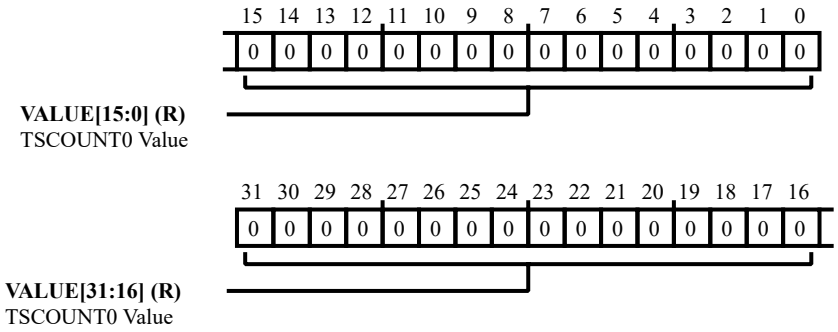

Figure 2-14: CGU_TSCOUNT0 Register Diagram

Table 2-18: CGU_TSCOUNT0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	TSCOUNT0 Value. The CGU_TSCOUNT0.VALUE bit field holds the time stamp counter 32 LSBs.

Time Stamp Counter 32 MSB Register

The CGU_TSCOUNT1 register address is used to read the CoreSight time stamp counter MSB 32-bit (bits [63:32]) value.

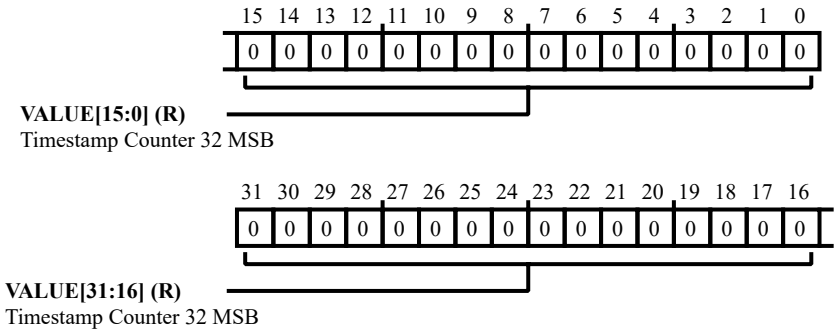

Figure 2-15: CGU_TSCOUNT1 Register Diagram

Table 2-19: CGU_TSCOUNT1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Timestamp Counter 32 MSB. The CGU_TSCOUNT1.VALUE bit field holds the time stamp counter 32 MSBs.

Time Stamp Control Register

The CGU_TSCTL register controls the operation of the CoreSight time stamp counter.

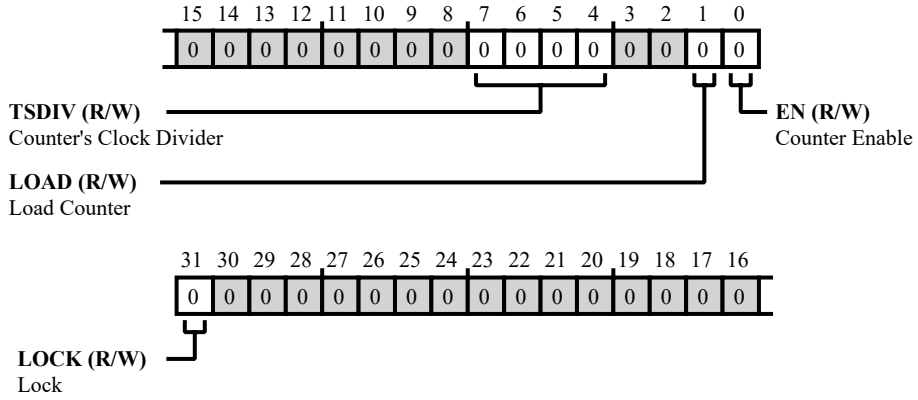

Figure 2-16: CGU_TSCTL Register Diagram

Table 2-20: CGU_TSCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. Setting the CGU_TSCTL.LOCK bit locks this register.	
		0	Unlock
		1	Lock
7:4 (R/W)	TSDIV	Counter's Clock Divider. The CGU_TSCTL.TSDIV bit field divides SYSCLK by 2^{TSDIV}.	
		0-15	Divides SYSCLK by 2^{TSDIV}
1 (R/W)	LOAD	Load Counter. Writing one to the CGU_TSCTL.LOAD bit causes CoreSight time stamp counter to be loaded from the CGU_TSVALUE0 and CGU_TSVALUE1 registers.	
		0	Always read as "0"
0 (R/W)	EN	Counter Enable. The CGU_TSCTL.EN bit enables or disables the CoreSight time stamp counter.	
		0	Counter Disabled
		1	Counter Enabled

Time Stamp Counter Initial 32 LSB Value Register

The CGU_TSVALUE0 register holds the least significant bits (bits [31:0]) value that is initially loaded to the CoreSight time stamp counter.

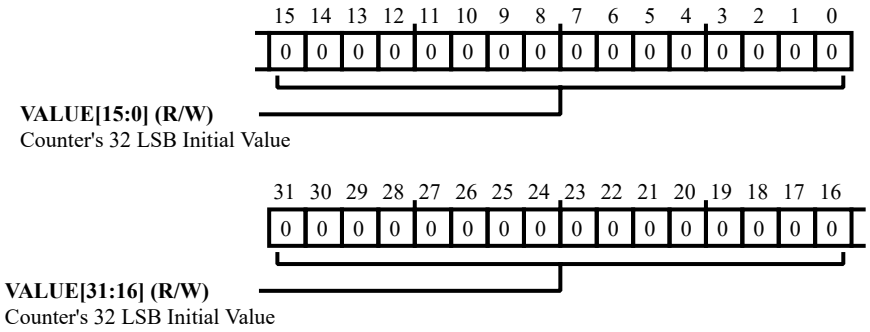

Figure 2-17: CGU_TSVALUE0 Register Diagram

Table 2-21: CGU_TSVALUE0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Counter's 32 LSB Initial Value. The CGU_TSVALUE0.VALUE bit field holds the LSBs value that is initially loaded to the CoreSight time stamp counter.

Time Stamp Counter Initial MSB Value Register

The CGU_TSVALUE1 register holds the most significant bits (bits [63:32]) value that is initially loaded to the CoreSight time stamp counter.

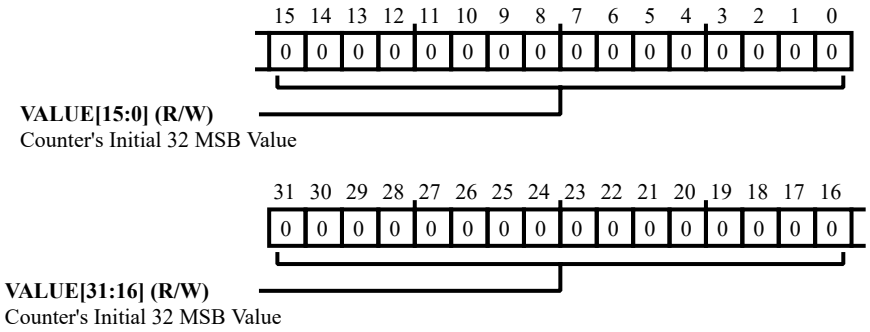

Figure 2-18: CGU_TSVALUE1 Register Diagram

Table 2-22: CGU_TSVALUE1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Counter's Initial 32 MSB Value. The CGU_TSVALUE1.VALUE bit field holds the MSBs value that is initially loaded to the CoreSight time stamp counter.

3 Clock Distribution Unit (CDU)

The Clock Distribution Unit (CDU) consists of an array of multiplexors that select clocks originated from up to four different clock sources. These sources are different clocks that are generated from the Clock Generation Units (CGUs). The multiplexors are configured by software. All clocks multiplexors have up to four different sources. Unused input clocks are grounded internally and never selected. The output clock signal for each multiplexor is assigned to one or more destinations within the processor.

CDU Features

The CDU modules supports the following features:

- Generation of up to 14 output clocks
- Output clock buffers that can be disabled by software
- Multiplexors that are configured by writing to configuration registers (`CDU_CFG[n]`)
- Clocks originated in CGU0 that are selected by default
- A CDU status register (`CDU_STAT`) that indicates a configuration change is in-progress

CDU Functional Description

The CDU functions as a set of software-configurable multiplexors that select clocks from different sources.

CDU Block Diagram

The ***CGU/CDU Block Diagram*** figure shows the functional blocks within the CDU. As shown in the figure, the CDU takes different clocks generated by the CGU blocks and provides flexibility to route any clock from possible options to the output CDU clocks. The output clocks from the CDU are connected to specific targets such as the DDR module. All of the targets are clocked through the CDU output clocks rather than being directly clocked by CGU clocks.

This configuration provides the flexibility to meet the specific clock requirements of the different modules in the system (such as the core, DDR, or SPI module) without compromising the clocking of other modules. Such a flexibility is not possible with a single CGU in the system. With two CGUs:

- Each CGU has its own set of clock multipliers and dividers, providing a greater number of orthogonal clocks than possible with a single CGU.

Figure 3-1: CGU/CDU Block Diagram

The DDR is clocked from the DCLK (DCLK_0 and DCLK_1) from CGU0 or CGU1. This configuration provides the flexibility to program the DDR with frequencies orthogonal to the core clock frequencies. (Orthogonal frequencies have independent signal states. For example, frequency and amplitude modulation signals on the same carrier can be detected without interfering with each other).

CDU Definitions

The ***Clock Descriptions*** table provides a brief description of the clocks supported by the processor.

Table 3-1: Clock Descriptions

Clock	Description
CCLK0_0	CCLK0 derived from CGU0
CCLK1_0	CCLK1 derived from CGU0
SYSCLK_0	SYSCLK derived from CGU0
SCLK0_0	SCLK0 derived from CGU0
SCLK1_0	SCLK1 derived from CGU0
DCLK_0	DCLK derived from CGU0
OCLK_0	OCLK derived from CGU0
CCLK0_1	CCLK0 derived from CGU1
SYSCLK_1	SYSCLK derived from CGU1
SCLK0_1	SCLK0 derived from CGU1
SCLK1_1	SCLK1 derived from CGU1
DCLK_1	DCLK derived from CGU1
OCLK_1	OCLK derived from CGU1
CDU_CLKOn	Clocks that come out of the CDU module and go to different blocks

ADSP-2184x CDU Register List

Clock Distribution Unit

Table 3-2: ADSP-2184x CDU Register List

Name	Description
CDU_CFG[n]	CDU Configuration
CDU_REVID	CDU Revision ID
CDU_STAT	CDU Status

CDU Clock Configuration Options

The ***CDU Targets*** table provides information about clock source and destination options.

Table 3-3: CDU Targets

CDU0 Input				CDU0 Output	Target
IN0_CLKOn	IN1_CLKOn	IN2_CLKOn	IN3_CLKOn		
CCLK0_0	CCLK0_1	CCLK2_0	N/A	CLKO0	SHARC-FX and its accelerators
CCLK0_0	CCLK0_1	CCLK2_0	N/A	CLKO1	A55 Subsystem

Table 3-3: CDU Targets (Continued)

CDU0 Input				CDU0 Output	Target
IN0_CLKOn	IN1_CLKOn	IN2_CLKOn	IN3_CLKOn		
CCLK0_0	CCLK0_1	CCLK2_0	N/A	CLKO2	Reserved
DCLK_0	DCLK_1	DCLK1_0	N/A	CLKO3	LPDDR4
OCLK_0	OCLK_1	N/A	N/A	CLKO4	CAN
SCLK1_0	N/A	N/A	N/A	CLKO5	SPDIF
SCLK0_0	OCLK_0	N/A	N/A	CLKO6	SPI

SCLK0_0	SYSCLK_1	N/A	N/A	CLKO14	MSHC

*1 See the Enhanced PWM Clocking section in the PWM chapter.

CDU Programming Model

The CDU_CFG[n] registers are a system configuration resource. These registers are accessed by a system configuration routine that also handles the configuration of other system modules. Writes to a CDU_CFG[n] register must occur when there is not a CDU_CLKOn configuration change in progress. If a CGUn inputs are selected, that CGUn configuration must be completed first.

Changing the PLL and Clock Frequency

1. Read the CGU_STAT register. Verify that:
   - CGU_STAT.PLLEN =1 (enabled)
   - CGU_STAT.PLOCK =1 (PLL is not locking)
   - CGU_STAT.CLKSALGN =0 (clocks aligned)
2. Write the desired values into the CGU_DIV.CSEL, CGU_DIV.S0SEL, CGU_DIV.SYSSEL, CGU_DIV.S1SEL, CGU_DIV.DSEL and CGU_DIV.OSEL bits with the CGU_DIV.UPDT bit cleared (= 0).
3. Read the CGU_STAT register. Verify that:
   - CGU_STAT.PLLEN = 1 (enabled)

- CGU_STAT.PLOCK = 1 (not locking)
- CGU_STAT.CLKSALGN = 0 (clocks aligned)

4. Read the CDU_STAT register. Verify that the CDU_STAT.CLKO0 = 0 (no CLKOn configuration change in progress).
5. Write to the CDU_CFG[n].SEL bit to select the clock source (the CDU_CFG[n].EN bit should =1.)
6. Read the CDU_CFG[n] register. Verify that the CDU_CFG[n].SEL has the programmed value.

CLKOn is reconfigured.

Changing the Clock Frequency

Use the following procedure to change a clock frequency.

1. Read the CGU_STAT register to verify that the CGU_STAT.CLKSALGN bit =0 (clocks aligned).
2. Write the desired values into the CGU_DIV.CSEL, CGU_DIV.S0SEL, CGU_DIV.SYSSEL, CGU_DIV.S1SEL, CGU_DIV.DSEL and CGU_DIV.OSEL bits with the CGU_DIV.UPDT bit = 1.
3. Read the CGU_DIV registers to verify that the CGU_DIV.CSEL, CGU_DIV.S0SEL, CGU_DIV.SYSSEL, CGU_DIV.S1SEL, CGU_DIV.DSEL and CGU_DIV.OSEL bit values are correct.
4. Read the CGU_STAT register to verify that the CGU_STAT.CLKSALGN = 0 (clocks aligned).
5. If clocks switch from CGUm clocks to CGUn input clocks, read the CGU_SCBF_STAT and CGU_CCBF_STAT registers. The CGU_CCBF_STAT[1:0] bit field corresponds to the CCLK1 and CCLK0 clock buffers, respectively. The CGU_SCBF_STAT[3:0] bit field corresponds to the OUTCLK, DCLK, SCLK1, and SCLK0 clock buffers, respectively.
6. Read the CDU_STAT register.
7. Write to the CDU_CFG[n].SEL bit to select the clock source (CDU_CFG[n].EN = 1).
8. Read the CDU_CFG[n] register. Verify that the CDU_CFG[n].SEL bit field has the programmed value.
9. Verify that the CDU_STAT.CLKO0 bit field = 0.

ADSP-2184x CDU Register Descriptions

Clock Distribution Unit (CDU) contains the following registers.

Table 3-4: ADSP-2184x CDU Register List

Name	Description
CDU_CFG[n]	CDU Configuration
CDU_REVID	CDU Revision ID

Table 3-4: ADSP-2184x CDU Register List (Continued)

Name	Description
CDU_STAT	CDU Status

CDU Configuration

The CDU_CFG[n] registers control the configuration of the clock multiplexors. CDU0_CFG[n] corresponds to output clock CDU_CLKO[n].

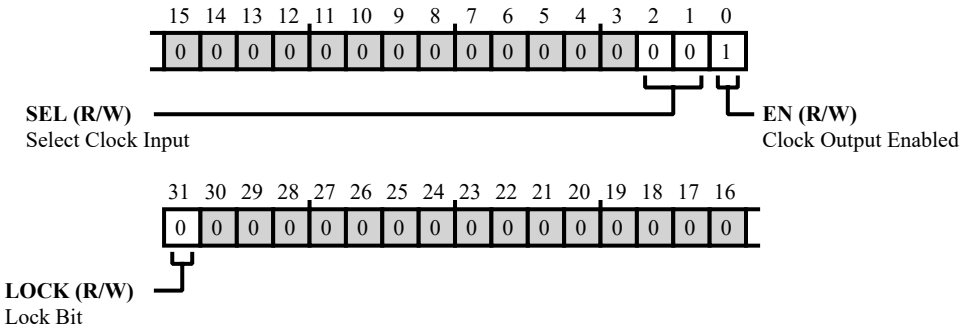

Figure 3-2: CDU_CFG[n] Register Diagram

Table 3-5: CDU_CFG[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock Bit.	
2:1 (R/W)	SEL	Select Clock Input.	
		0	IN0_CLKOn Selected
		1	IN1_CLKOn Selected
		2	IN2_CLKOn Selected
		3	IN3_CLKOn Selected
0 (R/W)	EN	Clock Output Enabled. The CDU_CFG[n].EN bit enables clock output.	

CDU Revision ID

The CDU_REVID register reports the version of the CDU.

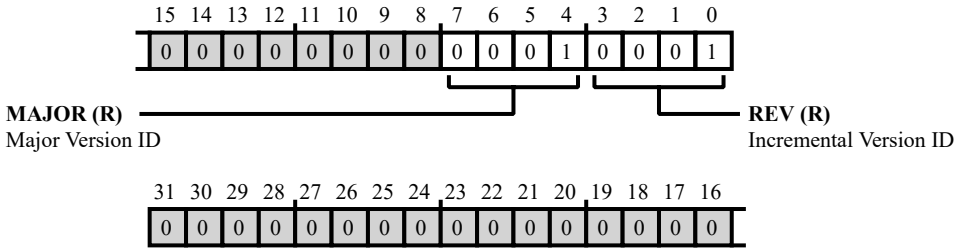

Figure 3-3: CDU_REVID Register Diagram

Table 3-6: CDU_REVID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:4 (R/NW)	MAJOR	Major Version ID.
3:0 (R/NW)	REV	Incremental Version ID.

CDU Status

The CDU_STAT register reflects the status a change in the configuration of the clock muxes.

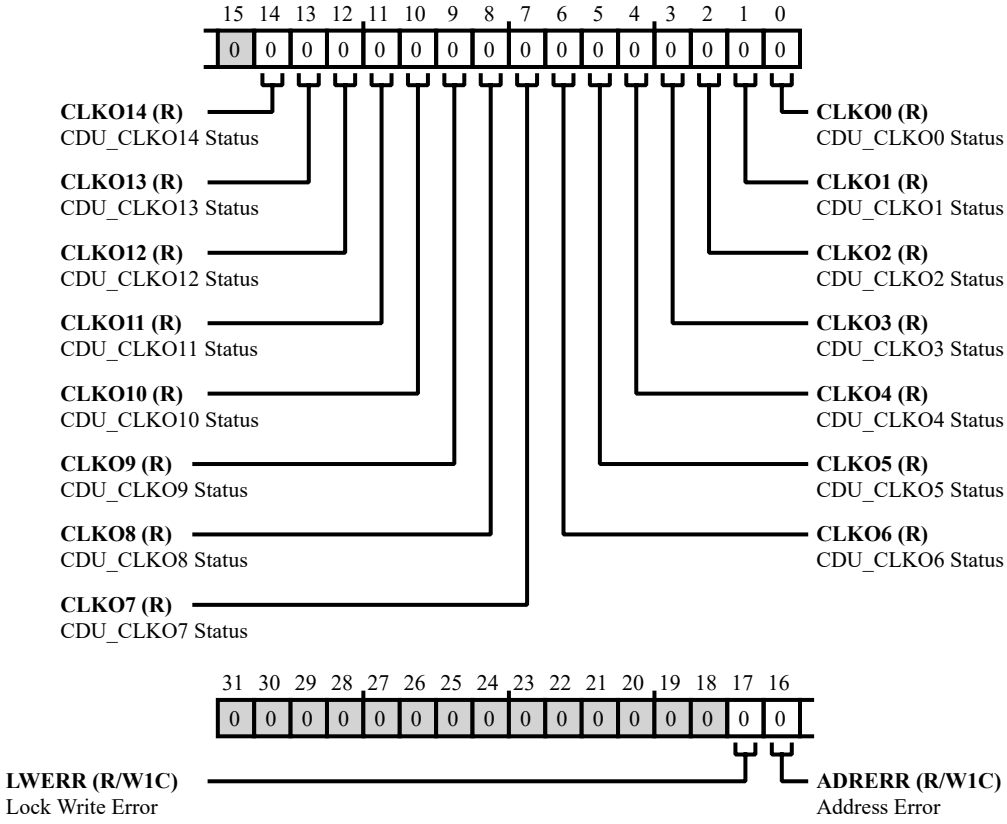

Figure 3-4: CDU_STAT Register Diagram

Table 3-7: CDU_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W1C)	LWERR	Lock Write Error. The CDU_STAT.LWERR bit indicates a lock error where write transactions try to access write protected registers.	
		0	No Lock Write Error
		1	Lock Write Error
16 (R/W1C)	ADRERR	Address Error. The CDU_STAT.ADRERR bit indicates an address error where read or write transactions try to access unimplemented addresses or accesses are non-aligned.	
		0	No Address Error
		1	Address Error

4 Fractional PLL (Frac-N PLL)

This processor uses the Fractional Phased-locked Loop (Frac-N PLL) to generate precise and low-jitter audio clock frequencies.

IMPORTANT: In this chapter, ADI uses the abbreviation Frac-N PLL to refer to the entire Fractional PLL module. The Frac-N PLL subblocks are the Fractional PLL (FPLL) and Digital PLL (DPLL). The FPLL subblock generates a clock frequency that is a fractional multiple of CLKIN. The DPLL subblock performs phase alignment with the output clock to an external reference clock (FIN).

The Fractional Phased-locked Loop (Frac-N PLL) operates in one of two modes:

- FPLL Only Mode–generates a clock with frequency values that are fractional multiples of the CLKIN frequency. As an example, the processor can output an audio clock of frequency 24.576 MHz generated from a 25 MHz CLKIN frequency.
- DPLL Plus FPLL Mode–consists of a digital filter and controller (DPLL), combined with the FPLL to create a dual-loop PLL. The DPLL provides fractional and integer parts of divider values to the FPLL block. The Frac-N PLL output clock feeds back the signal to the DPLL for phase-alignment with the external reference clock (FIN). As an example, you can obtain a 1 KHz PPS output from the EMAC block, to use as a reference for generating a 24.576 MHz audio clock that is phase-aligned to the pulses per second (PPS) output.

Frac-N PLL Features

The Frac-N PLL supports the following features:

- Generation of a clock with frequency values that are fractional multiples of the CLKIN frequency.
- Phase-alignment of the output clock with a selected external reference clock (FIN).
- FIN sources from DAI0/DAI1 PCGx_EXTCLK, GPIO (FRACNPLL_PTP_CLK), or RGMII PTP PPS0-3 signals.
- FPLL frequency, DPLL frequency, and phase lock interrupt and trigger.
- DPLL frequency unlock interrupt.
- FPLL and DPLL trigger wait (TWAIT).
- Routing of the Frac-N PLL signals to the SYS_CLKOUT.

- Routing of the Frac-N PLL output clock to the Timer and PWM blocks.

Frac-N PLL Definitions

To make the best use of the Frac-N PLL, it is helpful to understand the following terms.

Phase-locked Loop (PLL)

A feedback circuit designed to synchronize one circuit board to the phase of its on board clock with an external timing signal. PLL circuits operate by comparing the phase of an external signal to the phase of a clock signal produced by a voltage controlled crystal oscillator (VCXO).

Fractional Phase-locked Loop (Frac-N PLL)

The entire fractional PLL module used to generate precise and low-jitter audio clock frequencies. The Frac-N PLL consists of two subblocks, the FPLL and the DPLL.

Fractional PLL (FPLL)

The FPLL subblock of the Frac-N PLL that generates a clock frequency, which is a fractional multiple of the CLKIN.

Digital PLL (DPLL)

The DPLL subblock of the Frac-N PLL that performs phase alignment with the output clock to an external reference clock (FIN).

Digital Audio Interfaces (DAI)

Consists of a group audio peripherals connected using the Signal Routing Unit (SRU). The SRU connects inputs and outputs of the DAI peripherals with each other and to the external pins. This arrangement permits peripherals to be interconnected and accommodates different audio configurations without making separate external pin connections.

Ethernet Media Access Controller (EMAC)

The EMAC peripheral in the processor enables network connectivity to applications through an Ethernet interface. This function enables applications to support TCP/IP based network communication. At the system end, the module supports direct connection with the system crossbar bus for memory or memory-mapped registers (MMR) transactions.

Pulse-Width Modulator (PWM)

The processor component that provides a way of controlling certain analog quantities, by varying the pulse width of a fixed frequency rectangular waveform.

FIN (external reference clock)

An external reference clock used to compare against the Frac-N PLL output clock by the DPLL for phase-alignment corrections.

Phase/Frequency Detector (PFD)

A linear or binary phase detector that compares the phase difference between the input reference signal and the output signal from a voltage controlled oscillator (VCO).

Precision Clock Generator (PCG)

Used to produce a pair of signals from a clock input signal. The PCG normally generates two signals used as a serial bit clock and frame sync pair.

Precision Time Protocol (PTP)

A protocol used to synchronize clocks in processors and their peripherals. On a processor, it achieves clock accuracy in the sub-microsecond range, making it suitable for measurement and control systems.

Pulses-per-Second (PPS)

A signal that has a width of less than one second and a sharply rising or abruptly falling edge that accurately repeats once per second.

Signal Routine Unit (SRU)

A precision clock generator component that routes all of the precision clock generator (PCG) signals in one digital audio interface (DAI) for external usage.

Trigger Routing Unit (TRU)

The processor component that provides a system level sequence control without core intervention. It maps the trigger controllers (trigger generators) to trigger targets (triggers receivers). The receiver endpoints can be configured to respond to triggers in different ways.

Voltage Controlled Oscillator (VCO)

An electronic oscillator where the voltage input controls the oscillation frequency. The applied input voltage determines the instantaneous oscillation frequency.

Frac-N PLL Functional Description

This section provides a description of the Frac-N PLL, including a list of its registers, interrupts, and functional block diagrams.

Frac-N PLL Block Diagram

The *Frac-N PLL Block Diagram* shows the organization and communication of the Frac-N PLL It contains the following major components.

- FPLL subblock
- DPLL subblock
- Clock multiplexers–that switch between functional modes and select the FIN source
- REG-interface–configure and control the FPLL, DPLL, and clock multipliers. The REG-IF also reads the status parameters.

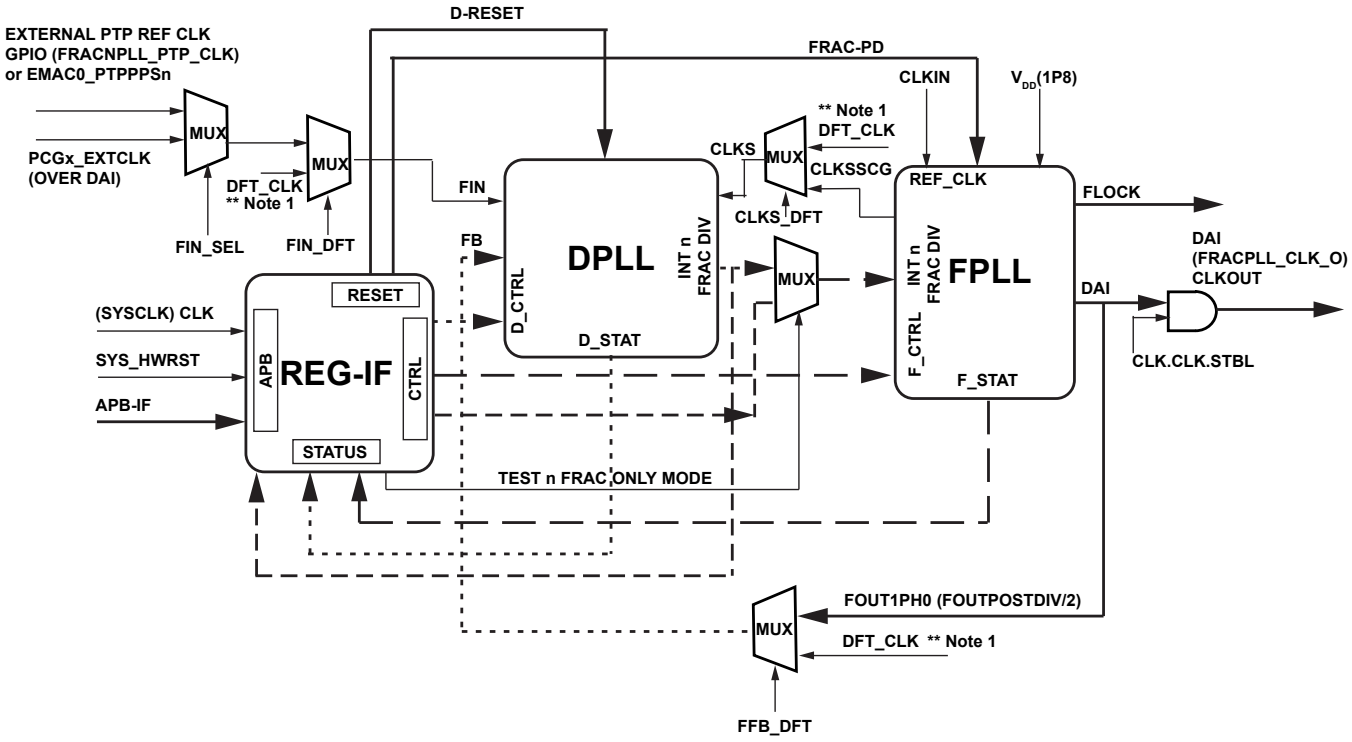

Figure 4-1: Frac-N PLL Block Diagram © Silicon Creations

NOTE: 1. The DFT_CLK is for Analog Devices internal use only.

FPLL Detailed Block Diagram

The FPLL generates a clock with a frequency value that is a fractional multiple of the CLKIN frequency.

The *FPLL Detailed Subblock Diagram* shows how the FPLL generates a clock with a frequency value that is a fractional multiple of the CLKIN frequency.

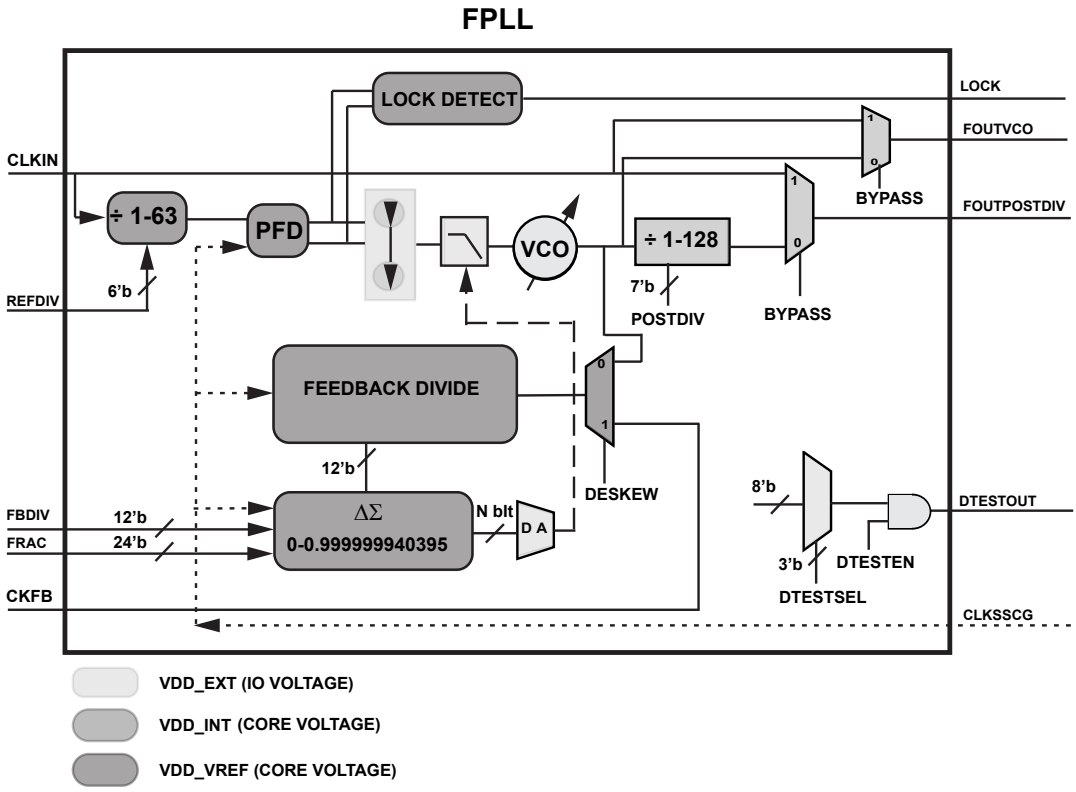

Figure 4-2: FPLL Detailed Subblock Diagram © Silicon Creations

The CLKIN is the input clock source for the FPLL. (See the *High Performance SHARC-FX DSP Core With Arm-Based Connectivity/Safety-Preliminary Data Sheet* for the specific CLKIN frequency range.) The CLKIN frequency is divided with the `FRACNPLL_FPLL_CTL1.REFDIV` field and then goes to the voltage controlled oscillator (VCO). The VCO multiplies the divided CLKIN with the fractional value using the configured `FRACNPLL_FPLL_CTL1.INT` and `FRACNPLL_FPLL_CTL0.FRAC` fields. Engineers can further divide the VCO output (FOUTVCO) with the post divider (POSTDIV), using the configured `FRACNPLL_FPLL_CTL1.POSTDIV` field. FOUTPOSTDIV is the resulting output clock.

Set (=1) the `FRACNPLL_FPLL_CTL0.BYPASS` bit and bypass the CLKIN directly to the FOUTPOSTDIV output. They can further divide the FOUTPOSTDIV frequency 2, 4, 8, and 16 to generate the FOUTPOSTDIV/2, FOUTPOSTDIV/4, FOUTPOSTDIV/8 or FOUTPOSTDIV/16 signals. The CLKSSCG signal works as a synchronization signal, and feeds back to the DPLL when in the DPLL plus FPLL Mode. This clock typically operates at a low frequency (same frequency as the PLL input clock), but also has a low duty cycle (typically about 10-20%).

DPLL and FPLL Block Diagram

The DPLL synchronizes the FPLL clock output with the on-chip (RGMII PTP PPS) or the off-chip (DAI0/DAI1/GPIO) reference clock (FIN). The *DPLL Detailed Subblock Diagram with FPLL Interface* shows a detailed diagram of the DPLL subblock and its interface to the FPLL subblock.

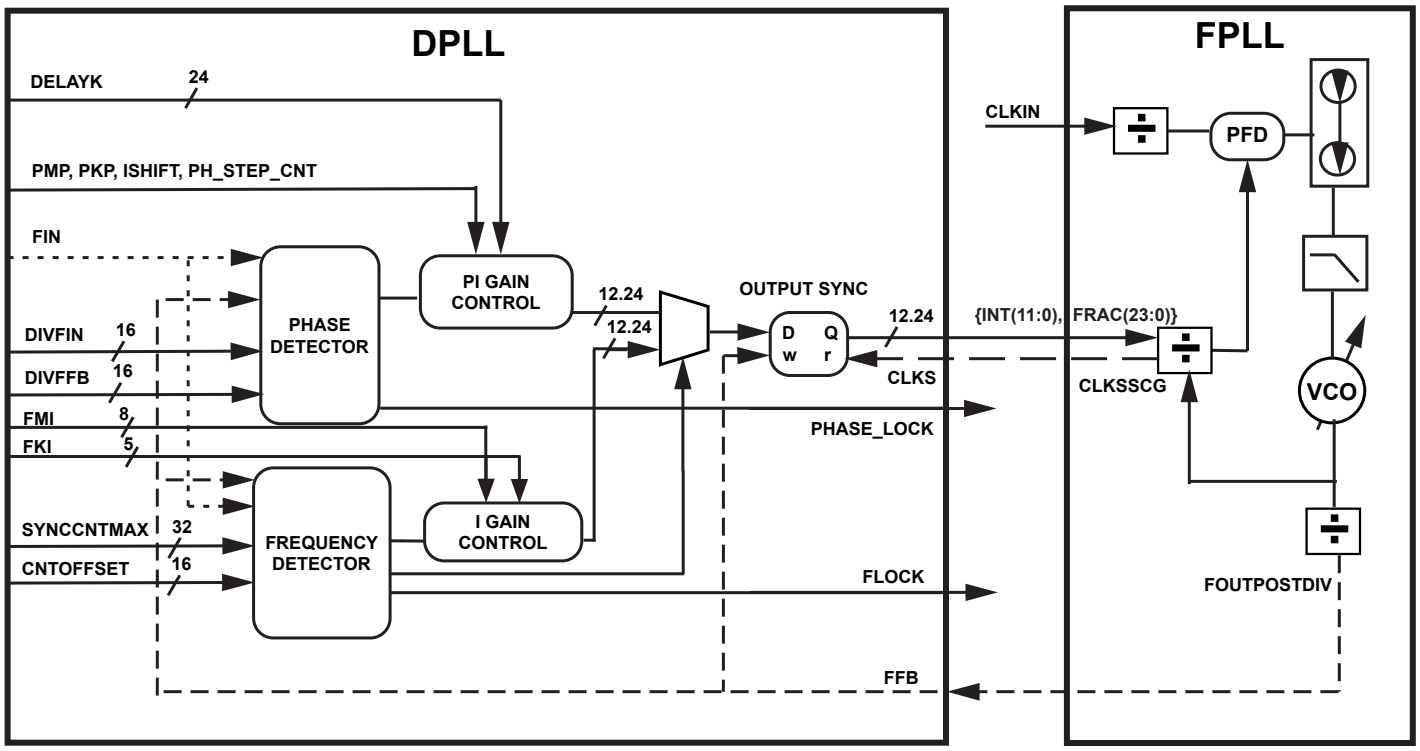

Figure 4-3: DPLL Detailed Subblock Diagram with FPLL Interface © Silicon Creations

The DPLL interfaces to the FPLL by controlling its integer and fractional feedback division bits. The DPLL has a broadly tuneable bandwidth to filter noisy references. Because the FPLL has a separate clean reference, its own noise characteristics and not those of the reference dominates the noise at the FPLL output.

The DPLL uses three phases of acquisition: frequency tracking, phase settling control, and phase tracking. Each phase has separate programmable gains to tune the DPLL performance for the specific application.

- ***Frequency gain control and frequency tolerance control (tracking)***–modify the response time of the PLL when in frequency tracking mode and permit tracking or filtering of a reference, tuned to the expected noise of the reference.
- ***Phase settling control***–manages the transition from frequency tracking mode to phase tracking mode with a high gain to ensure the DPLL can lock under *all* conditions.
- ***Phase tracking***–enables the DPLL to have a very low bandwidth, effectively averaging out higher frequency noise that can happen because of spread spectrum or other noisy input references.

ADSP-2184x FRACNPLL Register List

The FRACnPLL module combines DPLL and Frac PLL to generate an on-chip, low jitter, precision audio clock.

Table 4-1: ADSP-2184x FRACNPLL Register List

Name	Description
FRACNPLL_CTL	Integration Control Register
FRACNPLL_DPLL_CTL0	DPLL Control Register 0
FRACNPLL_DPLL_CTL1	DPLL Control Register 1

101	FRACNPLL1_FRACPLL_TRIGS	FRACNPLL1 Frac Pll Start Trigger	Pulse

Frac-N PLL Architectural Concepts

This section covers the following major concepts:

- Interrupts and Triggers
- DAI Clock Selection
- Frac-N PLL CLKOUT Clock Selection
- Usage of Frac-N PLL Output Clock

Interrupts and Triggers

NOTE: For the SHARC-FX core, configure the interrupt controller for the FRACNPLL_FRAC_LOCK interrupt to use an edge-sensitive interrupt to avoid multiple re-entries inside the ISR.

The Cortex-A55 core does not support the FRACNPLL_FRAC_LOCK interrupt.

The following triggers and interrupts are part of the Frac-N PLL.

- Lock Interrupt-Trigger
- DPLL Unlock Interrupt
- TWAIT Trigger Receiver

Lock Interrupt-Trigger

The Frac-N PLL supports the following lock interrupts.

- FPLL frequency lock (FPLL_FLOCK)
- DPLL frequency lock (DPLL_FLOCK)
- DPLL phase lock (DPLL_PLOCK)

These interrupts can be sent to the SEC/NVIC using the interrupt signal FRACNPLL_FRAC_LOCK. The same signal routes the interrupt to the trigger routing unit as the trigger requester signal FRACPLL_TRIGM and to the GPIO (FRACNPLL_FLOCK).

Configure the FRACNPLL_CTL.LOCK_SEL field to select one of the following values:

- 0–routes none of the three interrupts
- 1–uses the FPLL frequency lock (FPLL_FLOCK)
- 2–uses the DPLL frequency lock (DPLL_FLOCK)
- 3–uses the DPLL phase lock (DPLL_PLOCK)

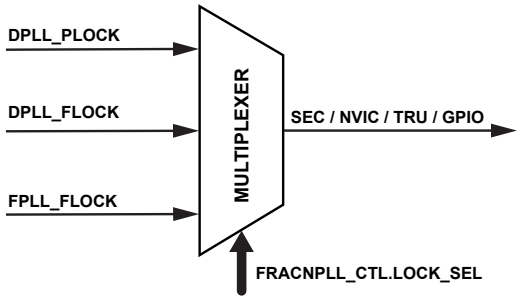

Figure 4-4: Frac-N PLL Lock Interrupt and Trigger Multiplexer

DPLL Unlock Interrupt

Applications can route the DPLL frequency unlock signal to SEC/NVIC FRAC_UNLOCK interrupt. This interrupt can detect the loss of the FIN reference clock signal and take any necessary action at the system level.

TWAIT Trigger Receiver

This processor has an available trigger (receiver) wait or TWAIT to release the power down and reset signal of the FPLL and DPLL. This auto-synchronizes the start of an operation on any available system event. Set (=1) the FRACNPLL_CTL.F_TWAIT (FPLL) and FRACNPLL_CTL.D_TWAIT (DPLL) bits to indicate one of the two operating modes. (See Frac-N PLL Operating Modes for more information.)

Engineers can configure both PLLs and released from reset by clearing (=0) the FRACNPLL_CTL.FCPD (required) and the FRACNPLL_CTL.DCRESET (release from reset) bits. When the respective TWAIT bit is set (=1), an actual reset to FPLL/DPLL does not get unasserted immediately. The reset waits for the trigger to arrive. Once the trigger arrives, the FPLL or DPLL reset is unasserted.

CAUTION: The TWAIT only controls the reset-deassertion. TWAIT bits do not gate the reset assertion to FPLL and DPLL.

DAI Clock Selection

The *Frac-N PLL DAI CLock Multiplexer* figure shows how it provides the FPLL output clock FOUTPOSTDIV in available sub-multiples (2, 4, 6, or 8), which can route different values of clock frequencies to the DAI, without disturbing the feedback clock or the DPLL frequency and phase lock.

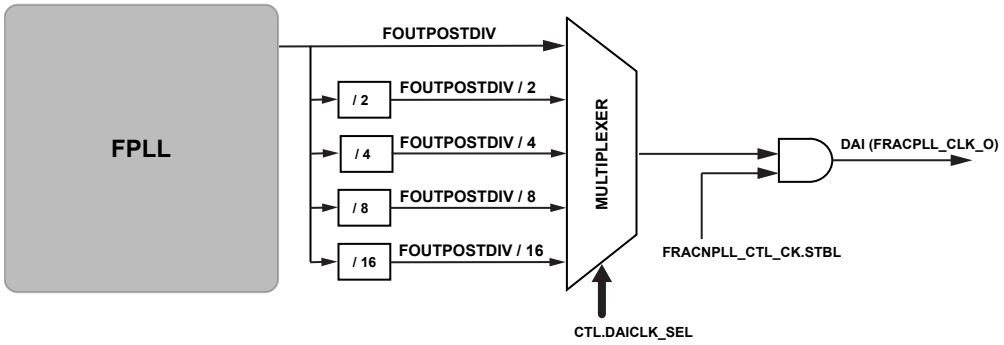

Figure 4-5: Frac-N PLL DAI Clock Multiplexer

For a FOUTPOSTDIV clock of frequency 98.304 MHz, one can program the multiplexer to select output clock values that include: 49.152 MHz (/2), 24.576 MHz (/4), 12.288 MHz (/8), and 6.144 MHz (/16). See the *DAI Output Clock Selection* table for valid configuration values for the `FRACNPLL_CTL.DAICLK_SEL` field. Engineers can set (=1) a clock gating control after the multiplexer using the `FRACNPLL_CTL.CK_STBL` bit to ensure sending out only a stable clock.

Table 4-5: DAI Output Clock Selection

FRACNPLL_CTL. DAICLK_SEL Value	Clock Selected	Example Frequency
0	No Clock	N/A
1	FOUTPOSTDIV/16	6.144 MHz
2	FOUTPOSTDIV/8	12.288 MHz
3	FOUTPOSTDIV/4	24.576 MHz
4	FOUTPOSTDIV/2	45.152 MHz
5	FOUTPOSTDIV (Default)	98.304 MHz

Frac-N PLL CLKOUT Clock Selection

The *FPLL CLKOUT Multiplexer* diagram shows how a multiplexer detects all clocks and synchronization signals (CLKSSCG) for the Frac-N PLL.

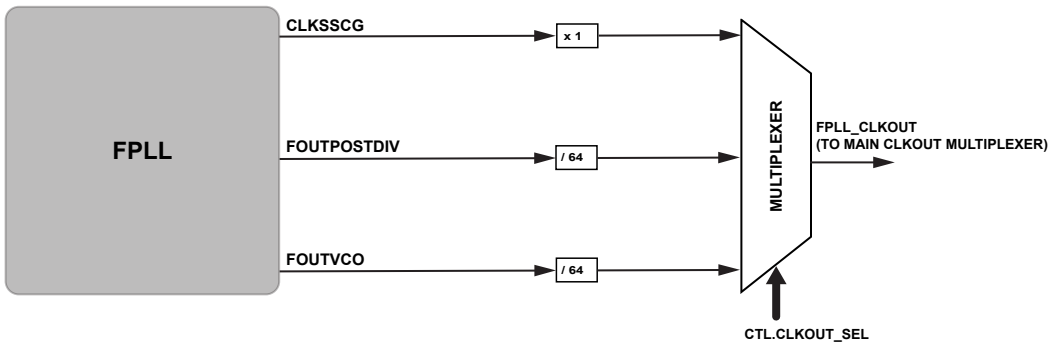

Figure 4-6: FPLL CLKOUT Multiplexer

Configure the `FRACNPLL_CTL.CLKOUT_SEL` field to program the multiplexer by using the values in the *FPLL_CLKOUT Multiplexer Selection* table. To meet the maximum operating pad frequency, adequately-added divider stages exist on each clock path (based on their maximum operating frequency) before connecting to the FPLL CLKOUT multiplexer. The output of the CLKOUT multiplexer merges to the main CLKOUT multiplexer. See the Clock Generation Unit (CGU) section for more information.

Table 4-6: FPLL_CLKOUT Multiplexer Selection

FRACNPLL_CTL. CLKOUT_SEL Value	Signal Routed to FPLL_CLKOUT Multiplexer
1	CLKSSCG
2	FOUTPOSTDIV/64 (Default)
3	FOUTVCO/64

Usage of Frac-N PLL Output Clock

Users can route the FPLL output clock to the following processor modules:

- Digital Audio Interface (DAI)
- Timer
- Pulse-Width Modulator (PWM)

Digital Audio Interface (DAI)

The FPLL output clock is routed to one of the PCGx_EXTCLK signals. The output clock can also be one of the source signals for Group D of the Signal Routing Unit (SRU). This method routes the clock to one or more DAI0/1 pin buffers for external use.

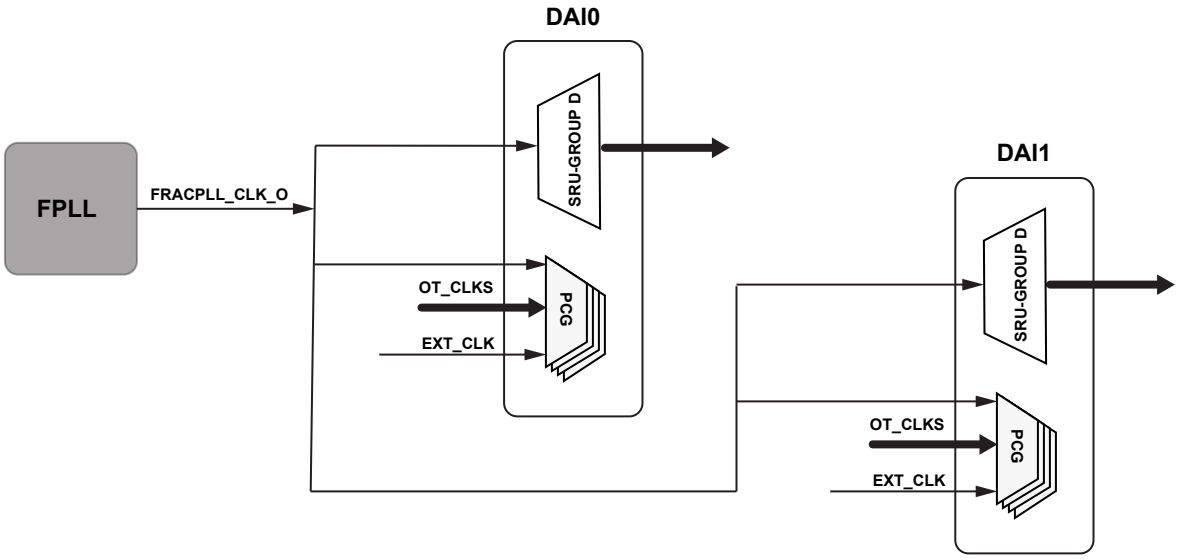

Figure 4-7: FPLL Output to PCG or SRU

Timer

The FPLL output clock connects to the TM0_ACLK port of the all the timers (through multiplexers) and with the other TM0_ACLK sources. Configure the `MISCREG_CLK_MUX_SEL.PCG_CLKSEL` field to select the PCG clock or set (=1) the `MISCREG_CLK_MUX_SEL.PCG_CLKSELF` bit to select the FPLL clock for the timer.

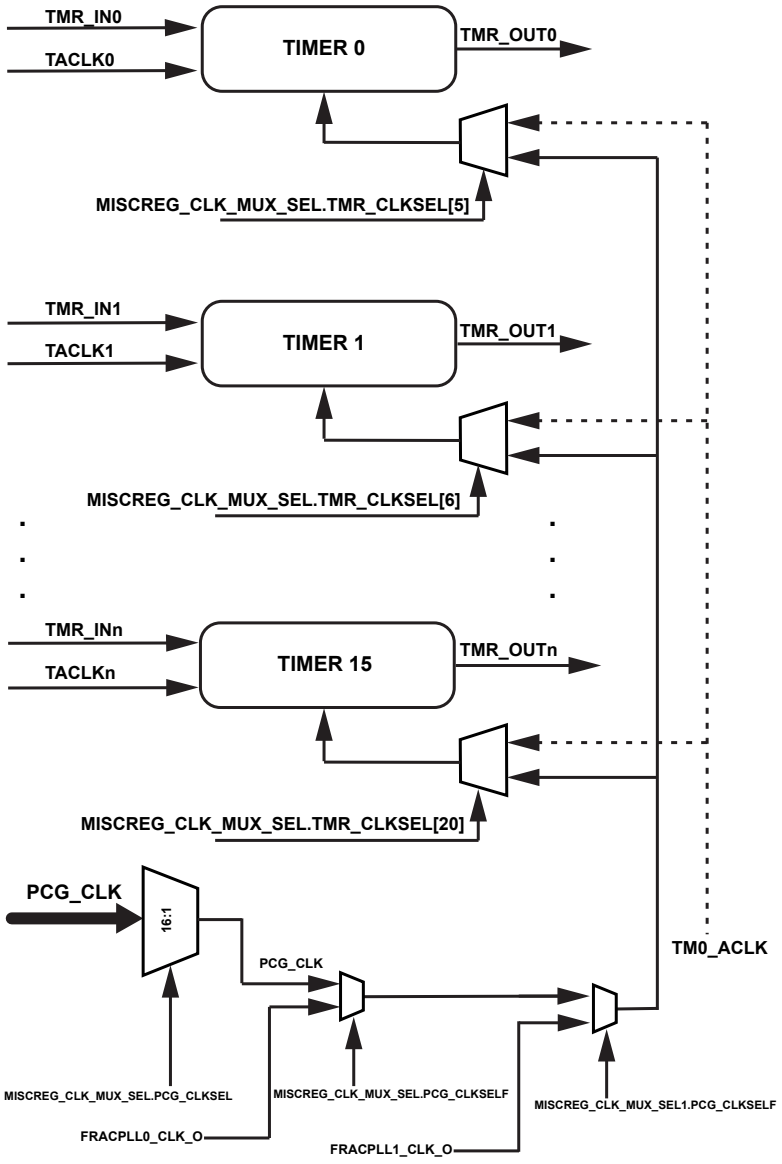

Figure 4-8: FPLL Output Clock Usage for Timer

Pulse-Width Modulator (PWM)

The FPLL output clock is used as an operating clock for the on chip PWM along with the SYSCLK to synchronize the PWM output with the FPLL output clock. Configure the `MISCREG_CLK_MUX_SEL.EPWM_CLKSEL` field to select the PCG clock or set (=1) the `MISCREG_CLK_MUX_SEL.EPWM_CLKSELF` bit to select the FPLL clock for the PWM.

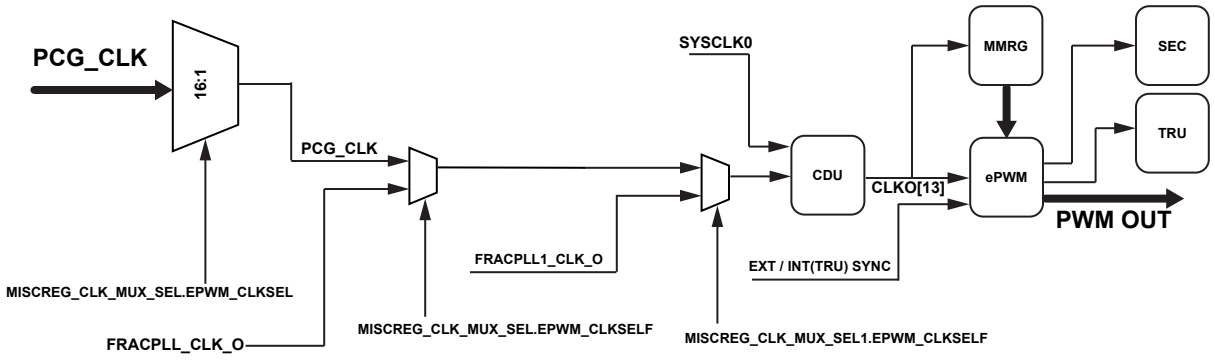

Figure 4-9: FPLL Output Clock Usage for PWM

Frac-N PLL Operating Modes

The Frac-N PLL operates in one of these two modes:

- FPLL Only Mode–clock generation using only the FPLL
- DPLL Plus FPLL Mode–clock generation synchronous with a lower frequency of an external reference clock source (FIN)

FPLL Only Mode

The FPLL generates a clock with frequency values that are fractional multiples of the CLKIN frequency. For example, a CLKIN frequency of 25 MHz can generate an audio clock of frequency 24.576 MHz. The output clock can be used from the FPLL either internally with audio peripherals (using the PCG) or driven out of the chip using DAI pin(s) and connected to external audio components. Configure the `FRACNPLL_FPLL_CTL0` and `FRACNPLL_FPLL_CTL1` registers to control the FPLL clock generation.

The *Clock Multiplexer Configurations for FPLL Only Mode* table shows the values for the different clock multiplexer configurations.

Table 4-7: Clock Multiplexer Configurations for FPLL Only Mode

Multiplexer Name	Register Bit Field	Required Value	Default Value
FIN	FRACNPLL_CTL.FIN_SEL	0	1
FIN-DFT	FRACNPLL_CTL.FIN_DFT	0	1
FFB-DFT	FRACNPLL_CTL.FFB_DFT	0	1
CLKS-DFT	FRACNPLL_CTL.CLKS_DFT	0	1
INT-DFT	FRACNPLL_CTL.DDIV_OVR	1	0
FRAC-DFT	FRACNPLL_CTL.FDIV_OVR	1	0

DPLL Plus FPLL Mode

DPLL Plus FPLL Mode–clock generation synchronized and multiplied with an external clock reference (FIN).

Use the DPLL or multiply and synchronize the output clock of FPLL with a lower-frequency external reference clock source (FIN). The DPLL provides the fractional and integer part of divider values to the FPLL. The processor feeds back the output clock of the FPLL (FOUTPH1 or FOUTPOSTDIV/2) to the DPLL to align with the FIN external clock reference phase.

FIN (External Reference Clock) Sources

Use one of the following options to select the FIN:

- Internal Ethernet PTPPPS signal – RGMII/EMAC0 block, that is, EMAC0_PTPPPS0 through EMAC0_PTPPPS03.
- External Ethernet PTPPPS or any other reference clock source – the GPIO (FRACNPLL_PTP_CLK) of the processor.
- External reference clock source connected – any DAI (0/1) pin of the processor routed using the PCGx_EXTCLK SRU signal.

Use the following steps to configure the FIN source:

1. Configure the value of the `FRACNPLL_CTL.FIN_SEL` field (=1) to select the FIN from DAI (`PCGx_EXTCLK`) or configure the value (=2) to select the FIN from the GPIO (FRACNPLL_PTP_CLK) or one of the EMAC0_PTPPPS0 through EMAC0_PTPPPS3 signals.
2. When the `FRACNPLL_CTL.FIN_SEL` field value (=1), engineers can configure the `MISCREG_CLK_MUX_SEL.PCG_MCLKSEL` bit to select the FIN source from different PCGx_EXTCLK signals. (See the *FIN Source Selection using MISCREG_CLK_MUX_SEL.PCG_MCLKSEL* table.)
3. When the `FRACNPLL_CTL.FIN_SEL` field value (=2), the `MISCREG_CLK_MUX_SEL.PTP_RCLKSEL` field can select the FIN source from either the GPIO (FRACNPLL_PTP_CLK) or one of the EMAC0_PTPPPS0 through EMAC0_PTPPPS3 signals. (See *FIN Source Selection using MISCREG_CLK_MUX_SEL. PTP_RCLKSEL* table).

   NOTE: The `FRACNPLL_CTL.REFCLK_IE` bit must be set (=1) when configuring GPIO (FRACNPLL_PTP_CLK) as the FIN source.

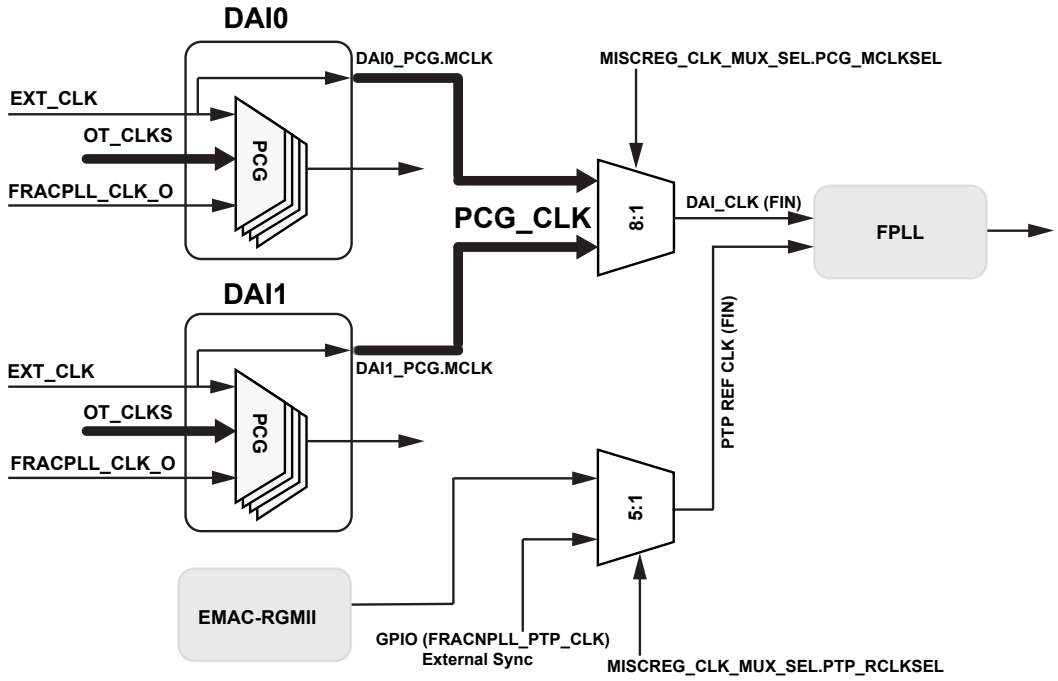

Figure 4-10: Possible FIN Sources

Table 4-8: FIN Source Selection using `MISCREG_CLK_MUX_SEL.PCG_MCLKSEL`

SL Number	**`MISCREG_CLK_MUX_SEL.PCG_MCLKSEL`**	FIN Source
1	0	DAI0_PCGA_EXTCLK
2	1	DAI0_PCGB_EXTCLK
3	2	DAI0_PCGC_EXTCLK
4	3	DAI0_PCGD_EXTCLK
5	4	DAI1_PCGA_EXTCLK
6	5	DAI1_PCGB_EXTCLK
7	6	DAI1_PCGC_EXTCLK
8	7	DAI1_PCGD_EXTCLK

Table 4-9: FIN source selection using `MISCREG_CLK_MUX_SEL.PTP_RCLKSEL`

SL Number	**`MISCREG_CLK_MUX_SEL.PTP_RCLKSEL`**	FIN Source
1	0	GPIO (FRACNPLL_PTP_CLK)
2	1	EMAC0_PTPPPS0

Table 4-9: FIN source selection using `MISCREG_CLK_MUX_SEL.PTP_RCLKSEL` (Continued)

SL Number	`MISCREG_CLK_MUX_SEL.PTP_RCLKSEL`	FIN Source
3	2	EMAC0_PTPPPS1
4	3	EMAC0_PTPPPS2
5	4	EMAC0_PTPPPS3

DPLL Plus FPLL Clock Multiplexer Configuration

The *Clock Multiplexer Configurations for the DPLL Plus FPLL Mode* table describes the multiplexer configurations.

Table 4-10: Clock Multiplexer Configurations for the DPLL Plus FPLL Mode

Multiplexer Name	Register Bit Field	Required Value	Default Value
FIN	`FRACNPLL_CTL.FIN_SEL`	1 or 2	1
FIN-DFT	`FRACNPLL_CTL.FIN_DFT`	1	1
FFB-DFT	`FRACNPLL_CTL.FFB_DFT`	1	1
CLKS-DFT	`FRACNPLL_CTL.CLKS_DFT`	1	1
INT-DFT	`FRACNPLL_CTL.DDIV_OVR`	0	0
FRAC-DFT	`FRACNPLL_CTL.FDIV_OVR`	0	0

Frac-N PLL Programming Model

This section describes the procedures to program the two Frac-N PLL operating modes.

- Programming FPLL Only Mode
- FPLL Only Mode TWAIT
- Programming Model for DPLL Plus FPLL Mode
- DPLL Plus FPLL Mode TWAIT (ADI does not recommend using this procedure.)
- Programming the FIN Unlock and Re-lock DPLL

Programming FPLL Only Mode

Use the following steps to program the FPLL Only Mode multiplexer configuration:

1. Configure the Frac-N PLL clock multiplexer using Table 4-7 Clock Multiplexer Configurations for FPLL Only Mode.
2. Keep DPLL and FPLL in reset by setting (=1) the `FRACNPLL_CTL.DCRESET` and `FRACNPLL_CTL.FCPD`) bits. By default, these bits are set after system reset.

3. Keep the FRACNPLL_CTL.CK_STBL bit cleared (=0). By default, these bits are cleared after system reset.
4. Configure the FRACNPLL_FPLL_CTL0.FRAC, FRACNPLL_FPLL_CTL1.INT, FRACNPLL_FPLL_CTL1.REFDIV, and FRACNPLL_FPLL_CTL1.POSTDIV fields.
5. Release FPLL from reset by clearing (=0) the FRACNPLL_CTL.FCPD bit.
6. Wait for the FPLL frequency lock by polling the FRACNPLL_STAT.FSLOCK bit (blocking mode) *or* configure the FRACNPLL_CTL.LOCK_SEL bit to generate the FPLL frequency lock interrupt (non-blocking mode).
7. Release the clock by setting (=1) the FRACNPLL_CTL.CK_STBL bit.

FPLL Only Mode TWAIT

Use this procedure to invoke the trigger receiver.

1. Configure Frac-N PLL clock multiplexer using Table 4-7 Clock Multiplexer Configurations for FPLL Only Mode.
2. Keep DPLL and FPLL in reset by setting (=1) the FRACNPLL_CTL.DCRESET and FRACNPLL_CTL.FCPD bits. By default, these bits are set after system reset.
3. Keep the FRACNPLL_CTL.CK_STBL bit cleared (=0). By default, these bits are cleared after system reset.
4. Configure the FRACNPLL_FPLL_CTL0.FRAC, FRACNPLL_FPLL_CTL1.INT, FRACNPLL_FPLL_CTL1.REFDIV, and FRACNPLL_FPLL_CTL1.POSTDIVfields.
5. Wait for the FPLL frequency lock by polling the FRACNPLL_STAT.FSLOCK bit (blocking mode) *or* configure the FRACNPLL_CTL.LOCK_SEL bit to generate the FPLL frequency lock interrupt (non-blocking mode).
6. Release the clock by setting (=1) the FRACNPLL_CTL.CK_STBL bit.
7. Set (=1) the FRACNPLL_CTL.F_TWAIT bit.
8. Set (=1) the FRACNPLL_CTL.FCPD bit.

On arrival of the trigger, the actual reset to FPLL is de-asserted and the FPLL starts operating as expected.

Programming Model for DPLL Plus FPLL Mode

Use the following steps to program the DPLL plus FPLL mode:

1. Configure Frac-N PLL clock multiplexer as per Table 4-10 Clock Multiplexer Configurations for the DPLL Plus FPLL Mode.
2. Keep DPLL and FPLL in reset by setting (=1) the FRACNPLL_CTL.DCRESET and FRACNPLL_CTL.FCPD bits. By default, these bits are set after a system reset.

3. Keep the FRACNPLL_CTL.CK_STBL bit cleared (=0). By default, these bits are cleared after system reset.
4. Configure parameters in the DPLL registers FRACNPLL_DPLL_CTL0 through FRACNPLL_DPLL_CTL9, including values for FRACNPLL_DPLL_CTL5.INT_PRESET and FRACNPLL_DPLL_CTL4.FRAC_PRESET. Clear the FRACNPLL_DPLL_CTL4.HOLD and FRACNPLL_DPLL_CTL7.PRESET_EN bits.
5. Release the DPLL reset by clearing (=0) the FRACNPLL_CTL.DCRESET bit.
6. Set (= 1) the FRACNPLL_DPLL_CTL7.PRESET_EN bit.
7. Set (= 1) the FRACNPLL_DPLL_CTL4.HOLD bit.
8. Configure the FRACNPLL_FPLL_CTL0/1 registers. FRACNPLL_FPLL_CTL0.FRAC and FRACNPLL_FPLL_CTL1.INT should be set to zero as these values DPLL provides in this mode. FPLL uses the FRACNPLL_DPLL_CTL5.INT_PRESET and FRACNPLL_DPLL_CTL4.FRAC_PRESET values programmed in step four, plus with the values programmed in FRACNPLL_FPLL_CTL1.REFDIV, and FRACNPLL_FPLL_CTL1.POSTDIV bit fields as a starting point for further frequency and phase lock process.
9. Once the FPLL has asserted a frequency lock, set (=1) the FRACNPLL_STAT.FSLOCK bit, and wait for the DPLL to assert its frequency lock (FRACNPLL_STAT.DSFLOCK=1).
10. Once the DPLL has asserted frequency lock, clear (=0) FRACNPLL_DPLL_CTL7.PRESET_EN and FRACNPLL_DPLL_CTL4.HOLD bits and wait for the DPLL to assert its phase lock (FRACNPLL_STAT.DSPHASE_LOCK=1).

    The DPLL phase lock can take few milliseconds to seconds. ADI recommends you use a non-blocking mode to generate an interrupt after the DPLL phase lock event.
11. Release the clock by setting (=1) the FRACNPLL_CTL.CK_STBL bit.

IMPORTANT: Programming the exact values of the FPLL and DPLL register settings for different FIN and FPLL output clock frequencies is not part of this chapter. The supported values of FIN and FPLL output clock frequencies and the required software routines to program the FPLL and DPLL are available using the FPLL Service along with the CrossCore Embedded Studio® software. ADI recommends you always use this service for programming the Frac-N PLL.

DPLL Plus FPLL Mode TWAIT

CAUTION: ADI does not recommend attempting to use the TWAIT feature in the DPLL Plus FPLL Mode.

Because of the complicated programming model, using the TWAIT feature for the DPLL plus FPLL mode may require the trigger to arrive somewhere the middle of the previously mentioned Programming Model for DPLL Plus FPLL Mode steps. This means a user must add an interrupt to use the TWAIT feature.

Programming the FIN Unlock and Re-lock DPLL

When the FIN is temporarily absent, the DPLL can become unlocked. Once the FIN clock signal enables, the DPLL attempts to lock again. To ensure a smooth DPLL unlock and relock sequence, use the following procedure:

1. Configure the DPLL to generate the unlock interrupt. See DPLL Unlock Interrupt for more information.
2. When the DPLL unlocks because of the FIN absence, it generates a DPLL unlock interrupt. Inside the unlock interrupt service routine, set (=1) the `FRACNPLL_DPLL_CTL4.HOLD` bit. Note: the application can use any other interrupt mechanism as well (for example, SPDIF receiver loss of lock interrupt if SPDIF receiver is the source of FIN) instead of DPLL unlock interrupt to signal loss of FIN.
3. DPLL cannot generate lock interrupt when in hold state. So, the application must have a way to interrupt the core when FIN is reconnected back (for example, SPDIF receiver lock interrupt if SPDIF receiver is the source of FIN). Inside the interrupt service routine, clear (=0) the `FRACNPLL_DPLL_CTL4.HOLD` bit to release DPLL hold.
4. Wait for the DPLL to assert a phase lock (`FRACNPLL_STAT.DSPHASE_LOCK`=1) again. Use the DPLL phase lock interrupt in this case for the non-blocking mode.

ADSP-2184x FRACNPLL Register Descriptions

The Fractional Phase-locked loop (FRACNPLL) contains the following registers.

Table 4-11: ADSP-2184x FRACNPLL Register List

Name	Description
FRACNPLL_CTL	Integration Control Register
FRACNPLL_DPLL_CTL0	DPLL Control Register 0
FRACNPLL_DPLL_CTL1	DPLL Control Register 1
FRACNPLL_DPLL_CTL2	DPLL Control Register 2
FRACNPLL_DPLL_CTL3	DPLL Control Register 3
FRACNPLL_DPLL_CTL4	DPLL Control Register 4
FRACNPLL_DPLL_CTL5	DPLL Control Register 5
FRACNPLL_DPLL_CTL6	DPLL Control Register 6
FRACNPLL_DPLL_CTL7	DPLL Control Register 7
FRACNPLL_DPLL_CTL8	DPLL Control Register 8
FRACNPLL_DPLL_CTL9	DPLL Control Register 9
FRACNPLL_DPLL_STAT0	DPLL Status Register 0
FRACNPLL_DPLL_STAT1	DPLL Status Register 1
FRACNPLL_DPLL_STAT2	DPLL Status Register 2

Table 4-11: ADSP-2184x FRACNPLL Register List (Continued)

Name	Description
FRACNPLL_FPLL_CTL0	Fractional PLL Control Register 0
FRACNPLL_FPLL_CTL1	Fractional PLL Control Register 1
FRACNPLL_STAT	Integration Status Register

Integration Control Register

The FRACNPLL_CTL register controls DPLL reset, DFT modes, clock selections, and trigger wait and power down functions.

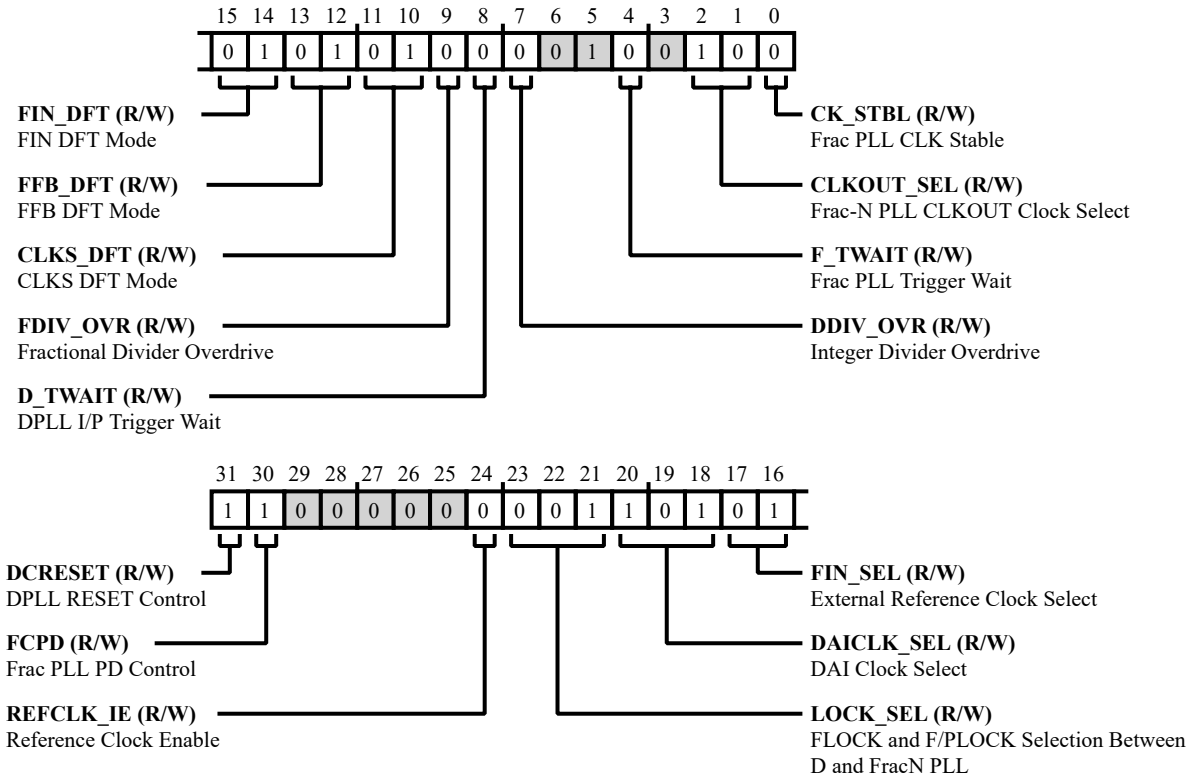

Figure 4-11: FRACNPLL_CTL Register Diagram

Table 4-12: FRACNPLL_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	DCRESET	DPLL RESET Control. Resets all internal counters and registers to their default state
30 (R/W)	FCPD	Frac PLL PD Control. Power down for PLL
24 (R/W)	REFCLK_IE	Reference Clock Enable. Input Enable for PLL REFCLK over GPIO
23:21 (R/W)	LOCK_SEL	FLOCK and F/PLOCK Selection Between D and FracN PLL. FPLL FLOCK/PLOCK and DPLL FLOCK/PLOCK selection

Table 4-12: FRACNPLL_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
20:18 (R/W)	DAICLK_SEL	DAI Clock Select. Selects the output of Frac-N PLL DAI clock multiplexer. 0 - No clock 1 - FOUTPOSTDIV/16 2 - FOUTPOSTDIV/8 3 - FOUTPOSTDIV/4 4 - FOUTPOSTDIV/2 5 - FOUTPOSTDIV
17:16 (R/W)	FIN_SEL	External Reference Clock Select. Multiplex selection for external reference clock. 0 - No clock 1 - Reference clock from DAI 2 - Reference clock from internal or external EMAC-PTPPPS
15:14 (R/W)	FIN_DFT	FIN DFT Mode. DFT mode for external reference clock. 0 - No clock 1 - DAI or EMAC ref clock 2 - DFT ref clock
13:12 (R/W)	FFB_DFT	FFB DFT Mode. DFT mode for feedback clock. 0 - No clock 1 - Feedback clock form FPLL (FOUT1PH0) 2 - DFT feedback clock
11:10 (R/W)	CLKS_DFT	CLKS DFT Mode. DFT mode for CLKS. 0 - No clock 1 - CLKS form FPLL (CLKSSCG) 2 - DFT CLK
9 (R/W)	FDIV_OVR	Fractional Divider Overdrive. Fractional divider override to FPLL in FPLL only mode
8 (R/W)	D_TWAIT	DPLL I/P Trigger Wait.
7 (R/W)	DDIV_OVR	Integer Divider Overdrive. Integer divider override to FPLL in FPLL only mode

Table 4-12: FRACNPLL_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
4 (R/W)	F_TWAIT	Frac PLL Trigger Wait. Frac PLL I/P Trigger Wait
2:1 (R/W)	CLKOUT_SEL	Frac-N PLL CLKOUT Clock Select. Selects the output of FPLL CLKOUT multiplexer which will be given as input to the main CLKOUT multiplexer. 1 - CLKSSCG 2 - FOUTPOSTDIV/64 3 - FOUTVCO/64
0 (R/W)	CK_STBL	Frac PLL CLK Stable. Setting the `FRACNPLL_CTL.CK_STBL` bit ensures sending out a stable clock by enabling clock gating control after the Frac-N PLL DAI clock multiplexer.

DPLL Control Register 0

The FRACNPLL_DPLL_CTL0 register contains the DPLL count offset value used for frequency multiplication in the frequency control loop.

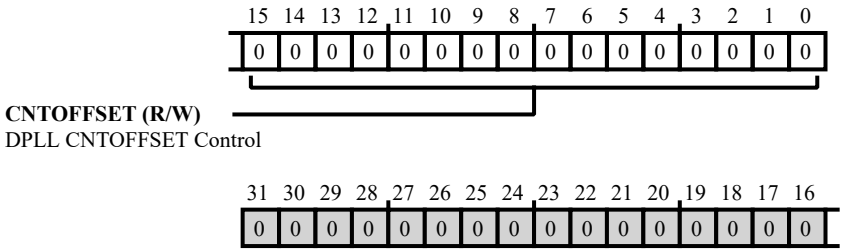

Figure 4-12: FRACNPLL_DPLL_CTL0 Register Diagram

Table 4-13: FRACNPLL_DPLL_CTL0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	CNTOFFSET	DPLL CNTOFFSET Control. Allows for frequency multiplication in the frequency control loop. By setting CNTOFFSET to SYNCCNTMAX / K, where K is the multiplication ratio, the frequency detector will output a zero frequency error when CNTOFFSET pulses have been counted from the reference and SYNCCNTMAX pulses have been counted from the feedback.

DPLL Control Register 1

The FRACNPLL_DPLL_CTL1 register controls DPLL delay.

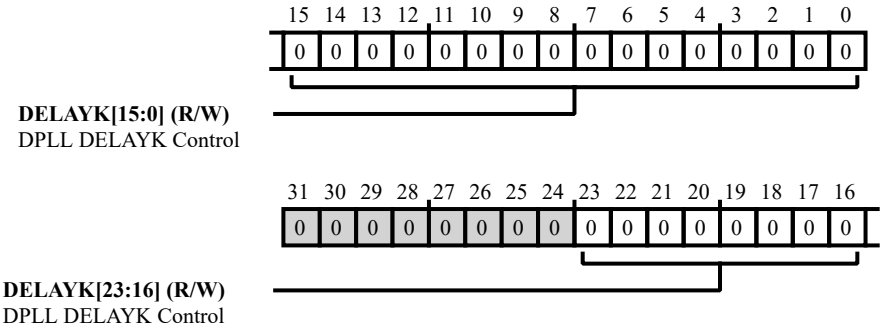

Figure 4-13: FRACNPLL_DPLL_CTL1 Register Diagram

Table 4-14: FRACNPLL_DPLL_CTL1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:0 (R/W)	DELAYK	DPLL DELAYK Control. The FRACNPLL_DPLL_CTL1.DELAYK bit field indicates the phase locking loop counts for DELAYK for each of PH_STEP_CNT gain settings from M * 2^K * $2^{PH_STEP_CNT}$ down to M * 2^K. Total lock count is PH_STEP_CNT*DELAYK

DPLL Control Register 2

The FRACNPLL_DPLL_CTL2 register shows the DPLL integer divider for FIN and FFB.

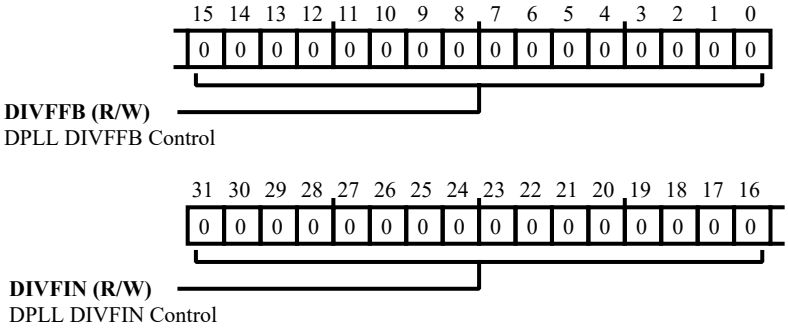

Figure 4-14: FRACNPLL_DPLL_CTL2 Register Diagram

Table 4-15: FRACNPLL_DPLL_CTL2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	DIVFIN	DPLL DIVFIN Control. The FRACNPLL_DPLL_CTL2.DIVFIN bit field indicates the integer divider for FIN.
15:0 (R/W)	DIVFFB	DPLL DIVFFB Control. The FRACNPLL_DPLL_CTL2.DIVFFB bit field indicates the integer divider for FFB.

DPLL Control Register 3

The FRACNPLL_DPLL_CTL3 register controls the gain for the integral frequency comparison loop and frequency operations.

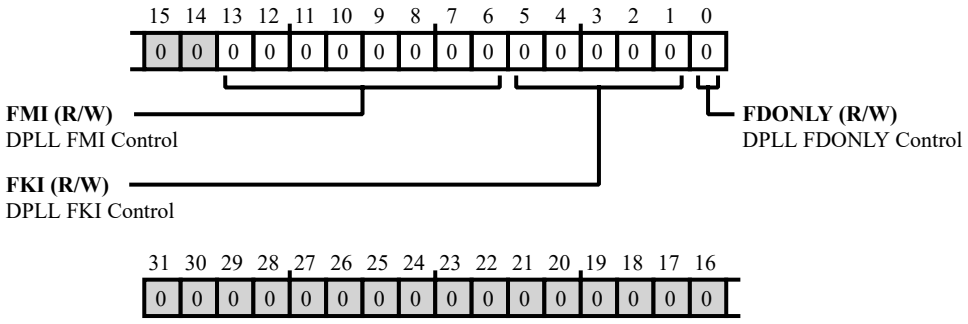

Figure 4-15: FRACNPLL_DPLL_CTL3 Register Diagram

Table 4-16: FRACNPLL_DPLL_CTL3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
13:6 (R/W)	FMI	DPLL FMI Control. The FRACNPLL_DPLL_CTL3.FMI bit field indicates the M gain for the integral frequency comparison loop where Gain=M * 2^K.
5:1 (R/W)	FKI	DPLL FKI Control. The FRACNPLL_DPLL_CTL3.FKI bit field indicates the K gain for the integral frequency comparison loop where Gain=M * 2^K.
0 (R/W)	FDONLY	DPLL FDONLY Control. The FRACNPLL_DPLL_CTL3.FDONLY bit indicates whether test mode or normal operation is used. 0 - Frequency Control Only (Test Mode) 1 - Normal Operation (Frequency and Phase)

DPLL Control Register 4

The FRACNPLL_DPLL_CTL4 register controls the hold output state and FRAC output.

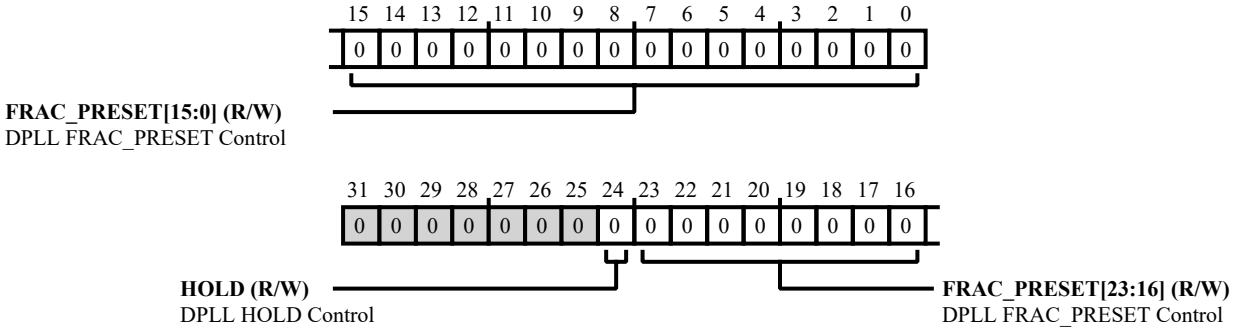

Figure 4-16: FRACNPLL_DPLL_CTL4 Register Diagram

Table 4-17: FRACNPLL_DPLL_CTL4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
24 (R/W)	HOLD	DPLL HOLD Control. The FRACNPLL_DPLL_CTL4.HOLD bit indicates the hold output state of the DPLL. 0 - Normal operation 1 - Hold. The PLL will not phase lock in this state.
23:0 (R/W)	FRAC_PRESET	DPLL FRAC_PRESET Control. The FRACNPLL_DPLL_CTL4.FRAC_PRESET bit field indicates the preset FRAC output. When PRESET_EN=1, the output is set to this value.

DPLL Control Register 5

The FRACNPLL_DPLL_CTL5 register controls some diagnostic operations and ISHIFT fields.

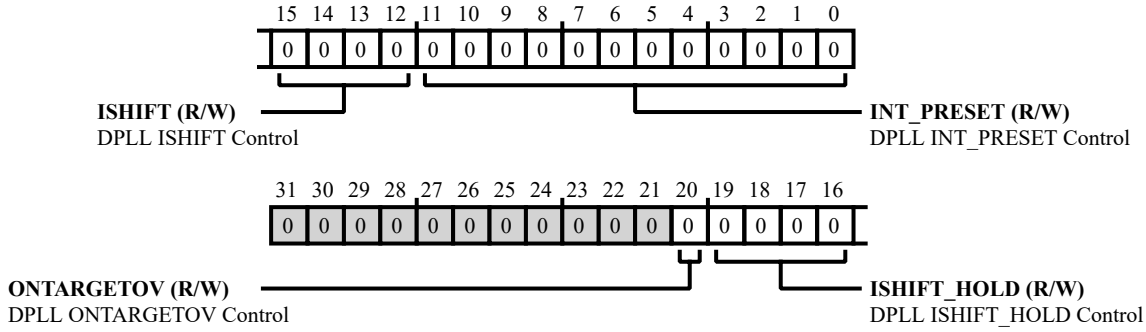

Figure 4-17: FRACNPLL_DPLL_CTL5 Register Diagram

Table 4-18: FRACNPLL_DPLL_CTL5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
20 (R/W)	ONTARGETOV	DPLL ONTARGETOV Control. The FRACNPLL_DPLL_CTL5.ONTARGETOV bit indicates diagnostic control (test mode) or normal operation. 0 - Diagnostic Mode 1 - Normal Operation
19:16 (R/W)	ISHIFT_HOLD	DPLL ISHIFT_HOLD Control. The FRACNPLL_DPLL_CTL5.ISHIFT_HOLD bit field indicates the ISHIFT value used after exiting from HOLD Gain of 2^-ISHIFT from P-Path to I-Path integrator in phase lock mode.
15:12 (R/W)	ISHIFT	DPLL ISHIFT Control. The FRACNPLL_DPLL_CTL5.ISHIFT bit field indicates gain of $2^{-ISHIFT}$ from P-Path to I-Path integrator in phase lock mode.
11:0 (R/W)	INT_PRESET	DPLL INT_PRESET Control. The FRACNPLL_DPLL_CTL5.INT_PRESET bit field indicates the preset INT output. When PRESET_EN=1b1, the output is set to this value.

DPLL Control Register 6

The FRACNPLL_DPLL_CTL6 register controls FFB clock delays.

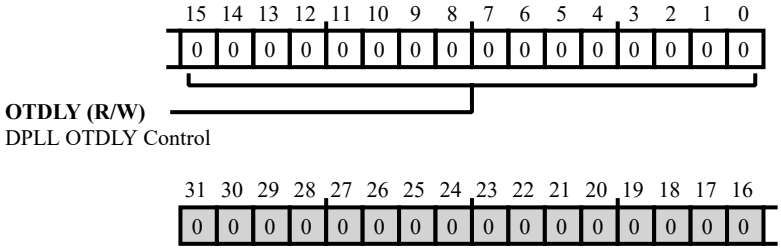

Figure 4-18: FRACNPLL_DPLL_CTL6 Register Diagram

Table 4-19: FRACNPLL_DPLL_CTL6 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	OTDLY	DPLL OTDLY Control. The FRACNPLL_DPLL_CTL6.OTDLY bit field indicates the delay in FFB clock periods from when FLOCK=1 to when the DPLL transfers control from the frequency comparison loop to the phase comparison loop. The delay allows additional settling and avoids glitches in FLOCK output. The recommended value is 25.

DPLL Control Register 7

The FRACNPLL_DPLL_CTL7 register controls DPLL bits used for diagnostics and gain functions.

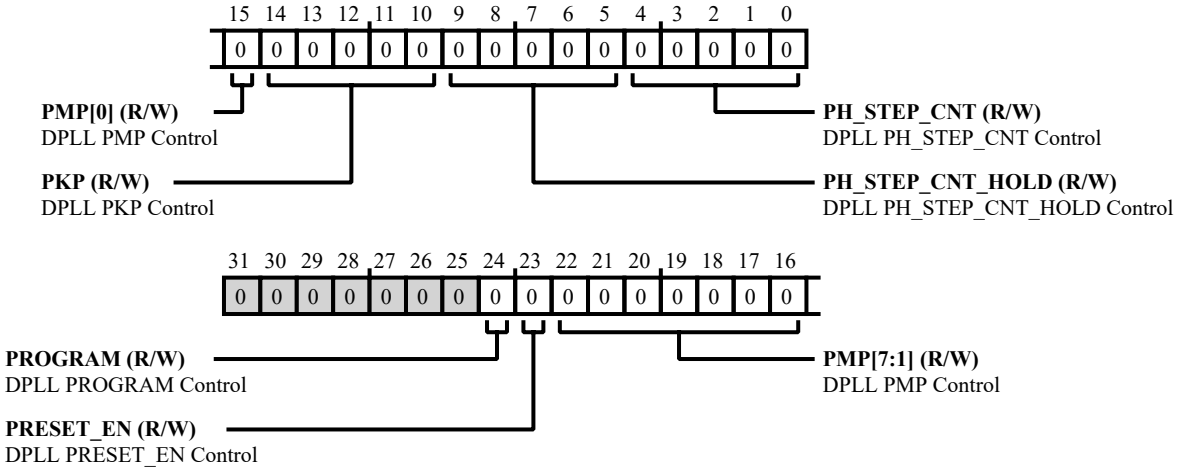

Figure 4-19: FRACNPLL_DPLL_CTL7 Register Diagram

Table 4-20: FRACNPLL_DPLL_CTL7 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
24 (R/W)	PROGRAM	DPLL PROGRAM Control. The FRACNPLL_DPLL_CTL7.PROGRAM bit indicates diagnostic control (test mode) or normal operation. 0 - Diagnostic Mode 1 - Normal Operation
23 (R/W)	PRESET_EN	DPLL PRESET_EN Control. The FRACNPLL_DPLL_CTL7.PRESET_EN bit indicates whether the preset INT and FRAC values are loaded into DPLL. 0 - Normal Operation 1 - Switch to FRAC_PRESET and INT_PRESET and relock
22:15 (R/W)	PMP	DPLL PMP Control. The FRACNPLL_DPLL_CTL7.PMP bit field indicates the M gain for the proportional phase comparison loop where Gain=M * 2^K.
14:10 (R/W)	PKP	DPLL PKP Control. The FRACNPLL_DPLL_CTL7.PKP bit field indicates the K gain for the proportional phase comparison loop where Gain=M * 2^K.

Table 4-20: FRACNPLL_DPLL_CTL7 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
9:5 (R/W)	PH_STEP_CNT_HOLD	DPLL PH_STEP_CNT_HOLD Control. The `FRACNPLL_DPLL_CTL7.PH_STEP_CNT_HOLD` bit field indicates the PH_STEP_CNT value used after exiting from HOLD. Number of steps in phase lock process. Initial gain is Gain_init= M * 2^{K} * $2^{PH_STEP_CNT}$. Total lock count is PH_STEP_CNT*DELAYK.
4:0 (R/W)	PH_STEP_CNT	DPLL PH_STEP_CNT Control. The `FRACNPLL_DPLL_CTL7.PH_STEP_CNT` bit field indicates the number of steps in phase lock process. Initial gain is Gain_init= M * 2^{K} * $2^{PH_STEP_CNT}$. Total lock count is PH_STEP_CNT*DELAYK

DPLL Control Register 8

The FRACNPLL_DPLL_CTL8 register controls inputs for FIN pulses.

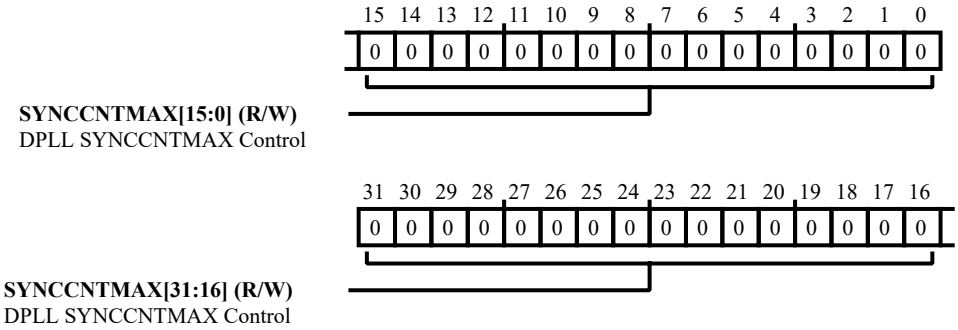

Figure 4-20: FRACNPLL_DPLL_CTL8 Register Diagram

Table 4-21: FRACNPLL_DPLL_CTL8 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	SYNCCNTMAX	DPLL SYNCCNTMAX Control. FIN pulses are counted for FRACNPLL_DPLL_CTL8.SYNCCNTMAX to determine a frequency match.

DPLL Control Register 9

The FRACNPLL_DPLL_CTL9 register holds the target pulse count used for frequency comparison.

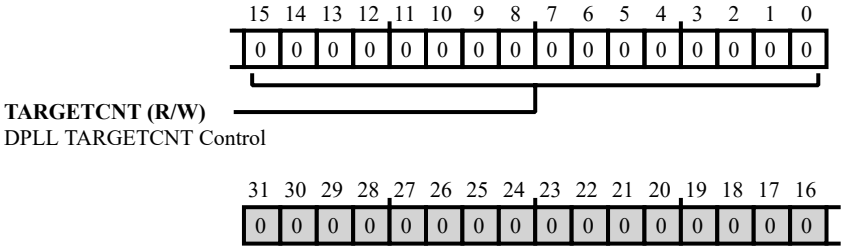

Figure 4-21: FRACNPLL_DPLL_CTL9 Register Diagram

Table 4-22: FRACNPLL_DPLL_CTL9 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	TARGETCNT	DPLL TARGETCNT Control. The FRACNPLL_DPLL_CTL9.TARGETCNT bit field indicates whether the number of pulse counts between FIN and FFB is less than TARGETCNT. The frequency comparator declares a frequency match (When FLOCK=1).

DPLL Status Register 0

The FRACNPLL_DPLL_STAT0 register contains the fractional portion of the feedback divide value.

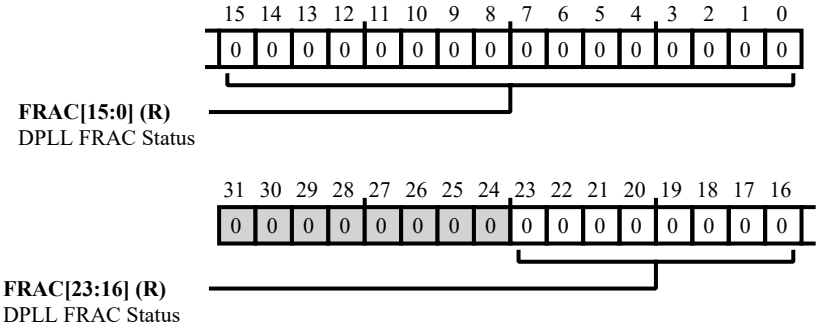

Figure 4-22: FRACNPLL_DPLL_STAT0 Register Diagram

Table 4-23: FRACNPLL_DPLL_STAT0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:0 (R/NW)	FRAC	DPLL FRAC Status. The FRACNPLL_DPLL_STAT0.FRAC bit field indicates the fractional portion of feedback divide value.

DPLL Status Register 1

The FRACNPLL_DPLL_STAT1 register contains the fractional portion of the phase detector integrator output.

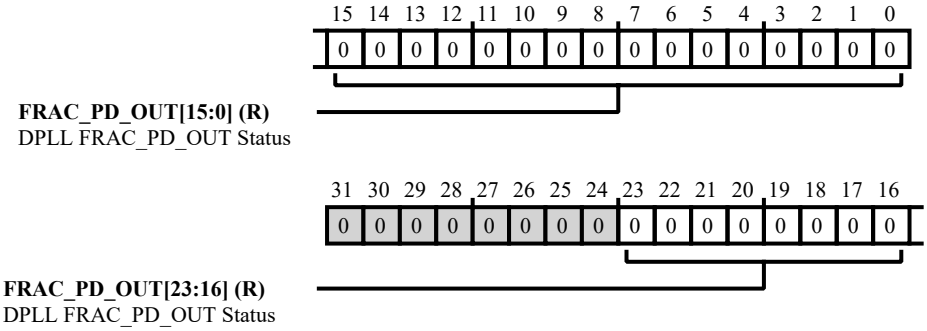

Figure 4-23: FRACNPLL_DPLL_STAT1 Register Diagram

Table 4-24: FRACNPLL_DPLL_STAT1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:0 (R/NW)	FRAC_PD_OUT	DPLL FRAC_PD_OUT Status. The FRACNPLL_DPLL_STAT1.FRAC_PD_OUT bit field indicates the fractional bits of the phase detector integrator output.

DPLL Status Register 2

The FRACNPLL_DPLL_STAT2 register contains the integer portion of the phase detector integrator output.

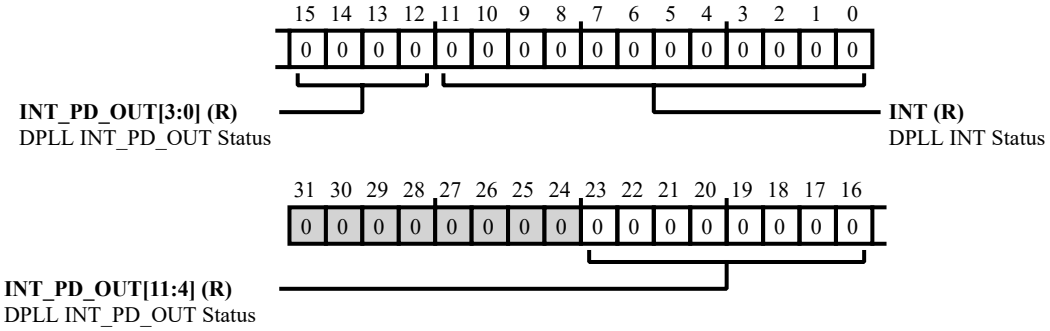

Figure 4-24: FRACNPLL_DPLL_STAT2 Register Diagram

Table 4-25: FRACNPLL_DPLL_STAT2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:12 (R/NW)	INT_PD_OUT	DPLL INT_PD_OUT Status. The FRACNPLL_DPLL_STAT2.INT_PD_OUT bit field indicates the integer bits of the phase detector integrator output.
11:0 (R/NW)	INT	DPLL INT Status. The FRACNPLL_DPLL_STAT2.INT bit field indicates the integer divider for Frac-N PLL, clocked out on the rising edge of CLKS.

Fractional PLL Control Register 0

The FRACNPLL_FPLL_CTL0 register contains the fractional divider setting for Fractional-N PLL, various power down controls, and bypass control.

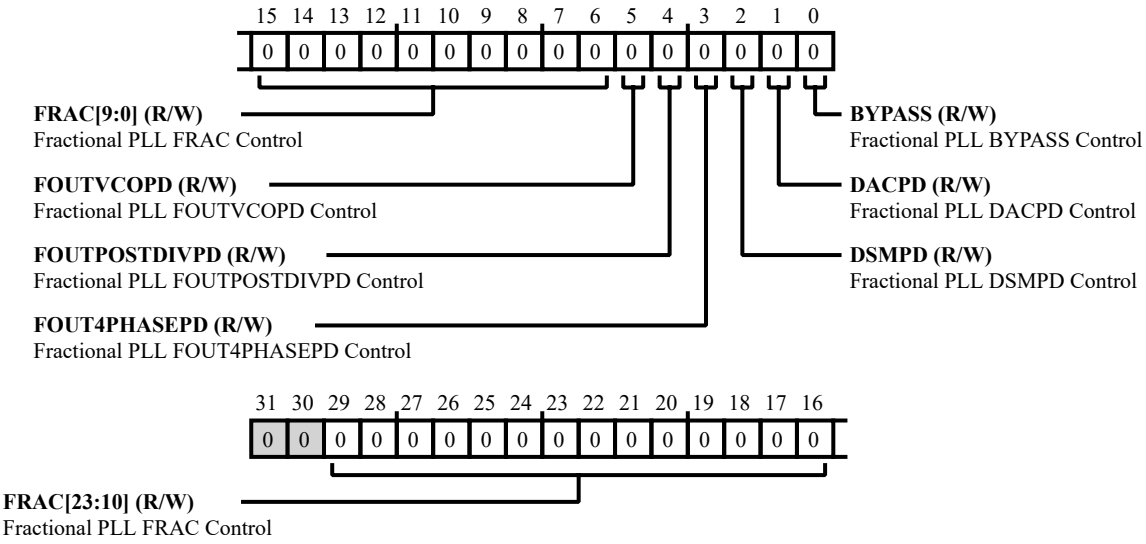

Figure 4-25: FRACNPLL_FPLL_CTL0 Register Diagram

Table 4-26: FRACNPLL_FPLL_CTL0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:6 (R/W)	FRAC	Fractional PLL FRAC Control. Fractional divider setting for Fractional-N PLL, clocked out on the rising edge of CLKS
5 (R/W)	FOUTVCOPD	Fractional PLL FOUTVCOPD Control. VCO rate output clock power down
4 (R/W)	FOUTPOSTDIVPD	Fractional PLL FOUTPOSTDIVPD Control. Post divide power down
3 (R/W)	FOUT4PHASEPD	Fractional PLL FOUT4PHASEPD Control. Power down of 4 phase clock generator; 4phase output is also powered down by FOUTPOSTDIVPD
2 (R/W)	DSMPD	Fractional PLL DSMPD Control. Power down Delta-Sigma Modulator; 0-> DSM is active; 1-> DSM is powered down
1 (R/W)	DACPD	Fractional PLL DACPD Control. Power down noise canceling DAC in FRAC mode; 0-> DAC is active (default mode); 1-> DAC is not active (test mode only)

Table 4-26: FRACNPLL_FPLL_CTL0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W)	BYPASS	Fractional PLL BYPASS Control. FREF is bypassed to FOUTPOSTDIV

Fractional PLL Control Register 1

The FRACNPLL_FPLL_CTL1 register contains the reference divide value, post divide setting, and feedback divide value.

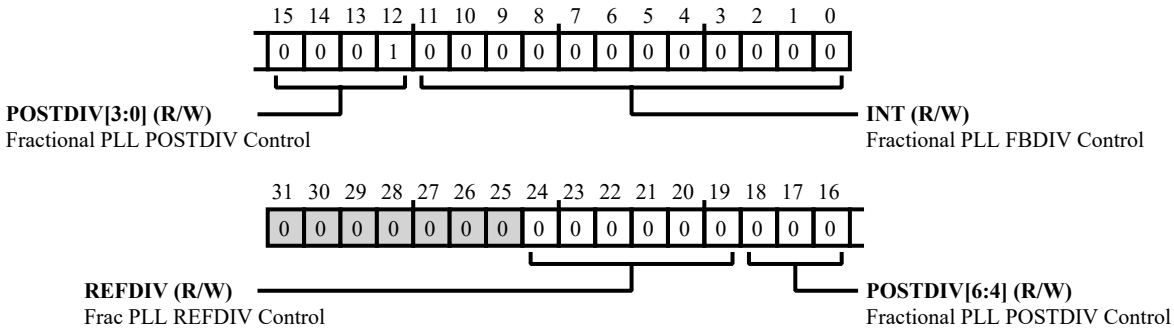

Figure 4-26: FRACNPLL_FPLL_CTL1 Register Diagram

Table 4-27: FRACNPLL_FPLL_CTL1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
24:19 (R/W)	REFDIV	Frac PLL REFDIV Control. Reference divide value (1 to 63)
18:12 (R/W)	POSTDIV	Fractional PLL POSTDIV Control. PLL post divide setting (1 to 127).
11:0 (R/W)	INT	Fractional PLL FBDIV Control. PLL feedback divide value (16 to 4095)

Integration Status Register

The FRACNPLL_STAT status register contains phase, frequency lock status of FPLL and DPLL along with DPLL transition status.

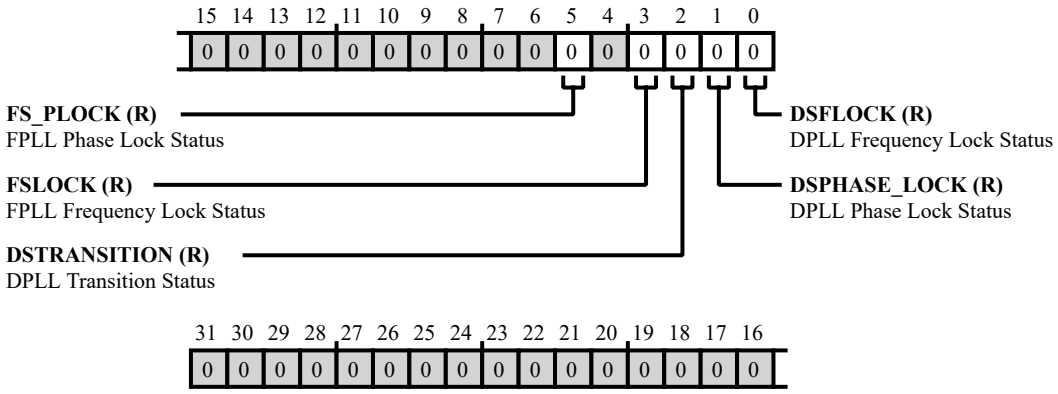

Figure 4-27: FRACNPLL_STAT Register Diagram

Table 4-28: FRACNPLL_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
5 (R/NW)	FS_PLOCK	FPLL Phase Lock Status. The FRACNPLL_STAT.FS_PLOCK bit indicates whether the FPLL has achieved a phase lock.
3 (R/NW)	FSLOCK	FPLL Frequency Lock Status. The FRACNPLL_STAT.FSLOCK bit indicates whether the FPLL has achieved a frequency lock.
2 (R/NW)	DSTRANSITION	DPLL Transition Status. The FRACNPLL_STAT.DSTRANSITION bit indicates the control transition output. Test Mode Output. When FRACNPLL_STAT.DSTRANSITION = 0, it occurs after transition to fine tune phase control (PHASE LOCK=1b1), When FRACNPLL_STAT.DSTRANSITION = 1, it occurs after phase control engaged (FLOCK=1b1).
1 (R/NW)	DSPHASE_LOCK	DPLL Phase Lock Status. The FRACNPLL_STAT.DSPHASE_LOCK bit indicates whether the DPLL is in fine tune phase tracking mode. When FRACNPLL_STAT.DSPHASE_LOCK = 1, the DPLL is settled and phase locked. When FRACNPLL_STAT.DSPHASE_LOCK = 0, the DPLL is still settling or (if FLOCK=1b0) not frequency locked.

Table 4-28: FRACNPLL_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/NW)	DSFLOCK	DPLL Frequency Lock Status. The `FRACNPLL_STAT.DSFLOCK` bit indicates whether the DPLL has achieved a frequency lock. When `FRACNPLL_STAT.DSFLOCK` = 1, the frequencies have maintained lock within TARGETCNT for OTDLY FFB clock periods When `FRACNPLL_STAT.DSFLOCK` = 0, the frequency comparator has detected a mismatch in FIN and FFB pulse counts.

5 Dynamic Power Management (DPM)

The dynamic power management (DPM) unit of the processor controls transitions between different power-saving modes.

DPM provides facility for shutting down clocks for various peripherals. Shutting down peripheral's clocks is considered a power saving feature. To support peripheral clock gating functionality, DPM_PER_DIS0 and DPM_PER_DIS1 are available in the DPM module. The bits in these registers need to be programmed to shut off the clocks to peripherals that are not used in an application to save clock switching power.

DPM Features

The DPM allows programs to control the power mode of the processor as follows.

- Permits operation of multiple, external wake-up sources

DPM Functional Description

The DPM can be programmed to transition between power modes.

ADSP-2184x DPM Register List

A set of registers govern DPM operations. For more information on DPM functionality, see the DPM register descriptions.

Table 5-1: ADSP-2184x DPM Register List

Name	Description
DPM_CTL	Control Register
DPM_PER_DIS0	Peripherals Disable Register 0
DPM_PER_DIS1	Peripherals Disable Register 1
DPM_REVID	Revision ID
DPM_STAT	Status Register

DPM Definitions

To make the best use of the DPM, it is useful to understand the following terms.

CGU

Acronym for the clock generation unit (CGU), which is comprised of the PLL and PCU

DPM

Acronym for the dynamic power management (DPM) controller.

Full-on mode

The normal operating mode in which all clock domains are derived from the PLL.

PCU

Acronym for the PLL control unit (PCU).

PLL

Acronym for the phase-locked loop (PLL).

RCU

Acronym for the reset control unit (RCU).

DPM Operating Modes

The DPM includes several operating modes. The modes are:

- Reset
- Full-on

Reset State

Reset is the initial state of the processor and is the result of a hardware or software triggered event. The DPM itself does not trigger entering reset. The external SYS_HWRST pin or the RCU triggers entering reset. The DPM responds to reset by transitioning to its default state.

From Reset, the DPM always transitions to PLL Bypassed state.

Full-on Mode

Full-on mode is the default state of the DPM after Reset.

In full-on mode, the processor can reach its maximum clock rate and power dissipation can be at its highest.

DPM Event Control

The DPM event is triggered when an enabled wake-up is asserted. The DPM generates bus errors when a misaligned access to a register occurs. It also generates errors when an attempt is made to access unused DPM address space or a write-protected register.

DPM Events

The DPM event interrupt is triggered when any bit in the DPM_STAT register is set, indicating that an enabled wake-up was asserted. The DPM event interrupt stays active until the user clears any bits that are set in the DPM_STAT register.

DPM Errors

The DPM generates a bus error when a read or write transaction is attempted to an unused address within the DPM address range. It also generates a bus error when a misaligned access is made to a DPM register. In addition to the bus error, the DPM sets the DPM_STAT.ADDRERR bit.

If a write to a write-protected DPM register is attempted, the DPM generates a bus error. In addition, the DPM sets the DPM_STAT.LWERR bit.

ADSP-2184x DPM Register Descriptions

Dynamic Power Management (DPM) contains the following registers.

Table 5-2: ADSP-2184x DPM Register List

Name	Description
DPM_CTL	Control Register
DPM_PER_DIS0	Peripherals Disable Register 0
DPM_PER_DIS1	Peripherals Disable Register 1
DPM_REVID	Revision ID
DPM_STAT	Status Register

Control Register

The DPM_CTL register controls sleep modes selections and PLL operations of the DPM. A write protect feature permits locking out changes to this register.

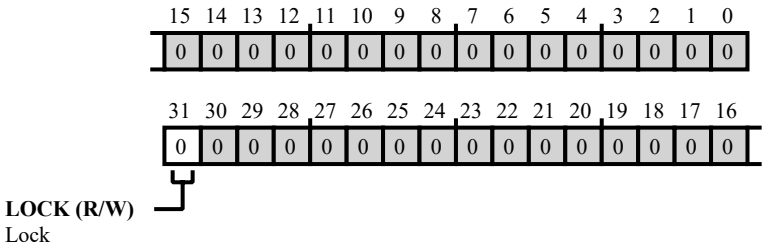

Figure 5-1: DPM_CTL Register Diagram

Table 5-3: DPM_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the DPM_CTL.LOCK bit is set, the DPM_CTL register is read only (locked).	
		0	Unlock
		1	Lock

Peripherals Disable Register 0

The DPM_PER_DIS0 register is used to shut off the clocks to peripherals that are not used in an application in order to save clock switching power.

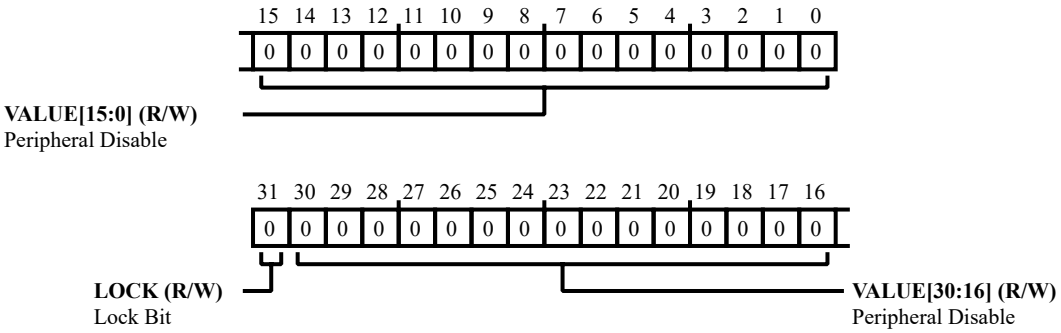

Figure 5-2: DPM_PER_DIS0 Register Diagram

Table 5-4: DPM_PER_DIS0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock Bit.	
30:0 (R/W)	VALUE	Peripheral Disable. The DPM_PER_DIS0.VALUE bits are used to shut of clocks in individual peripherals.	
		0	SH0_FIR0
		1	SH0_IIR0

Revision ID

The DPM_REVID register provides the revision of the DPM module.

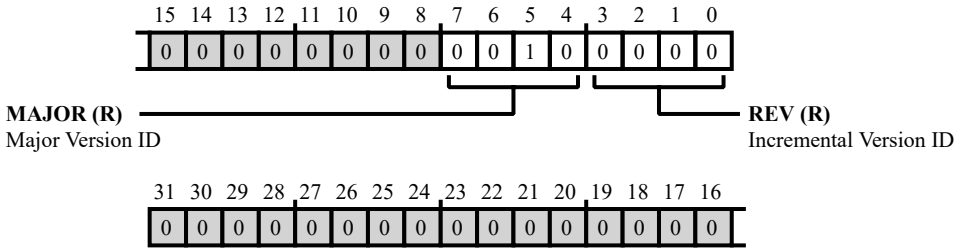

Figure 5-4: DPM_REVID Register Diagram

Table 5-6: DPM_REVID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:4 (R/NW)	MAJOR	Major Version ID.
3:0 (R/NW)	REV	Incremental Version ID.

Status Register

The DPM_STAT register contains bits that report the state of the module and various errors.

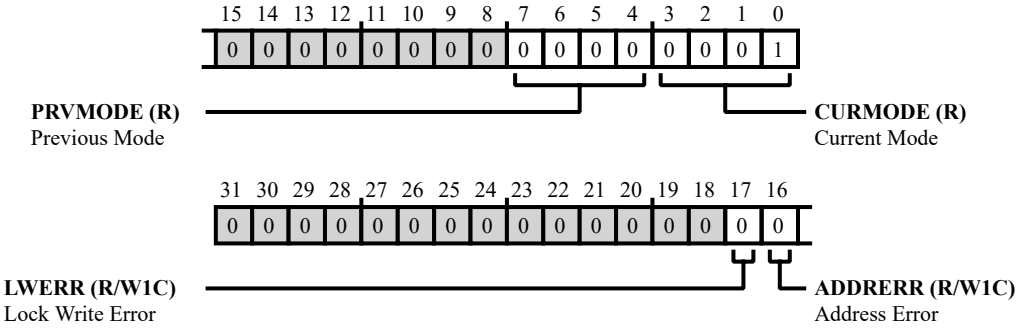

Figure 5-5: DPM_STAT Register Diagram

Table 5-7: DPM_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W1C)	LWERR	Lock Write Error. The DPM_STAT.LWERR bit indicates that a write transaction attempted an access to a write protected register. Triggers the DPMLV_PSLVERR interrupt.	
		0	Inactive
		1	Active
16 (R/W1C)	ADDRERR	Address Error. The DPM_STAT.ADDRERR bit indicates that a read or write transaction attempted an access to an unimplemented address or a write transaction attempted an access to a read only register or accesses are non aligned. Triggers the DPMLV_PSLVERR interrupt.	
		0	Inactive
		1	Active
7:4 (R/NW)	PRVMODE	Previous Mode. The DPM_STAT.PRVMODE bit field indicates the previous mode of the module.	
		0	Reset
		1	Full-On
		2	Reserved
		3	Reserved
		4	Reserved
		5-15	Reserved

Table 5-7: DPM_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3:0 (R/NW)	CURMODE	Current Mode. The `DPM_STAT.CURMODE` bit field indicates the current mode of the module.	
		0	Reserved
		1	Full-On
		2	Reserved
		3	Reserved
		4-15	Reserved

6 Reset Control Unit (RCU)

Reset is the initial state of the processor at power-on or the run-time state of any core, as controlled by another core in the device using the RCU or as a result of a hardware or software triggered event. In this state, all control registers are set to their default values and functional units are idle. Exiting a full system hardware reset results with only the host core being released from reset and ready to boot (core 1(SHARC-FX) on the ADSP-2184x/SC84x processors).

The following table shows the cores that are released from reset. Exiting core n only reset starts with this core n being ready to execute the code from the software vector register (RCU_SVECT2).

Additional information on reset and booting can be found in the *Boot ROM and Booting the Processor* chapter.

Product	Core Released from Reset by RCU
ADSP-2184x	Core 1
ADSP-SC84x	Core 0

The Reset Control Unit (RCU) controls how all the functional units enter and exit reset. Differences in functional requirements and clocking constraints define how reset signals are generated. Programs must guarantee that none of the reset functions puts the system into an undefined state or causes resources to stall. This functionality is important when only one of the cores is reset (programs must ensure that there is no pending system activity involving the core that is being reset). While core resets and software system resets are controlled directly in the RCU, hardware resets can come from the TRU or SEC.

RCU Features

The RCU module supports the following features:

- Hardware reset through the $\overline{\text{SYS_HWRST}}$ pin
- Software system reset through the RCU control (RCU_CTL) register
- Hardware system reset through:
  - TRU module
  - SEC module (System Fault Unit)
- Core reset through RCU Core Reset Output (RCU_CRCTL) register

RCU Functional Description

This section provides information on the function of RCU module.

Software reset using RCU registers

Setting the RCU_STAT.SWRST bit issues a software reset for all system units except the RTC module and RCU_BCODE, RCU_CRCTL and RCU_STAT registers.

Core reset RCU registers

A core can be individually reset by software, or by setting the RCU_CRCTL.CR[n] bit.

ADSP-2184x RCU Register List

The Reset Control Unit (RCU) controls how all the functional units in the processor enter and exit Reset. Differences in functional requirements and clocking constraints exist (units in different clock domains have to enter reset asynchronously, but units exit reset in a deterministic way), and these differences define how reset signals are generated. Reset signals propagate through all functional units asynchronously. For more information on RCU functionality, see the RCU register descriptions.

Table 6-1: ADSP-2184x RCU Register List

Name	Description
RCU_BCODE	Boot Code Register
RCU_CRCTL	Core Reset Outputs Control Register
RCU_CRSTAT	Core Reset Outputs Status Register
RCU_CTL	Control Register
RCU_MSG	Message Register
RCU_MSG_CLR	Message Clear Bits Register
RCU_MSG_SET	Message Set Bits Register
RCU_SIDIS	System Interface Disable Register
RCU_SISTAT	System Interface Status Register
RCU_SRRQSTAT	System Reset Request Status Register
RCU_STAT	Status Register
RCU_SVECT0	Software Vector Register 0
RCU_SVECT1	Software Vector Register 1
RCU_SVECT2	Software Vector Register 2
RCU_SVECT_LCK	SVECT Lock Register

ADSP-2184x RCU Trigger List

Table 6-2: ADSP-2184x RCU Trigger List Generators

Trigger ID	Name	Description	Sensitivity
None			

Table 6-3: ADSP-2184x RCU Trigger List Receivers

Trigger ID	Name	Description	Sensitivity
147	RCU0_SYSRST0	RCU0 System Reset Receiver 0	Pulse
148	RCU0_SYSRST1	RCU0 System Reset Receiver 1	Pulse

RCU Definitions

To make the best use of the RCU, it is useful to understand the terms in this section.

The target or source defines the following are types of resets.

Hardware Reset (by target)

All functional units except a small subsection of debug interfaces are set to their default states. State is lost in all non-volatile storage.

System Reset (by target)

All functional units except the RCU, flash interface, and debug are set to their default states.

Core n Only Reset (by target)

Affects Core n only. The system software must guarantee that a bus requester cannot access the core in reset state.

Hardware Reset (by source)

The $\overline{\text{SYS_HWRST}}$ input signal is asserted active (pulled low).

System Reset (by source)

Software can trigger the reset by writing to the RCU_CTL register or by another functional unit such as the TRU or any of the generic reset inputs.

RCU Architectural Concepts

To understand the architecture of the RCU, it is important to consider the reset sources and how differing resets affect the functional units of the processor.

The RCU provides the hardware that controls how all the functional units enter and exit reset. Differences in functional requirements and clocking constraints define how reset signals are generated. For example, units in different clock domains must enter reset asynchronously but exit reset in a deterministic way.

The program must guarantee that none of the reset functions put the system in an undefined state or cause resources to stall. This functionality is important when only one of the cores is reset. The program must guarantee that there is no pending system activity involving Core n before it is reset. For example, there must be no pending transactions to core 0 when the core 0 is reset and vice-versa.

The ***RCU Reset Sources*** table defines how reset sources affect the different functional units.

Table 6-4: RCU Reset Sources

Reset Source	Reset Type	Affected Functional Units
SYSCLK clock domain system reset by the Fault Unit (FMU) or TRU completer	System Reset	All functional units, except: • RTC (if present) • RCU_STAT • RCU_BCODE • the units on the VDDEXT power domain
`RCU_CTL.SYSRST` bit set (software triggered reset)	System Reset	All functional units, except: • RTC (if present) • RCU_STAT • RCU_BCODE • the units on the VDDEXT power domain
`RCU_CRCTL.CR[n]` bit set (software triggered reset)	Core Only Reset	Core n only

RCU Status and Error Signals

The `RCU_STAT` register reflects status and error information. There are three kinds of errors that can occur in the RCU. The reset out error is triggered when `RSTOUT` is both asserted and deasserted at the same time. The lock write error occurs if an attempt is made to write a lock RCU register. The address error occurs if a read-only register is written to or if an attempt is made to a reserved address within the RCU MMR address range.

Core n Reset In

Core n can be requested to stop its IO activity and acknowledge to the requester when the task is completed.

To reset core n:

1. Clear the `RCU_CRSTAT.CR[n]` bit.
2. Disable interrupts to core n.
3. Set (=1) `RCU_CRCTL.CR[n]` to reset core n.

4. Check the RCU_CRSTAT.CR[n] bit. If core n is in reset, continue.

Core n Reset Out

To take core n out of reset:

1. Clear the RCU_CRCTL.CR[n] bit.
2. Check the RCU_CRSTAT.CR[n] bit. If core n is in out of reset, continue.

ADSP-2184x RCU Register Descriptions

Reset Control Unit (RCU) contains the following registers.

Table 6-5: ADSP-2184x RCU Register List

Name	Description
RCU_BCODE	Boot Code Register
RCU_CRCTL	Core Reset Outputs Control Register
RCU_CRSTAT	Core Reset Outputs Status Register
RCU_CTL	Control Register
RCU_MSG	Message Register
RCU_MSG_CLR	Message Clear Bits Register
RCU_MSG_SET	Message Set Bits Register
RCU_SIDIS	System Interface Disable Register
RCU_SISTAT	System Interface Status Register
RCU_SRRQSTAT	System Reset Request Status Register
RCU_STAT	Status Register
RCU_SVECT0	Software Vector Register 0
RCU_SVECT1	Software Vector Register 1
RCU_SVECT2	Software Vector Register 2
RCU_SVECT_LCK	SVECT Lock Register

Boot Code Register

The RCU_BCODE register can be used to determine if and how core boots. This register is set to its default values by RESET.

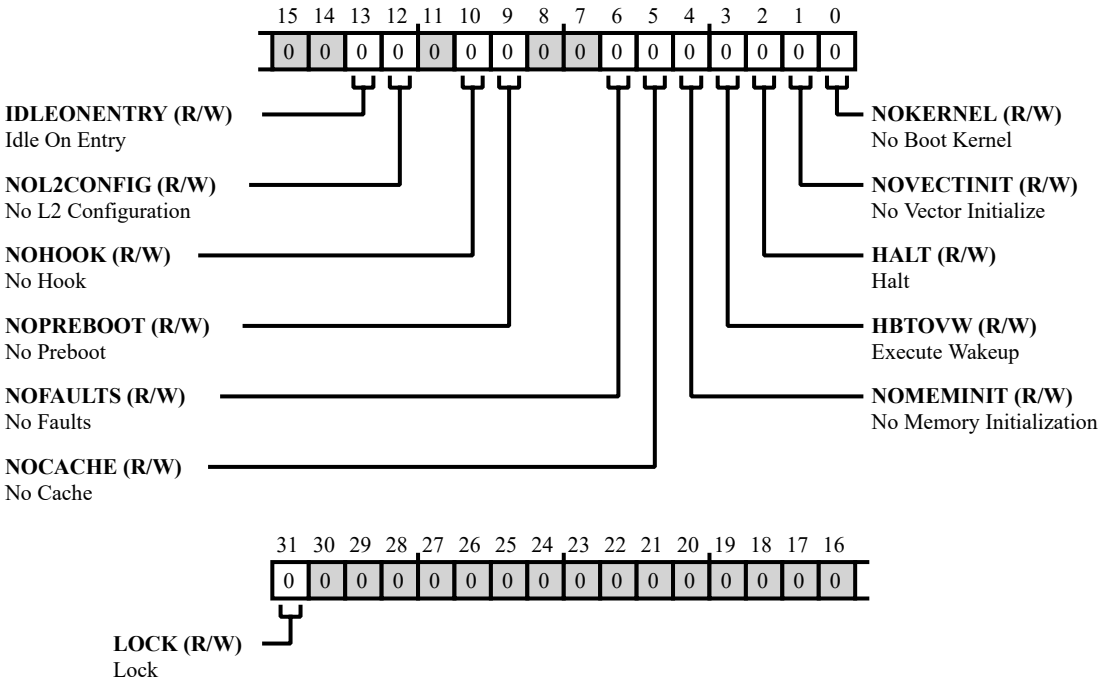

Figure 6-1: RCU_BCODE Register Diagram

Table 6-6: RCU_BCODE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the RCU_BCODE.LOCK bit is set, the RCU_BCODE register is read only (locked).	
		0	Unlock
		1	Lock
13 (R/W)	IDLEONENTRY	Idle On Entry. The RCU_BCODE.IDLEONENTRY bit configures the RCU to enter the idle state at startup.	
		0	Do not enter idle state
		1	Enter idle state

Table 6-6: RCU_BCODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	NOL2CONFIG	No L2 Configuration. The `RCU_BCODE.NOL2CONFIG` bit configures the RCU to not perform the L2 memory configuration.	
		0	Configure L2 memory
		1	Do not configure L2 memory
10 (R/W)	NOHOOK	No Hook. The `RCU_BCODE.NOHOOK` bit configures the RCU to not perform the hook routine.	
		0	Perform hook routine
		1	Do not perform hook routine
9 (R/W)	NOPREBOOT	No Preboot. The `RCU_BCODE.NOPREBOOT` bit configures the RCU to not perform the customer preboot routine.	
		0	Perform preboot
		1	Do not perform preboot
6 (R/W)	NOFAULTS	No Faults. The `RCU_BCODE.NOFAULTS` bit configures the RCU to not perform fault initialization.	
		0	Perform fault initialization
		1	Do not perform fault initialization
5 (R/W)	NOCACHE	No Cache. The `RCU_BCODE.NOCACHE` bit configures the RCU to not perform a cache initialization and to not enable the cache.	
		0	Enable and initialize cache
		1	Do not initialize or enable cache
4 (R/W)	NOMEMINIT	No Memory Initialization. The `RCU_BCODE.NOMEMINIT` bit configures the RCU to not perform a memory initialization.	
		0	Perform memory initialization
		1	Do not perform memory initialization

Table 6-6: RCU_BCODE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	HBTOVW	Execute Wakeup. The `RCU_BCODE.HBTOVW` bit configures the RCU to execute a wakeup.	
		0	Do not wakeup
		1	Execute wakeup
2 (R/W)	HALT	Halt. The `RCU_BCODE.HALT` bit configures the RCU to execute the no boot routine.	
		0	Do not execute routine
		1	Execute routine
1 (R/W)	NOVECTINIT	No Vector Initialize. The `RCU_BCODE.NOVECTINIT` bit configures the RCU to not vector to the application.	
		0	Vector
		1	Do not vector
0 (R/W)	NOKERNEL	No Boot Kernel. The `RCU_BCODE.NOKERNEL` bit configures the RCU to not execute the boot kernel.	
		0	Execute boot kernel
		1	Do not execute boot kernel

Core Reset Outputs Control Register

The RCU core reset control n registers (RCU_CRCTL) include a lock bit (RCU_CRCTL.LOCK) and a core reset bit (RCU_CRCTL.CR[n]) for each core reset signal on the product.

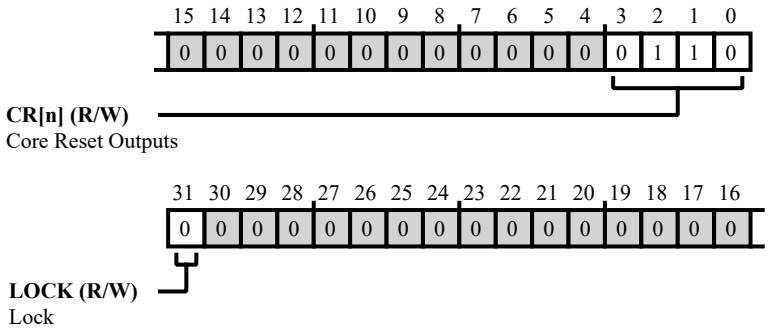

Figure 6-2: RCU_CRCTL Register Diagram

Table 6-7: RCU_CRCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the RCU_CRCTL.LOCK bit is set, the RCU_CRCTL register is read only (locked).	
		0	Unlock
		1	Lock
3:0 (R/W)	CR[n]	Core Reset Outputs. The RCU_CRCTL.CR[n] bits control CRES[1:0] core reset signals. The RCU_CRES[n] signals can be individually controlled. They are reset to their default value by a hard reset or a system reset. For each RCU_CRES[n], the selected RCU0_CRMSKi[n] bit is cleared.	
		0	RCU_CRES[3:0] Deasserted
		1	Reserved
		2	RCU_CRES[1] SHARC0 reset control bit asserted
		4	RCU_CRES[2] A55 reset control bit asserted
		8	RCU_CRES[3] DEBUG reset control bit asserted
		15	RCU_CRES[3:0] Asserted

Core Reset Outputs Status Register

The RCU core reset status register (RCU_CRSTAT) contains status bits, indicating which core reset signals have been asserted.

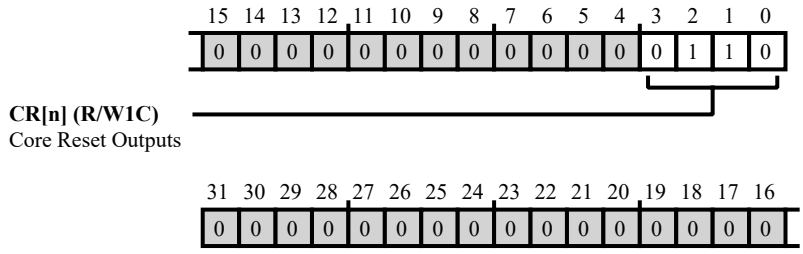

Figure 6-3: RCU_CRSTAT Register Diagram

Table 6-8: RCU_CRSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
3:0 (R/W1C)	CR[n]	Core Reset Outputs. The RCU_CRSTAT.CR[n] bits indicate which cores have been reset since the last time the bit was cleared. Bits masked by CORE_DISABLE_MASK[15:0] are permanently disabled and the corresponding CR bits set. CR bits are sticky, they need to be cleared by software.	
		0	RCU_CRES[1:0] deasserted. CR[n] corresponds to RCU_CRES[n].
		1	RCU_CRES[0] ARM A5 reset control bit asserted
		2	RCU_CRES[1] SHARC0 reset control bit asserted
		4	RCU_CRES[2] A55 reset control bit asserted
		8	RCU_CRES[3] DEBUG reset control bit asserted
		15	RCU_CRES[3:0] were asserted since the last time bits were cleared. CR[n] corresponds to RCU_CRES[n].

Control Register

The RCU control register (RCU_CTL) provides a register lock, enables for the core and system reset requests inputs and control for the Reset Output pin.

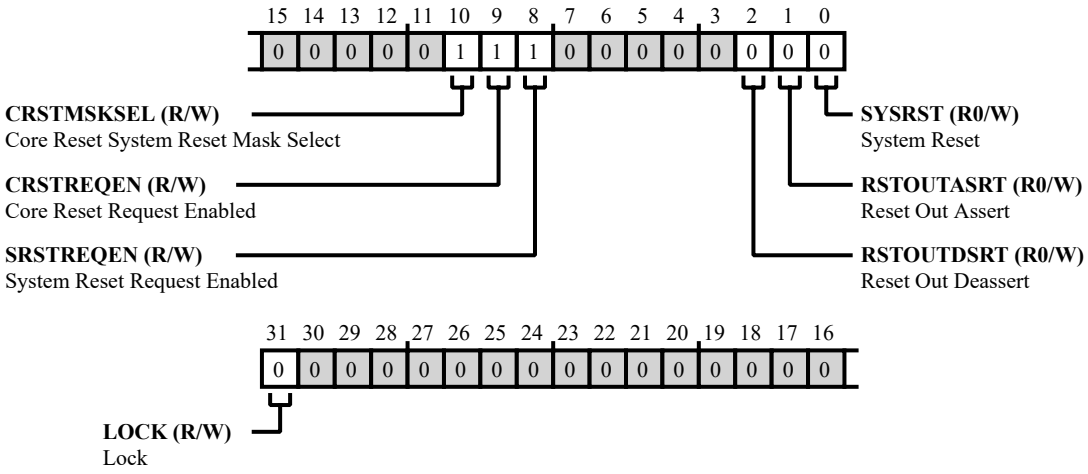

Figure 6-4: RCU_CTL Register Diagram

Table 6-9: RCU_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the RCU_CTL.LOCK bit is set, the RCU_CTL register is read only (locked). This bit is cleared by a hard reset or any system reset event.	
		0	Unlock
		1	Lock
10 (R/W)	CRSTMSKSEL	Core Reset System Reset Mask Select. The RCU_CTL.CRSTMSKSEL bit selects the core reset system reset mask. This bit is cleared by a hard reset.	
9 (R/W)	CRSTREQEN	Core Reset Request Enabled. The RCU_CTL.CRSTREQEN bit controls whether the SYSCLK domain source(s) of reset is/are enabled to reset the core(s) when asserted. This bit is cleared by hard reset or any system reset event.	
		0	Disabled
		1	Enabled

Table 6-9: RCU_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	SRSTREQEN	System Reset Request Enabled. The RCU_CTL.SRSTREQEN bit controls whether the SYSCLK domain sources of reset are enabled to do a system reset when asserted. This bit is cleared by a hard reset.	
		0	Disabled
		1	Enabled
2 (R0/W)	RSTOUTDSRT	Reset Out Deassert. The RCU_CTL.RSTOUTDSRT bit controls the deassertion of the system reset pin.	
		0	No Action
		1	Deassert RSTOUT
1 (R0/W)	RSTOUTASRT	Reset Out Assert. The RCU_CTL.RSTOUTASRT bit controls assertion of the system reset pin.	
		0	No Action
		1	Assert RSTOUT
0 (R0/W)	SYSRST	System Reset. The RCU_CTL.SYSRST bit provides reset for all system units.	
		0	No Action
		1	System Reset

Message Register

The RCU_MSG is a general-purpose register. It is intended to provide flexibility for Boot ROM code and to pass predefined variables to the debugger. Please see the Booting chapter for product-specific details.

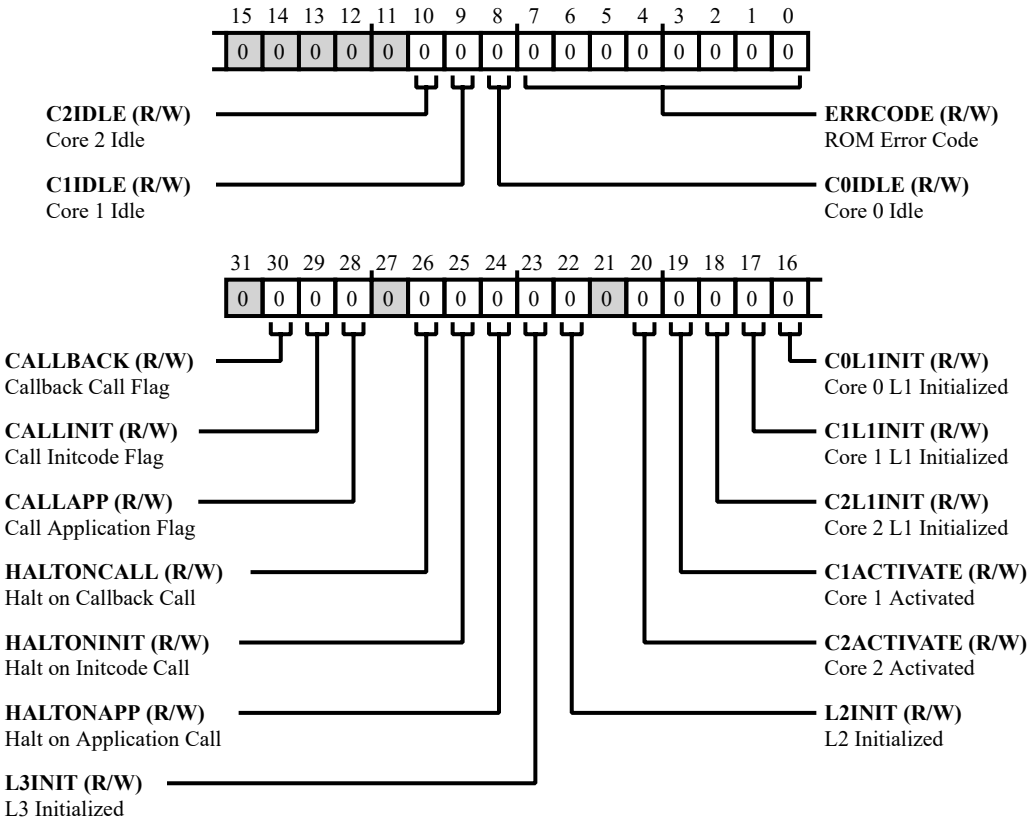

Figure 6-5: RCU_MSG Register Diagram

Table 6-10: RCU_MSG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
30 (R/W)	CALLBACK	Callback Call Flag. The RCU_MSG.CALLBACK bit indicates that a flag has been set by the boot code prior to a callback call.	
		0	Flag not set
		1	Flag set

Table 6-10: RCU_MSG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R/W)	CALLINIT	Call Initcode Flag. The `RCU_MSG.CALLINIT` bit indicates that a flag has been set by the boot code prior to an initcode call.	
		0	Flag not set
		1	Flag set
28 (R/W)	CALLAPP	Call Application Flag. The `RCU_MSG.CALLAPP` bit indicates that a flag has been set by the boot code prior to an application call.	
		0	Flag not set
		1	Flag set
26 (R/W)	HALTONCALL	Halt on Callback Call. The `RCU_MSG.HALTONCALL` bit generates an emulation exception prior to a callback call.	
		0	Do not generate exception
		1	Generate exception
25 (R/W)	HALTONINIT	Halt on Initcode Call. The `RCU_MSG.HALTONINIT` bit generates an emulation exception prior to an initcode call.	
		0	Do not generate exception
		1	Generate exception
24 (R/W)	HALTONAPP	Halt on Application Call. The `RCU_MSG.HALTONAPP` bit generates an emulation exception prior to an application call.	
		0	Do not generate exception
		1	Generate exception
23 (R/W)	L3INIT	L3 Initialized. The `RCU_MSG.L3INIT` bit indicates that the L3 resource is initialized.	
		0	Resource not initialized
		1	Resource initialized
22 (R/W)	L2INIT	L2 Initialized. The `RCU_MSG.L2INIT` bit indicates that the L2 resource is initialized.	
		0	Resource not initialized
		1	Resource initialized

Table 6-10: RCU_MSG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
20 (R/W)	C2ACTIVATE	Core 2 Activated. The RCU_MSG.C2ACTIVATE bit is used by tools for activation of Core 2.	
19 (R/W)	C1ACTIVATE	Core 1 Activated. The RCU_MSG.C1ACTIVATE bit is used by tools for activation of Core 1.	
18 (R/W)	C2L1INIT	Core 2 L1 Initialized. The RCU_MSG.C2L1INIT bit indicates that the core 2 L1 resource is initialized.	
17 (R/W)	C1L1INIT	Core 1 L1 Initialized. The RCU_MSG.C1L1INIT bit indicates that the core 1 L1 resource is initialized.	
		0	Resource not initialized
		1	Resource initialized
16 (R/W)	C0L1INIT	Core 0 L1 Initialized. The RCU_MSG.C0L1INIT bit indicates that the core 0 L1 resource is initialized.	
		0	Resource not initialized
		1	Resource initialized
10 (R/W)	C2IDLE	Core 2 Idle. The RCU_MSG.C2IDLE bit indicates that core 2 is in a safe idle state in ROM.	
9 (R/W)	C1IDLE	Core 1 Idle. The RCU_MSG.C1IDLE bit indicates that core 1 is in a safe idle state in ROM.	
8 (R/W)	C0IDLE	Core 0 Idle. The RCU_MSG.C0IDLE bit indicates that core 0 is in a safe idle state in ROM.	
7:0 (R/W)	ERRCODE	ROM Error Code. The RCU_MSG.ERRCODE bit indicates the error code of the ROM. It is valid only when in the error handler.	

Message Clear Bits Register

The RCU_MSG_CLR register is used to clear bits in RCU_MSG register. Reading this register returns 0x00000000.

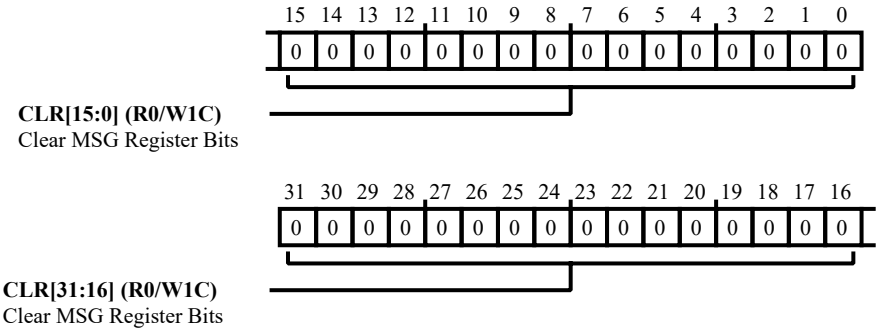

Figure 6-6: RCU_MSG_CLR Register Diagram

Table 6-11: RCU_MSG_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R0/W1C)	CLR	Clear MSG Register Bits. The RCU_MSG_CLR.CLR bit resets MSG bit n.

Message Set Bits Register

The RCU_MSG_SET register is used to set bits in RCU_MSG register. Reading this register returns 0x00000000.

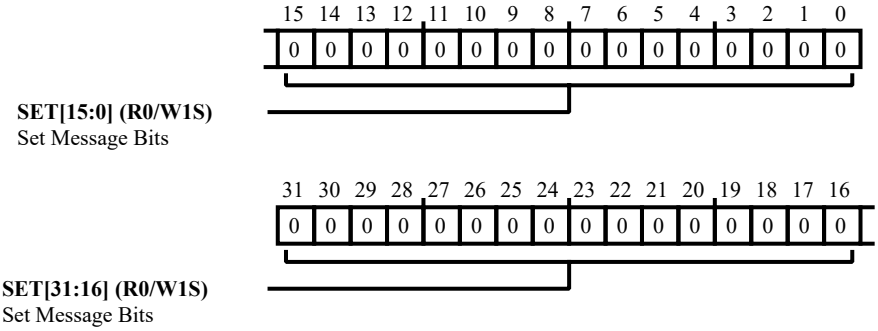

Figure 6-7: RCU_MSG_SET Register Diagram

Table 6-12: RCU_MSG_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R0/W1S)	SET	Set Message Bits. The RCU_MSG_SET.SET bit sets MSG bit n.

System Interface Disable Register

The RCU system interface disable register (RCU_SIDIS) lets the RCU assert a system interface disable request to functional units in the processor. This register is set to its default values by a hard reset or any system reset event. For information on mapping between RCU_SIDIS bits and functional units, see the RCU functional description.

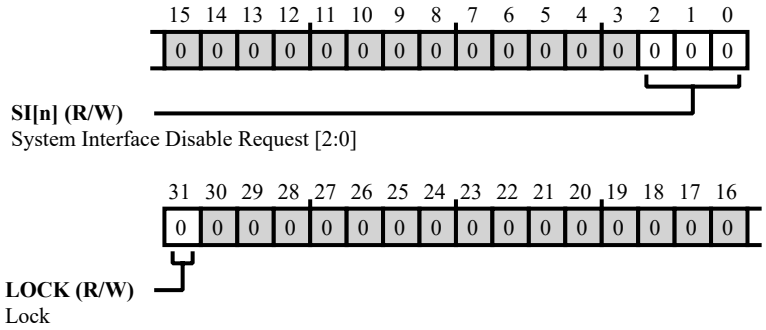

Figure 6-8: RCU_SIDIS Register Diagram

Table 6-13: RCU_SIDIS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the RCU_SIDIS.LOCK bit is set, the RCU_SIDIS register is read only (locked).	
		0	Unlock
		1	Lock
2:0 (R/W)	SI[n]	System Interface Disable Request [2:0]. Each RCU_SIDIS.SI[n] bit corresponds to a functional unit in the processor that supports the system interface disable request-acknowledge protocol.	
		0	RCU_SI_DISABLE_REQ[2:0] deasserted
		1	RCU_SI_DISABLE_REQ[0] system interface disable request to SHARC0 asserted
		2	RCU_SI_DISABLE_REQ[1] system interface disable request to A55 asserted
		4	Reserved
		7	RCU_SI_DISABLE_REQ[2:0] asserted

System Interface Status Register

The RCU system interface status register (RCU_SISTAT) indicates whether a functional unit has or has not acknowledged an RCU unit disable request.

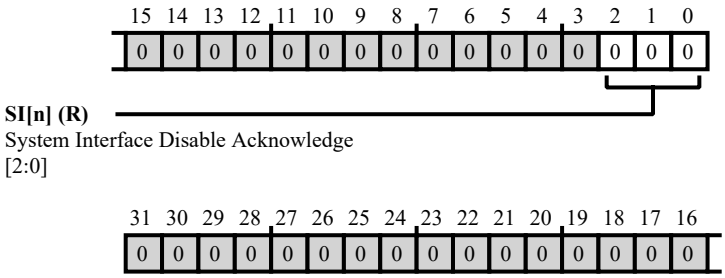

Figure 6-9: RCU_SISTAT Register Diagram

Table 6-14: RCU_SISTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
2:0 (R/NW)	SI[n]	System Interface Disable Acknowledge [2:0]. The RCU_SISTAT.SI[n] bit indicates whether a functional unit has or has not acknowledged an RCU unit disable request.	
		0	No Acknowledge
		1	RCU_SI_DISABLE_ACK[0] system interface disable acknowledge from SHARC0 asserted
		2	RCU_SI_DISABLE_ACK[1] system interface disable acknowledge from A55 asserted
		4	Reserved
		7	SI_DISABLE_ACK[2:0] asserted

System Reset Request Status Register

The RCU system reset request status register (RCU_SRRQSTAT) contains status bits, indicating which system reset request input triggered a system reset. This register is set to its default values by a hard reset.

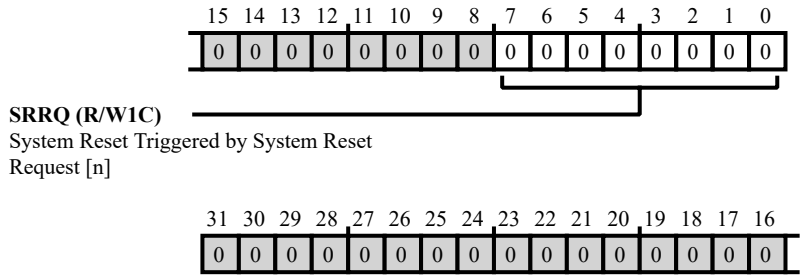

Figure 6-10: RCU_SRRQSTAT Register Diagram

Table 6-15: RCU_SRRQSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7:0 (R/W1C)	SRRQ	System Reset Triggered by System Reset Request [n]. The RCU_SRRQSTAT.SRRQ bits are set by the assertion of the corresponding system reset request input and deasserted by writing "1" to the bit. The RCU_SRRQSTAT register is cleared by a hard reset.	
		1	RCU_SRRQ[0], System Reset Request from SEC asserted
		2	RCU_SRRQ[1], System Reset Request from TRGS_RCU0_SYSRST0 asserted
		4	RCU_SRRQ[2], System Reset Request from TRGS_RCU0_SYSRST1 asserted
		8	RCU_SRRQ[3], System Reset Request from CTI3 asserted

Status Register

The RCU status register (RCU_STAT) contains status bits for all RCU reset sources, reset status, and boot mode inputs. Status bits for reset sources are sticky and can cleared by software. Error status bits are cleared by any reset event.

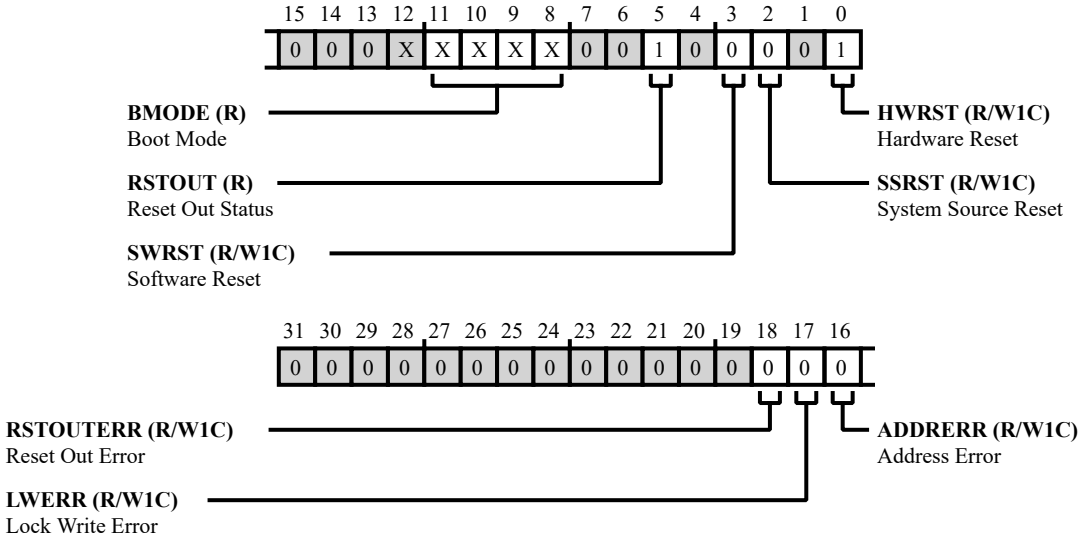

Figure 6-11: RCU_STAT Register Diagram

Table 6-16: RCU_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
18 (R/W1C)	RSTOUTERR	Reset Out Error. The RCU_STAT.RSTOUTERR bit indicates (if set) that a write attempted to set the RCU_CTL.RSTOUTASRT and RCU_CTL.RSTOUTDSRT simultaneously. This condition triggers a bus error.	
		0	No Error
		1	Error Occurred
17 (R/W1C)	LWERR	Lock Write Error. The RCU_STAT.LWERR bit indicates (when set) there was an attempted write to an RCU register while the RCU_CTL.LOCK bit was set and the global lock bit is enabled (SPU_CTL.GLCK bit =1). This status bit is sticky; write-1-to-clear	
		0	No Error
		1	Error Occurred

Table 6-16: RCU_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W1C)	ADDRERR	Address Error. The RCU_STAT.ADDRERR bit indicates that the RCU generated an address error. This status bit is sticky; write-1-to-clear it.	
		0	No Error
		1	Error Occurred
11:8 (R/NW)	BMODE	Boot Mode. The RCU_STAT.BMODE bits indicate the input on the boot mode pins.	
5 (R/NW)	RSTOUT	Reset Out Status. The RCU_STAT.RSTOUT bit indicates the assertion status of the system reset pin.	
		0	RSTOUT Deasserted
		1	RSTOUT Asserted
3 (R/W1C)	SWRST	Software Reset. The RCU_STAT.SWRST bit indicates that a system reset (which was triggered by software) has occurred since the last time a hardware reset occurred or since the RCU_STAT.SWRST bit was cleared by software.	
		0	Inactive
		1	Reset Occurred
2 (R/W1C)	SSRST	System Source Reset. The RCU_STAT.SSRST bit indicates that a system reset triggered by hardware in the system clock domain, clock A domain, or clock B domain has occurred since the last time a hardware reset occurred or since the RCU_STAT.SSRST bit was cleared by software.	
		0	Inactive
		1	Reset Occurred
0 (R/W1C)	HWRST	Hardware Reset. The RCU_STAT.HWRST bit indicates that a hardware reset has occurred.	
		0	Inactive
		1	Reset Occurred

Software Vector Register 0

The RCU_SVECT0 register contains the default location of the first instruction to execute after a reset.

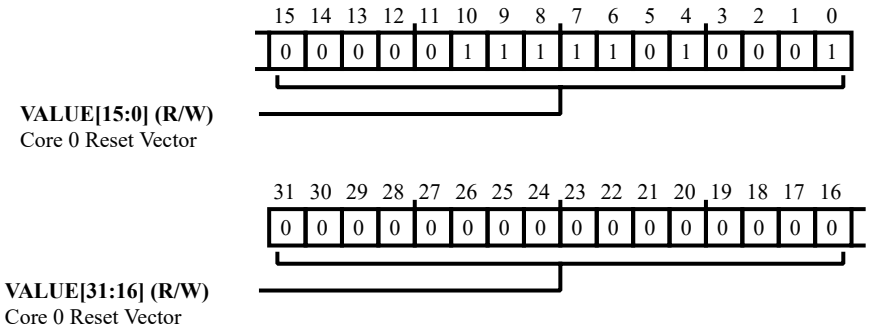

Figure 6-12: RCU_SVECT0 Register Diagram

Table 6-17: RCU_SVECT0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Core 0 Reset Vector. Core0 jumps to the address in the RCU_SVECT0.VALUE bit field after reset.

Software Vector Register 1

The RCU_SVECT1 register contains the default location of the first instruction to execute after a reset.

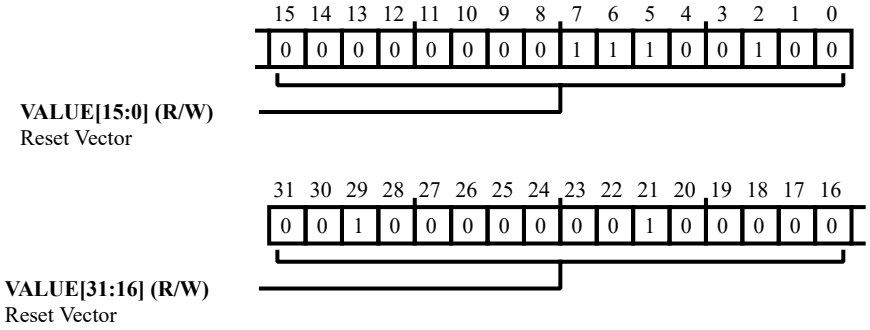

Figure 6-13: RCU_SVECT1 Register Diagram

Table 6-18: RCU_SVECT1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Reset Vector. Core1 jumps to the address in the RCU_SVECT1.VALUE bit field after reset.

Software Vector Register 2

The RCU_SVECT2 register contains the default location of the first instruction to execute after a reset.

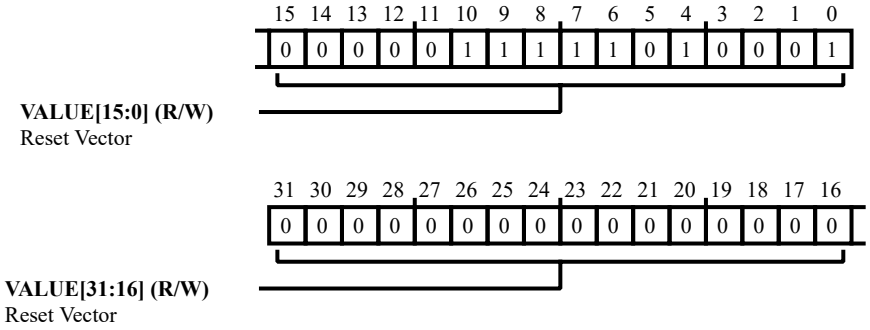

Figure 6-14: RCU_SVECT2 Register Diagram

Table 6-19: RCU_SVECT2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Reset Vector. Core2 jumps to the address in the RCU_SVECT2.VALUE bit field after reset.

SVECT Lock Register

The RCU software vector lock register (RCU_SVECT_LCK) provides a register lock and software vector n enable bits for each processor core on the product. This register is set to its default values by a hard reset or any system reset event.

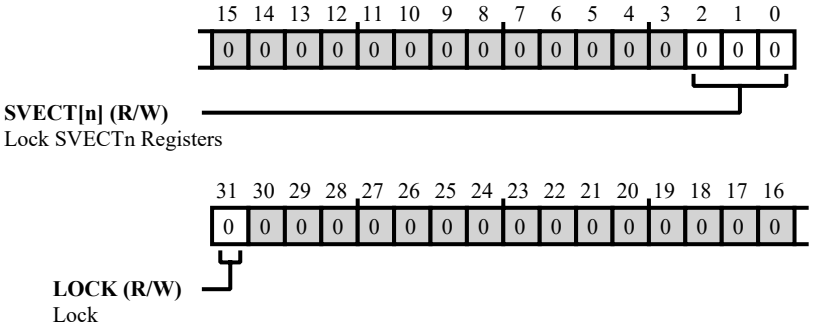

Figure 6-15: RCU_SVECT_LCK Register Diagram

Table 6-20: RCU_SVECT_LCK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the RCU_SVECT_LCK.LOCK bit is set, the RCU_SVECT_LCK register is read only (locked).	
		0	Unlock
		1	Lock
2:0 (R/W)	SVECT[n]	Lock SVECTn Registers. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the RCU_SVECT_LCK.SVECT[n] bit is set, the SVECT registers are read only (locked).	

7 System Event Controller (SEC) and Generic Interrupt Controller (GIC)

System event management is the responsibility of the system event controller (SEC). The SEC manages the configuration of all system event sources. The SEC also manages the propagation of system events to all connected cores and the system fault interface.

All the peripheral interrupts are routed using a single SEC interrupt to the desired core. The SEC allows programmability of the peripheral interrupt's priority, supporting up to 256 priority levels that are arbitrated within the SEC itself. The SEC also allows these interrupts to be grouped and masked by priority level and provides the flexibility to choose which core(s) the interrupt is routed to.

The SEC also supports self-nesting of interrupts, which is required when sharing a single interrupt request to an individual core, as this allows for a higher-priority peripheral interrupt to be passed to the core while it is currently servicing a lower-priority peripheral interrupt. For more information, refer to "Self-Nesting Mode for System Event Controller Interrupt (SECI)" in the *SHARC+ Core Programming Reference*.

For more information about the Arm GIC, visit the Arm Information Center.

SEC Features

The following list describes the system event controller features.

- Comprehensive system event source management including interrupt enable, fault enable, priority, core mapping, and source grouping.
- Fault management including fault action configuration, timeout, external indication, and system reset.
- Determinism where all system events have the same propagation delay and provide unique identification of a specific system event source.
- Distributed programming model where each system event source control and all status fields are independent of all others.
- Completer control port which provides access to all SEC registers for configuration, status, and interrupt or fault service model.

- Global locking supports a register level protection model to prevent writes to “locked” registers.

SEC Functional Description

The following sections provide a functional description of the SEC.

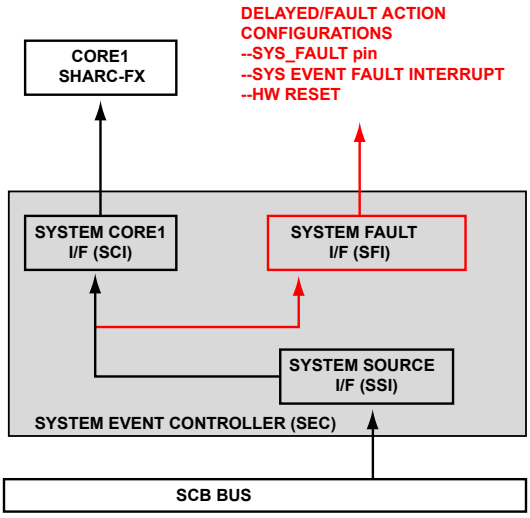

Figure 7-1: SEC Interrupt Signal Flow

ADSP-2184x SEC Register List

The System Event Controller (SEC) manages the system fault sources, including control features such as enable/disable and active/pending source status. For more information on SEC functionality, see the SEC register descriptions.

Table 7-1: ADSP-2184x SEC Register List

Name	Description
SEC_CACT[n]	SCI Active Register n
SEC_CCTL[n]	SCI Control Register n
SEC_CGMSK[n]	SCI Group Mask Register n
SEC_CPLVL[n]	SCI Priority Level Register n
SEC_CPMSK[n]	SCI Priority Mask Register n
SEC_CPND[n]	Core Pending Register n
SEC_CSID[n]	SCI Source ID Register n
SEC_CSTAT[n]	SCI Status Register n
SEC_END	Global End Register
SEC_FCOPP	Fault COP Period Register
SEC_FCOPP_CUR	Fault COP Period Current Register

Table 7-1: ADSP-2184x SEC Register List (Continued)

Name	Description
SEC_FCTL	Fault Control Register
SEC_FDLY	Fault Delay Register
SEC_FDLY_CUR	Fault Delay Current Register
SEC_FEND	Fault End Register
SEC_FSID	Fault Source ID Register
SEC_FSRDLY	Fault System Reset Delay Register
SEC_FSRDLY_CUR	Fault System Reset Delay Current Register
SEC_FSTAT	Fault Status Register
SEC_GCTL	Global Control Register
SEC_GSTAT	Global Status Register
SEC_RAISE	Global Raise Register
SEC_SCTL[n]	Source Control Register n
SEC_SSTAT[n]	Source Status Register n

SEC Definitions

The event controller uses the following definitions.

SCI

SEC core interface, core interface subblock of the SEC

SEA

SEC system event aggregator generates an aggregate request to the SEC based on the active events at a given time.

SID (Identification, unique)

Source numeric identifier for each system source connected to the SEC.

SFI

SEC Fault Interface, fault management subblock of the SEC.

SPR

SEC prioritizer determines the highest priority pending interrupt and the highest priority active interrupt. The SPR provides these interrupts in the appropriate registers of the SCI for the priority and nesting model of the SCI.

SSI

SEC source interface, system event source control, and status subblock of the SEC.

System Events

System source indications including interrupts and faults.

System Source

Point of origin of system event.

SEC System Event Aggregator (SEA)

System event sources request event service from the SEC. To reduce the number of required SSI channels in the SEC, the System Event Aggregator (SEA) acts as an intermediate aggregator between the source and the SEC. All unique system events have dedicated inputs to the SEA. The SEA generates an aggregate request to the SEC based on which events are active at a given time.

To determine the active event for a given SEC ID, read the `SEC_SSTAT[n].CHID` bit field. The *Combined SEC and GIC Interrupt List* table shows five SEAs connected to SEC ID 251-255. All the sources grouped over the SEA are error events for a set of peripherals like the FIR-IIR, SPI-UART-LP-EPPI, MDMA, SPORT, and SWU. An error event from a peripheral is only expected when that peripheral is enabled. To mask SEA events from sources, disable the source peripheral conditions. There are no registers to mask events from the SEA, but there is a provision to mask the complete group output at the SEC.

Events are handled with a fixed priority order, on a first-come, first-served basis. If multiple events corresponding to the same SEC ID are active at the same time, the priority level is order dependent with the lower SEA IDs having the higher priority. The SEA events are level-based, so they remain high until the events are cleared at the source ensuring no event is missed. There is no support for nesting in a group since they all have same the SEC ID. An SEA event must be handled completely before addressing the next event.

SEC Block Diagram

The *SEC Block Diagram* shows the event management architecture.

System sources connect to the SEC through the SSI. Each core has a dedicated SCI. The SFI provides fault action connections to the rest of the system.

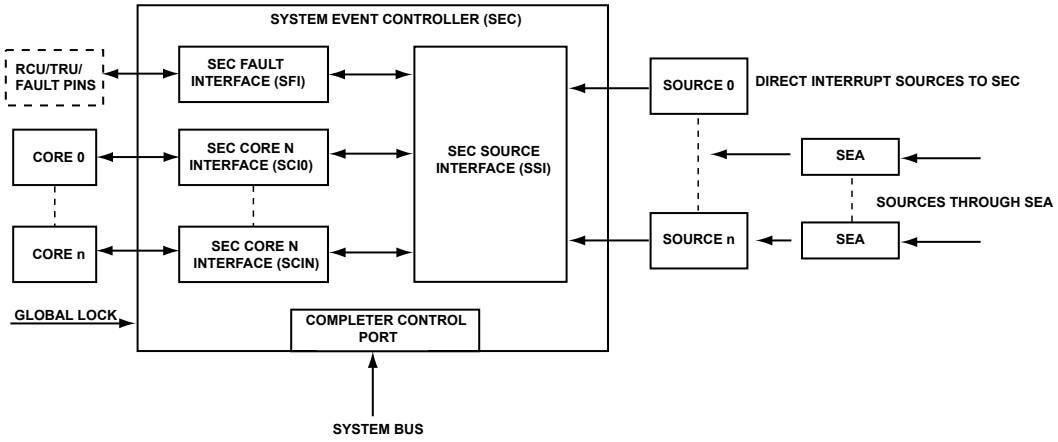

Figure 7-2: SEC Block Diagram

As shown in the figure, the SEC has three blocks for event management. The SFI monitors and manages any fault event triggered from various fault input sources. System interrupt sources are routed to the SFI through SEC source interface (SSI).

SEC Fault Interface (SFI)

The SFI manages fault events and associated actions. The fault management support provided in the SEC helps satisfy the safety requirements of various applications. The SSI provides the highest priority pending source that is enabled as a fault. The SFI captures this value and enables a countdown, and once the countdown expires, takes the prescribed action.

Fault actions which can be configured, as shown in *SFI Block Diagram*, include

- Trigger Output
- System Reset
- Fault Output
    - Computer Operating Properly (COP) mode
    - Fault Mode

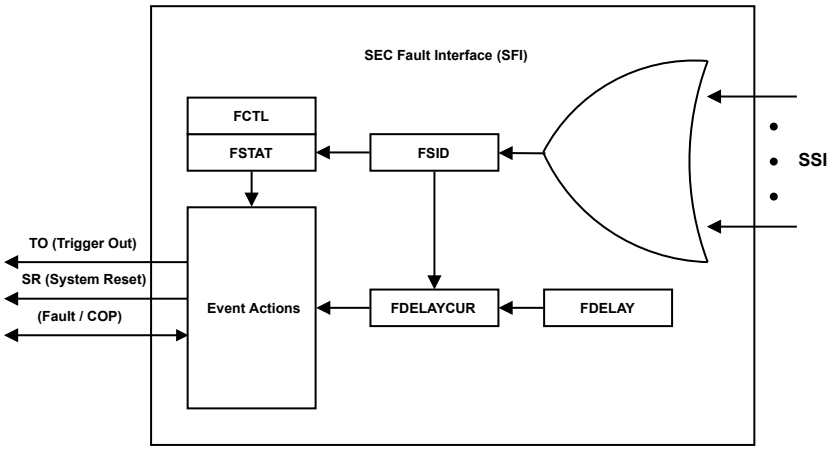

Figure 7-3: SFI Block Diagram

Fault Management

System sources can be enabled as fault sources in the SEC_SCTL[n] register. When a source enabled as a fault moves to pending, it is forwarded to the SFI as a fault indication. The pending bit (SEC_FSTAT.PND) indicates a source has signaled a fault assertion but it has not yet triggered the event actions (if delay is enabled). The SEC fault interface sets the SEC_FSTAT.PND bit when the fault source ID register (SEC_FSID) is updated on assertion of a fault source input. The system source pending triggers a fault pending and after a programmable delay the fault moves to active. Event actions then execute if appropriate action is not taken by the core. The SEC_FSTAT.ACT bit indicates that the SEC has received a fault source input, the delay has expired, and the fault actions are enabled.

The SEC_FSTAT.NPND bit indicates if one or more sources have signaled a fault assertion, but the input has not yet triggered the fault pending detection in the SEC fault interface. The SEC sets the SEC_FSTAT.NPND bit when the fault interface detects assertion of any enabled fault source input, while either the SEC_FSTAT.PND or SEC_FSTAT.ACT bits are set. The SEC clears the SEC_FSTAT.NPND bit when there are no fault sources waiting.

A fault indication from an external device can also be detected on sampling the fault signals. When a fault is detected the SEC_FSTAT.ACT and SEC_FSID.FEXT bits are set. The assertion of either signal results in a fault input detection.

The SEC_FEND register receives a fault end indication from the core. The core writes the SID of the fault to the SEC_FEND register. If the SID matches the value in the SEC_FSID register, the SEC_FSTAT.PND and SEC_FSTAT.ACT bits are cleared.

SEC Core Interface (SCI)

The SCI manages communication between the corresponding core and the SEC. The SEC prioritizer (SPR) of the SCI receives pending, active, and priority information from the SSI for each system event source assigned to this SCI. The SPR determines the highest priority pending system event and the SCI determines whether it propagates to the core. The SCI maintains the coherency for the system event service model implemented on the connected core.

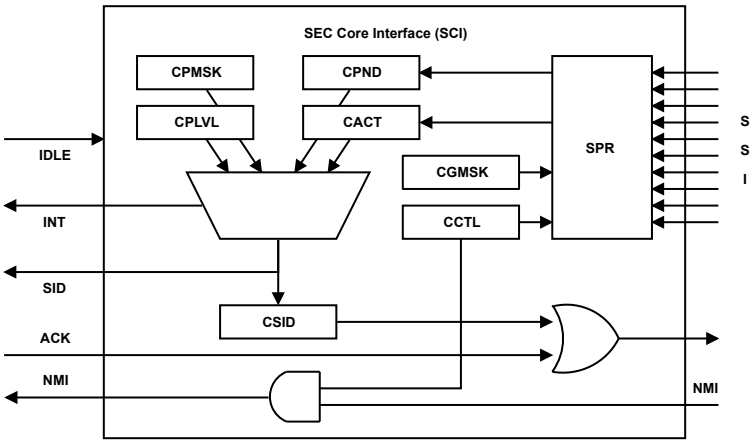

Figure 7-4: SCI Overview Block Diagram

SEC Source Interface (SSI)

The SSI manages all of the system event sources. It maintains the status of each source in the corresponding `SEC_SSTAT[n]` register. The corresponding `SEC_SCTL[n]` register manages the control of each source. A pending and enabled event passes its indication and priority to the SCI to which it is assigned for further processing.

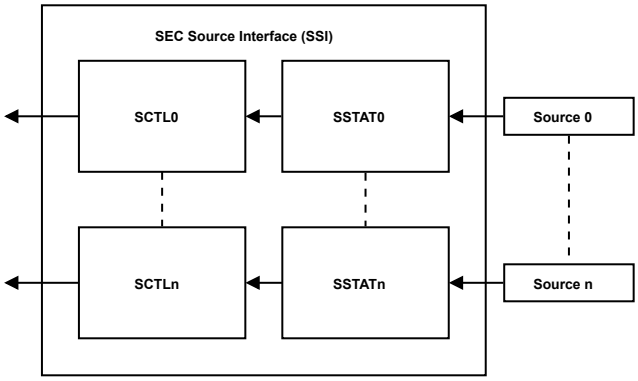

Figure 7-5: SSI Overview Block Diagram

SEC Architectural Concepts

The following sections describe SEC architectural features.

System Interrupt Groups

System sources can be assigned to groups using the `SEC_SCTL[n].GRP` bit field. Source groups allow fast context switching for system interrupts at each SCI. The `SEC_CGMSK[n]` register allows quick masking of interrupt groups of unlimited size with a single write operation.

System Interrupt Flow

An enabled and asserted system interrupt source is latched at the SSI and routed to the appropriate SCI based on the core target select (`SEC_SCTL[n].CTG`) bit field setting. The SEC priority ordering determines the highest priority pending system interrupt and the SCI updates the `SEC_CPND[n].SID` and `SEC_CACT[n].PRIO` bit

field values. The SCI compares the SEC_CPND[n] register value against the highest priority active source in the SEC_CACT[n] register).

The priority level register (SEC_CPLVL[n]) determines how many of the MSBs the SEC uses in the comparison. The priority mask register (SEC_CPMSK[n]) and the group mask register (SEC_CGMSK[n]) determines which pending interrupt sources participate. If the SEC_CPND[n] register value is a higher priority (lower value) than the priority of the SEC_CACT[n] register from the comparison based on the SEC_CPLVL[n] register, the system interrupt output is asserted. The source ID register (SEC_CSID[n]) is updated with the SEC_CPND[n].SID bit field value and forwarded to the connected core.

After the core provides an interrupt acknowledgment, the interrupt source is active, until the SEC completes interrupt service with a write to the SEC_END.SID bit field with the same value. Note the following:

- Interrupt acknowledgement occurs with an MMR write of the SEC_CSID[n] register or the core version of the SEC_CSID[n] register.
- Interrupt active status indication is SEC_SSTAT[n].ACT==1.

The following sequence shows the example flow for a single interrupt.

1. The SEC compares the SEC_CPND[n] register value to the SEC_CACT[n] register value. If the interrupt in the SEC_CPND[n] register is higher priority, continue.
2. The SEC copies the SEC_CPND[n] register value to the SEC_CSID[n] register and asserts the interrupt signal.
3. The core reads the SEC_CSID[n] register (or core version).
4. The core writes to the SEC_CSID[n] register (or core version, asserts the acknowledge signal).
5. The SEC deasserts the interrupt signal and clears the SEC_SSTAT[n].PND bit and sets the SEC_SSTAT[n].ACT bit of the source going active.
6. The core writes the SEC_CSID[n] of the active interrupt to the SEC_END register.
7. The SEC clears the SEC_SSTAT[n].ACT bit of the source being ended.

The following sequence shows the example flow for interrupt nesting where interrupt A is a lower priority and occurs earlier than interrupt B.

1. The SEC compares the SEC_CPND[n] (A) register value to the SEC_CACT[n] register and if the interrupt in the SEC_CPND[n] register is a higher priority, continue.
2. The SEC copies SEC_CPND[n] (A) register to the SEC_CSID[n] register and asserts the interrupt signal.
3. The core reads the SEC_CSID[n] (A) register (or core version).
4. The core writes to the SEC_CSID[n] register (or core version, asserts the acknowledge signal).
5. The SEC deasserts the INT signal and clears the SEC_SSTAT[n].PND bit and sets the SEC_SSTAT[n].ACT bit of the source (A) going active.

6. The SEC compares the SEC_CPND[n] (B) register value to the SEC_CACT[n] (A) register value. If the SEC_CACT[n] (B) register value is a higher priority, continue.
7. The SEC copies the SEC_CPND[n] (B) register value to SEC_CSID[n] register and asserts the interrupt signal.
8. The core reads the SEC_CSID[n] (B) register (or core version).
9. The core writes to the SEC_CSID[n] register (or core version, asserts the acknowledge signal).
10. The SEC deasserts the INT signal and clears the SEC_SSTAT[n].PND bit and sets the SEC_SSTAT[n].ACT bit of the source (B) going active.
11. The core writes the SEC_CSID[n] of the active interrupt (B) to the SEC_END register.
12. The SEC clears the SEC_SSTAT[n].ACT bit of the source (B) being ended.
13. The core writes the SEC_CSID[n] of the active interrupt (A) to the SEC_END register.
14. The SEC clears the SEC_SSTAT[n].ACT bit of the source (A) being ended.

System Interrupt Priorities

Each system interrupt source has its own programmable priority level which is configured using the SEC_SCTL[n].PRIO bit field. The SCI evaluates the priority of all pending sources to determine the source of the highest priority pending system interrupt for forwarding to the attached core. If more than one source of the pending system interrupt has the same priority setting, the SCI chooses the one with the lowest SID. For example, if SID 0, SID 1, and SID 2 are all pending and have the same priority setting, the SCI chooses SID 0 as the highest-priority source.

SEC Error

The processor includes an SEC error (SEC_GSTAT.ERR) as a source input to the SEC to allow for handling the error as an interrupt or fault.

SEC Programming Model

Implementing a system interrupt service model using the SEC requires, at a minimum:

- Proper configuration of a system interrupt source (for example a peripheral or DMA)
- A core interrupt or event service model

The core must be configured for response to system interrupts from the SEC. The SEC must be configured to enable and map the system interrupt source to the correct SCI and to forward interrupts to the connected core.

The system interrupt source must be configured to generate interrupt assertions. Alternatively, the processor can use software triggering for interrupt assertion. Software driven interrupts are generated by writing the source ID of the interrupt to be triggered to the SEC_RAISE register.

Programming Concepts

The following list provides the basic programming concepts necessary for configuring the SEC.

- Configuring an SSI as a system interrupt for a specific core.
- Configuring an SCI to provide system interrupts to the connected core (See Configuring a System Source to Interrupt a Core).
- Configuring an SSI as a system fault (See Configuring a System Source as a Fault).
- Configuring the SFI to manage system faults.

Programming Examples

This section provides example programming tasks that are typical for SEC usage.

Fault Management Interface Programming Model

The SFI interface can be programmed to manage fault events from system sources and associated actions such as issuing a system reset when watchdog expiration event occurs.

1. Set the `SEC_GCTL.EN` bit to enable the SEC.
2. Write to the `SEC_FCTL` register to configure specific fault actions.
    - Trigger Output. Set the `SEC_FCTL.TOEN` bit for the SEC to produce trigger outputs when a fault becomes active. The `SEC_FCTL.TES` bit can be programmed to select the event that directs the SEC to assert trigger output when a fault is pending or active. Configure receivers for SEC fault trigger generator output.

      NOTE: If the `SEC_FCTL.TOEN` and or the `SEC_FCTL.TES` bits =1 (Trigger Output Enabled and Trigger on Fault Pending), an external fault (if enabled by the `SEC_FCTL.FIEN` bit) will not issue a trigger since Fault Pending is bypassed for external faults.
    - System Reset. The Reset Control Unit (RCU) controls how the functional units enter and exit reset. Configure the `RCU_CTL.SRSTREQEN` bit. This bit controls whether the sources of reset are enabled to perform a system reset. To issue a system reset request when a fault becomes active, set the `SEC_FCTL.SREN` bit. The SEC fault system reset delay register (`SEC_FSRDLY`) can be programmed for the delay, if required, from a fault becoming active to system reset request assertion.
    - Fault Output. This configuration allows the SEC to indicate the fault status based on the `SEC_FCTL.CMS` bit configuration.
        - Computer Operating Normally (COP) mode. To configure fault output for COP mode, set the `SEC_FCTL.FOEN` bit to enable fault output. Set the `SEC_FCTL.CMS` bit to select COP mode to toggle the fault pin when no fault is active. Program the `SEC_FCOPP` period register with a desired width value for the COP toggled output pin.

- Fault mode. Set the SEC_FCTL.FOEN bit to enable fault output. The SEC_FCTL.CMS bit should be set to Fault mode to toggle the fault pin when a fault is active.

3. If required, program the Fault Input to sample fault inputs from external devices on fault pins. Configure the SEC_FCTL.FIEN bit to enable the SEC to sample a fault input from an external device.

   ADDITIONAL INFORMATION: The SEC_FCTL.FIEN bit should be set only while the SEC_FCTL.EN bit is low. If the SEC_FCTL.EN bit is already high and the SEC_FCTL.FIEN bit needs to be set, the SEC_FCTL.EN bit should be cleared first. Fault input can only be enabled when Fault mode is selected by the SEC_FCTL.CMS bit.

4. Program the required fault delay to the SEC_FDLY.COUNT bit field if a delay between fault source assertion and the fault response is required.

5. Configure the SEC_FCTL register to enable the SEC.

   ADDITIONAL INFORMATION: The SEC_FCTL.EN bit should be set only while the SEC_FSTAT.ACT bit is low.

6. Write to the control register of a specific source register using the SEC_SCTL[n] register to enable the source as a fault.

Configuring a System Source to Interrupt a Core

To configure a system source to interrupt a core, the SEC itself must be enabled with the source interface (SSI) and core interface (SCI) properly initialized. Specifically, the SCI must be set up to accept interrupt signaling from the SEC and pass them to the specified core, and the SSI must properly enable each of the peripheral interrupt sources to generate interrupt signals and optionally define a priority scheme that overrides the default priority settings. In summary:

1. Write to the SEC_GCTL register to enable the SEC.
2. Write to the appropriate SCI SEC_CCTL[n] register to enable SEC interrupts to be sent to that core.
3. Write to the appropriate SSI SEC_SCTL[n] register to enable that peripheral as an interrupt source and to set the core target field to map the source to the desired SCI.
4. (Optional) By default, all the SEC interrupts are grouped as a single priority level, so passing of peripheral interrupt requests from the SEC is based solely on the default enumerated source ID. By programming the SEC_CPLVL[n].PLVL register, interrupt sources can be grouped into priority levels within the SEC such that arbitration is first performed by source ID within a grouped priority level before proceeding to the next priority level, thus providing the flexibility to have lower-priority interrupt sources considered before higher-priority sources.

   ADDITIONAL INFORMATION: The SEC_CPMSK[n] and SEC_CGMSK[n] registers must also can be programmed to mask the interrupts based on the customized levels and grouping.

Core/SEC Handshake Requirements to Ensure Proper Interrupt Handling

A specific handshake with the SEC is required to handle interrupts associated with an individual core. The handshake ensures that nested interrupts are properly tracked and that new peripheral interrupts being raised within the SEC are either passed immediately to the core or held off and queued within the SEC for later servicing.

Use the following procedure to write a custom dispatcher inside the Interrupt Service Routine. Note that the core needs to read and acknowledge the SEC_CSID[n] register by writing the same value. The core must also write to the SEC_END register after the ISR execution completes.

1. Read the SEC_CSID[n] register to obtain the source ID of the peripheral interrupt request.
2. Write the read value back to the SEC_CSID[n] register to send the acknowledge signal to the SEC that the core has accepted and begun processing the interrupt request.
3. Execute the actual ISR (typically a call to a specific handler function from a look-up table based on the peripheral source ID). Write to the SEC_GCTL register to enable the SEC.
4. Write the value of the SEC_CSID[n] register of the active interrupt (read in step 1 above) to the SEC_END register to signal to the SEC that the interrupt has now been serviced.
5. Return from interrupt.

This procedure allows a higher-priority interrupt raised by the SEC to be serviced by the core after step 2. The SEC knows what it passed to the core because of the write to the SEC_CSID[n] register. After the core acknowledges that write, the SEC knows whether newly raised peripheral interrupts are a higher priority than the highest-priority interrupt currently being processed by the core.

- When a higher priority, the SEC pushes the current SEC_CSID[n] value to an internal stack, writes the new SEC_CSID[n] value, and asserts a new SEC interrupt request.
- When a lower priority, the SEC queues the interrupt until the core writes to the SEC_END register with the source ID of the higher-priority interrupt, confirming that it was fully processed.

At this point the SEC_CSID[n] value is popped from the internal stack and any pending peripheral interrupt requests are arbitrated before the SEC writes the new SEC_CSID[n] value and asserts a new interrupt request. At the same time the core self-nests the latched SEC interrupt requests as needed. When a higher-priority interrupt is presented to the core the write to the SEC_END register in the SEC handler epilog code guarantees that each nested level has the required handshake to signal to the SEC block that each individual source ID interrupt request is fully serviced. See the *SHARC+ Core Programming Reference* for more details about SEC handler code.

Configuring a System Source as a Fault

Use the following procedure configure a system source as a fault.

1. Write to the SEC_GCTL register to enable the SEC.
2. Write to the SEC_FCTL register to configure specific fault actions.
3. Write to the SEC_FDLY bit field to specify fault delay.

4. Write to the control register of a specific source to enable the source as a fault.

Configuring the WDOG Expiry Event to Issue a System Reset

Use the following procedure to configure the WDOG timer to issue a system reset.

1. Configure the SEC_GCTL register to enable the SEC.

```
*pREG_SEC0_GCTL = BITM_SEC_GCTL_EN;
```

2. Configure the SEC_FCTL register to choose the Fault response mode. In the following code example, the system reset is issued.

```
*pREG_RCU0_CTL |= BITM_RCU_CTL_SRSTREQEN;
*pREG_SEC0_FCTL |= BITM_SEC_FCTL_SREN;
```

3. Configure the SEC_SCTL[n].SEN and SEC_SCTL[n].FEN bits in the registers to determine how the fault source is handled. To configure the WDOG as the fault source, program the register. The program can configure any interrupt as the fault source by programming the corresponding register.

```
 *pREG_SEC0_SCTL3 = BITM_SEC_SCTL_FEN|BITM_SEC_SCTL_SEN;
```

ADDITIONAL INFORMATION: The SEC ID corresponding to WDOG0 is 3, as indicated in the ADSP-2184x Interrupt List .

4. Write to the enable bit.

```
*pREG_SEC0_FCTL |= BITM_SEC_FCTL_EN;
```

SEC Programming Restrictions

Setting the SEC_FCTL.EN bit while the SEC_FSTAT.ACT bit is high can result in unpredictable behavior. To avoid this issue, set the SEC_FCTL.EN bit while the SEC_FSTAT.ACT bit is low. The SEC_FSTAT.ACT bit is only set when the SEC_FCTL.EN bit is high. Therefore, the problem can only occur if the SEC_FCTL.EN bit transitions from 1 to 0 and then to 1 again.

Writing to SEC_FEND to end a fault with both the SEC_FCTL.FOEN bit and the SEC_FCTL.FIEN bit set can result in erroneous external fault detection. If this operation (ending a fault) and configuration (fault input and fault output enabled) are required by the application, clear the SEC_FCTL.FOEN bit prior to writing to SEC_FEND. The recommended sequence for ending a fault with the SEC_FCTL.FIEN or SEC_FCTL.FOEN==1 is as follows:

1. Clear the SEC_FCTL.FOEN bit.
2. Write to the SEC_FEND register.
3. Set the SEC_FCTL.FOEN bit.

ADSP-2184x SEC Register Descriptions

System Event Controller (SEC) contains the following registers.

Table 7-6: ADSP-2184x SEC Register List

Name	Description
SEC_CACT[n]	SCI Active Register n
SEC_CCTL[n]	SCI Control Register n
SEC_CGMSK[n]	SCI Group Mask Register n
SEC_CPLVL[n]	SCI Priority Level Register n
SEC_CPMSK[n]	SCI Priority Mask Register n
SEC_CPND[n]	Core Pending Register n
SEC_CSID[n]	SCI Source ID Register n
SEC_CSTAT[n]	SCI Status Register n
SEC_END	Global End Register
SEC_FCOPP	Fault COP Period Register
SEC_FCOPP_CUR	Fault COP Period Current Register
SEC_FCTL	Fault Control Register
SEC_FDLY	Fault Delay Register
SEC_FDLY_CUR	Fault Delay Current Register
SEC_FEND	Fault End Register
SEC_FSID	Fault Source ID Register
SEC_FSRDLY	Fault System Reset Delay Register
SEC_FSRDLY_CUR	Fault System Reset Delay Current Register
SEC_FSTAT	Fault Status Register
SEC_GCTL	Global Control Register
SEC_GSTAT	Global Status Register
SEC_RAISE	Global Raise Register
SEC_SCTL[n]	Source Control Register n
SEC_SSTAT[n]	Source Status Register n

SCI Active Register n

The SEC SCI active interrupt register (SEC_CACT[n]) contains the source ID and priority of the highest priority active interrupt detected by the SEC prioritizer.

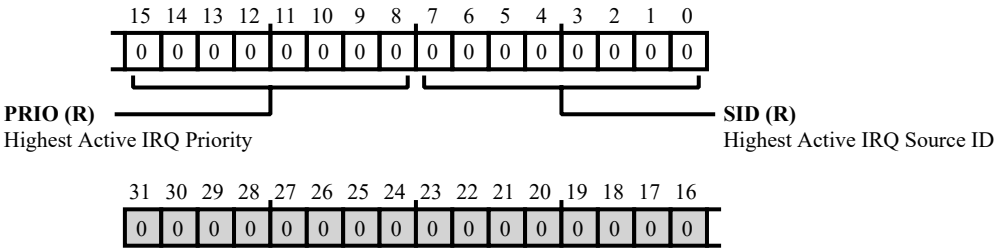

Figure 7-6: SEC_CACT[n] Register Diagram

Table 7-7: SEC_CACT[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/NW)	PRIO	Highest Active IRQ Priority. The SEC_CACT[n].PRIO indicates the priority value of the highest priority active interrupt for core n.
7:0 (R/NW)	SID	Highest Active IRQ Source ID. The SEC_CACT[n].SID identifies the source ID value of the highest priority active interrupt for core n.

SCI Control Register n

The SEC control register (SEC_CCTL[n]) contains SCI control bits for all system sources.

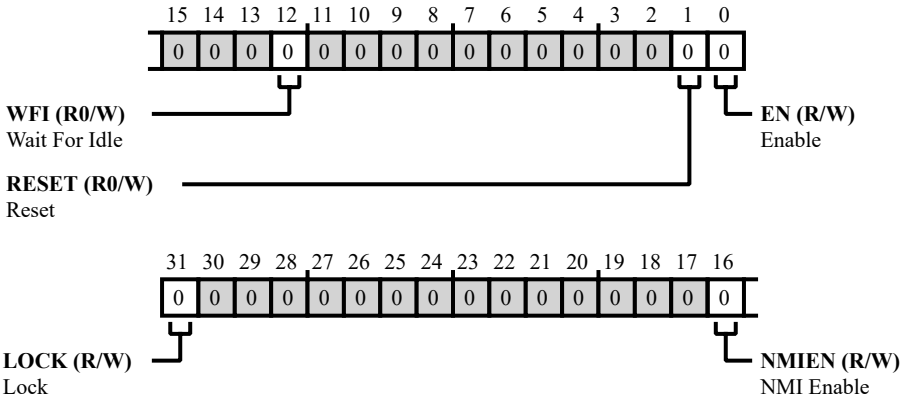

Figure 7-7: SEC_CCTL[n] Register Diagram

Table 7-8: SEC_CCTL[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock is enabled (SPU_CTL.GLCK bit =1) and the SEC_CCTL[n].LOCK bit is enabled, the SEC_CCTL[n] register is read only.	
		0	Unlock
		1	Lock
16 (R/W)	NMIEN	NMI Enable. The SEC_CCTL[n].NMIEN bit controls NMI propagation to the core. When the SEC_CCTL[n].NMIEN bit is enabled, the SCI allows NMIs to propagate to the core for servicing.	
		0	Disable
		1	Enable
12 (R0/W)	WFI	Wait For Idle. When set, the SEC_CCTL[n].WFI bit forces the SCI to wait for indication of core idle before the SCI resumes activity.	
		0	No Action
		1	Wait for Idle

Table 7-8: SEC_CCTL[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R0/W)	RESET	Reset. When set, the `SEC_CCTL[n].RESET` bit resets all SCI registers to their default values.	
		0	No Action
		1	Reset
0 (R/W)	EN	Enable. The `SEC_CCTL[n].EN` bit controls operation of the SCI. Clearing the `SEC_CCTL[n].EN` bit halts the execution of the SCI without resetting status registers. (The INT signal to a core is not affected.) Setting the `SEC_CCTL[n].EN` bit enables the SCI to begin or resume operation with the current configuration and status.	
		0	Disable
		1	Enable

SCI Group Mask Register n

The SEC SCI group mask register (SEC_CGMSK[n]) contains selections for a group mask, an ungroup mask, and a register lock. This register contains the system interrupt group masks for the connected core. The core uses the SEC_CGMSK[n].UGRP and SEC_CGMSK[n].GRP fields to mask (disable) interrupts from the specified groups.

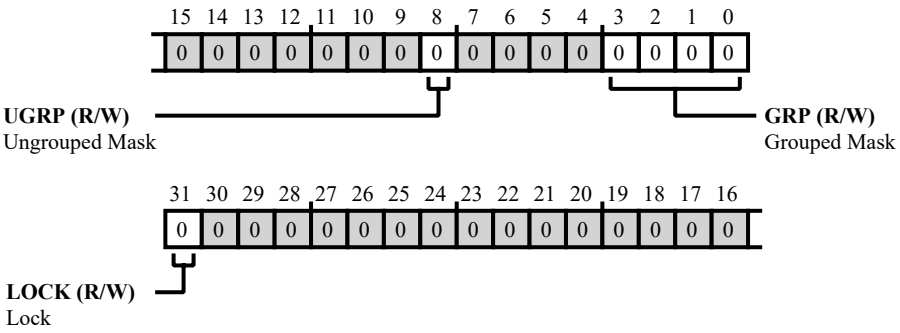

Figure 7-8: SEC_CGMSK[n] Register Diagram

Table 7-9: SEC_CGMSK[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock is enabled (SPU_CTL.GLCK bit =1) and the SEC_CGMSK[n].LOCK bit is enabled, the SEC_CGMSK[n] register is read only.	
		0	Unlock
		1	Lock
8 (R/W)	UGRP	Ungrouped Mask. The SEC_CGMSK[n].UGRP bit masks interrupts (if set) for the ungrouped interrupt sources for core n.	
		0	Unmask Ungrouped Sources
		1	Mask Ungrouped Sources
3:0 (R/W)	GRP	Grouped Mask. The SEC_CGMSK[n].GRP field selects a group of interrupt sources to mask for core n. (For more information about interrupt source groups, see the SEC_SCTL[n] register description.)	
		0	No groups masked
		1	Mask group 0
		2	Mask group 1
		3	Mask groups 0, 1

Table 7-9: SEC_CGMSK[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		4	Mask group 2
		5	Mask groups 0, 2
		6	Mask groups 1, 2
		7	Mask groups 0, 1, 2
		8	Mask group 3
		9	Mask groups 0, 3
		10	Mask groups 1, 3
		11	Mask groups 0, 1, 3
		12	Mask groups 2, 3
		13	Mask groups 0, 2, 3
		14	Mask groups 1, 2, 3
		15	Mask groups 0, 1, 2, 3

SCI Priority Level Register n

The SEC SCI priority level register (SEC_CPLVL[n]) contains selections for priority levels and a register lock. This register is used to divide the total number of priority levels into sub-levels. The sub-level priority resolution provides the tie breaker for simultaneously pending interrupts assigned to the same level.

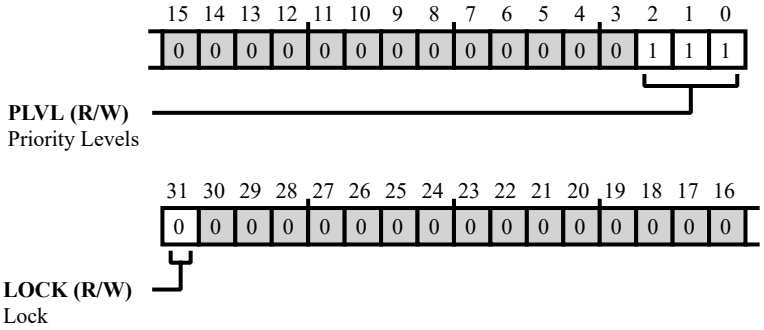

Figure 7-9: SEC_CPLVL[n] Register Diagram

Table 7-10: SEC_CPLVL[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock is enabled (SPU_CTL.GLCK bit =1) and the SEC_CPLVL[n].LOCK bit is enabled, the SEC_CPLVL[n] register is read only.	
		0	Unlock
		1	Lock
2:0 (R/W)	PLVL	Priority Levels. The SEC_CPLVL[n].PLVL field serves to divide the total number of interrupt priority levels into sub-levels. The sub-level priority resolution provides the tie breaker for simultaneously pending interrupts assigned to the same interrupt level. The sub-level priority value specifies the number of MSBs (minus 1) designated to interrupt levels, while the remaining LSBs are designated for sub-level specification. For example, if the SEC_CPLVL[n].PLVL field is set to two, the result is four priority levels are specified, because only the two MSBs are used for preemption evaluation. The remaining bits of the priority setting are used for sub-level prioritization.	
		0	1 MSBs (2 priority levels)
		1	2 MSBs (4 priority levels)
		2	3 MSBs (8 priority levels)
		3	4 MSBs (16 priority levels)
		4	5 MSBs (32 priority levels)
		5	6 MSBs (64 priority levels)

Table 7-10: SEC_CPLVL[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		6	7 MSBs (128 priority levels)
		7	8 MSBs (256 priority levels)

SCI Priority Mask Register n

The SEC SCI priority mask register (SEC_CPMSK[n]) contains the SCI priority mask for core n and includes a register lock.

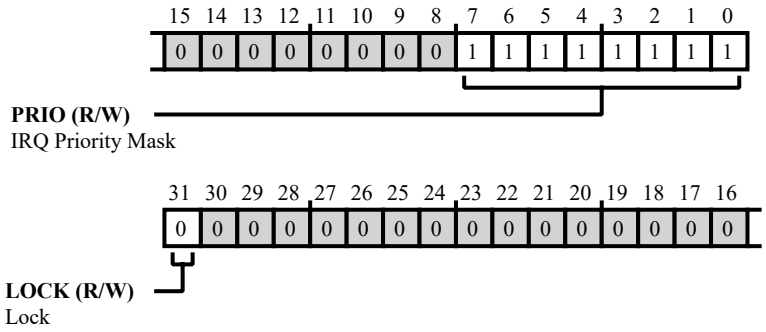

Figure 7-10: SEC_CPMSK[n] Register Diagram

Table 7-11: SEC_CPMSK[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock is enabled (SPU_CTL.GLCK bit =1) and the SEC_CPMSK[n].LOCK bit is enabled, the SEC_CPMSK[n] register is read only.	
		0	Unlock
		1	Lock
7:0 (R/W)	PRIO	IRQ Priority Mask. The SEC_CPMSK[n].PRIO contains the system interrupt priority mask for core n. The core uses the SEC_CPMSK[n].PRIO field to mask (block) interrupts below the specified level.	
		0	Priority level 0 (highest)
		1-254	
		255	Priority level 255 (lowest)

Core Pending Register n

The SCI pending interrupt register (SEC_CPND[n]) contains the source ID and priority of the highest priority pending interrupt detected by the SEC prioritizer.

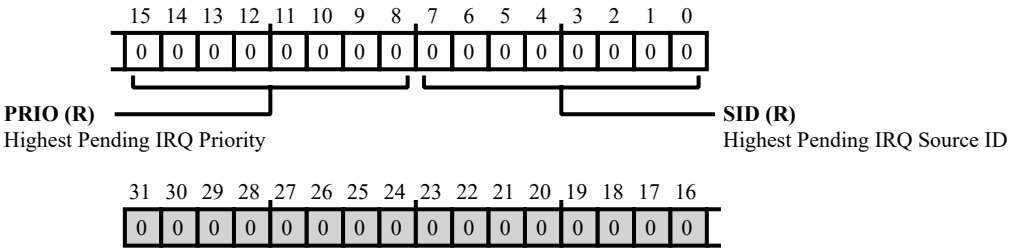

Figure 7-11: SEC_CPND[n] Register Diagram

Table 7-12: SEC_CPND[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/NW)	PRIO	Highest Pending IRQ Priority. The SEC_CPND[n].PRIO indicates the priority value of the highest priority pending interrupt for core n.
7:0 (R/NW)	SID	Highest Pending IRQ Source ID. The SEC_CPND[n].SID identifies the source ID value of the highest priority pending interrupt for core n.

SCI Source ID Register n

The SCI source ID register (SEC_CSID[n]) contains the source ID of the interrupt last issued to core n. The SEC_CSID[n] register value is loaded by the SCI when a system interrupt indication is sent to core n. The SCI does not change the SEC_CSID[n] until after the interface receives an interrupt acknowledge from core n. Writing to the SEC_CSID[n] register generates an interrupt acknowledge, but does not update the value in the register.

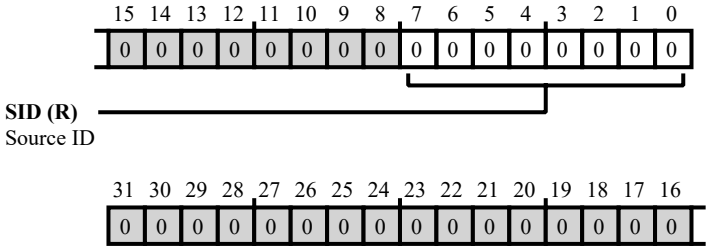

Figure 7-12: SEC_CSID[n] Register Diagram

Table 7-13: SEC_CSID[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/NW)	SID	Source ID. The SEC_CSID[n].SID bit is the source ID of the interrupt last issued to core n.

SCI Status Register n

The SCI status register (SEC_CSTAT[n]) contains status bits, indicating the operational status of the SCI.

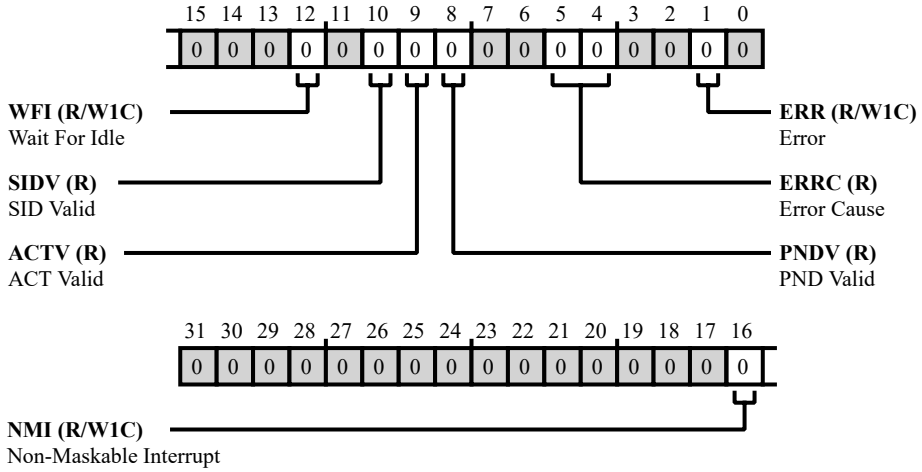

Figure 7-13: SEC_CSTAT[n] Register Diagram

Table 7-14: SEC_CSTAT[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W1C)	NMI	Non-Maskable Interrupt. The SEC_CSTAT[n].NMI bit indicates whether an NMI has occurred since the bit was last cleared.	
		0	No NMI Occurred
		1	NMI Occurred
12 (R/W1C)	WFI	Wait For Idle. The SEC_CSTAT[n].WFI bit indicates (if set) that the SCI is temporarily disabled, pending a core idle indication. This bit is set when SEC_CCTL[n].WFI is set.	
		0	Not Waiting
		1	Waiting
10 (R/NW)	SIDV	SID Valid. The SEC_CSTAT[n].SIDV bit indicates (if set) that the current value in the SEC_CSID[n] register is valid. The SCI sets the SEC_CSTAT[n].SIDV bit when the updating the SEC_CSID[n] register with a new value. The SEC_CSTAT[n].SIDV bit is cleared when the SEC_CSID[n] register is written. This status indication may be used to extract all pending interrupts in a single interrupt service routine.	
		0	Invalid
		1	Valid

Table 7-14: SEC_CSTAT[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/NW)	ACTV	ACT Valid. The SEC_CSTAT[n].ACTV bit indicates (if set) that the current value in the SEC_CACT[n] register is valid. The SCI sets the SEC_CSTAT[n].ACTV bit when updating the SEC_CACT[n] registers with a new value. The SEC_CSTAT[n].ACTV bit is cleared when the SEC_CSID[n] register is written.	
		0	Invalid
		1	Valid
8 (R/NW)	PNDV	PND Valid. The SEC_CSTAT[n].PNDV bit indicates (if set) that the current value in the SEC_CPND[n] register is valid. The SCI sets the SEC_CSTAT[n].PNDV bit when updating the SEC_CPND[n] register with a new value. The SEC_CSTAT[n].PNDV bit is cleared when the SEC_CSID[n] register is written.	
		0	Invalid
		1	Valid
5:4 (R/NW)	ERRC	Error Cause. The SEC_CSTAT[n].ERRC bits are updated on assertion of the SEC_CSTAT[n].ERR bit to indicate the SCI error type. SEC_CSTAT[n].ERRC is only updated on the assertion of SEC_CSTAT[n].ERR. Subsequent errors while SEC_CSTAT[n].ERR is asserted do not update SEC_CSTAT[n].ERRC.	
		0	Reserved
		1	Acknowledge Error. SCI has received an acknowledge without a pending, unacknowledged interrupt present.
		2	Reserved
		3	Reserved
1 (R/W1C)	ERR	Error. The SEC_CSTAT[n].ERR bit indicates that an error has occurred in the SCI. When SEC_CSTAT[n].ERR is set, the SCI updates the SEC_CSTAT[n].ERRC field to the value of the corresponding error cause.	
		0	No Error
		1	Error Occurred

Global End Register

The SEC global end register (SEC_END) contains a source ID interrupt service end field (SEC_END.SID). When a core has finished servicing an interrupt, the core writes the SEC_END.SID field in the SEC_END register. This write causes the SEC to clear the SEC_SSTAT[n].ACT bit in the SEC_SSTAT[n] register of the corresponding interrupt.

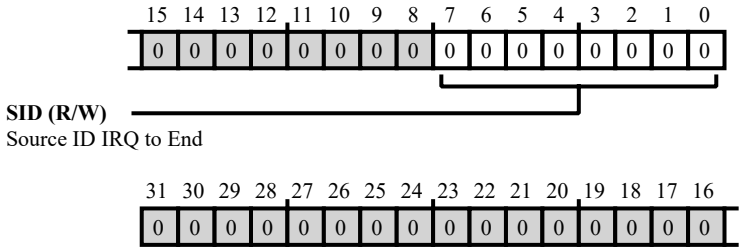

Figure 7-14: SEC_END Register Diagram

Table 7-15: SEC_END Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	SID	Source ID IRQ to End. The SEC_END.SID bit field contains the source ID interrupt service end value.

Fault COP Period Register

The SEC fault COP period register (SEC_FCOPP) contains the width value (count in (SEC) clock cycles) for the high and low phase of the computer operating properly (COP) toggled output on the COP pin. Note that the actual high/low phase value is the SEC_FCOPP.COUNT programmed value plus 1.

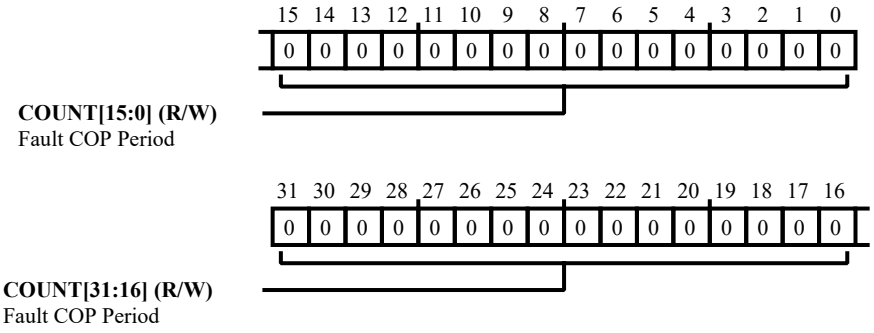

Figure 7-15: SEC_FCOPP Register Diagram

Table 7-16: SEC_FCOPP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	COUNT	Fault COP Period. The SEC_FCOPP.COUNT bit field is the width value for the high and low phase of the computer operating properly (COP) toggled output on the COP pin.

Fault COP Period Current Register

The SEC fault COP period current register (SEC_FCOPP_CUR) contains the active count (in (SEC) clock periods) for the current phase (high or low) of the computer operating properly (COP) toggled output on the COP pin. The SEC loads the SEC_FCOPP_CUR register from the SEC_FCOPP register when the SEC_FCOPP_CUR.COUNT field is cleared and the SEC is in COP mode (SEC_FCTL.CMS bit =1). The SEC decrements the SEC_FCOPP_CUR count each (SEC) clock cycle while SEC_FCTL.CMS is set and the SEC_FSTAT.ACT bit is not set.

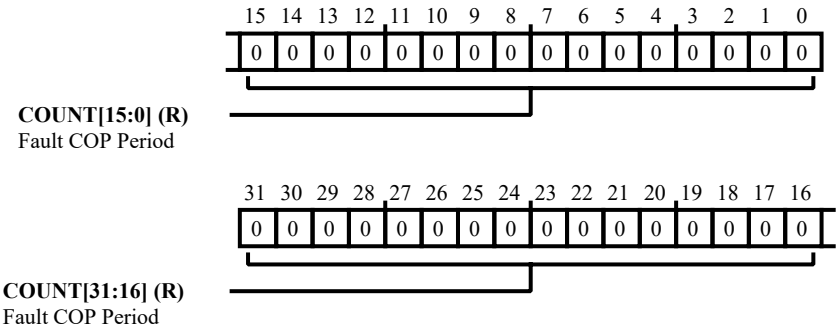

Figure 7-16: SEC_FCOPP_CUR Register Diagram

Table 7-17: SEC_FCOPP_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	COUNT	Fault COP Period. The SEC_FCOPP_CUR.COUNT bit field is the active count for the current phase (high or low) of the computer operating properly (COP) toggled output on the COP pin.

Fault Control Register

The SEC fault control register (SEC_FCTL) contains fault control bits for all SEC channels. This register controls the operation of the System Fault Management Interface (SFI).

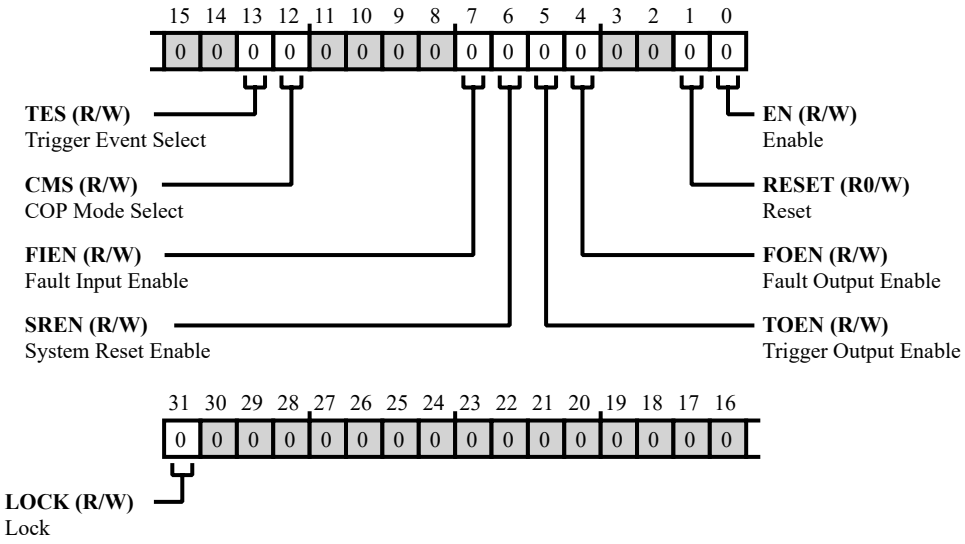

Figure 7-17: SEC_FCTL Register Diagram

Table 7-18: SEC_FCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock is enabled (SPU_CTL.GLCK bit =1) and the SEC_FCTL.LOCK bit is enabled, the SEC_FCTL register is read only.	
		0	UnLock
		1	Lock
13 (R/W)	TES	Trigger Event Select. The SEC_FCTL.TES bit selects the event that directs the SEC to assert trigger output. In fault pending mode, the SEC asserts trigger output when a fault is pending. In fault active mode, the SEC asserts trigger output when a fault is active.	
		0	Fault Active Mode
		1	Fault Pending Mode

Table 7-18: SEC_FCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	CMS	COP Mode Select. The SEC_FCTL.CMS selects the SEC mode for handling fault input. In COP mode, the SEC toggles the COP pin to indicate that no fault is active and ceases toggling the pin to indicate that a fault is active. In fault mode, the SEC deasserts the fault pin (=0) and fault_b pin (=1) when no fault is active and asserts the fault pin (=1) and fault_b pin (=0) when a fault is active. Not all processors feature both the fault and fault_b pins. Refer to the product data sheet for details.	
		0	Fault Mode
		1	COP Mode
7 (R/W)	FIEN	Fault Input Enable. The SEC_FCTL.FIEN bit enables the SEC to sample fault input. If SEC_FCTL.FIEN is set (=1), a fault indication from an external device sets the SEC_FSTAT.ACT bit and SEC_FSID.FEXT bit.	
		0	Disable
		1	Enable
6 (R/W)	SREN	System Reset Enable. The SEC_FCTL.SREN bit enables the SEC to issue a system reset request when a fault becomes active.	
		0	Disable
		1	Enable
5 (R/W)	TOEN	Trigger Output Enable. The SEC_FCTL.TOEN bit enables the SEC to produce trigger output when a fault becomes active.	
		0	Disable
		1	Enable
4 (R/W)	FOEN	Fault Output Enable. The SEC_FCTL.FOEN bit enables the SEC to indicate fault status, according to the SEC_FCTL.CMS bit configuration.	
		0	Disable
		1	Enable
1 (R0/W)	RESET	Reset. Setting the SEC_FCTL.RESET bit resets ALL SEC registers to their default values.	
		0	No Action
		1	Reset

Table 7-18: SEC_FCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	EN	Enable. The `SEC_FCTL.EN` bit controls the operational state of the SEC. Clearing the `SEC_FCTL.EN` bit halts the execution of the SEC without resetting status registers. Setting the `SEC_FCTL.EN` bit enables the SEC to begin or resume operation with the current configuration and status.	
		0	Disable
		1	Enable

Fault Delay Register

The SEC fault delay register (SEC_FDLY) contains the number (SEC_FDLY.COUNT field) of (SEC) clock periods to delay from fault pending to fault active, when actions are enabled.

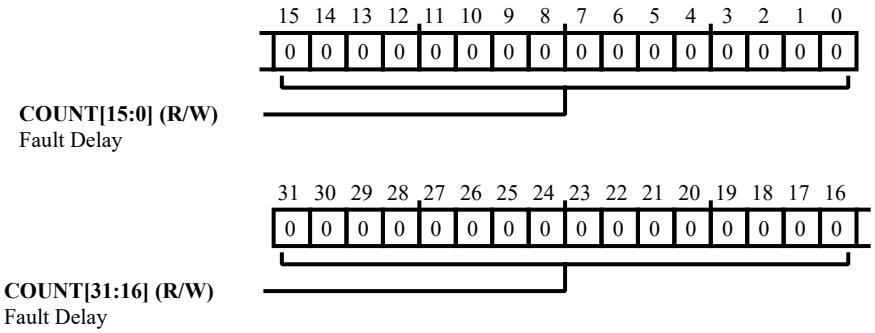

Figure 7-18: SEC_FDLY Register Diagram

Table 7-19: SEC_FDLY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	COUNT	Fault Delay. The SEC_FDLY.COUNT bit field is the number of (SEC) clock periods to delay from fault pending to fault active, when actions are enabled.

Fault Delay Current Register

The SEC fault delay current register (SEC_FDLY_CUR) contains the active count (SEC_FDLY_CUR.COUNT field) in (SEC) clock periods for the delay from fault pending to fault active, when actions are enabled. The count is loaded from the SEC_FDLY register when a fault becomes pending (SEC_FSTAT.PND bit is set). The SEC decrements the value in SEC_FDLY_CUR each (SEC) clock cycle while the SEC_FSTAT.PND bit is set.

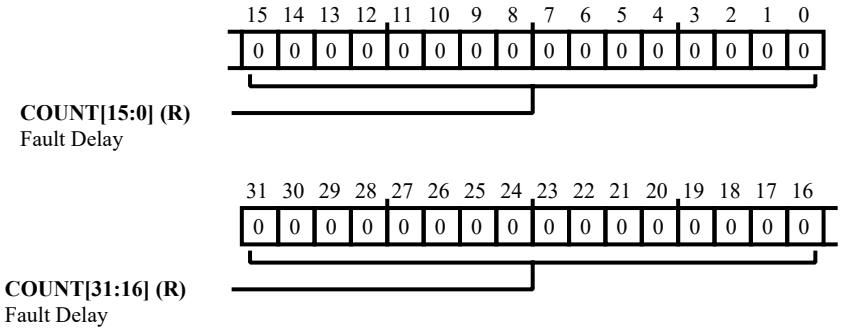

Figure 7-19: SEC_FDLY_CUR Register Diagram

Table 7-20: SEC_FDLY_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	COUNT	Fault Delay. The SEC_FDLY_CUR.COUNT bit field is the active count in (SEC) clock periods for the delay from fault pending to fault active, when actions are enabled.

Fault End Register

The SEC fault end register (SEC_FEND) contains fault source ID and internal/external fields. This register receives fault end indication from a core.

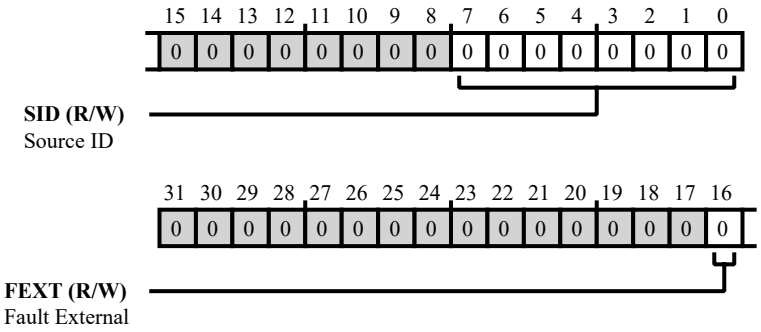

Figure 7-20: SEC_FEND Register Diagram

Table 7-21: SEC_FEND Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W)	FEXT	Fault External. Setting the SEC_FEND.FEXT bit, when the SEC_FEND.SID field is cleared, clears an active fault from an external source.	
		0	Fault Internal
		1	Fault External
7:0 (R/W)	SID	Source ID. The SEC_FEND.SID identifies a fault to be ended as indicated to the SEC by the core. The core loads the SEC_FEND.SID field value. If the SEC_FEND.SID value matches the SEC_FSID.SID value, the SEC_FSTAT.PND bit and SEC_FSTAT.ACT bit are cleared.	

Fault Source ID Register

The SEC fault source ID register (SEC_FSID) contains a fault source ID and internal/external fields.

NOTE:These bits are not reset by system reset so that a fault that automatically triggers a system reset to avoid a fault may be analyzed after the reset occurs.

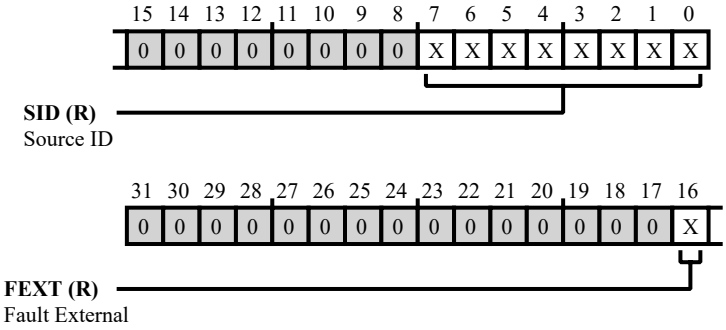

Figure 7-21: SEC_FSID Register Diagram

Table 7-22: SEC_FSID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/NW)	FEXT	Fault External. The SEC_FSID.FEXT bit indicates that the last active fault was asserted by an external device. The SEC sets the SEC_FSID.FEXT bit when the SEC_FSTAT.ACT bit is set by the fault input pins. The SEC_FSID.FEXT bit is cleared when the SEC_FSTAT.ACT bit is set by an internal fault or when the external fault is ended. When the SEC_FSID.FEXT bit is set, the SEC_FSID.SID is cleared.	
		0	Fault Internal
		1	Fault External
7:0 (R/NW)	SID	Source ID. The SEC_FSID.SID identifies the fault assertion detected by the SEC fault interface. The SEC loads the SEC_FSID.SID field value when a system fault indication is asserted. The SEC fault interface does not change the SEC_FSID.SID value until the fault is no longer pending or active, as indicated by the SEC_FSTAT.PND bit and SEC_FSTAT.ACT bit being cleared in the SEC_FSTAT register.	

Fault System Reset Delay Register

The SEC fault system reset delay register (SEC_FSRDLY) contains the number (SEC_FSRDLY.COUNT field) of (SEC) clock periods for the delay from a fault becoming active to system reset request assertion, if enabled.

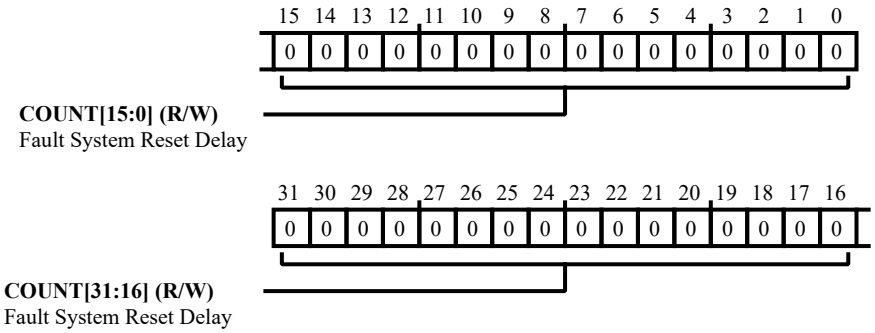

Figure 7-22: SEC_FSRDLY Register Diagram

Table 7-23: SEC_FSRDLY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	COUNT	Fault System Reset Delay. The SEC_FSRDLY.COUNT bit field is the number of (SEC) clock periods for the delay from a fault becoming active to system reset request assertion.

Fault System Reset Delay Current Register

The SEC fault system reset delay current register (SEC_FSRDLY_CUR) contains the active count (SEC_FSRDLY_CUR.COUNT field) in (SEC) clock periods for the delay from fault active to system reset assertion, if enabled. The count is loaded from the SEC_FSRDLY register when a fault becomes active (SEC_FSTAT.ACT bit is set). The SEC decrements the value in SEC_FSRDLY_CUR each (SEC) clock cycle while the SEC_FSTAT.ACT bit is set.

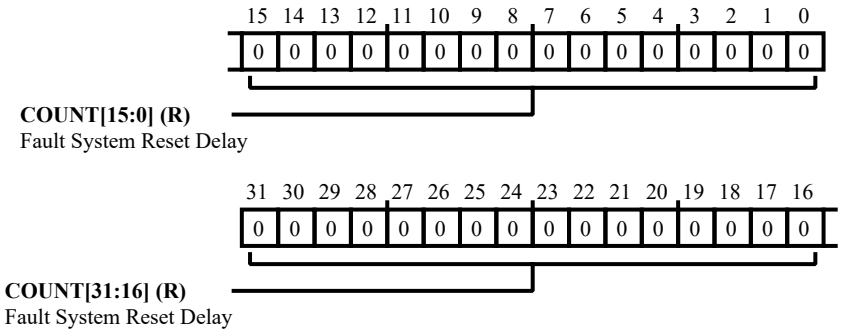

Figure 7-23: SEC_FSRDLY_CUR Register Diagram

Table 7-24: SEC_FSRDLY_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	COUNT	Fault System Reset Delay. The SEC_FSRDLY_CUR.COUNT bit field is the active count in (SEC) clock periods for the delay from fault active to system reset assertion.

Fault Status Register

The SEC fault status register (SEC_FSTAT) indicates the operational status of the SFI.

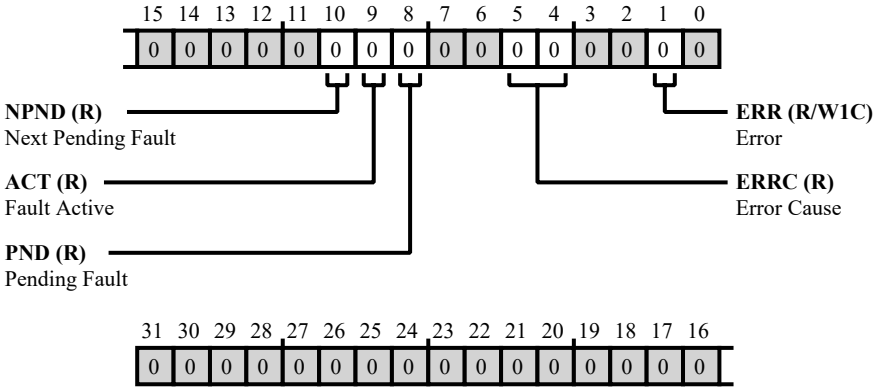

Figure 7-24: SEC_FSTAT Register Diagram

Table 7-25: SEC_FSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
10 (R/NW)	NPND	Next Pending Fault. The SEC_FSTAT.NPND bit indicates that one or more sources have signaled fault assertion, but the input has not yet triggered the fault pending detection in the SEC fault interface. The SEC sets the SEC_FSTAT.NPND bit when the fault interface detects assertion of any enabled fault source input, while either the SEC_FSTAT.PND or SEC_FSTAT.ACT bits are set. The SEC clears the SEC_FSTAT.NPND bit when there are no fault sources waiting.	
		0	Not Pending
		1	Pending
9 (R/NW)	ACT	Fault Active. The SEC_FSTAT.ACT bit indicates that the SEC has received a fault source input, the current fault delay count (in the SEC_FDLY_CUR register) has expired, and the fault actions are enabled. The SEC also sets the SEC_FSTAT.ACT bit on fault input detection if the SEC_FCTL.FIEN bit is set. The SEC_FSTAT.ACT bit is cleared by writing the ID value of the asserted fault from SEC_FSID register to the SEC_FEND register.	
		0	No Fault
		1	Active Fault

Table 7-25: SEC_FSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/NW)	PND	Pending Fault. The SEC_FSTAT.PND bit indicates a fault source has signaled a fault assertion to the SEC, but the SEC has not yet triggered the event actions due to the delay selected with the SEC_FDLY register. The SEC fault interface sets the SEC_FSTAT.PND bit when the SEC_FSID is updated on assertion of a fault source input. The SEC_FSTAT.PND bit is only set when the SEC_FSTAT.ACT bit is cleared. The SEC updates the SEC_FSID register with the SID value when the SEC_FSTAT.PND bit is set. The SEC_FSTAT.PND bit is cleared *either* by the SEC fault interface when the current delay count in the SEC_FDLY_CUR register expires *or* by writing the SEC_FSID.SID field value (which indicates the ID of the asserted fault) to the SEC_FEND register.	
		0	Not Pending
		1	Pending
5:4 (R/NW)	ERRC	Error Cause. When the SEC_FSTAT.ERR bit is asserted, the SEC updates SEC_FSTAT.ERRC field to convey the interrupt source error type. When the error type is source overflow, the status indicates that a source signal assertion occurred or an SEC raise operation was attempted while pending was already set. The source overflow is detected when the source is set for edge only. When the error type is end error, the status indicates that an end was received for a source while the SEC_FSTAT.ACT bit was not set.	
		0	Source Overflow Error
		1	Reserved
		2	End Error
		3	Reserved
1 (R/W1C)	ERR	Error. The SEC_FSTAT.ERR bit indicates an SEC fault interface error. When SEC_FSTAT.ERR is set, the SEC updates the SEC_FSTAT.ERRC field to indicate the corresponding error cause. When multiple errors occur, the SEC_FSTAT register captures the status for the first error and does not capture subsequent errors until the status is cleared.	
		0	No Error
		1	Error Occurred

Global Control Register

The SEC global control register (SEC_GCTL) provides register locking, reset, and enable for the SEC module.

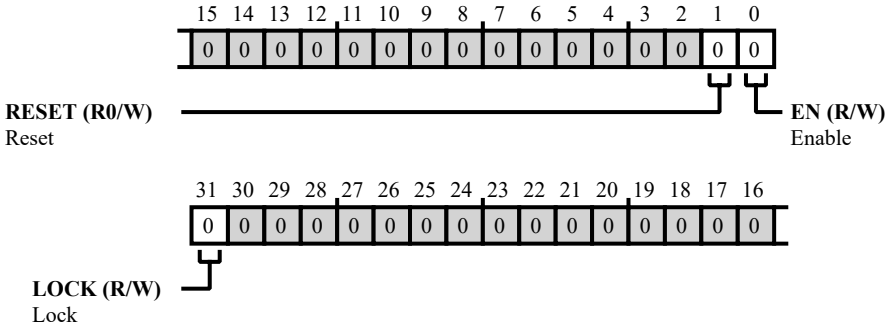

Figure 7-25: SEC_GCTL Register Diagram

Table 7-26: SEC_GCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock is enabled (SPU_CTL.GLCK bit =1) and the SEC_GCTL.LOCK bit is enabled, the SEC_GCTL register is read only.	
		0	Unlock
		1	Lock
1 (R0/W)	RESET	Reset. The SEC_GCTL.RESET bit is write-1-action and triggers a soft reset to all SEC registers.	
		0	No Action
		1	Reset
0 (R/W)	EN	Enable. The SEC_GCTL.EN bit is read/write and must be set for the SEC to begin/resume SEC operation with the current configuration and status. Clearing the SEC_GCTL.EN bit halts the execution of the SFI and all SCIs. All SSIs remain active, along with all error detection, without resetting status registers.	
		0	Disable
		1	Enable

Global Status Register

The SEC global status register (SEC_GSTAT) contains global status bits for the SEC.

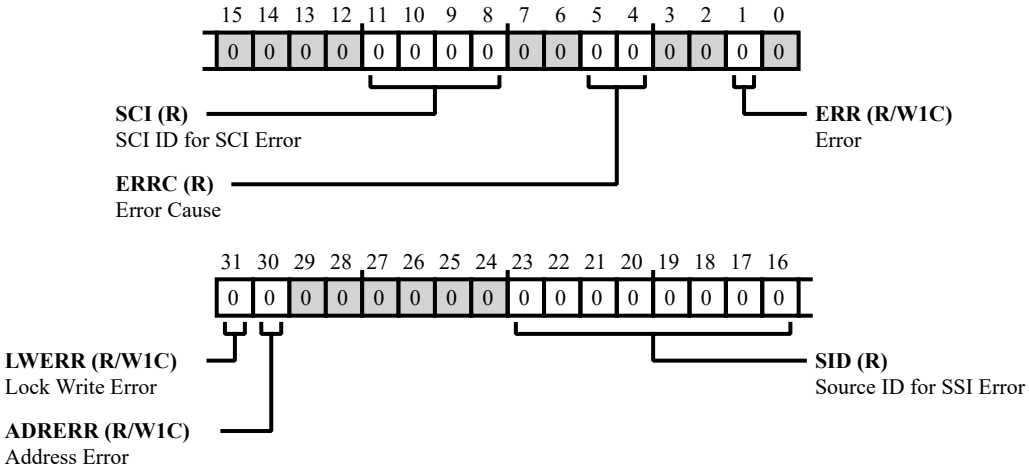

Figure 7-26: SEC_GSTAT Register Diagram

Table 7-27: SEC_GSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W1C)	LWERR	Lock Write Error. The SEC_GSTAT.LWERR bit indicates (when set) there was an attempted write to an SEC register while the SEC_GCTL.LOCK bit was set and while the global lock bit was enabled (SPU_CTL.GLCK bit =1). This status bit is sticky; write-1-to-clear it.	
		0	No Error
		1	Error Occurred
30 (R/W1C)	ADRERR	Address Error. The SEC_GSTAT.ADRERR bit indicates that the SEC generated and address error. This status bit is sticky; write-1-to-clear it.	
		0	No Error
		1	Error Occurred
23:16 (R/NW)	SID	Source ID for SSI Error. The SEC_GSTAT.SID bits indicate the source ID that generated the last SSI error conveyed in the SEC_GSTAT.ERRC field.	
11:8 (R/NW)	SCI	SCI ID for SCI Error. The SEC_GSTAT.SCI bits indicate the number for the specific SCI that generated the last SCI error conveyed in the SEC_GSTAT.ERRC field.	

Table 7-27: SEC_GSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5:4 (R/NW)	ERRC	Error Cause. When the SEC updates the `SEC_GSTAT.ERR` bit, the SEC updates the `SEC_GSTAT.ERRC` bits to indicate the error type. Note that for SCI errors, the error status represents an OR of all the errors from each SCI. Note that for SSI errors, the error status indicates an error is active for any SSI input. This error is an OR of all the interrupt source errors.	
		0	SFI Error
		1	SCI Error
		2	SSI Error
		3	Reserved
1 (R/W1C)	ERR	Error. The `SEC_GSTAT.ERR` bit indicates an error has occurred in the SEC. When the SEC asserts this bit (=1), the SEC updates the `SEC_GSTAT.ERRC` field to indicate the corresponding error cause. Even if multiple errors occur, only the first error is captured on assertion of this bit. This status bit is sticky; write-1-to-clear it.	
		0	No Error
		1	Error Occurred

Global Raise Register

The SEC global raise register (SEC_RAISE) contains a source ID event set-to-pending field (SEC_RAISE.SID). When a source ID value is written to this field, the SEC raises the source's event status to pending.

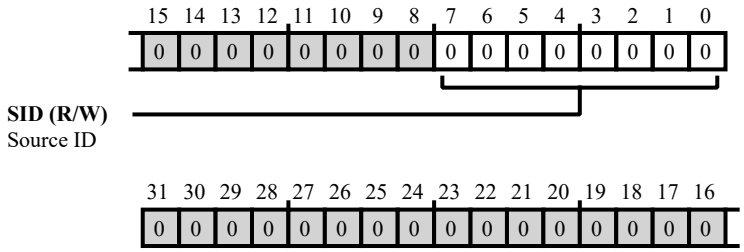

Figure 7-27: SEC_RAISE Register Diagram

Table 7-28: SEC_RAISE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	SID	Source ID. The SEC_RAISE.SID bit field is the source ID of event that is set to pending status.

Source Control Register n

The SEC source control register (SEC_SCTL[n]) contains control bits to configure the SEC event sources. This register controls the configuration of the corresponding SEC event source.

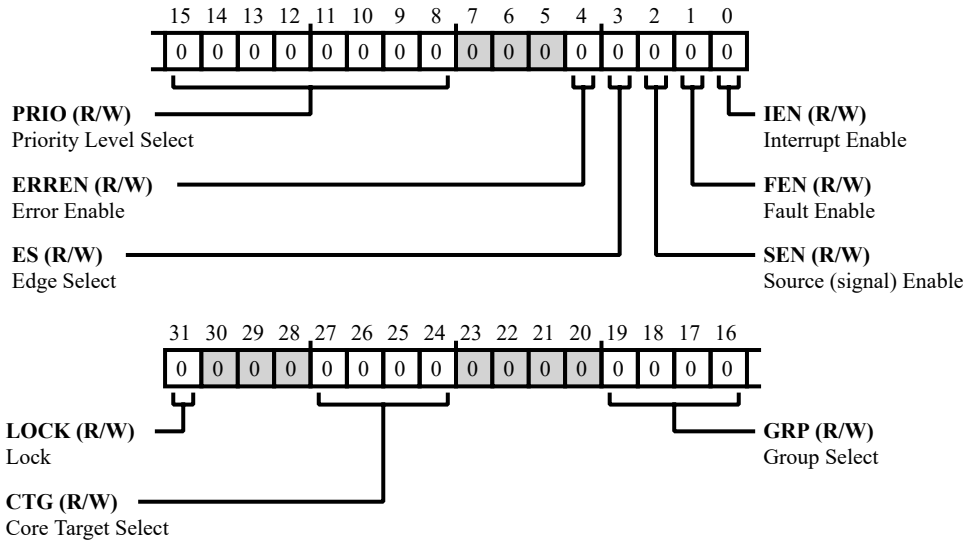

Figure 7-28: SEC_SCTL[n] Register Diagram

Table 7-29: SEC_SCTL[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock is enabled (SPU_CTL.GLCK bit =1) and the SEC_SCTL[n].LOCK bit is enabled, the SEC_SCTL[n] register is read only.	
		0	Unlock
		1	Lock
27:24 (R/W)	CTG	Core Target Select. The SEC_SCTL[n].CTG bits selects the specific SEC core interface to which the interrupt is mapped. Each system interrupt is mapped uniquely to one specific SEC core interface and (as a result) to a specific core.	
		1	CORE1 SHARC0
		2	Reserved

Table 7-29: SEC_SCTL[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
19:16 (R/W)	GRP	Group Select. The SEC_SCTL[n].GRP bits each select a specific group for the interrupt. Each system interrupt can be assigned to any combination of groups supported by the SEC_SCTL[n].GRP field. For example, consider the situation where SEC_SCTL[n].GRP0 represents interrupt group 0, SEC_SCTL[n].GRP1 represents interrupt group 1, and so on. One group might be used for all enabled interrupts (for example, group 0) and an additional group might be used for all wakeup interrupts (for example, group 1). This approach supports a model of all interrupts and just the wakeup subset. Before going to idle or sleep, all non-wakeup interrupts can be masked off to allow only wakeup interrupts to be enabled for service. Selecting no group (all SEC_SCTL[n].GRP bits = 0) places the interrupt source in the category of "ungrouped".	
15:8 (R/W)	PRIO	Priority Level Select. The SEC_SCTL[n].PRIO bits sets the relative priority for an interrupt request. A pending interrupt request forwards its SEC_SCTL[n].PRIO value to the SEC core interface.	
4 (R/W)	ERREN	Error Enable. The SEC_SCTL[n].ERREN bit permits the SEC_SSTAT[n].ERR status bit to be set on error detection. If SEC_SCTL[n].ERREN is cleared, no errors are detected.	
		0	Disable
		1	Enable
3 (R/W)	ES	Edge Select. The SEC_SCTL[n].ES bit selects the operational and sensitivity mode of the SEC source interface input.	
		0	Level Sensitive
		1	Edge Sensitive
2 (R/W)	SEN	Source (signal) Enable. The SEC_SCTL[n].SEN bit controls whether the system event source input signal may affect the pending status of the source. Clearing the SEC_SCTL[n].SEN bit disables the source input signal from affecting the pending status. Setting SEC_SCTL[n].SEN enables the source input signal to affect the pending status.	
		0	Disable
		1	Enable

Table 7-29: SEC_SCTL[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	FEN	Fault Enable. The `SEC_SCTL[n].FEN` bit controls whether the SEC may forward an interrupt request to the SEC fault interface as a fault source. This bit does not affect the ability of an interrupt source to set an interrupt as pending. The `SEC_SCTL[n].FEN` bit only affects whether the pending request may be forwarded to the SEC fault interface.	
		0	Disable
		1	Enable
0 (R/W)	IEN	Interrupt Enable. The `SEC_SCTL[n].IEN` bit controls whether the SEC may forward an interrupt request to a core for servicing. This bit does not affect the ability of an interrupt source to set an interrupt as pending.	
		0	Disable
		1	Enable

Source Status Register n

The SEC event source status register (SEC_SSTAT[n]) contains bits indicating the status of the corresponding event source n. An event source may be: pending, active, active and pending, or neither pending nor active.

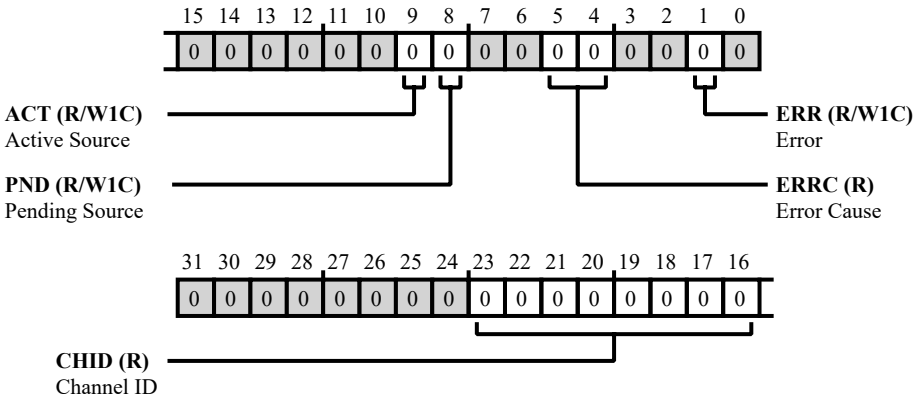

Figure 7-29: SEC_SSTAT[n] Register Diagram

Table 7-30: SEC_SSTAT[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
23:16 (R/NW)	CHID	Channel ID. The SEC_SSTAT[n].CHID bits indicate the ID of the specific source (from a set of sources sharing one SEC source interface input) that asserted the SEC source interface input. An SEC source interface input may support multiple system sources, in which case the assertion must be qualified by an identifier to determine the channel that generated the assertion. The SEC_SSTAT[n].CHID field provides this value in the form of a numeric reference that is mapped to a specific interrupt source. The prioritization for simultaneously asserted sources is according to ID, with 0 being the highest priority. The SEC_SSTAT[n].CHID is captured when the SEC source interface input is acknowledged.	
9 (R/W1C)	ACT	Active Source. The SEC_SSTAT[n].ACT bit indicates the source has been accepted by a core for servicing, but the service is not yet complete. An SEC_SSTAT[n].ACT bit is set by the SEC when the specific system interrupt is acknowledged by the core through the SEC core interface. An SEC_SSTAT[n].ACT bit is cleared by the SEC when the core provides interrupt service end indication for the specific system interrupt through the SEC core interface.	
		0	Not Active
		1	Active

Table 7-30: SEC_SSTAT[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W1C)	PND	Pending Source. The SEC_SSTAT[n].PND bit indicates the source has signaled an event request, but the event request has not been (or is not currently being) serviced. A SEC_SSTAT[n].PND bit is set by the SEC on detection of an assertion of the corresponding system source input. A SEC_SSTAT[n].PND bit is cleared by the SEC when the specific system event is acknowledged by the core through the SEC core interface or by a W1C operation.	
		0	Not Pending
		1	Pending
5:4 (R/NW)	ERRC	Error Cause. When the SEC_SSTAT[n].ERR bit is asserted, the SEC updates SEC_SSTAT[n].ERRC field to convey the interrupt source error type. When the error type is source overflow, the status indicates that a source signal assertion occurred or an SEC raise operation was attempted while pending was already set. The source overflow is detected when the source is set for edge only. When the error type is end error, the status indicates that an end was received for a source while the SEC_SSTAT[n].ACT bit was not set.	
		0	Source Overflow Error
		1	Reserved
		2	End Error
		3	Reserved
1 (R/W1C)	ERR	Error. The SEC_SSTAT[n].ERR bit indicates an error for a specific system interrupt source. When the SEC_SSTAT[n].ERR bit is set, the SEC updates the SEC_SSTAT[n].ERRC field to the value of the corresponding error cause. Even if multiple errors occur, only the first error is captured on assertion of the SEC_SSTAT[n].ERR bit.	
		0	No Error
		1	Error Occurred

GIC Overview

The generic interrupt controller (GIC) provides an interface to the dual Cortex A55 core in the processor and collects up to 419 interrupt requests from all processor system sources. In addition, the GIC also supports sixteen software generated interrupts and nine private peripheral interrupts that are internal to the Cortex A55 core and not connected to the SECs. All GIC interrupts are also connected to the SEC in the same order.

Each interrupt can be configured as a normal or a secure interrupt. Software force registers and software priority masking are also supported. The “Register Descriptions” section in this chapter provides brief descriptions of these Arm-based registers. For complete information refer to the *Arm® Generic Interrupt Controller Architecture version 3.0 and 4.0 Architecture Specification*.

GIC Functional Description

The GIC interrupt controller consists of three interfaces;

- Distributor interface
- Redistributor interface
- CPU interface

The distributor and the redistributor interfaces are used to configure interrupts; the CPU interface is used to handle interrupts.

GIC Distributer Interface

The distributor registers are memory-mapped. They are used to configures SPIs. The distributor block provides a programming interface to perform the following tasks.

- Interrupt prioritization and distribution of SPIs
- Enable and disable SPIs
- Set the priority level of each SPI
- Set each SPI to be level-sensitive or edge-triggered
- Assign each SPI to an interrupt group
- Control the active and pending state of SPIs.

GIC Redistributer Interface

There is one redistributor per connected core. The redistributors provide a programming interface to perform the following tasks.

- Enable and disable SGIs and PPIs
- Set the priority level of SGIs and PPIs
- Set each PPI to be level-sensitive or edge-triggered
- Assign each SGI and PPI to an interrupt group
- Control the state of SGIs and PPIs.

GIC CPU Interface

Each core contains a CPU interface that includes system registers that are used during interrupt handling. The CPU interfaces provide a programming interface to perform the following tasks.

- Provide general control and configuration to enable interrupt handling
- Acknowledge an interrupt
- Perform a priority drop and deactivation of interrupts
- Set an interrupt priority mask for the processor
- Define the preemption policy for the processor
- Determine the highest priority pending interrupt for the processor

In Arm CoreLink GICv3, the CPU interface registers are accessed as system registers: ICC_*_ELn, where “n” specifies the Exception level: EL1-EL3.

Refer to the GIC Register Descriptions in this chapter for details on the distributor and the redistributor interface registers. Refer to the *Arm® Generic Interrupt Controller Architecture Specification GIC architecture version 3.0 and 4.0* for details on the CPU interface registers.

GIC Block Diagram

The ***GIC Block Diagram*** shows the event management architecture.

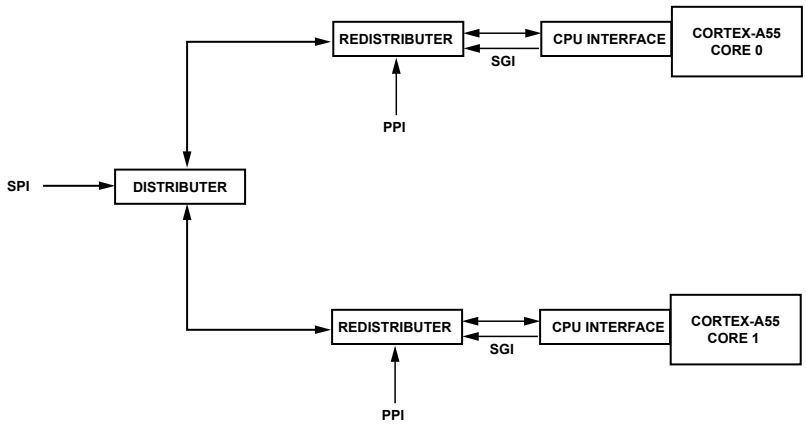

Figure 7-30: GIC Block Diagram

GIC Performance Monitoring Unit (GIC PMU)

The GIC contains a performance monitoring unit (PMU) for counting key GIC events from the distributor. Redistributor events are not tracked by the PMU. The delivery of PPI and SGI interrupts are counted by recording calls to the core interrupt service routine.

The PMU has five counters with snapshot capability and overflow interrupt. For all the GIC events, PMU count configuration and register information, please refer to the *Arm® CoreLink™ GIC 600 Generic Interrupt Controller Technical Reference Manual*.

Overflow interrupt

The overflow interrupt is enabled on a per counter basis by enabling the relevant bit of the register. Similarly, the overflow interrupt enable is disabled by corresponding writes to the register. When enabled, the interrupt activates when there is a write to the register for any counter or overflow on any enabled counter.

Snapshot

Each PMU counter, , has a corresponding snapshot register. On a snapshot event, all five counters are copied to their backup registers so that all consistent data is copied out over a longer period.

The snapshot events are as follows:

- Write of 1 to the GICP_ bit
- An overflow of an enabled counter when the bit is set

8 Trigger Routing Unit (TRU)

The TRU provides system-level sequence control without core intervention. The TRU maps trigger generators to trigger receivers. Receiver endpoints can be configured to respond to triggers in various ways. Multiple TRUs may be provided in a multiprocessor system to create a trigger network. Common applications enabled by the TRU include:

- Automatically triggering the start of a DMA sequence after a sequence from another DMA channel completes
- Software triggering
- Synchronization of concurrent activities

TRU Features

The TRU supports the following features:

- Automatically triggering the start of a DMA sequence after a sequence from another DMA channel completes. Once a DMA channel completes data transfer, it can act as a trigger generator and signal an internal trigger pulse to the programmed trigger receiver which can also be another DMA channel. The receiver trigger connected to the DMA channel kicks off the DMA transfer automatically. None of this requires core intervention once the initialization is done.
- Software triggers. The best use of triggers is to minimize core intervention. It is also possible to initiate a trigger pulse to a trigger receiver, in the software.
- Synchronization of concurrent activities. A single trigger generator can initiate a trigger pulse to multiple trigger receiver so that several system level activities can be synchronized on an internally or externally generated event.
- Configuration protection through register-level lock bits and global lock indication

TRU Functional Description

The following sections provide a description of the TRU.

ADSP-2184x TRU Register List

The Trigger Routing Unit (TRU) provides simple sequence control of distributed modules without the penalties associated with core intervention (for example, interrupt overhead). The TRU receives trigger inputs from all trigger generator inputs (MTI) and the TRU trigger receiver register (TRU_GEN). Based on these inputs, the TRU logic generates trigger outputs that initiate receiver operations in the processor core and peripherals. A set of registers governs TRU operations. For more information on TRU functionality, see the TRU register descriptions.

TRU Definitions

The following definitions are helpful when using the TRU module.

Trigger Generator

A trigger generator is any system module that provides trigger event indication to the TRU. Trigger generator modules define trigger events and conditions for assertion.

Trigger Generator ID

Trigger generators are assigned a unique numeric ID according to their physical connection to the TRU. Trigger receiver ID 0 is reserved and defined as null.

Trigger Receiver

A trigger receiver is any system module that receives a trigger event indication from the TRU. Trigger receiver modules define a trigger event response.

TRU Block Diagram

The trigger generator and the generator trigger register (GTR) generate trigger assertions. Each trigger receiver has a dedicated receiver select register (RSR) that specifies the unique trigger generator from which it receives the trigger indication.

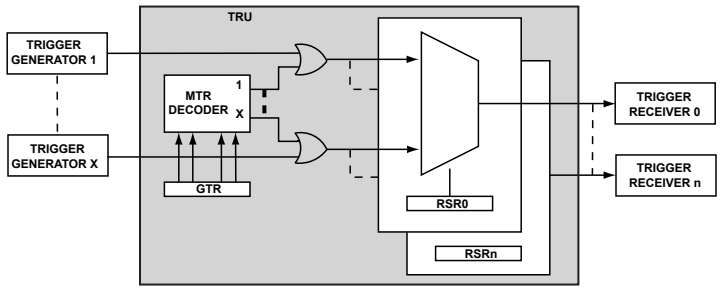

Figure 8-1: TRU Block Diagram

TRU Architectural Concepts

The TRU supports a simple trigger-in/trigger-out model for modules that comply with the triggering functional model. The TRU is the controller of the trigger system. Trigger outputs from trigger generators are mapped to trigger inputs of trigger receivers through a set of programmable registers (`TRU_RSR[n]`).

System modules are trigger generator only, trigger receiver only, or trigger generator and trigger receiver.

All of the trigger input and output signals are connected to a trigger routing unit (TRU) which manages the connections of triggers between modules.

In multi-processor systems, multiple TRU units are provided. These TRUs are networked together. Generic Trigger Ports (GTPs) are provided to forward trigger events from one TRU unit to another, forming a pathway from trigger generator to trigger receivers wherever they might lie in the system.

TRU Programming Model

Implementing sequence control using the TRU requires, at a minimum, proper configuration of a trigger receiver, a trigger generator, and the TRU module itself. The only requirement for the configuration procedure is that the trigger generator is configured and enabled as the last step.

Complete the following other steps:

- Configure the trigger receiver for response to triggers
- Configure the TRU to map the trigger generator to the trigger receiver through the `TRU_RSR[n]` registers
- Configure the trigger generator to generate trigger assertions
- Alternatively, use software triggering for trigger assertion. Writing the trigger generator ID to the GTR register generates software triggers.

Programming Concepts

The following concepts aid in programming the TRU.

- ***Trigger Sequence Configuration.*** A simple sequence consists of one trigger generator and one trigger receiver. More complex trigger sequences consist of several trigger receivers functioning as trigger receiver and trigger generator. Additionally, trigger sequences can loopback to the original generator forming a perpetual sequence.
- ***Software Triggering.*** Writing a trigger generator ID to the GTR generates a trigger within the TRU from the trigger generator ID specified.
- ***Synchronization.*** The TRU can be used to coarsely synchronize events by mapping multiple trigger receivers to the same trigger generator or by generating multiple trigger generator assertions simultaneously through the GTR.
- ***Configuration Protection.*** The `TRU_RSR[n].LOCK` bit and the `TRU_GCTL.LOCK` bit enable register level write-protection when the global lock is asserted in the SPU.

Programming Examples

The following examples shows the steps to create a single trigger.

Configuring a Simple Trigger Sequence

The following example shows the steps to create a simple trigger.

1. Enable the Global Lock feature bit on the SPU (set the `SPU_CTL.GLCK` bit).
2. Set the `TRU_GCTL.LOCK` bit to 1 so that the `TRU_GCTL` register becomes read-only.
3. Set the `TRU_GCTL.GENL` bit to 1 so that the `TRU_GEN` register becomes read-only.

TRU Event Control

The TRU is a major part of event control solutions. It is the center of the trigger functional model and can extend to support the interrupt and fault management models as well.

TRU Status and Error Signals

The TRU does not have dedicated status and error output signals other than the MMR interface. Receiver errors are reported to the generator over the standard peripheral bus protocol.

ADSP-2184x TRU Register Descriptions

Trigger Routing Unit (TRU) contains the following registers.

Table 8-5: ADSP-2184x TRU Register List

Name	Description
TRU_ERRADDR	Error Address Register
TRU_GCTL	Global Control Register
TRU_GEN	Generator Trigger Register
TRU_RSR[n]	Receiver Select Register
TRU_STAT	Status Information Register

Error Address Register

The TRU error address register (TRU_ERRADDR) holds the address from the memory-mapped register access generating an access error of TRU registers.

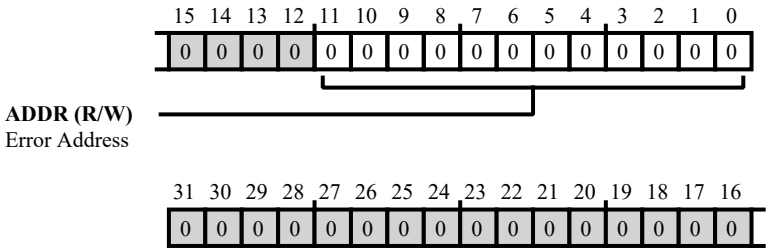

Figure 8-2: TRU_ERRADDR Register Diagram

Table 8-6: TRU_ERRADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
11:0 (R/W)	ADDR	Error Address. The TRU_ERRADDR.ADDR holds the address from the memory-mapped register access generating an access error of TRU registers. These errors occur on access to the TRU_RSR[n] or TRU_GEN registers when these registers are locked or on access to an invalid address. See the TRU_RSR[n] and TRU_GEN register descriptions for more information about locking. The TRU_ERRADDR register holds the address of the first error to occur. In the event of multiple errors occurring, the TRU_ERRADDR register contains the address of the first error. To re-enable the TRU_ERRADDR register for update, both status bits (TRU_STAT.LWERR and TRU_STAT.ADDRERR) in the TRU_STAT register must be cleared.

Global Control Register

The TRU global control register (TRU_GCTL) provides register locking, TRU reset, and TRU enable.

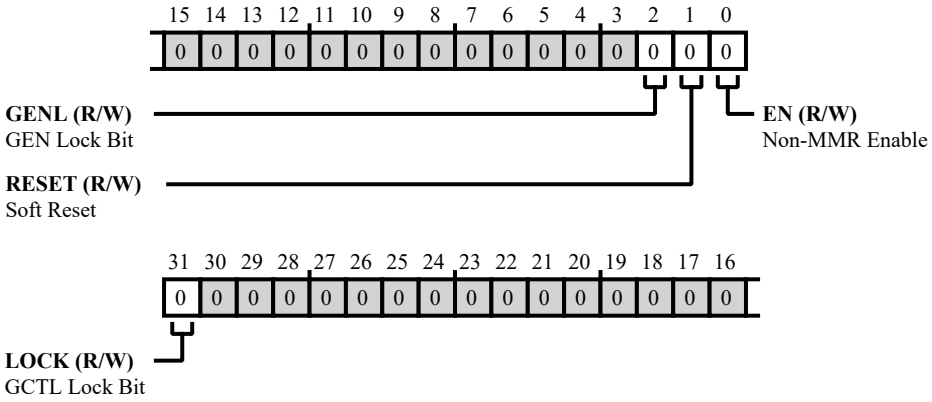

Figure 8-3: TRU_GCTL Register Diagram

Table 8-7: TRU_GCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	GCTL Lock Bit. If the global lock is enabled (SPU_CTL.GLCK bit =1) and the TRU_GCTL.LOCK bit is enabled, the TRU_GCTL register is read only.	
		0	Read Write
		1	Read Only
2 (R/W)	GENL	GEN Lock Bit. If the global lock is enabled (SPU_CTL.GLCK bit =1) and the TRU_GCTL.GENL bit is enabled, the TRU_GEN register is read only.	
		0	Read Write
		1	Read Only
1 (R/W)	RESET	Soft Reset. The TRU_GCTL.RESET bit is write-1-action and triggers a soft reset to all TRU registers.	
		0	No Action
		1	Soft Reset

Table 8-7: TRU_GCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	EN	Non-MMR Enable. The `TRU_GCTL.EN` bit is read/write and must be set for the TRU to propagate trigger events. All TRU register read/write operations continue to operate independent of the `TRU_GCTL.EN` bit.	
		0	No Trigger Events
		1	Propagate Trigger Events

Generator Trigger Register

The TRU generator trigger register (TRU_GEN) permits trigger generation through software by writing a trigger generator ID value to one of the four fields in the TRU_GEN register. If the global lock is enabled (SPU_CTL.GLCK bit =1) and the TRU_GCTL.LOCK bit is set, the TRU_GEN register is read only. Note this register is primarily used for debug to trigger a TRU output

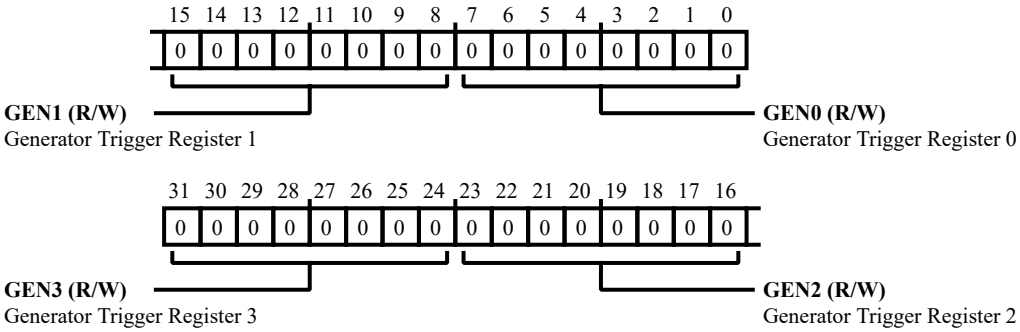

Figure 8-4: TRU_GEN Register Diagram

Table 8-8: TRU_GEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:24 (R/W)	GEN3	Generator Trigger Register 3. The TRU_GEN.GEN3 bit field is the trigger generator ID value for generator 3.	
		0	No Generator Specified
		1-182	Range of Valid Generators
23:16 (R/W)	GEN2	Generator Trigger Register 2. The TRU_GEN.GEN2 bit field is the trigger generator ID value for generator 2.	
		0	No Generator Specified
		1-182	Range of Valid Generators
15:8 (R/W)	GEN1	Generator Trigger Register 1. The TRU_GEN.GEN1 bit field is the trigger generator ID value for generator 1.	
		0	No Generator Specified
		1-182	Range of Valid Generators
7:0 (R/W)	GEN0	Generator Trigger Register 0. The TRU_GEN.GEN0 bit field is the trigger generator ID value for generator 0.	
		0	No Generator Specified
		1-182	Range of Valid Generators

Receiver Select Register

The TRU receiver select registers (TRU_RSR[n]) each provide trigger receiver selection and register locking.

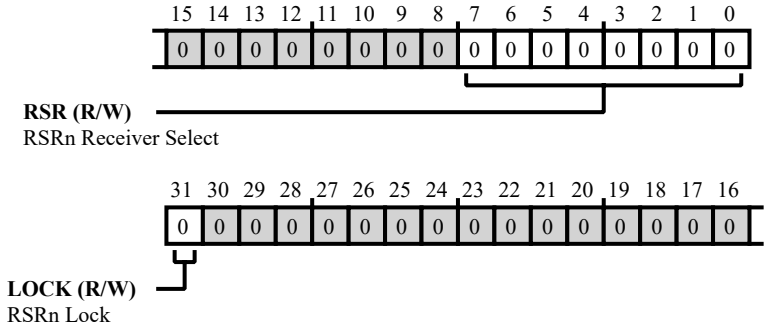

Figure 8-5: TRU_RSR[n] Register Diagram

Table 8-9: TRU_RSR[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	RSRn Lock. If the global lock is enabled (SPU_CTL.GLCK bit =1) and the TRU_RSR[n].LOCK bit is enabled, the TRU_RSR[n] register is read only.	
		0	Unlock Register
		1	Lock Register
7:0 (R/W)	RSR	RSRn Receiver Select. The TRU_RSR[n] register selects the trigger generator ID to which the trigger receiver responds. For example, when a TRU_RSR[n] register is set to respond to trigger generator ID n, a trigger that is generated by trigger generator ID n results in a trigger out to the receiver.	
		0	No Generator Specified
		1-182	Range of Valid Generators

Status Information Register

The TRU status register (TRU_STAT) contains the status of TRU_GEN and TRU_RSR[n] register writes and status of bus read/write errors.

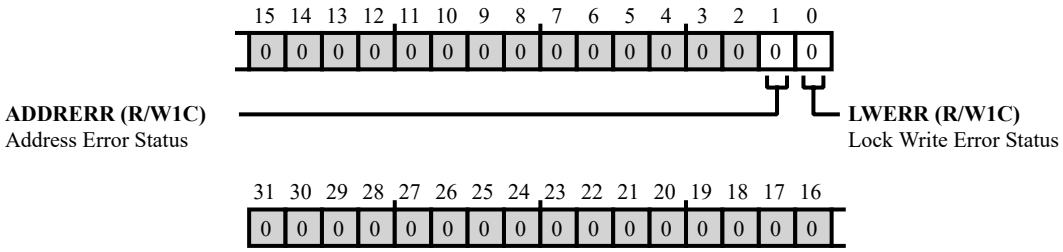

Figure 8-6: TRU_STAT Register Diagram

Table 8-10: TRU_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W1C)	ADDRERR	Address Error Status. The TRU_STAT.ADDRERR bit is set when an invalid address is provided for an MMR access while the TRU is selected. Writing a one to this bit clears the error indication. The TRU_ERRADDR register also is updated when an address error occurs during an MMR access while the TRU is selected.	
		0	No error
		1	Error occurred
0 (R/W1C)	LWERR	Lock Write Error Status. If TRU_STAT.LWERR is set, a lock write error has occurred. Writing a one to this bit clears the error indication.	
		0	No error
		1	Error occurred

9 L2 System Memory

L2 system memories have significant bandwidth for core accesses, but it is important to note that L2 responds slower to core accesses than L1 memories. L2 SRAM is the ideal storage for multiple processor cores to share data and instruction resources, such as semaphores, shared buffers, and code libraries. Due to sophisticated data integrity protection and write protection, L2 SRAM is also ideal for data and instructions critical for safe operation of the application.

L2 System Memory Features

The L2 system memory features include:

- Operation at `SYSCLK` frequency
- ECC protection of SRAM area
- ECC memory refresh

There are three instance of L2 system memory: L2CTL0, L2CTL1 and LCTL2.

- L2CTL0 contains 2M byte of RAM grouped into eight banks, 256K bytes each and 192K bytes of boot ROM.
- L2CTL1 contains 2M byte of RAM grouped into eight banks, 256K bytes each.
- SHARC core data ports can access L2 memory through direct path.

L2 System Memory Functional Description

The L2 system memory manages all of the L2 SRAM and ROM memory banks. The system memory interface arbitrates competing accesses, write protection, and ensures SRAM data integrity. The L2 system memory domain is a unified instruction and data memory. It can hold any mixture of code and data required by the system design.

The following sections provide a functional description of the L2 system memory.

ADSP-2184x L2CTL Register List

The L2 memory controller (L2CTL) includes the controls to manage each L2 memory bank independently. A set of registers governs L2CTL operations. For more information on L2CTL functionality, see the L2CTL register descriptions.

Table 9-1: ADSP-2184x L2CTL Register List

Name	Description
L2CTL_CTL	Control Register
L2CTL_EADDR0	Error Type 0 Address Register

L2 System Memory Block Diagram

The ***ADSP-2184x/ADSP-SC84x Complete L2 System Memory Block Diagram*** shows the complete L2 system memory, including the memory block instances L2CTL0, L2CTL1 and L2CTL2. The L2CTL0 block contains boot ROM code for Arm and eight banks of L2 RAM containing 256 Kbytes each. The Arm reset ISR (location 0x00000000) is mapped to this block.

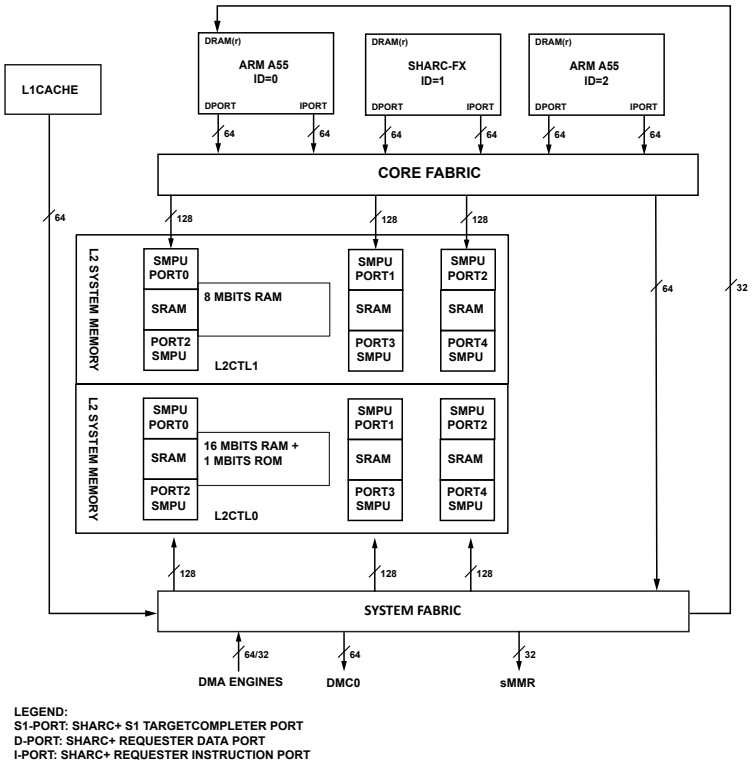

Figure 9-1: ADSP-2184x Complete L2 System Block Diagram

L2 System Memory Architectural Concepts

The following sections describe the architecture features of the L2 system memory.

Access Characteristics

The L2 system memory interface converts all 8-bit, 16-bit, 32-bit, and 64-bit accesses to 128-bit accesses. Additionally, it converts 8-bit, 16-bit, 32-bit, and 64-bit bursts to an equivalent internal 128-bit access. For example, the L2 system memory interface converts a 128-bit address-aligned burst of 8-bit accesses of burst length 16 to a single 128-bit access.

Read/Write Latency and Throughput

The L2 memory design is optimized for burst accesses at the crossbar interface. The L2 system memory buffers and converts write data of 8/16/32/64-bit to an equivalent 128-bit access. This conversion creates modulo-32-bit writes if the starting addresses are 32-bit aligned. A single 8-bit or 16-bit access, or a non-32-bit address-aligned 8-bit or 16-bit burst access to an ECC-enabled bank creates an extra latency of two SYSCLK cycles. No extra latency is seen if the ECC is disabled.

NOTE: Continuous 8/16-bit core access to an ECC-enabled L2 bank is not recommended from a throughput perspective.

L2 Memory Controller Block Diagram (Instance)

As shown in the ***L2 System Memory Block Diagram***, the L2 controller has five ports that interface to system crossbars. Port 0, port 1, and port 2 are 128-bit interfaces dedicated to core and MDMA3 traffic. Port 3 and port 4 are 128-bit interfaces that connect through DMA. For L2 SRAM, all ports (0/1/2/3/4) have a read channel and a write channel; for L2 ROM, all ports (0/1/2/3/4) have read channels only. The SRAM is organized in multiple banks; each bank has 256K Bytes. The 192KB ROM is divided into three banks of 64KB.

Within each bank, data is organized into words, with each word comprising 128 bits of data and 28 bits of ECC checksum. ROM memory is not protected by the ECC scheme. When the L2 controller accesses RAM and ROM cells, it always reads and writes whole 128-bit words. Despite this, the L2 controller supports 8-, 16-, 32-, and 64-bit reads and writes from cores and system by applying respective data masks.

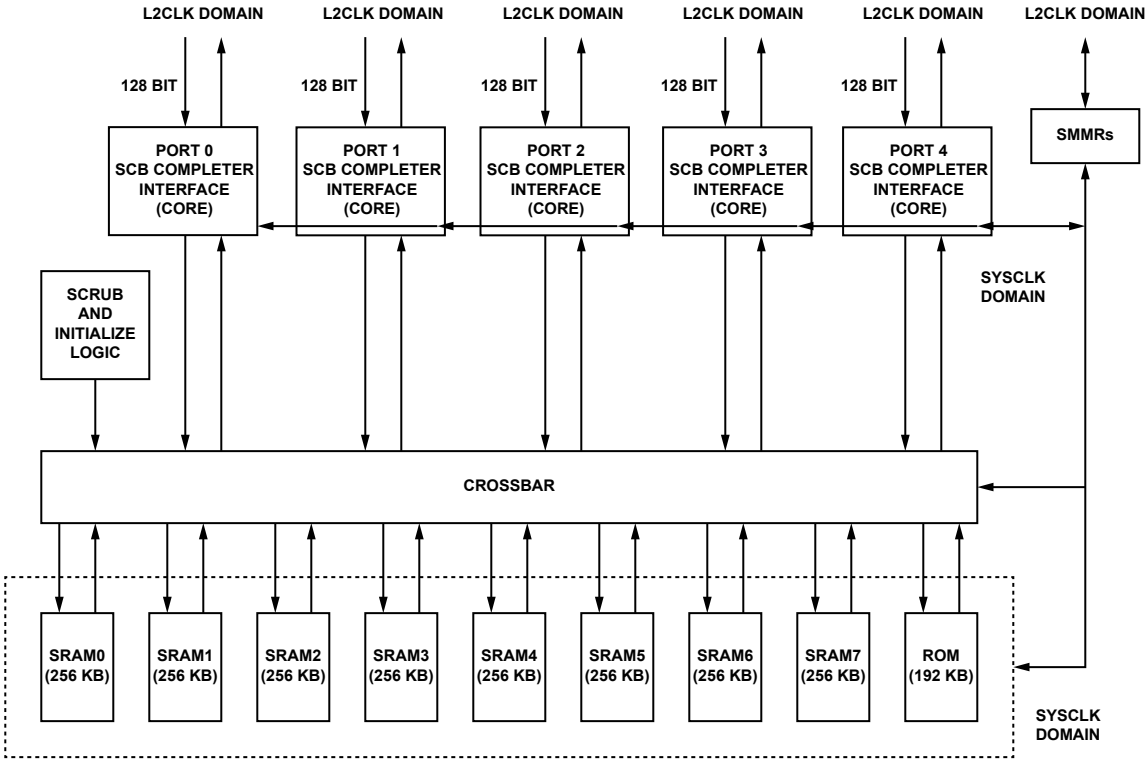

Figure 9-2: L2 System Memory Block Diagram

Arbitration and Priority

Each bank of L2 RAM or ROM has an arbiter which receives requests from the five crossbar ports.

Each arbiter follows a fixed priority scheme for giving grants when more than one channel requests the same bank. The arbiter also supports priority elevation through urgent priority requests.

NOTE: Attempting a write access to both L2 ROM spaces returns an error.

The ***Fixed Priority*** table shows the priority for fixed priority mode (with urgent priority disabled) for each SCB channel.

If two cores (or the 64-bit Max BW DMA) simultaneously try to access L2 for the same instance (both read or both write), even to different banks, software allows only one controller access at a time. One access port can support one read and write at the same time. However, if one core issues a write and the other issues a read, then access can proceed simultaneously. There is no extra latency inside L2, when the accesses are to different banks (assuming pending DMA traffic is also to a non-conflicting bank).

When a core and DMA both access the same bank via the same port (both read or both writes), the best access rate that DMA can achieve is one 128-bit access in every three SYSCLK cycles during the conflict period. This access rate is achieved by programming the read priority count register (`L2CTL_RPCR0.RPC0`) bit and the write priority count register (`L2CTL_WPCR0.WPC0`) to 0, while programming the `L2CTL_RPCR0.RPC1` and the `L2CTL_WPCR0.WPC1` bits to 1.

The arbiters also support priority elevation for a particular channel that has been starved of grants for many SYSCLK cycles. If a channel does not get a grant for *N* cycles after its request, then that channel can elevate the priority of its request by issuing an urgent priority request. This request causes that channel to become the highest priority controller for the next grant cycle (pipelined arbitration for urgent priority). The number of cycles *N*, after which the priority is elevated, can be programmed for each channel separately using the (`L2CTL_RPCR0`) and (`L2CTL_WPCR0`) registers.

Programming the bits in the (`L2CTL_RPCR0`) and (`L2CTL_WPCR0`) registers appropriately achieves the best grant rate for DMA. This grant rate of one in three SYSCLK cycles during the conflict period is achievable under the following conflict conditions:

- An access conflict between the core and DMA to the same memory bank in the fixed priority arbitration scheme with core activity always prioritized over DMA activity
- An access conflict within the pipelined implementation of urgent priority

To disable urgent priority requests, set the `L2CTL_CTL.DISURP` bit. This bit disables the urgent priority requests for all port channels. Each channel can also be prevented from raising the urgent priority request through the priority count register for the specific channel. However, there is no support for disabling urgent priority for a specific memory bank arbiter.

The ***Fixed Priority With Priority Elevation*** table provides the various priority levels for the L2 system memory.

Table 9-5: Fixed Priority With Priority Elevation

Channel	Priority Level
L2 Scrub/Initialization Request	21 (highest)
Port 0 Read Channel Urgent Request	20
Port 0 Write Channel Urgent Request	19
Port 1 Read Channel Urgent Request	18
Port 1 Write Channel Urgent Request	17
Port 2 Read Channel Urgent Request	16

Table 9-5: Fixed Priority With Priority Elevation (Continued)

Channel	Priority Level
Port 2 Write Channel Urgent Request	15
Port 3 Read Channel Urgent Request	14
Port 3 Write Channel Urgent Request	13
Port 4 Read Channel Urgent Request	12
Port 4 Write Channel Urgent Request	11
Port 0 Read Channel Normal Request	10
Port 0 Write Channel Normal Request	9
Port 1 Read Channel Normal Request	8
Port 1 Write Channel Normal Request	7
Port 2 Read Channel Normal Request	6
Port 2 Write Channel Normal Request	5
Port 3 Read Channel Normal Request	4
Port 3 Write Channel Normal Request	3
Port 4 Read Channel Normal Request	2
Port 4 Write Channel Normal Request	1 (lowest)

Data Integrity

The following sections provide information on how the L2 system memory ensures data integrity.

ECC Algorithm

Hsaio encoding calculates the ECC syndrome. A 7-bit syndrome is generated during write operation and stored as a 7-bit parity field along with the 32 data bits. Each data bit contributes to three parity bits according. Each parity bit represents the XOR value of 13 or 14 data bits according to the following mapping:

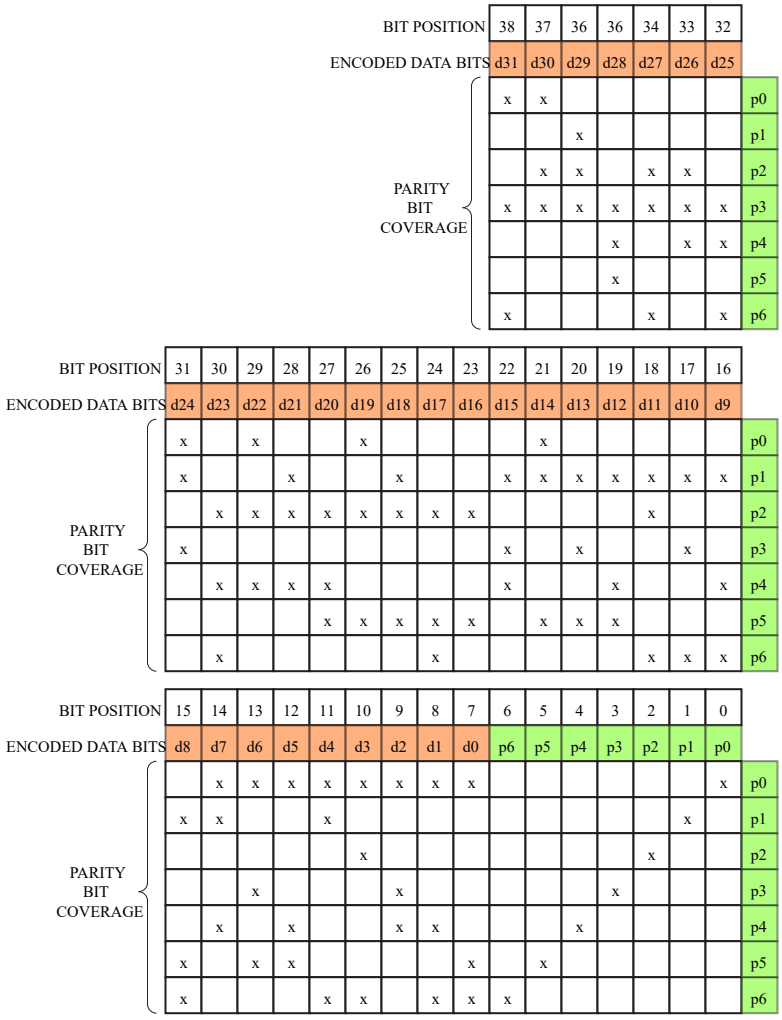

Figure 9-3: Hsaio Parity Bit Mapping

During read operation, the parity bits become part of the syndrome equation. The new syndrome bits are now the XOR values of the 13 or 14 data bits plus the respective stored parity bit. If any of the seven syndrome bits is set, an error situation is detected. An OR gate cross of the 7 bits reports the error, without specifying the type of the error.

If a single parity bit failed, the new 7-bit syndrome has 1 bit that is set. If a single data bit failed, the new syndrome has 3 bits that are set, because all three related parity bits fail. So, an XOR gate cross of all seven syndrome bits detects a single-bit error, indicating that an odd number of syndrome bits is set.

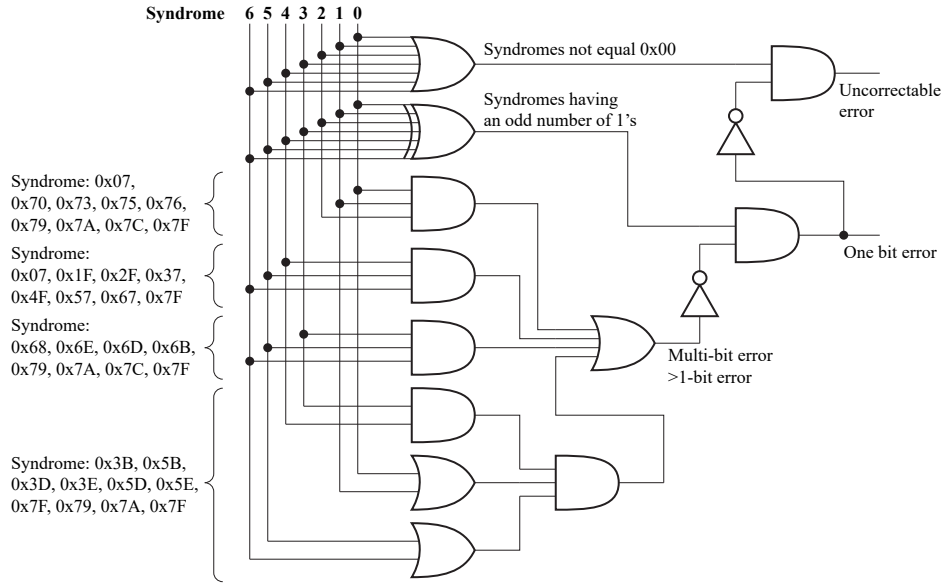

Figure 9-4: Hsiao Error Reports

The XOR gate detects single-bit errors and does not flag any dual-bit error. But the gate does flag 50% of the other multi-bit errors undesirably. Extra logic is implemented to increase the detection rate of multi-bit errors to 68.7% as shown in the figure.

If a single-bit error is detected, the failing bit can be localized and corrected. If all three syndrome bits corresponding to a specific data bit are 1, a data error is assumed. The respective data bit is toggled on its way to the system bus.

ECC Hardware Control

After reset, ECC protection is enabled. The boot code initializes all L2 SRAM data and checksum cells. ECC protection adds some cycle penalty when 8-bit and 16-bit values write L2 memory. Disable ECC protection for individual SRAM banks by setting the `L2CTL_CTL.BK0EDIS` through `L2CTL_CTL.BK7EDIS` disable bits. Due to caching mechanisms of the processor cores and data bursting of the DMA channels, 8-bit and 16-bit write accesses are uncommon. Typically, only two-dimensional DMA operations or un-cached 8-bit and 16-bit store instruction can trigger these writes.

ECC Error Management

The L2 system memory flags 2-bit and multi-bit errors to the system by:

- Raising the ECC_ERR interrupt
- Reporting a read error to the system bus
- Setting the sticky `L2CTL_STAT.ECCERR7-L2CTL_STAT.ECCERR0` status flag
- Latching the address of the failing operation into the respective `L2CTL_ERRADDR7-L2CTL_ERRADDR0` register.

There is one error status bit and one error address register per L2 SRAM bank.

Typically, ECC_ERR events are declared as system faults in the system event controller (SEC). Whether these faults are reported, the interrupt service routine can consult the L2CTL_STAT register and the L2CTL_ERRADDR0 through L2CTL_ERRADDR7 registers to determine whether:

- The data at the failing L2 address was critical enough to require an immediate reboot of the system
- The data at the failing L2 address was less critical or can be restored

The L2CTL_STAT.ECCERR0 through L2CTL_STAT.ECCERR7 flags are cleared with a W1C operation.

Memory Refresh

If data in L2 SRAM contains single-bit errors, the data is corrected on its way to the system buses. The corrected value is not written back to the SRAM location. To prevent any risk of accumulation of single-bit errors over time and to minimize likelihood of multi-bit errors, the L2 system memory provides a special memory refresh mechanism.

If there are dual-bit or multi-bit errors, the ECC_ERR interrupt is raised, and data is not written back to memory.

- TheL2CTL_SADR register with the start address of the scrub
- The L2CTL_SCNT register with the total number of 128-bit addresses to be scrubbed starting from the L2CTL_SADR address

Program the number of cycles between each scrub using the L2CTL_SCTL register. During the scrub, the L2 system memory issues a read, followed by a write-back operation if there is a single-bit ECC error. Once the L2 system memory completes scrubbing the programmed memory region, it generates an interrupt and starts again from the L2CTL_SADR address unless the L2CTL_SCTL.SEN bit is disabled. If the L2CTL_SCTL.SEN bit is cleared before completing the programmed address range, the scrub stops after completing any already issued scrub access. The scrub read/writes always start from the full 128-bit equivalent of the address written into the L2CTL_SADR register. A 128-bit value is always read, and the 128-bit value is written back. The scrub access has the highest priority. Programs can configure 8-bit, 16-bit, or 32-bit addresses in the L2CTL_SADR register. The lower 4 bits of this register are treated as *do-not-care* values because the internal memory array is always accessed when using 128 bits.

Memory refresh operation is meaningless when the L2CTL_CTL.BK0EDIS through L2CTL_CTL.BK7EDIS disable bits are set.

Power Modes

Each L2 memory bank supports low-power modes.

If the bank is not in use, put each L2 system memory bank into the following low-power modes to save power.

Deep Sleep Mode

Set the L2CTL_PCTL.BK7DS through L2CTL_PCTL.BK0DS control bits to enter this mode. This mode preserves the memory contents.

Shut Down Mode

Set the L2CTL_PCTL.BK7SD through L2CTL_PCTL.BK0SD control bits to enter this mode. The memory banks do not retain the data (existing data is lost).

NOTE: It may take up to 11 SYSCLK cycles to deactivate the power mode after writing to the L2CTL_PCTL register. Therefore, L2 access must be issued after this delay.

Access to a memory bank in shut down or deep sleep mode may result in an unpredictable behavior. Ensure that initialization/refresh and memory access to such banks are not issued.

There is no deep sleep or shut down mode for ROM memories.

L2 System Memory Event Control

The following sections describe event control features of the L2 system memory, such as error response.

ECC Error Interrupt

A bus error is signaled under any of the following conditions.

- A write access to ROM address space
- A read/write access to reserved address space
- An ECC multi-bit error in an ECC-enabled bank. A non-modulo, 32-bit write to an ECC-enabled bank can also potentially create a bus error response due to an ECC multi-bit error. This response is because the L2 system memory implements a 32-bit ECC, and therefore a non-modulo, 32-bit write results in a read. This read can create multi-bit errors even if the memory was initialized.

Bus error notifications are stored in the L2CTL_STAT register, and the addresses that generated the error on a given port are stored in the L2CTL_EADDR0/L2CTL_EADDR1 register of that port. The details of the error are stored in the L2CTL_ET0/L2CTL_ET1 register of the port.

ADSP-2184x L2CTL Register Descriptions

L2 Memory Controller (L2CTL) contains the following registers.

Table 9-6: ADSP-2184x L2CTL Register List

Name	Description
L2CTL_CTL	Control Register
L2CTL_EADDR0	Error Type 0 Address Register
L2CTL_EADDR1	Error Type 1 Address Register
L2CTL_EADDR2	Error Type 2 Address Register
L2CTL_EADDR3	Error Type 3 Address Register

L2CTL_REVID	Revision ID Register
L2CTL_RPCR0	Read Priority Count Register
L2CTL_RPCR1	Read Priority Count Register
L2CTL_SADR	Scrub Start Address Register
L2CTL_SCNT	Scrub Count Register
L2CTL_SCTL	Scrub Control Register
L2CTL_STAT	Status Register
L2CTL_STAT_1	L2 Port Error Status Register
L2CTL_WPCR0	Write Priority Count Register
L2CTL_WPCR1	Write Priority Count Register

Control Register

The L2CTL_CTL register includes a write protection bit, enables L2 banks, and selects mapping of banks (as ECC RAM or data RAM).

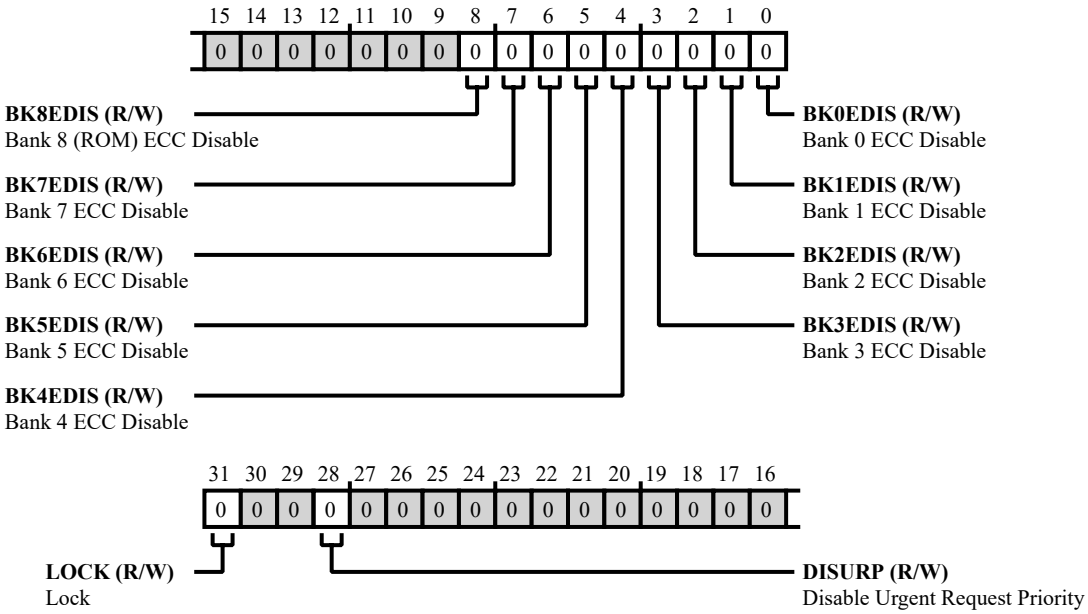

Figure 9-5: L2CTL_CTL Register Diagram

Table 9-7: L2CTL_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the L2CTL_CTL.LOCK bit is set, the L2CTL_CTL register is read only (locked).	
		0	Unlock
		1	Lock
28 (R/W)	DISURP	Disable Urgent Request Priority. The L2CTL_CTL.DISURP disables urgent request priority mode for all L2 banks.	
		0	Enable URP
		1	Disable URP

Table 9-7: L2CTL_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	BK8EDIS	Bank 8 (ROM) ECC Disable. The `L2CTL_CTL.BK8EDIS` bit disables L2 bank 8 (ROM) ECC operation. ECC operation should be enabled or disable before the start of L2 bank access.	
		0	Enable ECC
		1	Disable ECC
7 (R/W)	BK7EDIS	Bank 7 ECC Disable. The `L2CTL_CTL.BK7EDIS` bit disables L2 bank 7 ECC operation. ECC operation should be enabled or disable before the start of L2 bank access.	
		0	Enable ECC
		1	Disable ECC
6 (R/W)	BK6EDIS	Bank 6 ECC Disable. The `L2CTL_CTL.BK6EDIS` bit disables L2 bank 6 ECC operation. ECC operation should be enabled or disable before the start of L2 bank access.	
		0	Enable ECC
		1	Disable ECC
5 (R/W)	BK5EDIS	Bank 5 ECC Disable. The `L2CTL_CTL.BK5EDIS` bit disables L2 bank 5 ECC operation. ECC operation should be enabled or disable before the start of L2 bank access.	
		0	Enable ECC
		1	Disable ECC
4 (R/W)	BK4EDIS	Bank 4 ECC Disable. The `L2CTL_CTL.BK4EDIS` bit disables L2 bank 4 ECC operation. ECC operation should be enabled or disable before the start of L2 bank access.	
		0	Enable ECC
		1	Disable ECC
3 (R/W)	BK3EDIS	Bank 3 ECC Disable. The `L2CTL_CTL.BK3EDIS` bit disables L2 bank 3 ECC operation. ECC operation should be enabled or disable before the start of L2 bank access.	
		0	Enable ECC
		1	Disable ECC

Table 9-7: L2CTL_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	BK2EDIS	Bank 2 ECC Disable. The `L2CTL_CTL.BK2EDIS` bit disables L2 bank 2 ECC operation. ECC operation should be enabled or disable before the start of L2 bank access.	
		0	Enable ECC
		1	Disable ECC
1 (R/W)	BK1EDIS	Bank 1 ECC Disable. The `L2CTL_CTL.BK1EDIS` bit disables L2 bank 1 ECC operation. ECC operation should be enabled or disable before the start of L2 bank access.	
		0	Enable ECC
		1	Disable ECC
0 (R/W)	BK0EDIS	Bank 0 ECC Disable. The `L2CTL_CTL.BK0EDIS` bit disables L2 bank 0 ECC operation. ECC operation should be enabled or disable before the start of L2 bank access.	
		0	Enable ECC
		1	Disable ECC

Error Type 0 Address Register

The L2CTL_EADDR0 register holds the address that created an access error on the L2 port 0 bus interface. This register is be updated only if the corresponding error status bit (L2CTL_STAT.ERR0) is cleared. After the status bit is set for an error, further errors do not update the L2CTL_EADDR0 register until a W1C clears the corresponding status bit. If read and write access errors occur simultaneously, the register captures the write access error address.

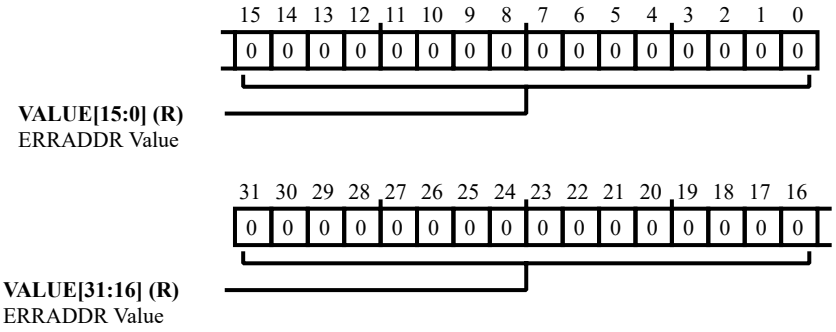

Figure 9-6: L2CTL_EADDR0 Register Diagram

Table 9-8: L2CTL_EADDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_EADDR0.VALUE bits hold the address causing the bus error.

Error Type 1 Address Register

The L2CTL_EADDR1 register holds the address that created an access error on the L2 port 1 bus interface. This register is be updated only if the corresponding error status bit (L2CTL_STAT.ERR1) is cleared. After the status bit is set for an error, further errors do not update the L2CTL_EADDR1 register until a W1C clears the corresponding status bit. If read and write access errors occur simultaneously, the register captures the write access error address.

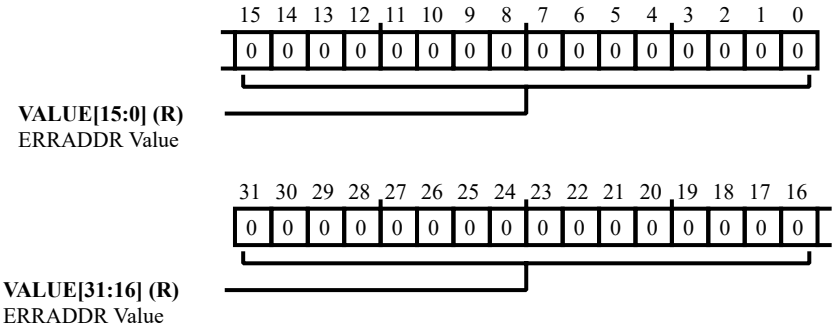

Figure 9-7: L2CTL_EADDR1 Register Diagram

Table 9-9: L2CTL_EADDR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_EADDR1.VALUE bits hold the address causing the bus error.

Error Type 2 Address Register

The L2CTL_EADDR2 register holds the address that created an access error on the L2 port 2 bus interface (cores). This register is be updated only if the corresponding error status bit (L2CTL_STAT_1.ERR2) is cleared. After the status bit is set for an error, further errors do not update the L2CTL_EADDR2 register until a W1C clears the corresponding status bit. If read and write access errors occur simultaneously, the register captures the write access error address.

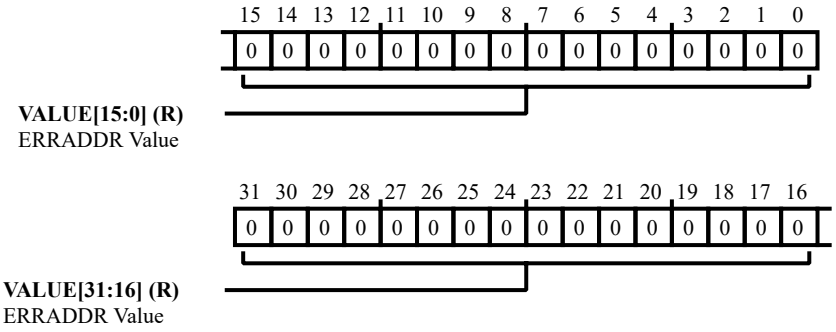

Figure 9-8: L2CTL_EADDR2 Register Diagram

Table 9-10: L2CTL_EADDR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_EADDR2.VALUE bits hold the address causing the bus error.

Error Type 3 Address Register

The L2CTL_EADDR3 register holds the address that created an access error on the L2 port 3 bus interface (DMA). This register is be updated only if the corresponding error status bit (L2CTL_STAT_1.ERR3) is cleared. After the status bit is set for an error, further errors do not update the L2CTL_EADDR3 register until a W1C clears the corresponding status bit. If read and write access errors occur simultaneously, the register captures the write access error address.

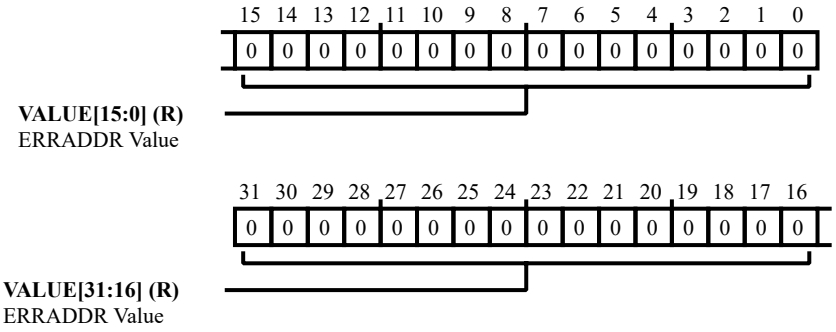

Figure 9-9: L2CTL_EADDR3 Register Diagram

Table 9-11: L2CTL_EADDR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_EADDR3.VALUE bits hold the address causing the bus error.

Error Type 4 Address Register

The L2CTL_EADDR4 register holds the address that created an access error on the L2 port 4 bus interface (DMA). This register is be updated only if the corresponding error status bit (L2CTL_STAT_1.ERR4) is cleared. After the status bit is set for an error, further errors do not update the L2CTL_EADDR4 register until a W1C clears the corresponding status bit. If read and write access errors occur simultaneously, the register captures the write access error address.

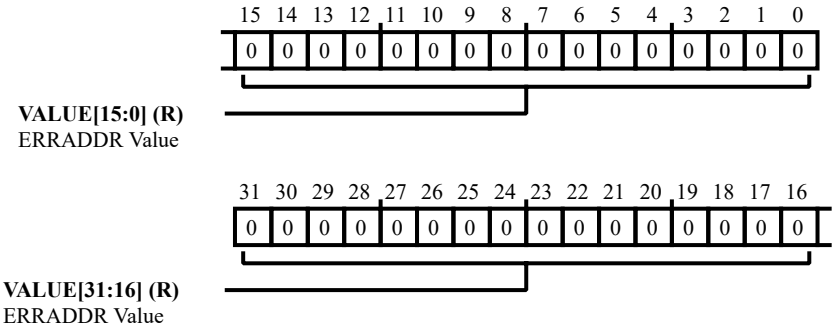

Figure 9-10: L2CTL_EADDR4 Register Diagram

Table 9-12: L2CTL_EADDR4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_EADDR4.VALUE bits hold the address causing the bus error.

ECC Error Address 0 Register

The L2CTL_ERRADDR0 register holds the address containing an ECC multi-bit error for the corresponding bank. The L2CTL updates this register only if the bank's status bit (L2CTL_STAT.ECCERR0) is cleared. After the bank's status bit is set for an error, further errors in the same bank are not detected until a W1C clears the status bit.

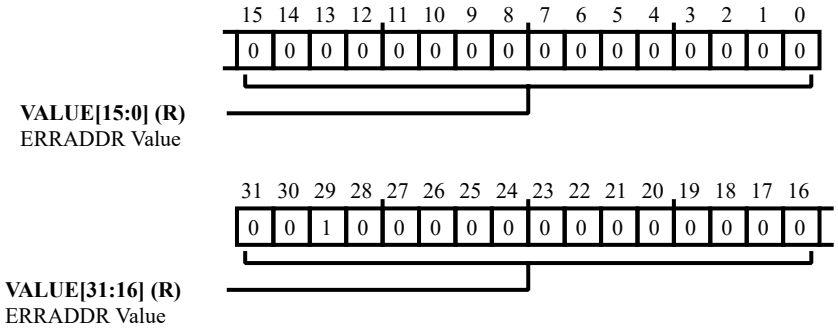

Figure 9-11: L2CTL_ERRADDR0 Register Diagram

Table 9-13: L2CTL_ERRADDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_ERRADDR0.VALUE bits hold the address containing the ECC double-bit error.

ECC Error Address 1 Register

The L2CTL_ERRADDR1 register holds the address containing an ECC multi-bit error for the corresponding bank. The L2CTL updates this register only if the bank's status bit (L2CTL_STAT.ECCERR1) is cleared. After the bank's status bit is set for an error, further errors in the same bank are not detected until a W1C clears the status bit.

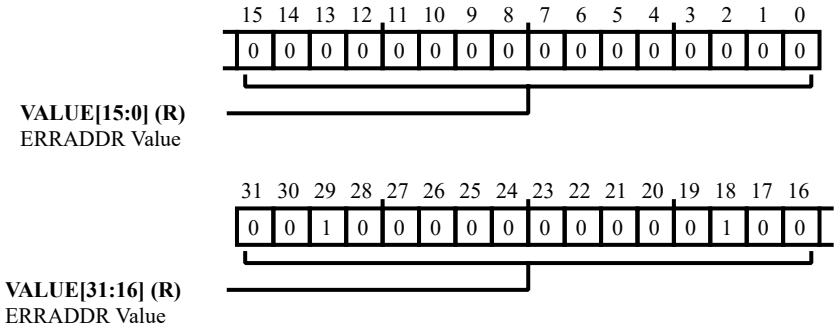

Figure 9-12: L2CTL_ERRADDR1 Register Diagram

Table 9-14: L2CTL_ERRADDR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_ERRADDR1.VALUE bits hold the address containing the ECC double-bit error.

ECC Error Address 2 Register

The L2CTL_ERRADDR2 register holds the address containing an ECC multi-bit error for the corresponding bank. The L2CTL updates this register only if the bank's status bit (L2CTL_STAT.ECCERR2) is cleared. After the bank's status bit is set for an error, further errors in the same bank are not detected until a W1C clears the status bit.

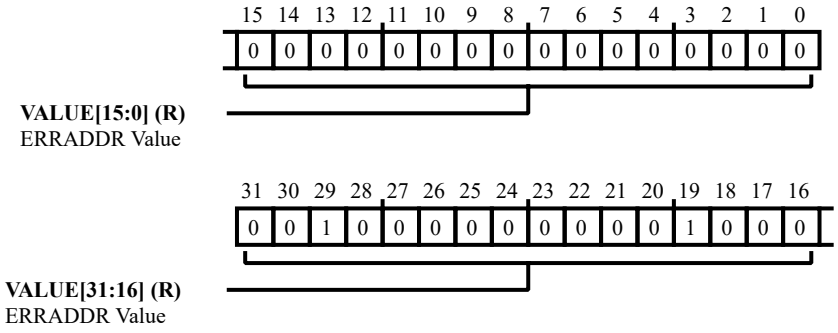

Figure 9-13: L2CTL_ERRADDR2 Register Diagram

Table 9-15: L2CTL_ERRADDR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_ERRADDR2.VALUE bits hold the address containing the ECC double-bit error.

ECC Error Address 3 Register

The L2CTL_ERRADDR3 register holds the address containing an ECC multi-bit error for the corresponding bank. The L2CTL updates this register only if the bank's status bit (L2CTL_STAT.ECCERR3) is cleared. After the bank's status bit is set for an error, further errors in the same bank are not detected until a W1C clears the status bit.

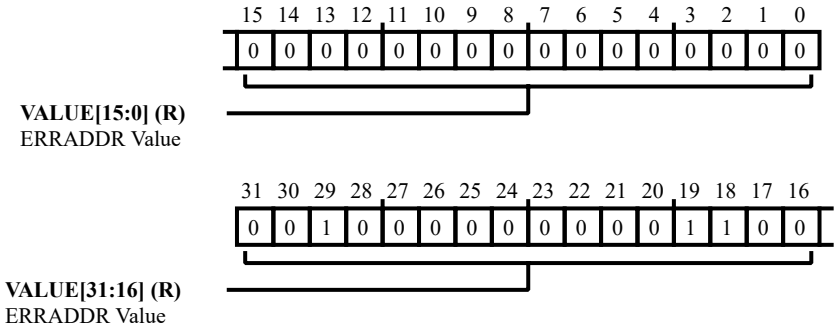

Figure 9-14: L2CTL_ERRADDR3 Register Diagram

Table 9-16: L2CTL_ERRADDR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_ERRADDR3.VALUE bits hold the address containing the ECC double-bit error.

ECC Error Address 4 Register

The L2CTL_ERRADDR4 register holds the address containing an ECC multi-bit error for the corresponding bank. The L2CTL updates this register only if the bank's status bit (L2CTL_STAT.ECCERR4) is cleared. After the bank's status bit is set for an error, further errors in the same bank are not detected until a W1C clears the status bit.

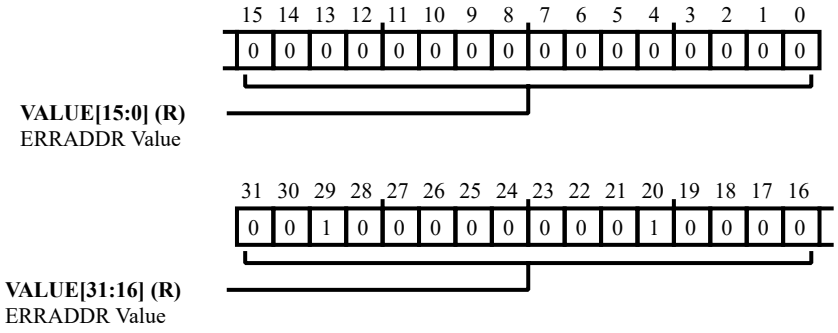

Figure 9-15: L2CTL_ERRADDR4 Register Diagram

Table 9-17: L2CTL_ERRADDR4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_ERRADDR4.VALUE bits hold the address containing the ECC double-bit error.

ECC Error Address 5 Register

The L2CTL_ERRADDR5 register holds the address containing an ECC multi-bit error for the corresponding bank. The L2CTL updates this register only if the bank's status bit (L2CTL_STAT.ECCERR5) is cleared. After the bank's status bit is set for an error, further errors in the same bank are not detected until a W1C clears the status bit.

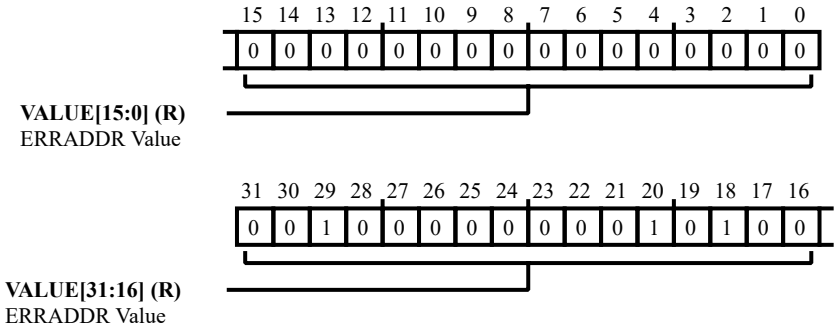

Figure 9-16: L2CTL_ERRADDR5 Register Diagram

Table 9-18: L2CTL_ERRADDR5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_ERRADDR5.VALUE bits hold the address containing the ECC double-bit error.

ECC Error Address 6 Register

The L2CTL_ERRADDR6 register holds the address containing an ECC multi-bit error for the corresponding bank. The L2CTL updates this register only if the bank's status bit (L2CTL_STAT.ECCERR6) is cleared. After the bank's status bit is set for an error, further errors in the same bank are not detected until a W1C clears the status bit.

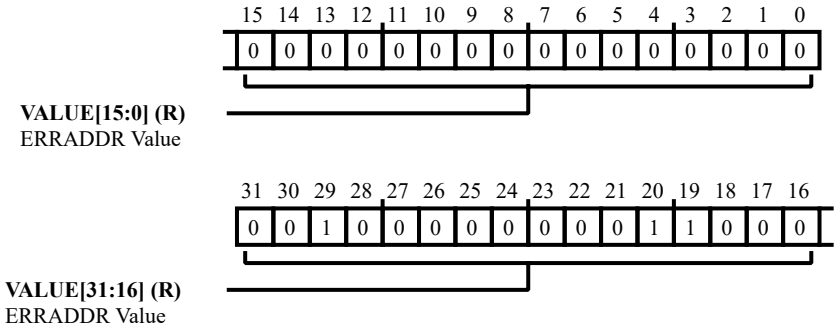

Figure 9-17: L2CTL_ERRADDR6 Register Diagram

Table 9-19: L2CTL_ERRADDR6 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_ERRADDR6.VALUE bits hold the address containing the ECC double-bit error.

ECC Error Address 7 Register

The L2CTL_ERRADDR7 register holds the address containing an ECC multi-bit error for the corresponding bank. The L2CTL updates this register only if the bank's status bit (L2CTL_STAT.ECCERR7) is cleared. After the bank's status bit is set for an error, further errors in the same bank are not detected until a W1C clears the status bit.

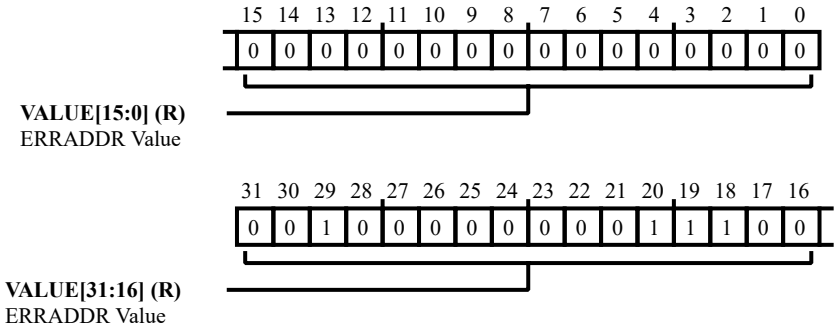

Figure 9-18: L2CTL_ERRADDR7 Register Diagram

Table 9-20: L2CTL_ERRADDR7 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_ERRADDR7.VALUE bits hold the address containing the ECC double-bit error.

ECC Error Address 8 Register

The L2CTL_ERRADDR8 register holds the address containing an ECC multi-bit error for the corresponding bank. The L2CTL updates this register only if the bank's status bit (L2CTL_STAT.ECCERR8) is cleared. After the bank's status bit is set for an error, further errors in the same bank are not detected until a W1C clears the status bit.

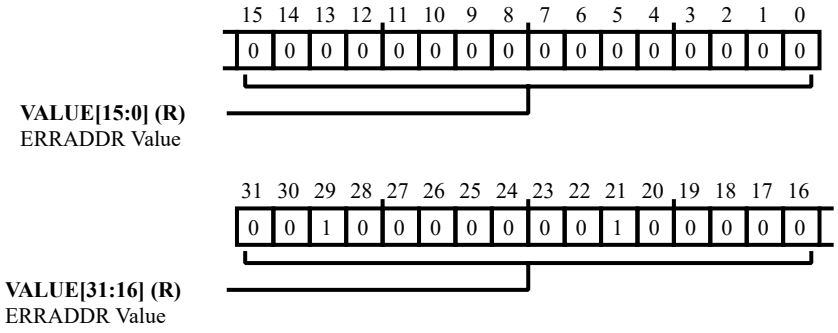

Figure 9-19: L2CTL_ERRADDR8 Register Diagram

Table 9-21: L2CTL_ERRADDR8 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	ERRADDR Value. The L2CTL_ERRADDR8.VALUE bits hold the address containing the ECC double-bit error.

Error Type 0 Register

The L2CTL_ET0 register holds information about the error transaction that has occurred on the bus for the corresponding L2 bus port 0. This register is updated only if the corresponding error status bit L2CTL_STAT.ERR0 is cleared. After the status bit is set for an error, further errors do not update the L2CTL_ET0 register until a W1C clears the corresponding status bit. If read and write access errors occur simultaneously, the L2CTL_ET0 captures the write access error, keeping in sync with the error address register (L2CTL_EADDR0).

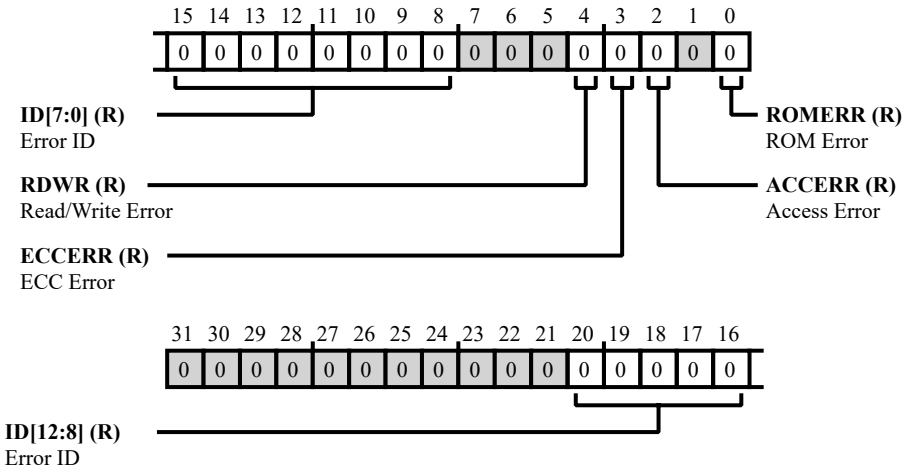

Figure 9-20: L2CTL_ET0 Register Diagram

Table 9-22: L2CTL_ET0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
20:8 (R/NW)	ID	Error ID. The L2CTL_ET0.ID bits hold the bus requester ID of the access that caused an error.	
4 (R/NW)	RDWR	Read/Write Error. The L2CTL_ET0.RDWR bit indicates whether a read or write access caused an error.	
		0	Read Access created Error
		1	Write Access created Error
3 (R/NW)	ECCERR	ECC Error. The L2CTL_ET0.ECCERR bit indicates whether the access had an ECC double-bit error.	
2 (R/NW)	ACCERR	Access Error. The L2CTL_ET0.ACCERR bit indicates whether the access went to a restricted bank.	

Table 9-22: L2CTL_ET0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/NW)	ROMERR	ROM Error. The `L2CTL_ET0.ROMERR` bit indicates whether a write access went to a ROM area.

Error Type 1 Register

The L2CTL_ET1 register holds information about the error transaction that has occurred on the bus for the corresponding L2 bus port 1. This register is updated only if the corresponding error status bit L2CTL_STAT.ERR1 is cleared. After the status bit is set for an error, further errors do not update the L2CTL_ET1 register until a W1C clears the corresponding status bit. If read and write access errors occur simultaneously, the L2CTL_ET1 captures the write access error, keeping in sync with the error address register (L2CTL_EADDR1).

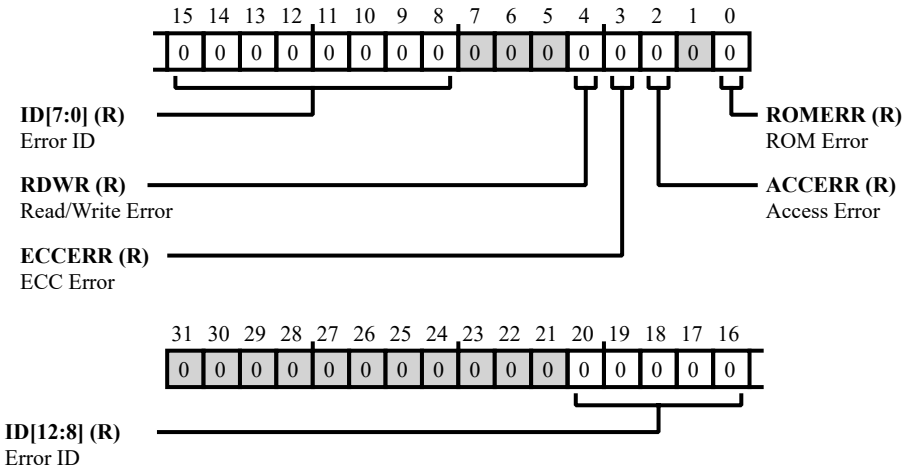

Figure 9-21: L2CTL_ET1 Register Diagram

Table 9-23: L2CTL_ET1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
20:8 (R/NW)	ID	Error ID. The L2CTL_ET1.ID bits hold the bus requester ID of the access that caused an error.	
4 (R/NW)	RDWR	Read/Write Error. The L2CTL_ET1.RDWR bit indicates whether a read or write access caused an error.	
		0	Read access created error
		1	Write access created error
3 (R/NW)	ECCERR	ECC Error. If the L2CTL_ET1.ECCERR bit =1, the access had an ECC double-bit error.	
2 (R/NW)	ACCERR	Access Error. If the L2CTL_ET1.ACCERR bit =1, the access went to a restricted bank.	
0 (R/NW)	ROMERR	ROM Error. If the L2CTL_ET1.ROMERR bit =1, a write access went to a ROM area.	

Error Type 2 Register

The L2CTL_ET2 register holds information about the error transaction that has occurred on the bus for the corresponding L2 bus port 2 (cores). This register is updated only if the corresponding error status bit L2CTL_STAT_1.ERR2 is cleared. After the status bit is set for an error, further errors do not update the L2CTL_ET2 register until a W1C clears the corresponding status bit. If read and write access errors occur simultaneously, the L2CTL_ET2 captures the write access error, keeping in sync with the error address register (L2CTL_EADDR2).

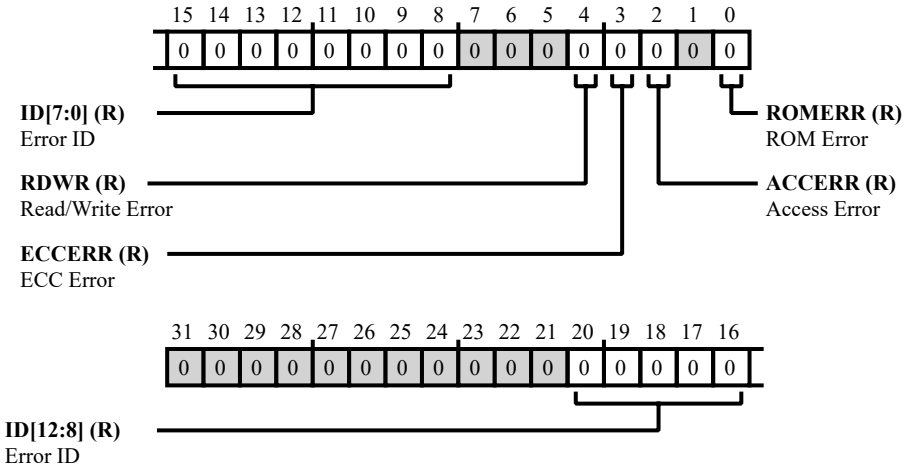

Figure 9-22: L2CTL_ET2 Register Diagram

Table 9-24: L2CTL_ET2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
20:8 (R/NW)	ID	Error ID. The L2CTL_ET2.ID bits hold the bus requester ID of the access that caused an error.
4 (R/NW)	RDWR	Read/Write Error. The L2CTL_ET2.RDWR bit indicates whether a read or write access caused an error.
3 (R/NW)	ECCERR	ECC Error. The L2CTL_ET2.ECCERR bit indicates whether the access had an ECC double-bit error.
2 (R/NW)	ACCERR	Access Error. If the L2CTL_ET2.ACCERR bit =1, the access went to a restricted bank.
0 (R/NW)	ROMERR	ROM Error. If the L2CTL_ET2.ROMERR bit =1, a write access went to a ROM area.

Error Type 3 Register

The L2CTL_ET3 register holds information about the error transaction that has occurred on the bus for the corresponding L2 bus port 3 (DMA). This register is updated only if the corresponding error status bit L2CTL_STAT_1.ERR3 is cleared. After the status bit is set for an error, further errors do not update the L2CTL_ET3 register until a W1C clears the corresponding status bit. If read and write access errors occur simultaneously, the L2CTL_ET3 captures the write access error, keeping in sync with the error address register (L2CTL_EADDR3).

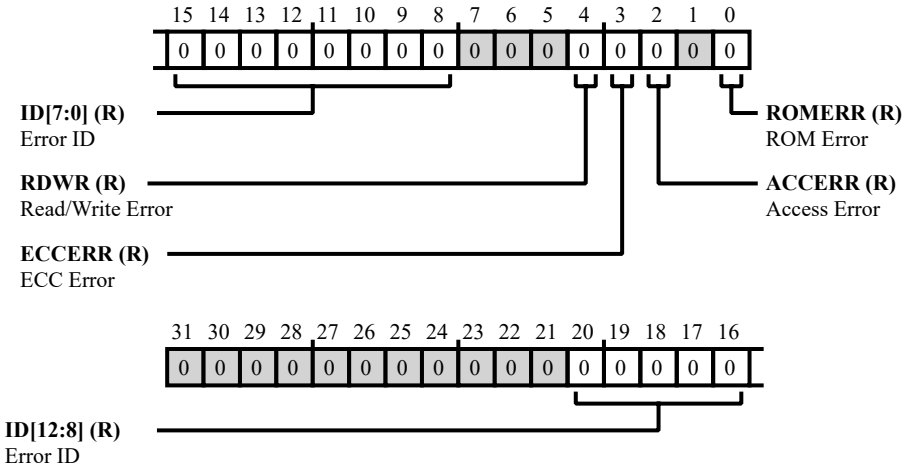

Figure 9-23: L2CTL_ET3 Register Diagram

Table 9-25: L2CTL_ET3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
20:8 (R/NW)	ID	Error ID. The L2CTL_ET3.ID bits hold the bus requester ID of the access that caused an error.
4 (R/NW)	RDWR	Read/Write Error. The L2CTL_ET3.RDWR bit indicates whether a read or write access caused an error.
3 (R/NW)	ECCERR	ECC Error. The L2CTL_ET3.ECCERR bit indicates whether the access had an ECC double-bit error.
2 (R/NW)	ACCERR	Access Error. If the L2CTL_ET3.ACCERR bit =1, the access went to a restricted bank.
0 (R/NW)	ROMERR	ROM Error. If the L2CTL_ET3.ROMERR bit =1, a write access went to a ROM area.

Error Type 4 Register

The L2CTL_ET4 register holds information about the error transaction that has occurred on the bus for the corresponding L2 bus port 4 (DMA). This register is updated only if the corresponding error status bit L2CTL_STAT_1.ERR4 is cleared. After the status bit is set for an error, further errors do not update the L2CTL_ET4 register until a W1C clears the corresponding status bit. If read and write access errors occur simultaneously, the L2CTL_ET4 captures the write access error, keeping in sync with the error address register (L2CTL_EADDR4).

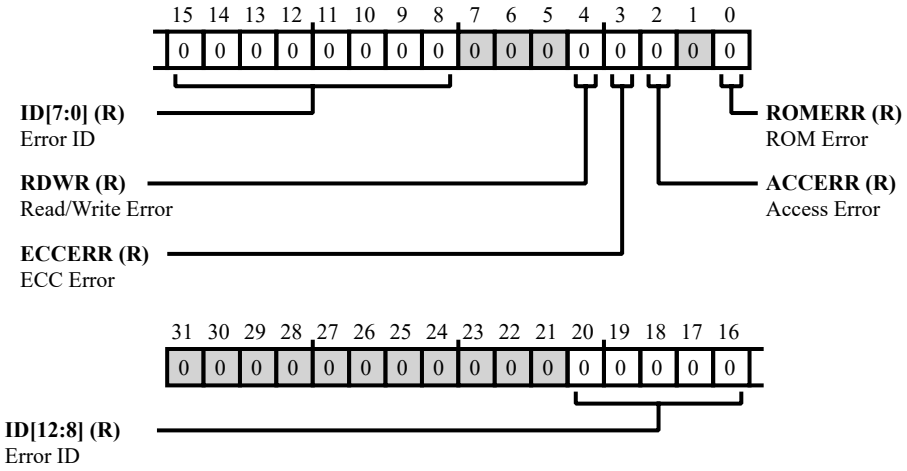

Figure 9-24: L2CTL_ET4 Register Diagram

Table 9-26: L2CTL_ET4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
20:8 (R/NW)	ID	Error ID. The L2CTL_ET4.ID bits hold the bus requester ID of the access that caused an error.
4 (R/NW)	RDWR	Read/Write Error. The L2CTL_ET4.RDWR bit indicates whether a read or write access caused an error.
3 (R/NW)	ECCERR	ECC Error. The L2CTL_ET4.ECCERR bit indicates whether the access had an ECC double-bit error.
2 (R/NW)	ACCERR	Access Error. If the L2CTL_ET4.ACCERR bit =1, the access went to a restricted bank.
0 (R/NW)	ROMERR	ROM Error. If the L2CTL_ET4.ROMERR bit =1, a write access went to a ROM area.

Initialization Register

The L2CTL_INIT register initializes memory banks with 128'b0 and ECC bits corresponding to 128'b0. Any writes to the bits in this register while initialization is occurring to any of the banks is ignored. All bits are W1A (Write 1 for Action).

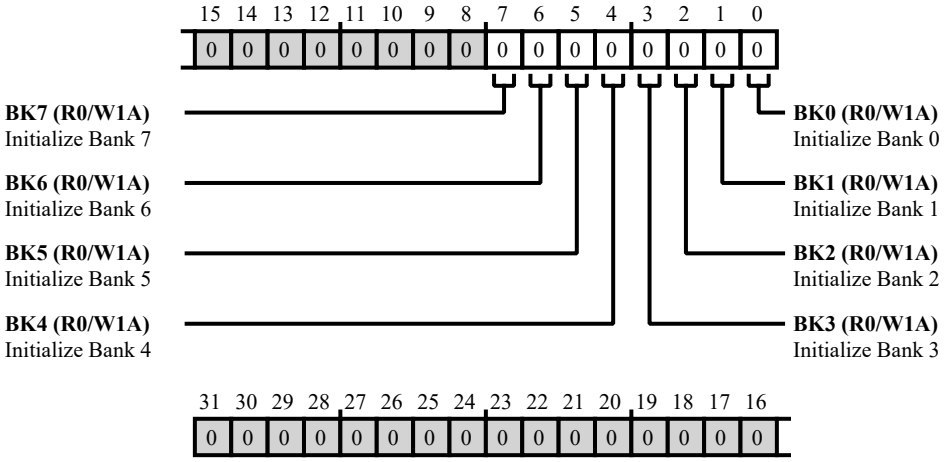

Figure 9-25: L2CTL_INIT Register Diagram

Table 9-27: L2CTL_INIT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7 (R0/W1A)	BK7	Initialize Bank 7. The write-1 to the L2CTL_INIT.BK7 bit initializes bank 7 with 128b0 and ECC bits corresponding to 128b0. Any write to this bit during the initialization of the banks is ignored.
6 (R0/W1A)	BK6	Initialize Bank 6. The write-1 to the L2CTL_INIT.BK6 bit initializes bank 6 with 128b0 and ECC bits corresponding to 128b0. Any write to this bit during the initialization of the banks is ignored.
5 (R0/W1A)	BK5	Initialize Bank 5. The write -1 to the L2CTL_INIT.BK5 bit initializes bank 5 with 128b0 and ECC bits corresponding to 128b0. Any write to this bit during the initialization of the banks is ignored.
4 (R0/W1A)	BK4	Initialize Bank 4. The write-1 to the L2CTL_INIT.BK4 bit initializes bank 4 with 128b0 and ECC bits corresponding to 128b0. Any write to this bit during the initialization of the banks is ignored.

Table 9-27: L2CTL_INIT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
3 (R0/W1A)	BK3	Initialize Bank 3. The write-1 to the `L2CTL_INIT.BK3` bit initializes bank 3 with 128b0 and ECC bits corresponding to 128b0. Any write to this bit during the initialization of the banks is ignored.
2 (R0/W1A)	BK2	Initialize Bank 2. The write-1 to the `L2CTL_INIT.BK2` bit initializes bank 2 with 128b0 and ECC bits corresponding to 128b0. Any write to this bit during the initialization of the banks is ignored.
1 (R0/W1A)	BK1	Initialize Bank 1. The write-1 to the `L2CTL_INIT.BK1` bit initializes bank 1 with 128b0 and ECC bits corresponding to 128b0. Any write to this bit during the initialization of the banks is ignored.
0 (R0/W1A)	BK0	Initialize Bank 0. The write-1 to the `L2CTL_INIT.BK0` bit initializes bank 0 with 128b0 and ECC bits corresponding to 128b0. Any write to this bit during the initialization of the banks is ignored.

Initialization Status Register

The L2CTL_ISTAT register holds the status of the RAM bank initialization. If set, the corresponding bank is initialized.

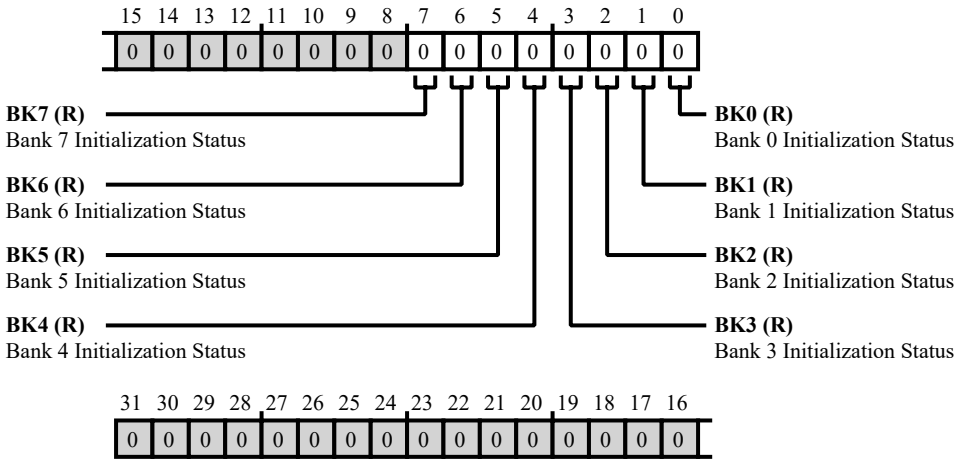

Figure 9-26: L2CTL_ISTAT Register Diagram

Table 9-28: L2CTL_ISTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7 (R/NW)	BK7	Bank 7 Initialization Status. The L2CTL_ISTAT.BK7 bits hold the bank 7 initialization status. A W1A on a BKxINIT bit clears this bit and the bit is set when initialization completes.
6 (R/NW)	BK6	Bank 6 Initialization Status. The L2CTL_ISTAT.BK6 bits hold the bank 6 initialization status. A W1A on a BKxINIT bit clears this bit and the bit is set when initialization completes.
5 (R/NW)	BK5	Bank 5 Initialization Status. The L2CTL_ISTAT.BK5 bits hold the bank 5 initialization status. A W1A on a BKxINIT bit clears this bit and the bit is set when initialization completes.
4 (R/NW)	BK4	Bank 4 Initialization Status. The L2CTL_ISTAT.BK4 bits hold the bank 4 initialization status. A W1A on a BKxINIT bit clears this bit and the bit is set when initialization completes.
3 (R/NW)	BK3	Bank 3 Initialization Status. The L2CTL_ISTAT.BK3 bits hold the bank 3 initialization status. A W1A on a BKxINIT bit clears this bit and the bit is set when initialization completes.
2 (R/NW)	BK2	Bank 2 Initialization Status. The L2CTL_ISTAT.BK2 bits hold the bank 2 initialization status. A W1A on a BKxINIT bit clears this bit and the bit is set when initialization completes.

Table 9-28: L2CTL_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
1 (R/NW)	BK1	Bank 1 Initialization Status. The `L2CTL_ISTAT.BK1` bits hold the bank 1 initialization status. A W1A on a BKxINIT bit clears this bit and the bit is set when initialization completes.
0 (R/NW)	BK0	Bank 0 Initialization Status. The `L2CTL_ISTAT.BK0` bits hold the bank 0 initialization status. A W1A on a BKxINIT bit clears this bit and the bit is set when initialization completes.

Power Control Register

The L2CTL_PCTL register has the various control settings for selectively enabling the deep sleep and shut down power saving features.

NOTE: The corresponding L2 bank should not be accessed if the power control feature is enabled for that bank. An access to a bank in deep sleep/shut down may create unpredictable behavior.

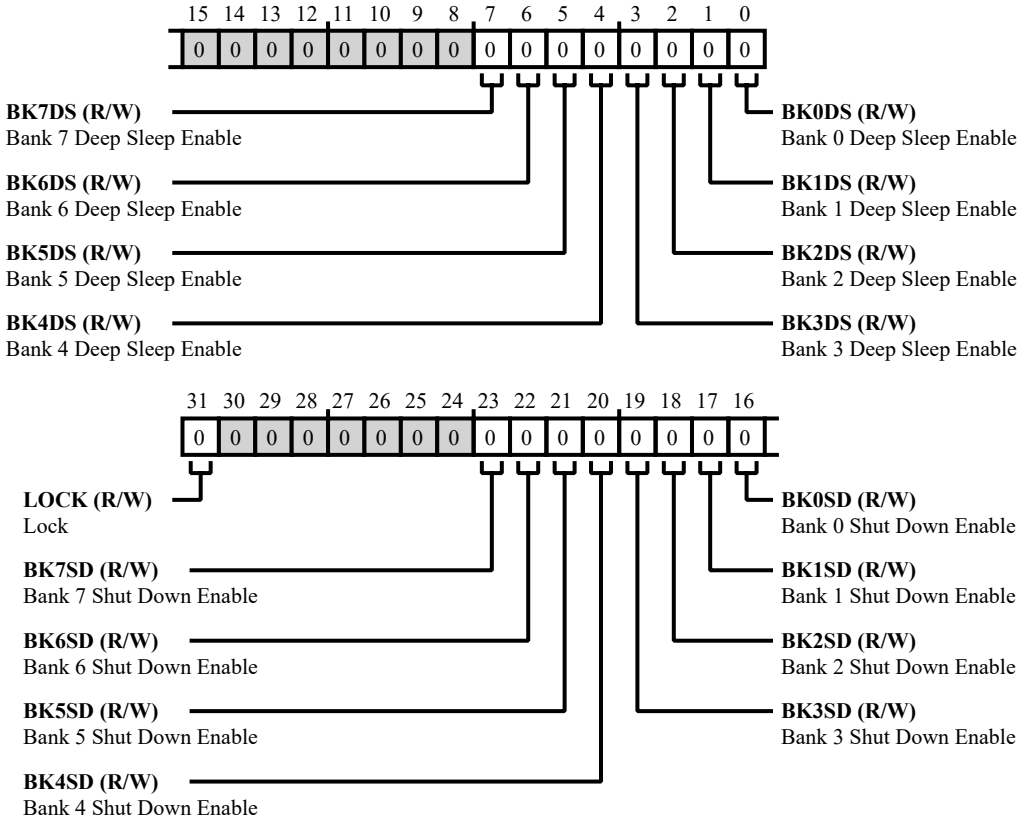

Figure 9-27: L2CTL_PCTL Register Diagram

Table 9-29: L2CTL_PCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the L2CTL_PCTL.LOCK bit is set, the L2CTL_PCTL register is read only (locked).	
		0	Unlock
		1	Lock
23 (R/W)	BK7SD	Bank 7 Shut Down Enable. The L2CTL_PCTL.BK7SD bits enables bank 7 shut down.	

Table 9-29: L2CTL_PCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
22 (R/W)	BK6SD	Bank 6 Shut Down Enable. The L2CTL_PCTL.BK6SD bits enables bank 6 shut down.
21 (R/W)	BK5SD	Bank 5 Shut Down Enable. The L2CTL_PCTL.BK5SD bits enables bank 5 shut down.
20 (R/W)	BK4SD	Bank 4 Shut Down Enable. The L2CTL_PCTL.BK4SD bits enables bank 4 shut down.
19 (R/W)	BK3SD	Bank 3 Shut Down Enable. The L2CTL_PCTL.BK3SD bits enables bank 3 shut down.
18 (R/W)	BK2SD	Bank 2 Shut Down Enable. The L2CTL_PCTL.BK2SD bits enables bank 2 shut down.
17 (R/W)	BK1SD	Bank 1 Shut Down Enable. The L2CTL_PCTL.BK1SD bits enables bank 1 shut down.
16 (R/W)	BK0SD	Bank 0 Shut Down Enable. The L2CTL_PCTL.BK0SD bits enables bank 0 shut down.
7 (R/W)	BK7DS	Bank 7 Deep Sleep Enable. The L2CTL_PCTL.BK7DS bits enables bank 7 deep sleep.
6 (R/W)	BK6DS	Bank 6 Deep Sleep Enable. The L2CTL_PCTL.BK6DS bits enables bank 6 deep sleep.
5 (R/W)	BK5DS	Bank 5 Deep Sleep Enable. The L2CTL_PCTL.BK5DS bits enables bank 5 deep sleep.
4 (R/W)	BK4DS	Bank 4 Deep Sleep Enable. The L2CTL_PCTL.BK4DS bits enables bank 4 deep sleep.
3 (R/W)	BK3DS	Bank 3 Deep Sleep Enable. The L2CTL_PCTL.BK3DS bits enables bank 3 deep sleep.
2 (R/W)	BK2DS	Bank 2 Deep Sleep Enable. The L2CTL_PCTL.BK2DS bits enables bank 2 deep sleep.
1 (R/W)	BK1DS	Bank 1 Deep Sleep Enable. The L2CTL_PCTL.BK1DS bits enables bank 1 deep sleep.
0 (R/W)	BK0DS	Bank 0 Deep Sleep Enable. The L2CTL_PCTL.BK0DS bits enables bank 0 deep sleep.

Revision ID Register

The L2CTL_REVID register provides the L2 Revision ID.

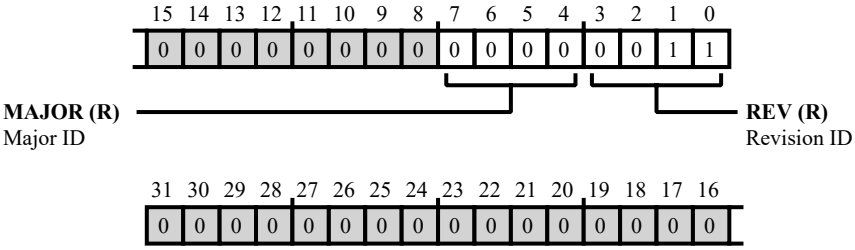

Figure 9-28: L2CTL_REVID Register Diagram

Table 9-30: L2CTL_REVID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:4 (R/NW)	MAJOR	Major ID. The L2CTL_REVID.MAJOR bit indicates L2 Major ID.
3:0 (R/NW)	REV	Revision ID. The L2CTL_REVID.REV bit indicates the L2 Revision ID.

Read Priority Count Register

The L2CTL_RPCR0 register stores the count value to be used for priority elevation for bus read channels of Port0 to Port3. If a bus channel is not granted access from the bank arbiter, the channel waits for the programmed number (stored in RPCx) of SYSCLK cycles, before the request is elevated to a high priority request. If a priority count value is programmed as zero for a channel, that channel does not raise the urgent priority request. Default value wait cycle for each channel is 15.

This is a read/write register, but a new value in the corresponding field must be written only when there are no outstanding transactions on the corresponding bus read channel. A best practice is to program this register before initiating an L2 access.

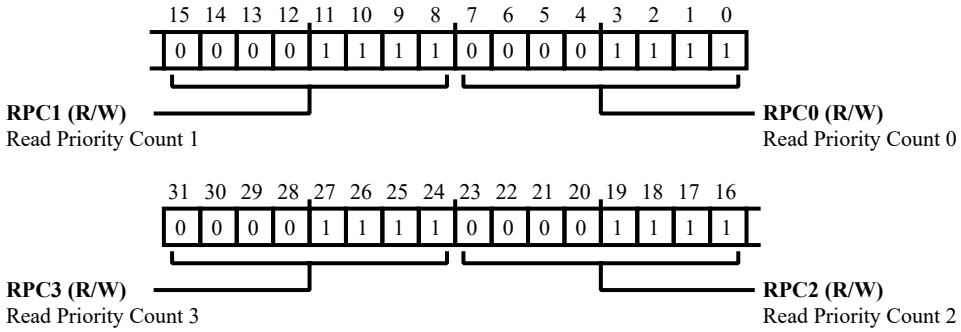

Figure 9-29: L2CTL_RPCR0 Register Diagram

Table 9-31: L2CTL_RPCR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	RPC3	Read Priority Count 3. The L2CTL_RPCR0.RPC3 bits hold the priority count for L2 bus read channel 3.
23:16 (R/W)	RPC2	Read Priority Count 2. The L2CTL_RPCR0.RPC2 bits hold the priority count for L2 bus read channel 2.
15:8 (R/W)	RPC1	Read Priority Count 1. The L2CTL_RPCR0.RPC1 bits hold the priority count for L2 bus read channel 1.
7:0 (R/W)	RPC0	Read Priority Count 0. The L2CTL_RPCR0.RPC0 bits hold the priority count for L2 bus read channel 0.

Read Priority Count Register

The L2CTL_RPCR1 register stores the count value to be used for priority elevation for bus read channel 4. If a bus channel is not granted access from the bank arbiter, the channel waits for the programmed number (stored in RPC4) of SYSCLK cycles, before the request is elevated to a high priority request. If a priority count value is programmed as zero for a channel, that channel does not raise the urgent priority request. Default value of RPC4 is 15.

This is a read/write register, but a new value in the corresponding field must be written only when there are no outstanding transactions on the corresponding bus read channel. A best practice is to program this register before initiating an L2 access.

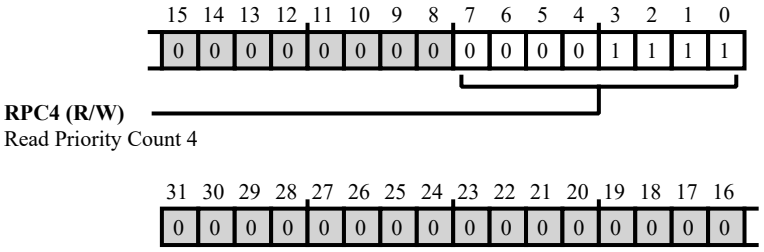

Figure 9-30: L2CTL_RPCR1 Register Diagram

Table 9-32: L2CTL_RPCR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	RPC4	Read Priority Count 4. The L2CTL_RPCR1.RPC4 bits hold the priority count for L2 bus read channel 4.

Scrub Start Address Register

The L2CTL_SADR register stores the scrub start address value. Writes to this register can be prevented by setting the L2CTL_SCTL.LOCK bit and the global lock.

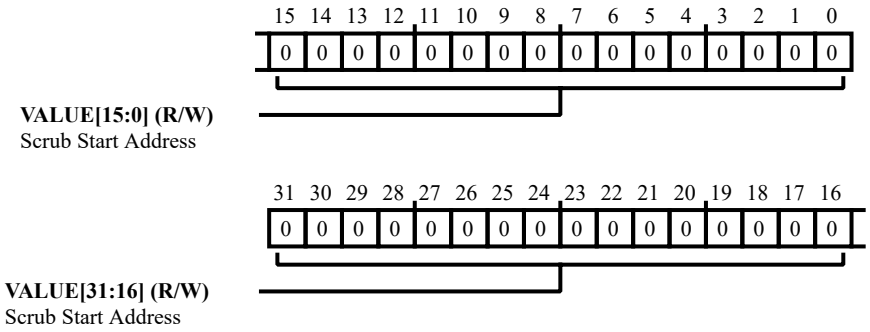

Figure 9-31: L2CTL_SADR Register Diagram

Table 9-33: L2CTL_SADR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Scrub Start Address. The L2CTL_SADR.VALUE bits hold the scrub start address. The writes to this register can be prevented by setting the L2_SCTL.LOCK and the global lock.

Scrub Count Register

The L2CTL_SCNT register determines the number of 128-bit locations scrubbed starting from the start address (L2CTL_SADR register). Writes to the L2CTL_SCNT register can be prevented by setting the L2CTL_CTL.LOCK bit and the global lock.

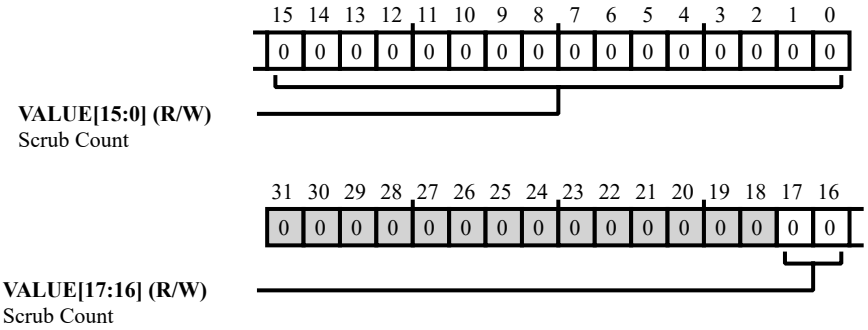

Figure 9-32: L2CTL_SCNT Register Diagram

Table 9-34: L2CTL_SCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
17:0 (R/W)	VALUE	Scrub Count. The L2CTL_SCNT.VALUE bits determines the number of 128-bit locations scrubbed starting from the start address. Ensure value programmed is less than the total addressable 128-bit L2 RAM locations available.

Scrub Control Register

The L2CTL_SCTL register holds the automatic scrub related controls. This is a read/write register. Memory scrub can be performed by programming the L2CTL_SADR (scrub start address) register with the start address of the scrub and the L2CTL_SCNT register with the total number of 128 -bit addresses to be scrubbed starting from the L2CTL_SADR register. The number of cycles between each scrub can be programmed with the L2CTL_SCTL.SRT bit.

During the scrub the controller issues a read followed by write back if there is a single bit ECC error. Once the L2 controller completes scrubbing the memory region mentioned using the L2CTL_SADR and the L2CTL_SCNT registers, an interrupt is generated and scrubbing re-starts from the start unless the scrub enable bit is disabled in the control register. If scrub enable is cleared before completing the address range used in the L2CTL_SADR and L2CTL_SCNT registers, the scrub stops after completing any already issued scrub access.

The scrub read/writes always start from the full 128-bit equivalent of the address written into the L2CTL_SADR register. A 128-bit value is always read and the 128-bit value is written back. The scrub access has the highest priority. Programs can configure 8-, 16-, or 32-bit addresses in the L2CTL_SADR register but the lower 3 bits are treated as don't care because the internal memory array is always accessed in a 128-bit mode.

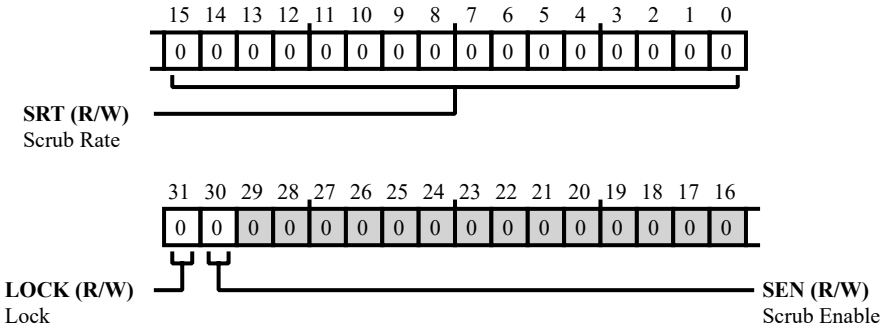

Figure 9-33: L2CTL_SCTL Register Diagram

Table 9-35: L2CTL_SCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the L2CTL_SCTL.LOCK bit is set, the L2CTL_SCTL register is read only (locked).	
		0	Unlock
		1	Lock
30 (R/W)	SEN	Scrub Enable. The L2CTL_SCTL.SEN bits enable automatic scrub.	

Table 9-35: L2CTL_SCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	SRT	Scrub Rate. The `L2CTL_SCTL.SRT` bits determines the number of clock cycles that elapsed between two automatic scrubs.

Status Register

The L2CTL_STAT register indicates ECC error status, refresh register status, and bus error status of Port0 and Port1.

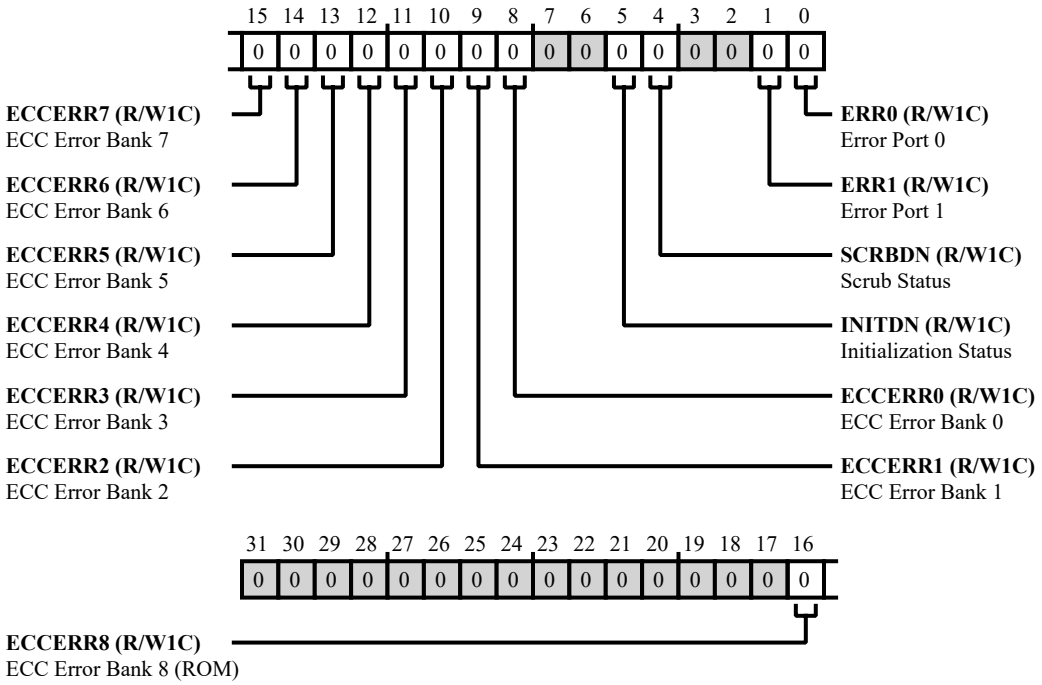

Figure 9-34: L2CTL_STAT Register Diagram

Table 9-36: L2CTL_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W1C)	ECCERR8	ECC Error Bank 8 (ROM). The L2CTL_STAT.ECCERR8 bit indicates that an ECC double-bit error occurred inside L2 bank 8 (ROM).	
		0	No Status
		1	ECC Double Bit Error
15 (R/W1C)	ECCERR7	ECC Error Bank 7. The L2CTL_STAT.ECCERR7 bit indicates that an ECC double-bit error occurred inside L2 bank 7.	
		0	No Status
		1	ECC Double Bit Error

Table 9-36: L2CTL_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
14 (R/W1C)	ECCERR6	ECC Error Bank 6. The `L2CTL_STAT.ECCERR6` bit indicates that an ECC double-bit error occurred inside L2 bank 6.	
		0	No Status
		1	ECC Double Bit Error
13 (R/W1C)	ECCERR5	ECC Error Bank 5. The `L2CTL_STAT.ECCERR5` bit indicates that an ECC double-bit error occurred inside L2 bank 5.	
		0	No Status
		1	ECC Double Bit Error
12 (R/W1C)	ECCERR4	ECC Error Bank 4. The `L2CTL_STAT.ECCERR4` bit indicates that an ECC double-bit error occurred inside L2 bank 4.	
		0	No Status
		1	ECC Double Bit Error
11 (R/W1C)	ECCERR3	ECC Error Bank 3. The `L2CTL_STAT.ECCERR3` bit indicates that an ECC double-bit error occurred inside L2 bank 3.	
		0	No Status
		1	ECC Double Bit Error
10 (R/W1C)	ECCERR2	ECC Error Bank 2. The `L2CTL_STAT.ECCERR2` bit indicates that an ECC double-bit error occurred inside L2 bank 2.	
		0	No Status
		1	ECC Double Bit Error
9 (R/W1C)	ECCERR1	ECC Error Bank 1. The `L2CTL_STAT.ECCERR1` bit indicates that an ECC double-bit error occurred inside L2 bank 1.	
		0	No Status
		1	ECC Double Bit Error

Table 9-36: L2CTL_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W1C)	ECCERR0	ECC Error Bank 0. The `L2CTL_STAT.ECCERR0` bit indicates that an ECC double-bit error occurred inside L2 bank 0.	
		0	No Status
		1	ECC Double Bit Error
5 (R/W1C)	INITDN	Initialization Status. The `L2CTL_STAT.INITDN` bit indicates whether initialization has been completed.	
		0	Initialization Not Complete
		1	Initialization Completed
4 (R/W1C)	SCRBDN	Scrub Status. The `L2CTL_STAT.SCRBDN` bit indicates whether a round of memory scrub has completed.	
		0	Scrub Not Complete
		1	Scrub Completed
1 (R/W1C)	ERR1	Error Port 1. The `L2CTL_STAT.ERR1` indicates whether the L2CTL has detected a bus access error on L2s bus port 1.	
		0	No Error
		1	Bus Access Error
0 (R/W1C)	ERR0	Error Port 0. The `L2CTL_STAT.ERR0` indicates whether the L2CTL has detected a bus access error on L2s bus port 0.	
		0	No Error
		1	Bus Access Error

L2 Port Error Status Register

The L2CTL_STAT_1 register stores the AXI Error Status from Port2 onwards. The register bits are sticky - once set it has to be explicitly reset by writing a 1 to that particular bit.

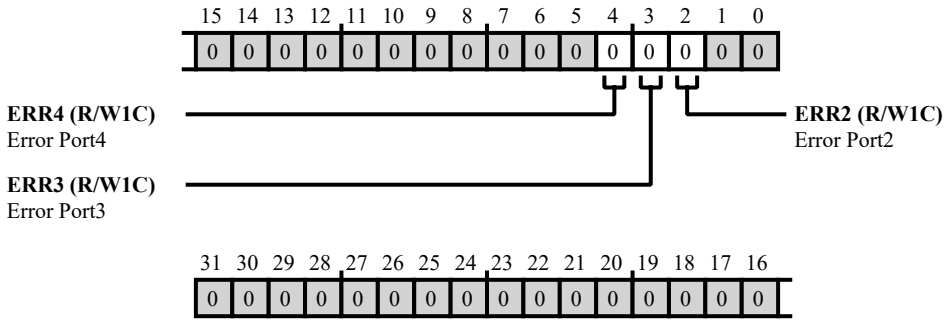

Figure 9-35: L2CTL_STAT_1 Register Diagram

Table 9-37: L2CTL_STAT_1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
4 (R/W1C)	ERR4	Error Port4. The L2CTL_STAT_1.ERR4 indicates whether the L2CTL has detected a bus access error on L2s bus port 4.
3 (R/W1C)	ERR3	Error Port3. The L2CTL_STAT_1.ERR3 indicates whether the L2CTL has detected a bus access error on L2s bus port 3.
2 (R/W1C)	ERR2	Error Port2. The L2CTL_STAT_1.ERR2 indicates whether the L2CTL has detected a bus access error on L2s bus port 2.

Write Priority Count Register

The L2CTL_WPCR0 register stores the count value to be used for priority elevation for bus write channels. If a bus channel is not granted access from the bank arbiter, the channel waits for the programmed number of SYSCLK cycles, before the request is elevated to a high priority request. If a priority count value is programmed as zero for a channel, that channel does not raise the urgent priority request.

This is a read/write register, but a new value in the corresponding field must be written only when there are no outstanding transactions on the corresponding bus write channel. A best practice is to program this register before initiating an L2 access.

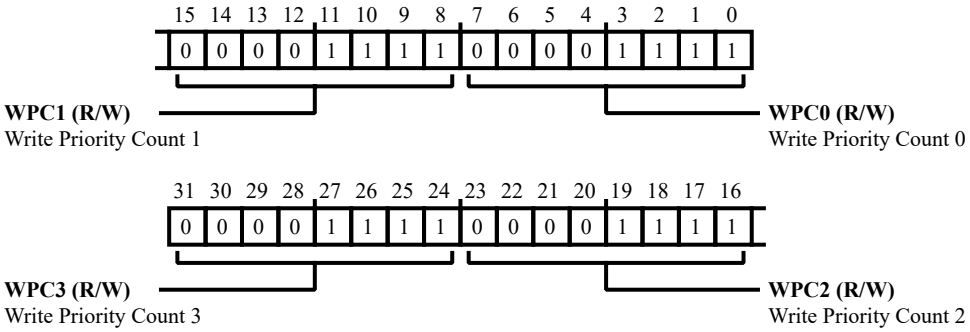

Figure 9-36: L2CTL_WPCR0 Register Diagram

Table 9-38: L2CTL_WPCR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	WPC3	Write Priority Count 3. The L2CTL_WPCR0.WPC3 bits hold the priority count for L2 bus write channel 3.
23:16 (R/W)	WPC2	Write Priority Count 2. The L2CTL_WPCR0.WPC2 bits hold the priority count for L2 bus write channel 2.
15:8 (R/W)	WPC1	Write Priority Count 1. The L2CTL_WPCR0.WPC1 bits hold the priority count for L2 bus write channel 1.
7:0 (R/W)	WPC0	Write Priority Count 0. The L2CTL_WPCR0.WPC0 bits hold the priority count for L2 bus write channel 0.

Write Priority Count Register

The L2CTL_WPCR1 register stores the count value to be used for priority elevation for bus write channels. If a bus channel is not granted access from the bank arbiter, the channel waits for the programmed number of SYSCLK cycles, before the request is elevated to a high priority request. If a priority count value is programmed as zero for a channel, that channel does not raise the urgent priority request.

This is a read/write register, but a new value in the corresponding field must be written only when there are no outstanding transactions on the corresponding bus write channel. A best practice is to program this register before initiating an L2 access.

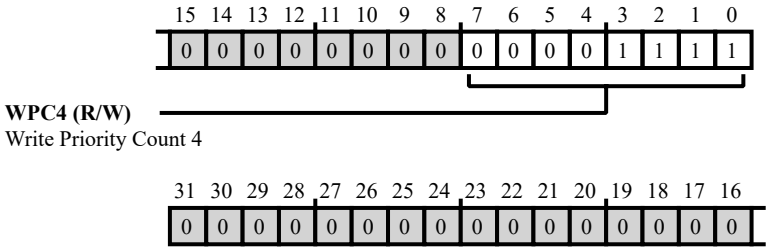

Figure 9-37: L2CTL_WPCR1 Register Diagram

Table 9-39: L2CTL_WPCR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	WPC4	Write Priority Count 4. The L2CTL_WPCR1.WPC4 bits hold the priority count for L2 bus write channel 4.

10 DDR Pre-fetch Buffer (DDRPFB)

The DDR Pre-fetch buffer is designed to reduce the latency for fetching instructions or reading data from DDR memory. The Pre-fetch buffer works in the background to reduce the latency of a subsequent data or instruction access by pre-fetching the next data for next address (using the principle of locality). The DDR pre-fetch buffer is integrated in the DDR path and uses the following features.

- SMART pre-fetching decision which is a direct access or pre-fetch based on the pattern seen in the previous read transactions issued
- ID based direct access where in a multi-controller scenario with more than four controllers avoids a slow controller (for example the SPORT) to flush out a buffer line that is being used by a fast requester (for example HSMDMA)
- Range based return zero feature

The *Pre-fetch Buffer Block Diagram* figure shows the functional blocks within the DDRPFB.

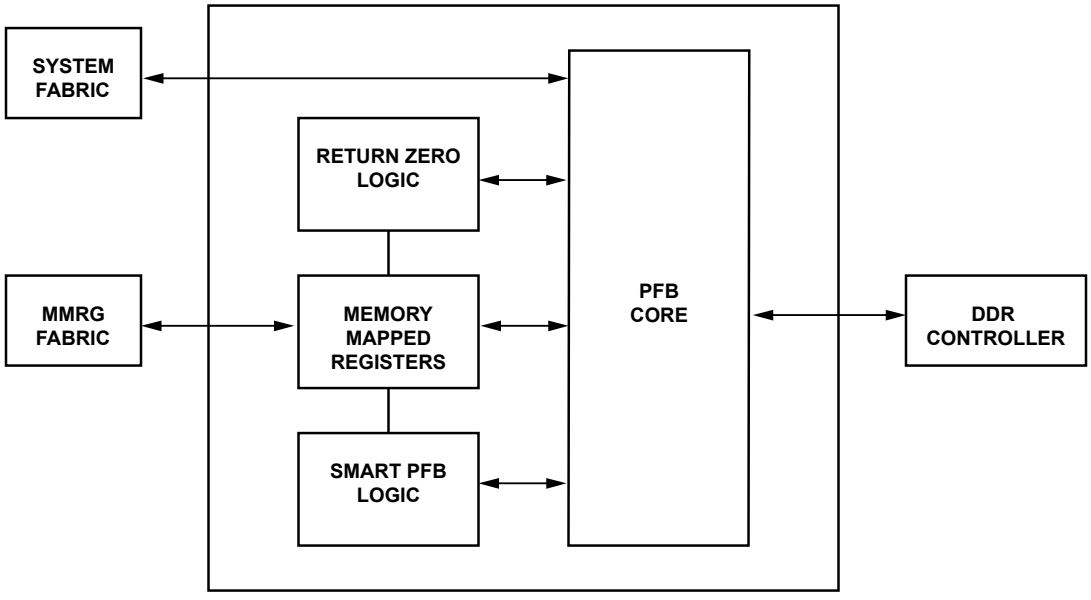

Figure 10-1: Pre-fetch Buffer Block Diagram

DDRPFB Features

The DDRPFB supports the following features:

- Smart Pre-fetch
- Direct DMC access
- Return Zero
- Controller ID based direct access
- Range based pre-fetch

Smart Pre-fetch

Smart pre-fetch is used for the worst case scenario where the controller fetches data at non continuous addresses which results no hits in the DDRPFB. To avoid fetching excess data for such non continuous read transactions, smart pre-fetching choses to start to fetch and/or pre-fetch requests from the DDRPFB to the DMC or gives direct access for such read requests. The decision is made based on the history of read transactions received at the input of the prefetch buffer. The `PFB_CTL1.SMART_FEATURE_EN` bit is used to enable this feature.

Data Invalidation

When the `PFB_CTL0.DATA_INVALIDATION` bit is set (=1), the complete pre-fetch buffer is invalidated. Clear this bit manually after setting it to make use of pre-fetch buffer.

Direct Access

In direct access, there are no pre-fetch accesses and the accesses are forwarded to the DMC directly. There is a one cycle latency while the pre-fetch buffer decides whether the access is direct or not. The read data from the DMC is directly forwarded to the controller without any latency impact and is not stored in the buffer.

Return Zero

This feature allows the program to configure a range of addresses range in L3 memory to always returns zero. To enable this feature, set (=1) the `PFB_CTL0.RETURN_ZERO` bit. The address range which require all zeros to be read is configured using the `PFB_ZERO_START.VAL` and `PFB_ZERO_END.VAL` registers. All the requests which that fall between the start and end addresses (that are aligned to 256 bytes) are returned with all zeros.

Controller ID Based Direct Access

This section explains how to configure a specific SCB controller for direct access or DDR pre-fetch access. Set the `PFB_CTL1.RQSTR_ID_FEATURE_EN` bit = 1 to use this feature. The following registers and bits are used to manage ID based direct access.

- The SCB controller ID is the ID of the SCB requester that is requesting data from the DDR. For ID information, see .

- The PFB_RQSTR_ID_EN.VAL bit field has four bits. It can take all 16 combinations. If this bit is cleared (=0) the corresponding SCB requester has direct access.
- The PFB_RQSTR0_ID, PFB_RQSTR1_ID, PFB_RQSTR2_ID and PFB_RQSTR3_ID registers are four IDs that are preprogrammed with the SCB ID. The configuration of these registers determine whether the DDRPFB gives a normal PFB enabled access or a direct access (if the corresponding PFB_RQSTR_ID_EN.VAL bit is set). If the SCB ID of the requester matches with the DDRPFB_MSTRx_ID, then the DDR pre-fetch operation is enabled.
- The PFB_RQSTR0_ID_MSK, PFB_RQSTR1_ID_MSK, PFB_RQSTR2_ID_MSK and PFB_RQSTR3_ID_MSK: When the PFB_RQSTR_ID_EN bit is set for some DDRPFB_MSTRx_ID, then the PFB enabled access is provided for a partial ID match of the SCB ID with the corresponding preprogrammed DDRPFB_MSTRx_ID. Clearing a bit masks the corresponding bit and the masked bits are not checked for a match.

The *DDRPFB Access Configurations* table shows the register configurations for different access types.

Table 10-1: DDRPFB Access Configurations

SCB Requester ID	DDRPFB_MSTR_ID_EN[0]	DDRPFB_MSTR0_ID	DDRPFB_MSTR0_ID_MASK	Access Type
XXXX	0	XXXX	XXXX	Direct access Irrespective of SCB requester ID, PFB_RQSTR0_ID and PFB_RQSTR0_ID_MSK, direct access is given to all the requests.
MMMM	1	NNNN	0000	DDRPFB enabled access DDRPFB does not check any bits of the SCB requester ID if it matches with PFB_RQSTR0_ID. Therefore, DDRPFB performs prefetch operation for all IDs. This is an example where DDR prefetch is enabled, though none of the bits of SCB ID matches with PFB_RQSTR0_ID.
MMXX	1	MMXX	1100	DDRPFB enabled access DDRPFB looks for only two MSBs from SCB ID matching the two MSBs of PFB_RQSTR0_ID. If they match, the DDRPFB performs a prefetch operation. Otherwise, direct access is given to such requests. In this example the two MSBs matching with the two MSBs of PFB_RQSTR0_ID configures a normal DDRPFB enabled access.
MMXX	1	NNXX	1100	Direct access The PFB looks for only the two MSBs from the SCB ID that match with the two MSBs of PFB_RQSTR0_ID. If they match, the PFB performs a normal operation. Otherwise, direct access is given to such requests. In this example, since the two MSBs do not match with the two MSBs of PFB_RQSTR0_ID, it is a direct access.

Range Based Pre-fetch

Range based prefetch allows an entire address range to be divided into 16 address ranges to selectively disable the pre-fetch buffer (while pre-fetching is enabled) for this address range using the PFB_RANGE_SELECT register. For example, the *Range Based Pre-fetch* table shows that if PFB_RANGE_SELECT [9] = 0, then the PFB is disabled for address range 90000000 to 9FFFFFFF.

The PFB_CTL1.RANGE_SHIFT bit field is used to configure pre-fetching 16 sections of the address map based on the most significant nibble in the input address. In the example PFB_CTL1.RANGE_SHIFT is 28.

Table 10-2: Range Based Pre-fetch

Sr. No.		PFB Operation
1	PFB_RANGE_SELECT [ARADDR_IN[31:28]] = 1 && PFB_CTL0.PREFETCH_EN = 1	PFB enabled operation
2	PFB_RANGE_SELECT [ARADDR_IN[31:28]] = 0 && PFB_CTL0.PREFETCH_EN = 1	PFB disabled operation
3	PFB_RANGE_SELECT [ARADDR_IN[31:28]] = X && PFB_CTL0.PREFETCH_EN = 0	PFB disabled operation

Table 10-3: Range Based Address Range Selections

Input bit	Address range for Pre-fetch
RANGE_SELECT[0]	00000000 – 0FFFFFFF
RANGE_SELECT[1]	10000000 – 1FFFFFFF
RANGE_SELECT[2]	20000000 – 2FFFFFFF
RANGE_SELECT[3]	30000000 – 3FFFFFFF
RANGE_SELECT[4]	40000000 – 4FFFFFFF
RANGE_SELECT[5]	50000000 – 5FFFFFFF
RANGE_SELECT[6]	60000000 – 6FFFFFFF
RANGE_SELECT[7]	70000000 – 7FFFFFFF
RANGE_SELECT[8]	80000000 – 8FFFFFFF
RANGE_SELECT[9]	90000000 – 9FFFFFFF
RANGE_SELECT[10]	A0000000 – AFFFFFFF
RANGE_SELECT[11]	B0000000 – BFFFFFFF
RANGE_SELECT[12]	C0000000 – CFFFFFFF
RANGE_SELECT[13]	D0000000 – DFFFFFFF
RANGE_SELECT[14]	E0000000 – EFFFFFFF
RANGE_SELECT[15]	F0000000 – FFFFFFFF

Programming Notes

The following guidelines should be noted when using range based pre-fetch.

- PFB_RANGE_SELECT.VAL is used to change the prefetch range
- When PFB_RANGE_SELECT.VAL = 5'bN, then ARADDR_IN[N+3:N] are used for range selection (here, N is programmable number)
  - When PFB_CTL1.RANGE_SHIFT = 28, logic behavior is same as above table
  - When PFB_CTL1.RANGE_SHIFT = 26, then ARADDR_IN[29:26] are used for range selection

For finer control of a small range the configurations in the following table can be used.

Sr. No.		PFB Operation
1	PFB_RANGE_SELECT [ARADDR_IN[N+3:N]] = 1 && PFB_CTL0.PREFETCH_EN = 1	PFB enabled operation
2	PFB_RANGE_SELECT [ARADDR_IN[N+3:N]] = 0 && PFB_CTL0.PREFETCH_EN = 1	PFB disabled operation
3	PFB_RANGE_SELECT [ARADDR_IN[N+3:N]] = X(don't care) && PFB_CTL0.PREFETCH_EN = 0	PFB disabled operation

ADSP-2184x PFB Register List

PFB

PFB_ZERO_END	Return Zero End Address Register
PFB_ZERO_START	Return Zero Start Address Register

DDRPFB Programming Model

The following sections describe how to program the DDRPFB.

Enabling the Pre-fetch Buffer and PFB Idle State

Set the PFB_CTL0.PREFETCH_EN bit (=1) to enable the DDR pre-fetch buffer.

When the PFB_STS0.PFB_IDLE bit = 1 there are no pending transactions between the DDRPFB and the DMC. When this bit = 0, there is at least one pending transaction between the DDRPFB and the DMC.

General Programming Guidelines

The following are few guidelines which need to be followed for proper functioning of DDR PFB.

- The PFB_STS0.PFB_IDLE indicates whether the DDRPFB is IDLE or not and can be polled to add delay to allow pending requests from the PFB to completer get completed.
- To issue a DMC reset during operation, the following steps are used to maintain data coherence and prevent system hangs.
  1. Block all requesters that are currently accessing DDR
  2. Check that the PFB is in the IDLE state by checking PFB_STS0.PFB_IDLE
  3. Issue a DMC reset
  4. Invalidate the PFB
  5. Unblock all requesters that need access to DDR
- During DDR initialization the PFB should be disabled. If the program needs to have the PFB enabled during DDR initialization, perform a PFB invalidation after DDR initialization is completed.
- The maximum possible value of PFB_CTL1.RANGE_SHIFT is ‘b11100. Any value that is more than ‘b11100 has no significance because the address bus width is 32-bits.

Guidelines For Achieving Maximum Performance

To achieve maximum performance, please note the following:

- Each DDR PFB line can hold 256 bytes of data. To achieve maximum performance the starting address of sequential memory accesses should be 256 bytes aligned
- Enable DDRPFB for requesters that support burst mode
- Burst mode with a burse size of 128 bits provide good performance compared to other combinations of burst size less than 128 bits
- Use the Requester ID based direct access feature for the SPORTs and IIR when there are more than four requesters acting at a time.
- Multiple requesters can be combined as a one requester when they are fetching data in interleaved fashion. This is accomplished by placing data in DDR in such a way that (for example), address A is for requester 1, A+x for requester 2, A+2x for again requester 1 and A +3x for requester 2. So in this example for requester 1 addresses A + 2nx are used and for requester 2 addresses A + (2n+1)x are used, where n = 0,1,2, and so on.
- Avoiding wrap access – Data defined in source code can be placed in memory in such a way that all requests from requester A55 is cache line aligned so that all requests from cache onwards are incremental accesses.
- The decision should be made on what is most suitable with respect to performance out of the various DDRPFB configurations, including DDRPFB disabled. In most cases PFB = enabled and the smart feature = enabled has better performance. For few use-cases PFB = enabled, smart feature disabled work best.

ADSP-2184x PFB Register Descriptions

Prefetch buffer mmr registers (PFB) contains the following registers.

Table 10-5: ADSP-2184x PFB Register List

Name	Description
PFB_BCR_END	Prefetch buffer fourth control register
PFB_BCR_START	Prefetch buffer third control register
PFB_CTL0	Control Register 0
PFB_CTL1	Control Register 1
PFB_RANGE_SELECT	Range Select Register
PFB_RQSTR0_ID	Requester ID 0 Register
PFB_RQSTR0_ID_MSK	Requester ID 0 Mask Register
PFB_RQSTR1_ID	Requester ID 1 Register
PFB_RQSTR1_ID_MSK	Requester ID 1 Mask Register
PFB_RQSTR2_ID	Requester ID 2 Register
PFB_RQSTR2_ID_MSK	Requester ID 2 Mask Register
PFB_RQSTR3_ID	Requester ID 3 Register
PFB_RQSTR3_ID_MSK	Requester ID 3 Mask Register

Table 10-5: ADSP-2184x PFB Register List (Continued)

Name	Description
PFB_RQSTR_ID_EN	Requester ID Enable Register
PFB_STS0	Prefetch Buffer First Status Register
PFB_ZERO_END	Return Zero End Address Register
PFB_ZERO_START	Return Zero Start Address Register

Prefetch buffer fourth control register

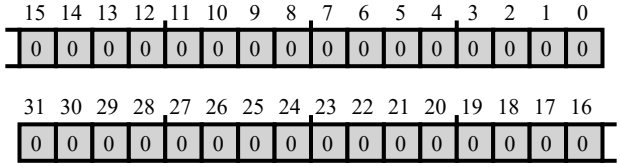

Figure 10-2: PFB_BCR_END Register Diagram

Table 10-6: PFB_BCR_END Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	BCR_END	End address of range in which fetch and prefetch requests launched at 4K boundary crossing.

Prefetch buffer third control register

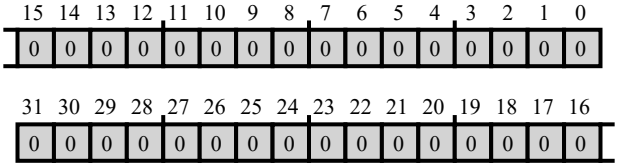

Figure 10-3: PFB_BCR_START Register Diagram

Table 10-7: PFB_BCR_START Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	BCR_START	Start address of range in which fetch and prefetch requests launched at 4K boundary crossing.

Control Register 0

The PFB_CTL0 register disables prefetching for up to sixteen address ranges. Bits[31:16] bits control the range selection for the instruction cache, and bits [15:0] control the range selection for the data cache.

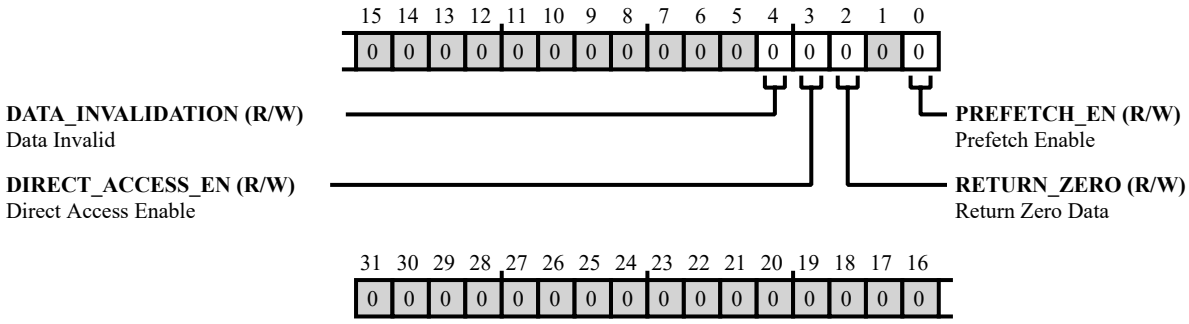

Figure 10-4: PFB_CTL0 Register Diagram

Table 10-8: PFB_CTL0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W)	DATA_INVALIDATION	Data Invalid. When the PFB_CTL0.DATA_INVALIDATION bit is set the prefetch buffer is invalid. The program must clear this bit manually.	
		0	Buffer valid
		1	Buffer invalid
3 (R/W)	DIRECT_ACCESS_EN	Direct Access Enable. When the PFB_CTL0.DIRECT_ACCESS_EN bit is set (=1) the prefetch buffer passes requests as is from a requester to a completer. No excess data is fetched and stored in prefetch buffer. When the PFB_CTL0.DIRECT_ACCESS_EN bit is cleared (=0) the prefetch buffer behaves as if it is disabled.	
		0	Direct access disabled
		1	Direct access enabled
2 (R/W)	RETURN_ZERO	Return Zero Data. When the PFB_CTL0.RETURN_ZERO bit is set, the prefetch buffer returns zero data for the address range configured in the PFB_ZERO_START and PFB_ZERO_END registers. The addresses in the PFB_ZERO_START and PFB_ZERO_END registers should be 128 byte aligned.	
		0	Return zero disabled
		1	Return zero data in selected address range

Table 10-8: PFB_CTL0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	PREFETCH_EN	Prefetch Enable. When the `PFB_CTL0.PREFETCH_EN` bit is set (=1), the prefetch buffer is enabled. Otherwise, the prefetch buffer is disabled.	
		0	Prefetch disabled
		1	Prefetch enabled

Control Register 1

The PFB_CTL1 register enables smart prefetch, range shifting, and direct access.

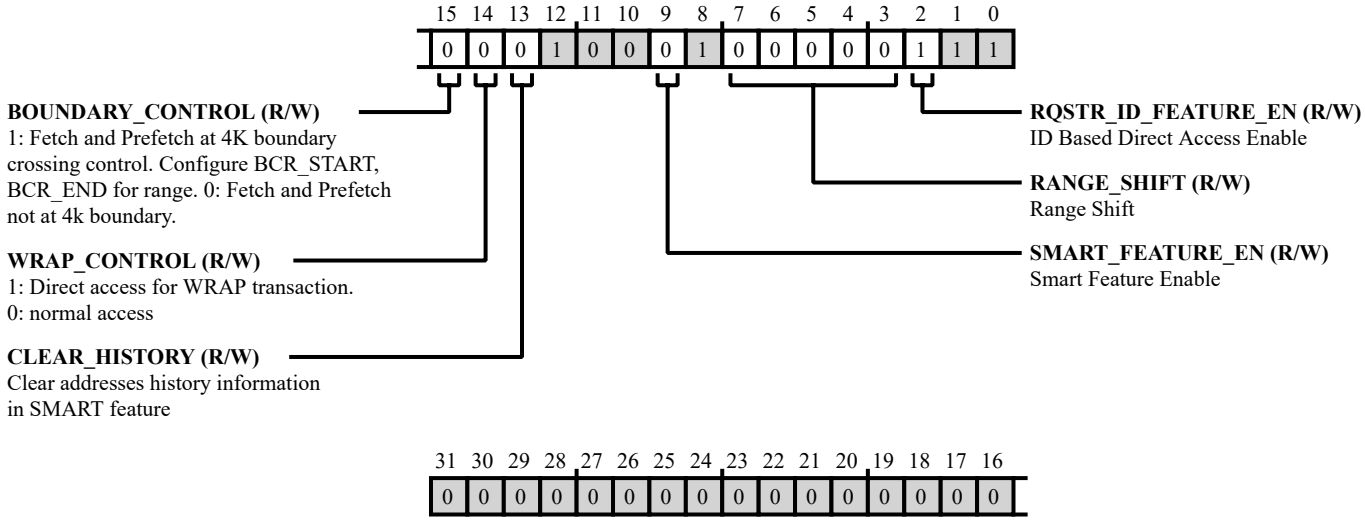

Figure 10-5: PFB_CTL1 Register Diagram

Table 10-9: PFB_CTL1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	BOUNDARY_CONTROL	1: Fetch and Prefetch at 4K boundary crossing control. Configure BCR_START, BCR_END for range. 0: Fetch and Prefetch not at 4k boundary..	
14 (R/W)	WRAP_CONTROL	1: Direct access for WRAP transaction. 0: normal access.	
13 (R/W)	CLEAR_HISTORY	Clear addresses history information in SMART feature.	
9 (R/W)	SMART_FEATURE_EN	Smart Feature Enable. Setting the PFB_CTL1.SMART_FEATURE_EN bit enables the SMART feature.	
		0	Smart prefetch disabled
		1	Smart prefetch enabled
7:3 (R/W)	RANGE_SHIFT	Range Shift. The PFB_CTL1.RANGE_SHIFT bit field determines which bits of the read address (that appear at the input of prefetch buffer) are used for the range select operation. By default this is the four MSBs are used. When this bit field is programmed to 5hN then [N+3:N] address bits are used for the range select operation.	

Table 10-9: PFB_CTL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	RQSTR_ID_FEATURE_EN	ID Based Direct Access Enable. The `PFB_CTL1.RQSTR_ID_FEATURE_EN` bit, when set (=1) enables the ID based direct access feature.	
		0	ID based direct access disabled
		1	ID based direct access enabled

Range Select Register

The PFB_RANGE_SELECT register determines whether the prefetch buffer is enabled or disabled in the specified address range.

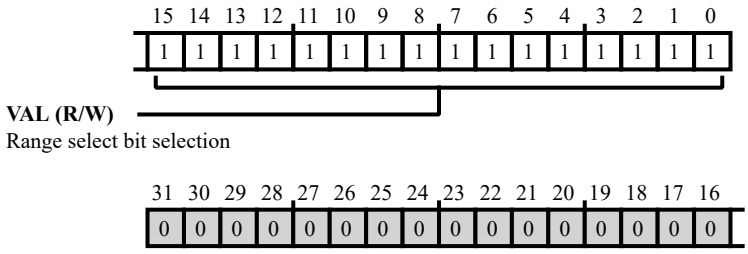

Figure 10-6: PFB_RANGE_SELECT Register Diagram

Table 10-10: PFB_RANGE_SELECT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VAL	Range select bit selection. Each bit in this bit field determines prefetch buffer should be enabled or disabled in that address range. This bit field is used in conjunction with RANGE_SHIFT bit field.

Requester ID 0 Register

The PFB_RQSTR0_ID register is used to configure the first requester ID for controller ID based direct access operations.

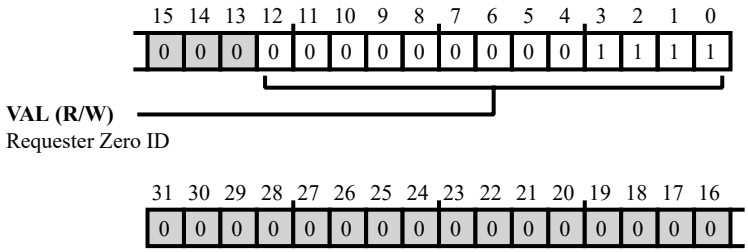

Figure 10-7: PFB_RQSTR0_ID Register Diagram

Table 10-11: PFB_RQSTR0_ID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12:0 (R/W)	VAL	Requester Zero ID. The PFB_RQSTR0_ID.VAL bit field identifies the first requester ID to be considered for ID based direct access.

Requester ID 0 Mask Register

The PFB_RQSTR0_ID_MSK register is used to mask the first requester ID for controller ID based direct access operations. The masked bits are not used in direct access operations.

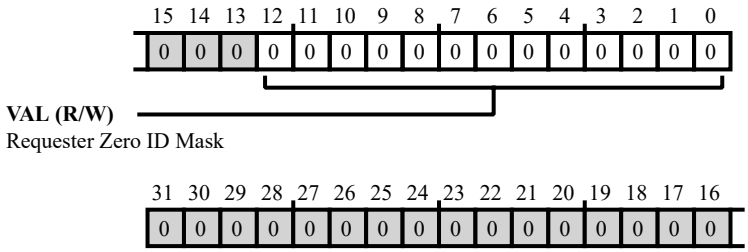

Figure 10-8: PFB_RQSTR0_ID_MSK Register Diagram

Table 10-12: PFB_RQSTR0_ID_MSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12:0 (R/W)	VAL	Requester Zero ID Mask. The PFB_RQSTR0_ID_MSK.VAL bit field masks the first requester ID to exclude from ID based direct access.

Requester ID 1 Register

The PFB_RQSTR1_ID register is used to configure the first requester ID for controller ID based direct access operations.

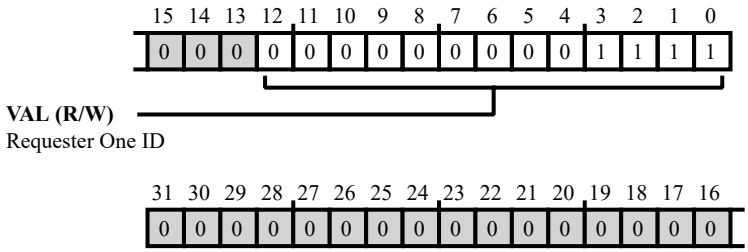

Figure 10-9: PFB_RQSTR1_ID Register Diagram

Table 10-13: PFB_RQSTR1_ID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12:0 (R/W)	VAL	Requester One ID. The PFB_RQSTR1_ID.VAL bit field identifies the second requester ID to be considered for ID based direct access.

Requester ID 1 Mask Register

The PFB_RQSTR1_ID_MSK register is used to mask the second requester ID for controller ID based direct access operations. The masked bits are not used in direct access operations.

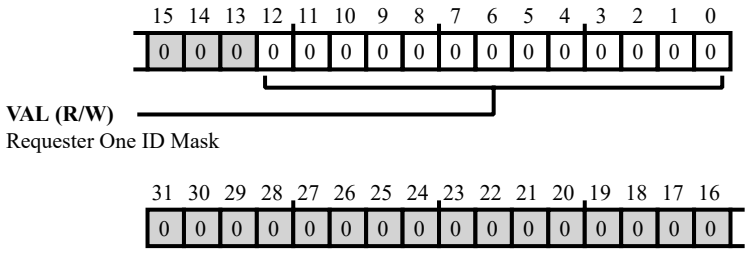

Figure 10-10: PFB_RQSTR1_ID_MSK Register Diagram

Table 10-14: PFB_RQSTR1_ID_MSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12:0 (R/W)	VAL	Requester One ID Mask. The PFB_RQSTR1_ID_MSK.VAL bit field masks the second requester ID to exclude from ID based direct access.

Requester ID 2 Register

The PFB_RQSTR2_ID register is used to configure the third requester ID for controller ID based direct access operations.

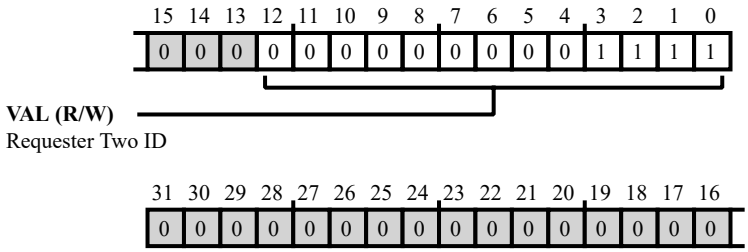

Figure 10-11: PFB_RQSTR2_ID Register Diagram

Table 10-15: PFB_RQSTR2_ID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12:0 (R/W)	VAL	Requester Two ID. The PFB_RQSTR2_ID.VAL bit field identifies the third requester ID to be considered for ID based direct access.

Requester ID 2 Mask Register

The PFB_RQSTR2_ID_MSK register is used to mask the third requester ID for controller ID based direct access operations. The masked bits are not used in direct access operations.

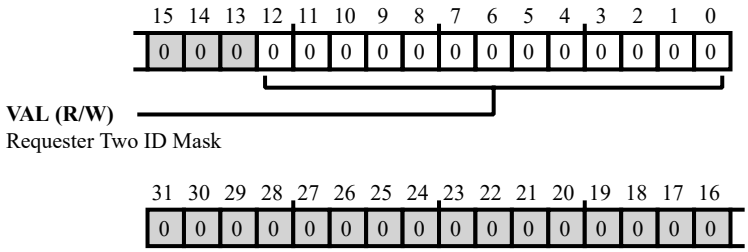

Figure 10-12: PFB_RQSTR2_ID_MSK Register Diagram

Table 10-16: PFB_RQSTR2_ID_MSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12:0 (R/W)	VAL	Requester Two ID Mask. The PFB_RQSTR2_ID_MSK.VAL bit field masks the third requester ID to exclude from ID based direct access.

Requester ID 3 Register

The PFB_RQSTR3_ID register is used to configure the fourth requester ID for controller ID based direct access operations.

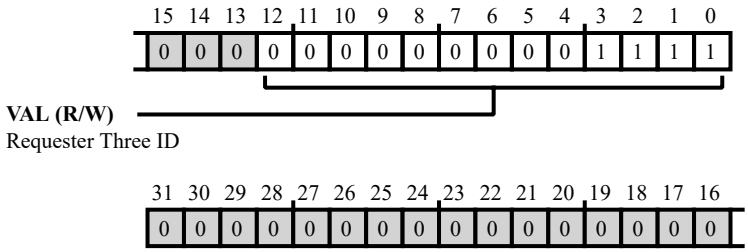

Figure 10-13: PFB_RQSTR3_ID Register Diagram

Table 10-17: PFB_RQSTR3_ID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12:0 (R/W)	VAL	Requester Three ID. The PFB_RQSTR3_ID.VAL bit field identifies the fourth requester ID to be considered for ID based direct access.

Requester ID 3 Mask Register

The PFB_RQSTR3_ID_MSK register is used to mask the fourth requester ID for controller ID based direct access operations. The masked bits are not used in direct access operations.

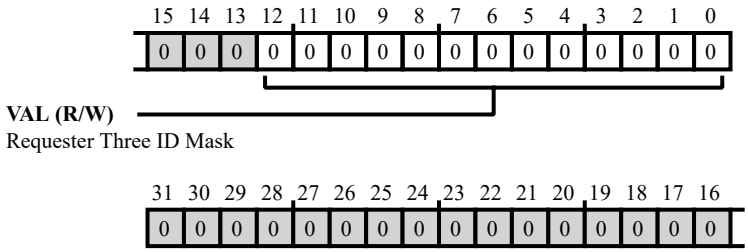

Figure 10-14: PFB_RQSTR3_ID_MSK Register Diagram

Table 10-18: PFB_RQSTR3_ID_MSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12:0 (R/W)	VAL	Requester Three ID Mask. The PFB_RQSTR3_ID_MSK.VAL bit field masks the fourth requester ID to exclude from ID based direct access.

Requester ID Enable Register

The PFB_RQSTR_ID_EN register is used to configure controller based direct access. As many as four controller IDs can be programmed for direct access. For more information, see "Controller ID Based Direct Access".

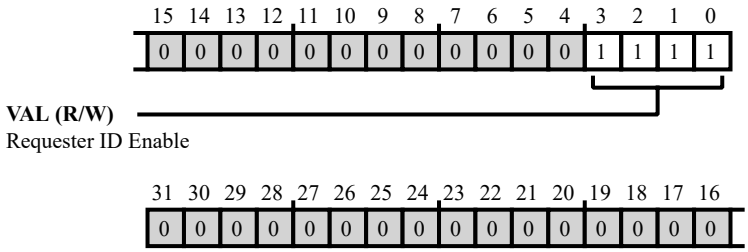

Figure 10-15: PFB_RQSTR_ID_EN Register Diagram

Table 10-19: PFB_RQSTR_ID_EN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
3:0 (R/W)	VAL	Requester ID Enable. The PFB_RQSTR_ID_EN.VAL bits are used to configure controller based direct access. As many as four controller IDs can be programmed for direct access. For more information, see "Controller ID Based Direct Access".

Prefetch Buffer First Status Register

The PFB_STS0 register indicates whether all fetch and prefetch operations from the PFB to the DDR are complete.

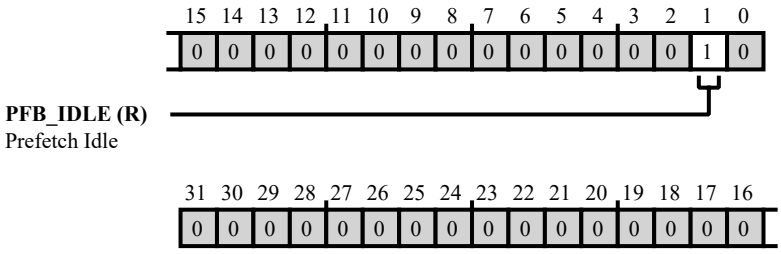

Figure 10-16: PFB_STS0 Register Diagram

Table 10-20: PFB_STS0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
1 (R/NW)	PFB_IDLE	Prefetch Idle. The PFB_STS0.PFB_IDLE bit, when set (=1), indicates all fetch and prefetch operations from the PFB to the DDR are complete.

Return Zero End Address Register

The PFB_ZERO_END register is used with the PFB_ZERO_START register to configure an address range in L3 memory to always returns zero.

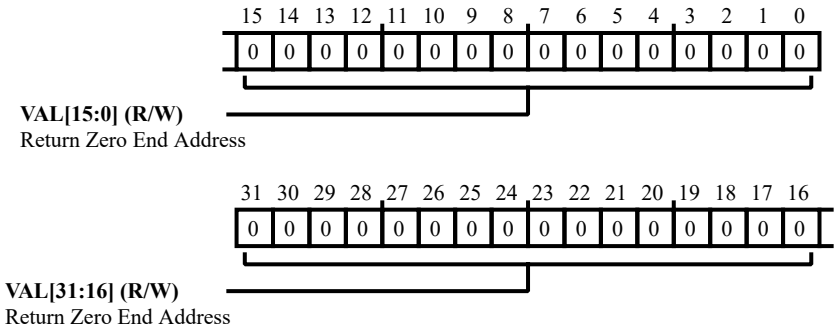

Figure 10-17: PFB_ZERO_END Register Diagram

Table 10-21: PFB_ZERO_END Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VAL	Return Zero End Address. The PFB_ZERO_END.VAL bit field is used to configure the end address (that are aligned to 256 bytes) that are returned with all zeros.

Return Zero Start Address Register

The PFB_ZERO_START register is used with the PFB_ZERO_END register to configure a range of addresses in L3 memory to always returns zero.

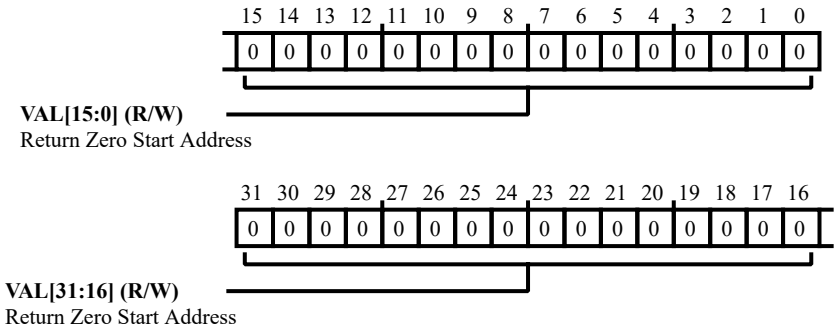

Figure 10-18: PFB_ZERO_START Register Diagram

Table 10-22: PFB_ZERO_START Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VAL	Return Zero Start Address. The PFB_ZERO_START.VAL bit field is used to configure the start address (that are aligned to 256 bytes) that are returned with all zeros.

11 One-Time Programmable Memory Controller (OTPC)

This chapter describes the operation of the OTP controller. The OTP module is a complete system integrating an OTP memory core with a programming controller, charge pump, and voltage regulator. A built-in Hamming Code Error Correction (ECC), and a fully implemented double-redundant program or read scheme protect the OTP data.

CAUTION: OTP memory does not support burst transfers, which are required to support cache line fills. As such, OTP memory should not be made cacheable. If it is, the OTP controller returns an error when a read access is attempted.

OTPC Features

The OTP memory and controller have the following features:

- Built-in redundant read mode
- Built-in integrated power supply
- Built-in Hamming Code Error Correction (ECC)
- Full word serial (single bit at a time) programming with internal VPP

NOTE: The OTP module is protected by the System Memory Protection Unit (SMPU) and is always secure by default. Non secure access to the OTP by any module will fail unless allowed by the SMPU.

OTPC Functional Description

ADSP-2184x OTPC Register List

The One-Time-Programmable Memory controller (OTPC) supports programming the OTP memory. A set of registers governs OTPC operations. For more information on OTPC functionality, see the OTPC register descriptions.

Table 11-1: ADSP-2184x OTPC Register List

Name	Description
OTPC_SECU_STATE	OTP Security State Register
OTPC_STAT	OTP Status Register

ADSP-2184x OTPC Interrupt List

Table 11-2: ADSP-2184x OTPC Interrupt List

Interrupt ID	Name	Description	Sensitivity	DMA Channel
216	OTPC0_ERR	OTPC0 Dual-bit Error	Level	

Error Correction

The OTP memory features a Hamming error correction implementation. Signal bit errors are automatically corrected, and dual-bit errors are detected. Refer to OTPC Interrupt Signals.

ECC is always enabled. ECC applies to each 16-bit segment. Because of this functionality, each 16-bit location can only be written to once. Writing to a 16-bit location a second time results in unexpected behavior.

OTP Layout

This section details the memory layout of the OTP memory.

Table 11-3: ADSP-2184x/SC84x OTP Layout

OTPC Event Control

The following sections provide information on OTP events and error management.

OTPC Interrupt Signals

When making 32-bit accesses to OTP memory, a double-bit error in any 16-bit segment triggers the OTPC_INT interrupt. The OTPC also has the OTPC dual bit error (OTPC0_ERR) with the SEC ID of 5.

OTPC Status and Error Signals

The OTP controller does not produce error signals.

OTP API Overview

The ROM/OTP SSLDD library provides a set of functions to facilitate OTP field access. The OTP memory is broken up into a set of specialized fields that are described in this section. The API removes the requirement of understanding the details of the layout or OTP access procedures.

All OTP accesses are made through the provided API.

OTP Programming

The OTP programming API provides a simple access, abstracting particulars of the OTP controller.

Any fields that contain zero or null pointers are skipped.

All addresses are assumed to be byte addresses unless otherwise noted.

OTP Reading

This API provides a unified source for retrieving OTP data fields.

All addresses are assumed to be byte addresses, unless otherwise noted.

A list of APIs follow:

`bool adi_rom_otp_get( OTPCMD cmd, uint32_t* data);`	OTP Get Field

OTP Get Field

Retrieves indicated data from OTP memory.

Name	OTP Get Field	
Prototype	`bool adi_rom_otp_get( OTPCMD cmd, uint32_t* data);`	
Argument	cmd	Indicates what data to fetch, based on the`OTPCMD` enum.
Argument	data	memory location to write the data to
Return Value	bool	true for a successful read
Stack Requirements	valid stack	

```
bool res = adi_rom_otp_get(otpcmd_info,data);
```

The data specified by the `OTPCMD` enum parameter is fetched from OTP memory and placed in the location specified by data. The `OTPCMD` enum contains entries for each field defined in OTP memory, for the most current list, refer to the OTP header file.

ADSP-2184x OTPC Register Descriptions

OTP Memory Controller (OTPC) contains the following registers.

Table 11-4: ADSP-2184x OTPC Register List

Name	Description
OTPC_SECU_STATE	OTP Security State Register
OTPC_STAT	OTP Status Register

OTP Security State Register

The OTPC_SECU_STATE register indicates the secure state. The register is updated only after the part is rebooted and locked.

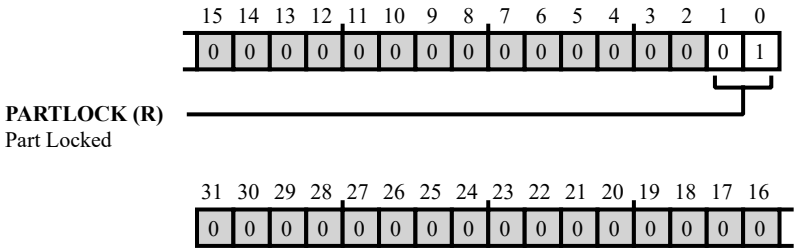

Figure 11-1: OTPC_SECU_STATE Register Diagram

Table 11-5: OTPC_SECU_STATE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
1:0 (R/NW)	PARTLOCK	Part Locked. The OTPC_SECU_STATE.PARTLOCK field indicates a locked part.	
		0	OPEN part
		1	Locked part
		2	Reserved
		3	Reserved

OTP Status Register

The OTPC_STAT register bits indicate errors and flag status and control the protection bits.

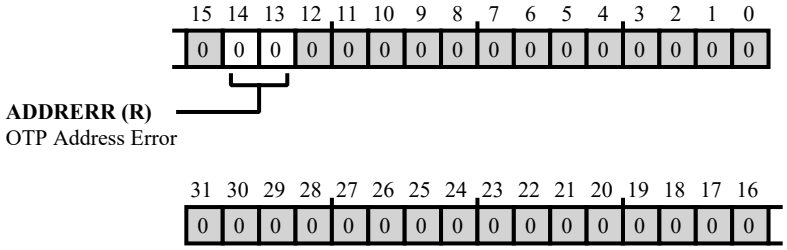

Figure 11-2: OTPC_STAT Register Diagram

Table 11-6: OTPC_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
14:13 (R/NW)	ADDRERR	OTP Address Error. The OTPC_STAT.ADDRERR bit field indicates errors which occur when the OTP programming address is out of range or tries to access protected space.	
		0	No error - proper OTP address
		1	OTP address out of range
		2	8-bit OTP address
		3	Protected OTP address

12 System Memory Protection Unit (SMPU)

The SMPU provides a flexible way of protecting memory regions against read or write access from any or all bus requester in the system. In addition, it can guard against memory access depending on security privileges of the system bus requester.

SMPU Features

The system memory protection unit has the following features.

- After reset, the default state of the system is fully open. The SMPUs admit any access to memory spaces by any controller.
- On reset, secure transactions are only allowed; non secure transactions are disabled.
- Each SMPU instance can be configured to monitor multiple regions. Each can be individually enabled.
- Each region can be configured with its own protection settings.
- Provides general read or write protection.
- Read and write transactions are restricted or allowed depending on the transaction ID.

On the ADSP-SC84x/ADSP-2184x processor, 15 SMPU instances are available to protect the L2, external memory (DMC) interface.

Table 12-1: SMPU Instances

Module	SMPU Instance	Controller Allowed	L2 Memory Address Range
L2-Core Port 0 (CL2_0)	2	Data port of both the SHARC-FX and Arm and IIR accelerator port	0x20400000 - 0x205FFFFF (L2 SRAM Banks 0-19) 0x20200000 – 0x2021FFFF (L2 Boot ROM 0 and 1)
L2 DMA Port 0 (DL2_0)	3	HSMDMA	0x20400000 - 0x208FFFFF (L2 SRAM Banks 0-19) 0x20200000 – 0x2021FFFF (L2 Boot ROM 0 and 1)
L2-Core Port 1 (CL2_1)	4	Data port of the SHARC-FX and Arm and IIR accelerator port	0x20600000 - 0x208FFFFF (L2 SRAM Banks 16-19)
L2 DMA Port 1 (DL2_1)	5	Peripheral and remaining DMA	0x20400000 - 0x208FFFFF (L2 SRAM Banks 0-19) 0x20200000 – 0x2021FFFF (L2 Boot ROM 0 and 1)

Table 12-1: SMPU Instances (Continued)

Module	SMPU Instance	Controller Allowed	L2 Memory Address Range
L2-Core Port 2 (CL2_2)	6	Instruction port of both SHARC-FX and FIR accelerator port	0x20400000 - 0x208FFFFF (L2 SRAM Banks 0-19) 0x20200000 – 0x2021FFFF (L2 Boot ROM 0 and 1)
DMC0	9	All allowed requesters	Entire range
SPI2/xSPI Flash Address Space	11	All allowed requesters	Entire range
OTP Memory	12	All allowed requesters	Entire range

All the SMPU instances can be configured up to eight regions.

- Up to eight outstanding read or write transactions supported on SMPU instances for Core_L2 and DMC0. Up to four outstanding read or write transactions supported on the SMPU instances for DMA_L2 and SPI flash address space.

SMPU Functional Description

The following sections provide details on the function of the SMPU module. If the region security settings allow transactions to go through, the ID in the ID-based region protection settings can still filter the transactions.

For the memory that an SMPU protects, programs can configure region-based settings with the `SMPU_RCTL[n]` registers. (There can be multiple SMPUs in a system.) The `SMPU_RCTL[n]` registers define the ID-based protection for memory regions.

If the target address does not reside in any configured memory region, the transaction permission resorts back to the global configuration setting.

Protection Units

Each SMPU provides two protection units, A and B for ID-based matching in the region-based memory protection. This feature provides a degree of flexibility for the user to match against multiple IDs.

Instruction Fetches

When the core executes instructions from memory, this operation is also considered a memory transaction. If the SMPU is configured to protect a memory region from read accesses that contain instructions, the core cannot fetch and execute these instructions.

Using Cache

When the processor uses both cache and the SMPU, there are a few issues to be aware of. If the SMPU is configured to protect a memory region from write accesses, instruction fetches from a core are still possible since instructions are not updated and replaced during run time.

NOTE: The debugger typically replaces an instruction with a breakpoint instruction for software breakpoints. If a memory region is protected against write accesses, software breakpoints are not possible unless the SMPU is configured with the appropriate system controller ID of the debugger. The configuration allows it to perform a write-access.

In the case where memory is used for data, a read access or cache fill is not possible if the memory is blocked from read accesses. If read accesses are allowed but write accesses are disallowed, then there is an issue with coherency. The cache is filled but when the cache is updated and must be written back to the SMPU protected memory, the write-access is blocked.

In general, exercise caution when using both the SMPU and cache.

Speculative Reads

If speculative reads are enabled (`SMPU_CTL.RSDIS` =0), the SMPU forwards the read transaction directly to the memory before checking the protection setting corresponding to the addressed memory region. This functionality saves one clock cycle in the clock domain of the SMPU. The SMPU checks the protection setting while the read transaction occurs with the memory. If the protection setting dictates that the target memory address is blocked, the SMPU blocks the read to the controller.

If speculative reads are disabled (`SMPU_CTL.RSDIS` =1), the SMPU checks the protection settings first and forwards the transaction to memory only if it passes the configured protection settings. This functionality incurs a one-cycle latency per read.

NOTE: Reads affect certain memory operations such as automatic clearing of the memory (that is, FIFOs). When the SMPU protects this type of memory, disable read speculation since the blocking can occur without the read transaction reaching the target memory.

ADSP-2184x SMPU Register List

The System Memory Protection Unit (SMPU) provides selective protection of the processor's memory resources. The SMPU includes a set of processor events that can be monitored during program execution. A set of registers governs SMPU operations. For more information on SMPU functionality, see the SMPU register descriptions.

Table 12-2: ADSP-2184x SMPU Register List

Name	Description
`SMPU_BADDR`	Bus Error Address Register
`SMPU_BDTLS`	Bus Error Details Register
`SMPU_CTL`	SMPU Control Register
`SMPU_EXACADD[n]`	Exclusive Access IDn Address
`SMPU_EXACSTAT[n]`	Exclusive Access Status
`SMPU_IADDR`	Interrupt Address Register

Table 12-2: ADSP-2184x SMPU Register List (Continued)

Name	Description
SMPU_IDTLS	Interrupt Details Register
SMPU_RADDR[n]	Region n Address Register
SMPU_RCTL[n]	Region n Control Register
SMPU_REVID	SMPU Revision ID Register
SMPU_RIDA[n]	Region n ID A Register
SMPU_RIDB[n]	Region n ID B Register
SMPU_RIDMSKA[n]	Region n ID Mask A Register
SMPU_RIDMSKB[n]	Region n ID Mask B Register
SMPU_SECURECTL	SMPU Control Secure Accesses Register
SMPU_SECURERCTL[n]	Region n Control Secure Accesses Register
SMPU_STAT	SMPU Status Register

SMPU Interrupts

The SMPU has one interrupt with the SEC ID = 142.

See the SEC chapter for complete information on interrupt generation and use.

Memory Writes

A write transaction to address n is prevented when the following is true.

Address n is in memory region m and memory region m is write-protected (SMPU_RCTL[n].WPROTEN =1) and ID is not a match. (See ID Comparison). The block occurs because the memory region is configured for write-protection and the ID comparison does not result in a match. If an ID comparison results in a match, the write transaction is allowed through.

Memory Reads

A read transaction from address n is prevented when the following is true:

- Address n is in memory region and memory region m is read-protected (SMPU_RCTL[n].RPROTEN =1) and
- ID is not a match

The block occurs because the memory region is configured for read protection and the ID comparison does not result in a match. If the ID comparison results in a match, the read transaction is permitted. (See ID Comparison).

ID Comparison

ID comparison automatically occurs during region-based memory protection. ID matches allow the transaction to bypass the configured memory protection for that region. The following sections describe the calculation of a write ID match and read ID match.

Write Transaction

The state of the following values determines the ID value that is compared with the ID of an incoming write transaction:

- The SMPU_RCTL[n].WIDCINV bit
- The SMPU_RIDA[n].ID and SMPU_RIDB[n].ID bit fields
- The SMPU_RIDMSKA[n].MSK and SMPU_RIDMSKB[n].MSK bit fields

Write IDA match = ((ID of incoming write transaction AND SMPU_RIDMSKA[n].MSK) == (SMPU_RIDA[n].ID AND SMPU_RIDMSKA[n].MSK))

Write IDB match = ((ID of incoming write transaction AND SMPU_RIDMSKB[n].MSK) == (SMPU_RIDB[n].ID AND SMPU_RIDMSKB[n].MSK))

Write ID match = (Write IDA match OR Write IDB match) XOR SMPU_RCTL[n].WIDCINV bit

Read Transaction

The state of the following values determines the ID value that is compared with the ID of an incoming read transaction:

- The SMPU_RCTL[n].RIDCINV bit
- The SMPU_RIDA[n].ID and SMPU_RIDB[n].ID bit fields
- The SMPU_RIDMSKA[n].MSK and SMPU_RIDMSKB[n].MSK bit fields

Read IDA match = ((ID of incoming read transaction AND SMPU_RIDMSKA[n].MSK) == (SMPU_RIDA[n].ID AND SMPU_RIDMSKA[n].MSK))

Read IDB match = ((ID of incoming read transaction AND SMPU_RIDMSKB[n].MSK) == (SMPU_RIDB[n].ID AND SMPU_RIDMSKB[n].MSK))

Read ID match = (Read IDA match OR Read IDB match) XOR SMPU_RCTL[n].RIDCINV

In the two cases described above, the incoming transaction (either write or read) ID is AND'ed with the configured mask value in protection unit A. It is then compared to the value of the configured ID value which is also AND'ed with the configured mask value in protection unit A. The mask provides a method to allow a group of IDs to match. This process is also performed for protection unit B. The two outcomes (from A and B) are then OR'ed together.

Depending on the setting of the SMPU_RCTL[n].RIDCINV or the SMPU_RCTL[n].WIDCINV bits, the ID match comparison is inverted or not. The final result after applying the inversion, SMPU_RCTL[n].RIDCINV, or SMPU_RCTL[n].WIDCINV, determines whether the transaction bypasses the protection.

Usage

The masks, SMPU_RIDMSKA[n] and SMPU_RIDMSKB[n], are AND'ed with both the incoming transaction ID and the configured ID in SMPU_RIDA[n].ID and SMPU_RIDB[n].ID, respectively. By default the masks are zero. If ID-based region protection is enabled by setting the SMPU_RCTL[n].WPROTEN or SMPU_RCTL[n].RPROTEN bit fields and the masks are not set, the ID comparison essentially compares zeros. The comparison allows all transactions to bypass (if the region-based security setting is also configured in a way to allow transactions to go through for the region). To have the ID-based region protection to function, the mask registers and ID registers must also be set.

System IDs

The ***System controller IDs*** table provides the IDs for the system controllers. An x means that the bit can be a 0 or a 1. There are multiple IDs associated with that system controller.

Table 12-3: System Controller IDs

ASIB Name	IID	SIID	ID
SP0A	0	0	11'b0000000x000
SP0B	0	1	11'b0000000x001
SP1A	0	2	11'b0000000x010

Memory Region

Memory regions can start at address 0x00000000 or at any address that is a multiple of its size. The ***Supported Memory Region Size and Alignment*** table shows the memory region sizes that the processor supports and the alignment of the memory region. (X values are do-not-care).

SMPU supports a maximum of eight regions.

Table 12-4: Supported Memory Region Size and Alignment

Size	SMPU_RCTLn.SIZE	Address	Possible Values for N
4KB	0b00000	0xXXXXX000	-
8KB	0b00001	0xXXXXN000	0x0, 0x2, 0x4, 0x8, 0xA, 0xC, 0xE
16KB	0b00010	0xXXXXN000	0x0, 0x4, 0x8, 0xC
32KB	0b00011	0xXXXXN000	0x0, 0x8
64KB	0b00100	0xXXXX0000	-
128KB	0b00101	0xXXXN0000	0x0, 0x2, 0x4, 0x8, 0xA, 0xC, 0xE
256KB	0b00110	0xXXXN0000	0x0, 0x4, 0x8, 0xC
512KB	0b00111	0xXXXN0000	0x0, 0x8
1MB	0b01000	0xXXX00000	-
2MB	0b01001	0xXXN00000	0x0, 0x2, 0x4, 0x8, 0xA, 0xC, 0xE
4MB	0b01010	0xXXN00000	0x0, 0x4, 0x8, 0xC
8MB	0b01011	0xXXN00000	0x0, 0x8
16MB	0b01100	0xXX000000	-
32MB	0b01101	0xXN000000	0x0, 0x2, 0x4, 0x8, 0xA, 0xC, 0xE
64MB	0b01110	0xXN000000	0x0, 0x4, 0x8, 0xC
128MB	0b01111	0xXN000000	0x0, 0x8
256MB	0b10000	0xX0000000	-
512MB	0b10001	0xN0000000	0x0, 0x2, 0x4, 0x8, 0xA, 0xC, 0xE
1GB	0b10010	0xN0000000	0x0, 0x4, 0x8, 0xC
2GB	0b10011	0xN0000000	0x0, 0x8
4GB	0b10100	0x00000000	-

For the case where the region size is selected as 4 GB, the region address must be at address 0x00000000.

NOTE: If a memory region address is not aligned to its size, the memory region start address protected by the SMPU is the configured address with the corresponding least significant bits masked. For example, if the size is configured for 16 KB (`SMPU_RCTL[n].SIZE` =0b00010), and the base address is configured for `SMPU_RADDR[n].BADDR`=0x00005018, the actual base address used by the SMPU is 0x00004000. When `SMPU_RADDR[n].BADDR` is read back, the program reads 0x00005000. This functionality is

because only bits [11:0] are reserved as 0's. Programs must use care when setting the base address as it is not always the true base address.

SMPU Definitions

To make the best use of the SMPU, it is useful to understand the terms in this section.

Global Protection

Guarding of the entire memory space for the SMPU instantiation.

Region-Based Protection

Guarding individual segments of memory inside the memory space for the SMPU instantiation.

ID Match

A successful comparison of the ID associated with the incoming transaction and the ID and MASK configured in the SMPU.

SMPU Block Diagram

The ***SMPU Top-Level Block Diagram*** shows the SMPU block.

As seen in the diagram, the SMPU sits between the memory port (SCB requester port) and the SCB fabric (SCB completer port). It acts as a gateway analyzing the transaction requests. It either rejects the transaction request or allows access based on the user-programmed configuration of the SMPU.

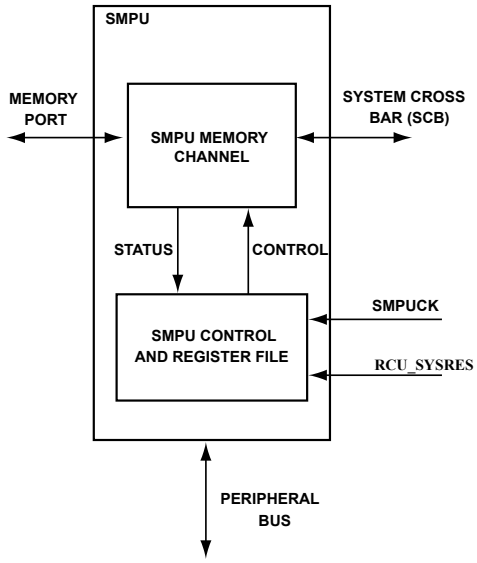

Figure 12-1: SMPU Top-Level Block Diagram

SMPU Architectural Concepts

The following sections provide brief descriptions of the architecture of the SMPU module.

Default Setting

At reset, the default state of the system is fully open. The SMPUs admit any access to memory spaces.

Latency

The SMPU adds latency to all the transactions to the memory except reads when read speculation is enabled (SMPU_CTL.RSDIS =0). In this case, read accesses are always forwarded to the memory and read responses are generated according to the SMPU settings. If read speculation is disabled (SMPU_CTL.RSDIS =1), reads are blocked if they cause a security or protection violation. The SMPU generates the SCB read response that corresponds to a blocked transaction.

If read speculation is enabled, the SMPU adds 1 clock cycle latency to the read transaction. If read speculation is disabled, the SMPU adds 2 clock cycles latency to the read transaction.

SMPU Operating Modes

The SMPU does not have any strict modes of operation. However, it can be configured for region-based protection where a controller with a particular ID can be blocked or allowed based on settings in the SMPU_RCTL[n] register.

Region-based protection is programmed with registers:

- SMPU_RCTL[n]
- SMPU_RADDR[n]
- SMPU_RIDA[n]
- SMPU_RIDMSKA[n]
- SMPU_RIDB[n]
- SMPU_RIDMSKB[n]

SMPU Interrupt Signals

There is one interrupt signal associated with the SMPU. If interrupts are enabled, the SMPU_STAT.IRQ bit is set. The SMPU_IRQ signal is asserted when the SMPU detects a memory access violation. The target address triggering the interrupt is found in the SMPU_IADDR register. The SMPU_IDTLS register provides further details about the cause of the interrupt.

Write errors are prioritized over read errors.

Protection violations (an ID-based violation) can trigger the SMPU interrupt and can be enabled independently. The protection violation interrupt is enabled by setting the SMPU_CTL.PINTEN bit.

The SMPU interrupt is asserted for any of the following conditions:

If a second memory access violation occurs while the SMPU_STAT.IRQ bit is set, the SMPU_STAT.IOVR (interrupt overrun) bit is set. The SMPU_IADDR and the SMPU_IDTLS registers are not updated until the SMPU_STAT.IRQ bit is cleared. Any information on the subsequent interrupt is lost. Once the SMPU_STAT.IRQ bit and the SMPU_STAT.IOVR bit are cleared, any new memory access violations can trigger an interrupt and its details can be captured.

NOTE: When a blocked access occurs, the SMPU triggers an interrupt when interrupt generation is enabled. The SMPU can also be configured to generate a bus error that propagates back to the system controller. The system controller can also trigger an interrupt due to this bus error.

NOTE: On the processor, each SMPU instance has an interrupt. All of the SMPU interrupts are OR'ed and mapped to a single SMPU interrupt on the SEC. While servicing the SMPU interrupt, check all of the SMPU_STAT registers to determine which triggered the interrupt. The interrupt service routine clears the SMPU_STAT.IRQ bit of all of the SMPU_STAT registers for which the interrupt is triggered.

SMPU Status and Error Signals

If bus errors are enabled (SMPU_CTL.PBEDIS =0), the SMPU generates and returns a bus error to the controller initiating the blocked access. This bit also sets the SMPU_STAT.BERR bit. The SMPU_BADDR and SMPU_BDTLS registers can be read to get the address and details of the transaction that caused the SMPU to generate the error.

Write errors are prioritized over read errors.

A bus error status is returned to the system controller if:

- an ID-based violation happened and the SMPU_CTL.PBEDIS bit =0

If a second memory access violation occurs while the SMPU_STAT.BERR bit is set, the SMPU_STAT.BEOVR bit (bus error overrun) is set. The SMPU_BADDR and the SMPU_BDTLS registers are not updated until the SMPU_STAT.IRQ bit is cleared. The information about the transaction that caused the SMPU_STAT.BEOVR bit to be set is lost.

NOTE: If both the protection violation interrupt is not enabled (SMPU_CTL.PINTEN =0) and the protection bus error is disabled (SMPU_CTL.PBEDIS =1), the SMPU blocks invalid transactions. However, it does not provide any status or interrupt information indicating that a transaction is blocked.

ADSP-2184x SMPU Register Descriptions

The System Memory Protection Unit (SMPU) contains the following registers.

Table 12-5: ADSP-2184x SMPU Register List

Name	Description
SMPU_BADDR	Bus Error Address Register
SMPU_BDTLS	Bus Error Details Register
SMPU_CTL	SMPU Control Register
SMPU_EXACADD[n]	Exclusive Access IDn Address
SMPU_EXACSTAT[n]	Exclusive Access Status
SMPU_IADDR	Interrupt Address Register
SMPU_IDTLS	Interrupt Details Register
SMPU_RADDR[n]	Region n Address Register
SMPU_RCTL[n]	Region n Control Register
SMPU_REVID	SMPU Revision ID Register
SMPU_RIDA[n]	Region n ID A Register
SMPU_RIDB[n]	Region n ID B Register
SMPU_RIDMSKA[n]	Region n ID Mask A Register
SMPU_RIDMSKB[n]	Region n ID Mask B Register
SMPU_SECURECTL	SMPU Control Secure Accesses Register
SMPU_SECURERCTL[n]	Region n Control Secure Accesses Register
SMPU_STAT	SMPU Status Register

Bus Error Address Register

Programs read the SMPU_BADDR and the SMPU_BDTLS registers to determine the cause of a bus error. Write errors are prioritized over read errors.

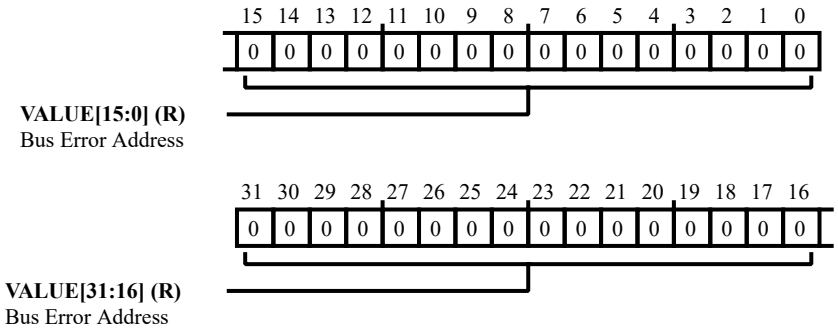

Figure 12-2: SMPU_BADDR Register Diagram

Table 12-6: SMPU_BADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Bus Error Address. The SMPU_BADDR.VALUE bit field contains the address of the bus error.

Bus Error Details Register

The SMPU_BDTLS register indicates the ID of the bus error transaction, whether the transaction that caused the last bus error was a read, a write, secure or non-secure.

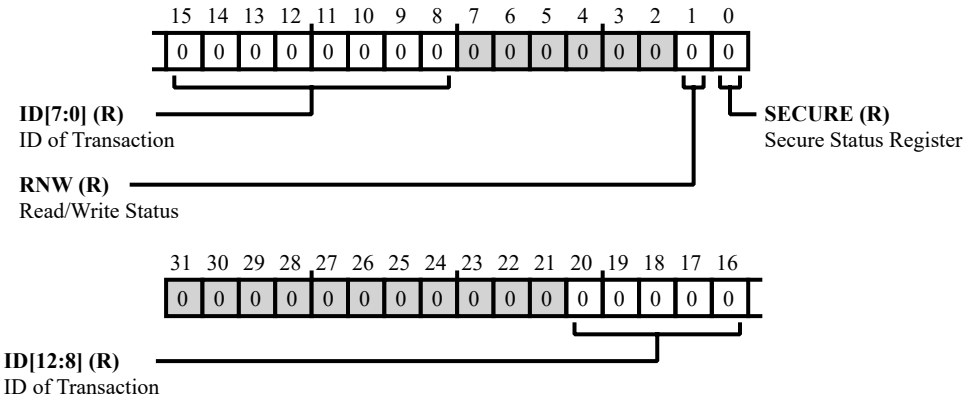

Figure 12-3: SMPU_BDTLS Register Diagram

Table 12-7: SMPU_BDTLS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
20:8 (R/NW)	ID	ID of Transaction. The SMPU_BDTLS.ID bit field provides the ID of the transaction that caused the bad address error.	
1 (R/NW)	RNW	Read/Write Status. The SMPU_BDTLS.RNW bit indicates whether the last transaction that caused the bad address error was a read or write.	
		0	Transaction that caused last bus error was a write
		1	Transaction that caused last bus error was a read
0 (R/NW)	SECURE	Secure Status Register. The SMPU_BDTLS.SECURE bit indicates whether the last transaction that caused the bad address error was secure or non-secure.	
		0	Transaction that caused last bus error was non-secure
		1	Transaction that caused last bus error was secure

SMPU Control Register

The SMPU_CTL register provides access to the locking control, error interrupts and SMPU violations.

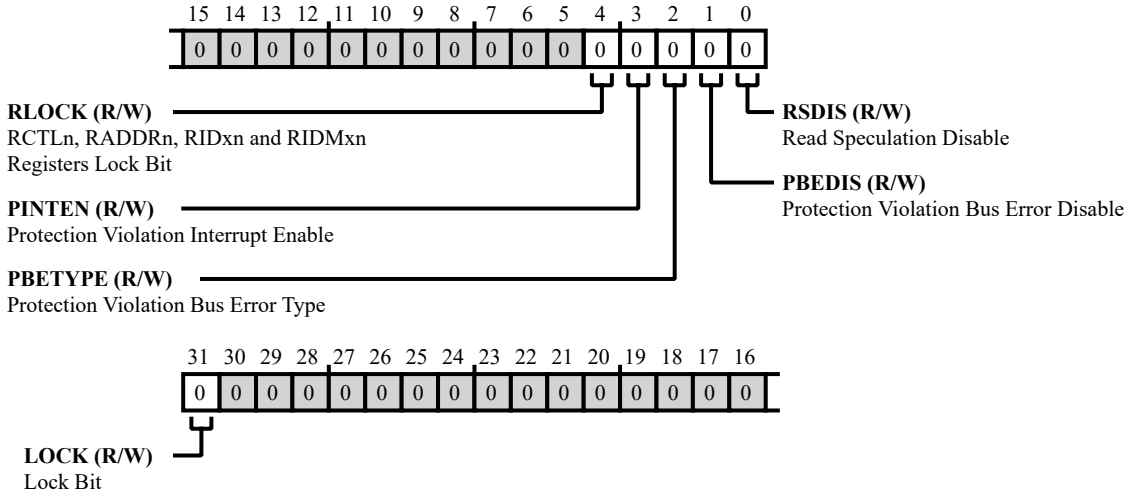

Figure 12-4: SMPU_CTL Register Diagram

Table 12-8: SMPU_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock Bit. When the SMPU_CTL.LOCK bit is set and the global lock signal is asserted from the SPU, the SMPU_CTL register is write-protected. Write-protection is disabled only when the global lock signal becomes deasserted again.	
		0	CTL Global Lock Disable. The SMPU_CTL register is not write-protected.
		1	CTL Global Lock Enable. The SMPU_CTL register is write-protected.
4 (R/W)	RLOCK	RCTLn, RADDRn, RIDxn and RIDMxn Registers Lock Bit. When the SMPU_CTL.RLOCK bit is set, all the registers associated with region-based control (SMPU_RCTL[n], SMPU_RADDR[n], SMPU_RIDA[n], SMPU_RIDB[n], SMPU_RIDMSKA[n] and SMPU_RIDMSKB[n]) are write-protected when the global lock signal is active from the SPU. Write access is allowed again when the global lock signal is deasserted.	
		0	Region Registers Write-Protect Enable. All region registers are not write-protected.
		1	Region Registers Write-Protect Disable. All region registers are write-protected.

Table 12-8: SMPU_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	PINTEN	Protection Violation Interrupt Enable. The SMPU_CTL.PINTEN bit controls whether or not an interrupt is generated when a protection violation occurs.	
		0	Protection Violation IRQ Disable. The protection violation interrupt is disabled.
		1	Protection Violation IRQ Enable. The protection violation interrupt is enabled.
2 (R/W)	PBETYPE	Protection Violation Bus Error Type. The SMPU_CTL.PBETYPE bit controls whether a protection violation produces a decode error or a completer error.	
		0	Decode Error Type. Decode error for transactions that violate the configured protection.
		1	Completer Error Type. Completer error for transactions which violate the configured protection.
1 (R/W)	PBEDIS	Protection Violation Bus Error Disable. If set, the SMPU_CTL.PBEDIS bit blocks protection violations, but does not cause a bus error.	
		0	Bus Error Generation Enable. Transactions which violate the configured protection are blocked and cause a bus error.
		1	Bus Error Generation Disable. Transactions which violate the configured protection are blocked but do not cause a bus error.
0 (R/W)	RSDIS	Read Speculation Disable. The SMPU_CTL.RSDIS bit controls whether or not the read addresses are checked before being sent to the completer.	
		0	Read Speculation Enable. Read addresses are sent to the completer without checking.
		1	Read Speculation Disable. Read addresses are checked before being sent to the completer.

Exclusive Access IDn Address

The SMPU_EXACADD[n] register provides the address ID of an exclusive access.

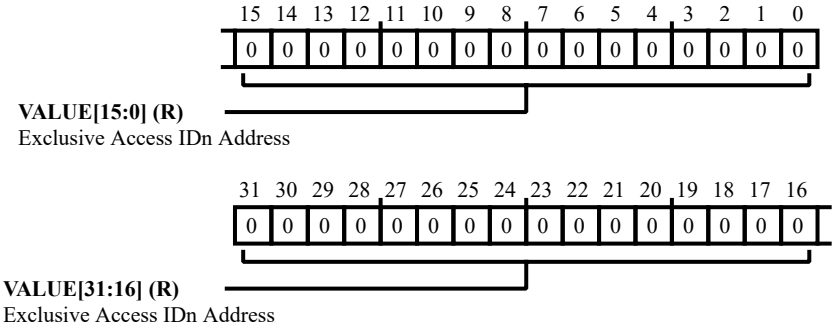

Figure 12-5: SMPU_EXACADD[n] Register Diagram

Table 12-9: SMPU_EXACADD[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Exclusive Access IDn Address.

Exclusive Access Status

The SMPU_EXACSTAT[n] register provides the exclusive access ID, read size and read length as well as the indication that the access was valid.

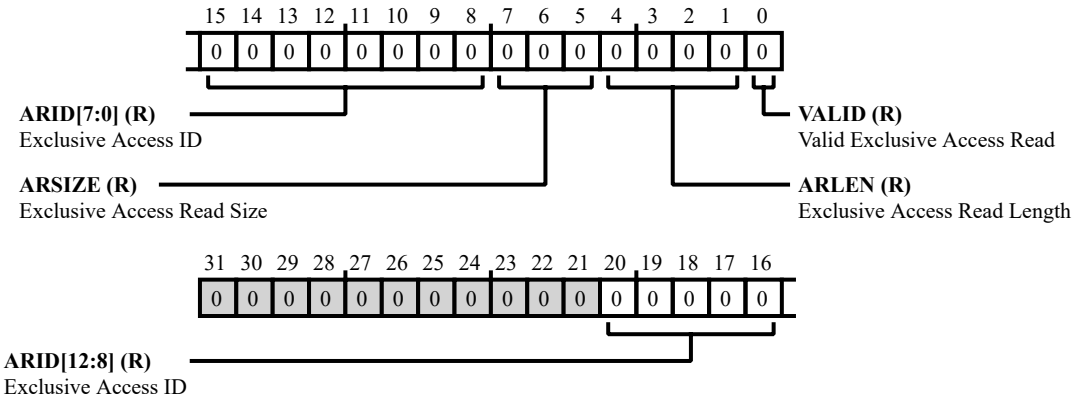

Figure 12-6: SMPU_EXACSTAT[n] Register Diagram

Table 12-10: SMPU_EXACSTAT[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
20:8 (R/NW)	ARID	Exclusive Access ID.
7:5 (R/NW)	ARSIZE	Exclusive Access Read Size.
4:1 (R/NW)	ARLEN	Exclusive Access Read Length.
0 (R/NW)	VALID	Valid Exclusive Access Read.

Interrupt Address Register

The SMPU_IADDR register indicates an attempt to make a read or write access to unimplemented addresses or accesses are non-aligned. The SMPU issues a bus error for this condition.

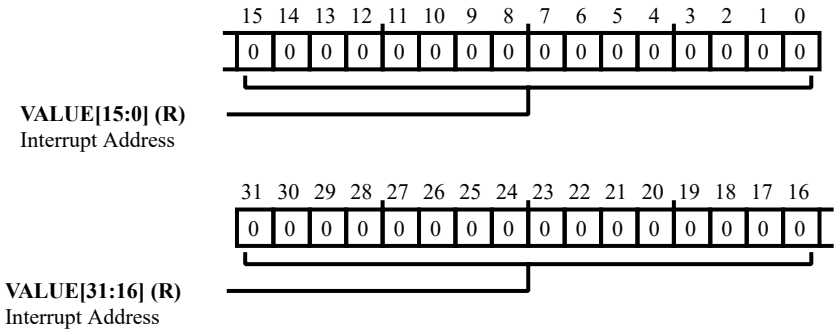

Figure 12-7: SMPU_IADDR Register Diagram

Table 12-11: SMPU_IADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Interrupt Address. The SMPU_IADDR.VALUE bit field is the address where an attempt to access an unimplemented address or a non-aligned access has occurred.

Interrupt Details Register

The SMPU_IDTLS register provides the ID of the last signaled interrupt, whether the interrupt was caused by a read or write, and whether the transaction that caused the last signaled interrupt was secure.

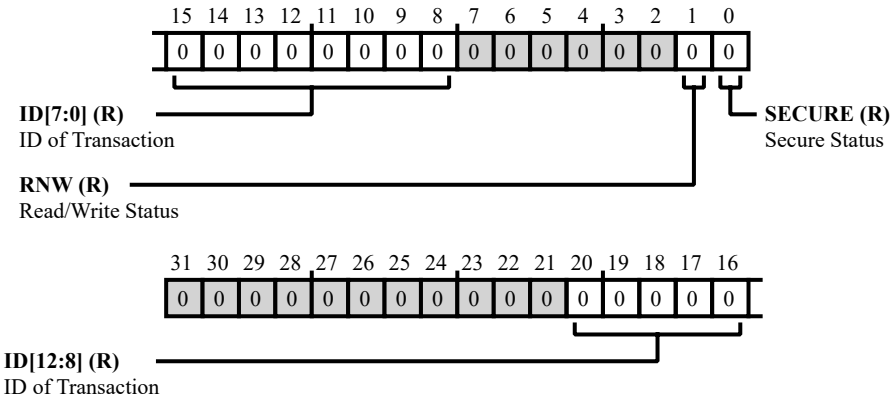

Figure 12-8: SMPU_IDTLS Register Diagram

Table 12-12: SMPU_IDTLS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
20:8 (R/NW)	ID	ID of Transaction. The SMPU_IDTLS.ID bit field provides the ID of the transaction that caused the interrupt.	
1 (R/NW)	RNW	Read/Write Status. The SMPU_IDTLS.RNW bit indicates whether the last transaction that caused the interrupt was a read or write.	
		0	Transaction that caused last signaled interrupt was a write
		1	Transaction that caused last signaled interrupt was a read
0 (R/NW)	SECURE	Secure Status. The SMPU_IDTLS.SECURE bit indicates whether the last transaction that caused the interrupt was secure or non-secure.	
		0	Transaction that caused last signaled interrupt was non-secure
		1	Transaction that caused last signaled interrupt was secure

Region n Address Register

The SMPU_RADDR[n] register is used to define the base address for a memory region to be protected.

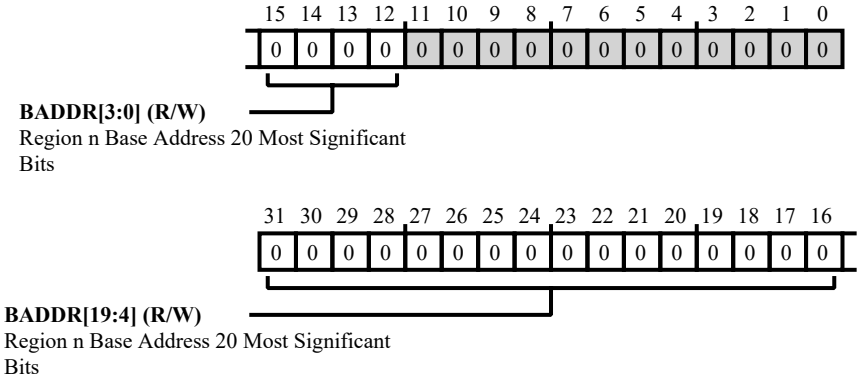

Figure 12-9: SMPU_RADDR[n] Register Diagram

Table 12-13: SMPU_RADDR[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:12 (R/W)	BADDR	Region n Base Address 20 Most Significant Bits. The SMPU_RADDR[n].BADDR bit field defines the base address for a memory region to be protected.

Region n Control Register

The SMPU_RCTL[n] register is used to define the level of protection for a region of memory. The protection of a region is controlled and defined by this register and the SMPU_RADDR[n], SMPU_RIDA[n], SMPU_RIDB[n], SMPU_RIDMSKA[n], and SMPU_RIDMSKB[n] registers.

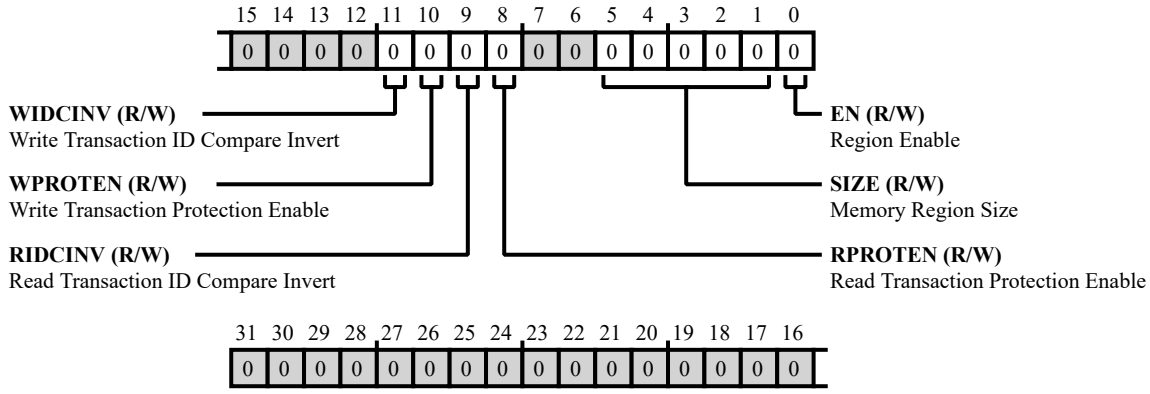

Figure 12-10: SMPU_RCTL[n] Register Diagram

Table 12-14: SMPU_RCTL[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	WIDCINV	Write Transaction ID Compare Invert. The SMPU_RCTL[n].WIDCINV bit inverts the write ID match result.	
		0	Write transaction ID comparison result not inverted
		1	Write transaction ID comparison result inverted
10 (R/W)	WPROTEN	Write Transaction Protection Enable. The SMPU_RCTL[n].WPROTEN bit enables protection against ID-based write transactions for the memory region.	
		0	Write transaction ID-based protection disabled
		1	Write transaction ID-based protection enabled
9 (R/W)	RIDCINV	Read Transaction ID Compare Invert. When the SMPU_RCTL[n].RIDCINV bit is set, the read ID match result is inverted.	
		0	Read transaction ID comparison result not inverted
		1	Read transaction ID comparison result inverted

Table 12-14: SMPU_RCTL[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	RPROTEN	Read Transaction Protection Enable. The `SMPU_RCTL[n].RPROTEN` bit enable bit to turn on protection against ID-based read transactions for the memory region.	
		0	Read transaction ID-based protection disabled
		1	Read transaction ID-based protection enabled
5:1 (R/W)	SIZE	Memory Region Size. The `SMPU_RCTL[n].SIZE` bit defines the size of the memory region to be protected.	
		0	4 KB
		1	8 KB
		2	16 KB
		3	32 KB
		4	64 KB
		5	128 KB
		6	256 KB
		7	512 KB

		14	64 MB
		15	128 MB
		16	256 MB
		17	512 MB
		18	1 GB
		19	2 GB
		20	4 GB
		21-31	Reserved

Table 12-14: SMPU_RCTL[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	EN	Region Enable. The `SMPU_RCTL[n].EN` bit enables the protection of a region.	
		0	Disabled
		1	Enabled

SMPU Revision ID Register

The SMPU_REVID register provides the major and minor revision numbers of this module.

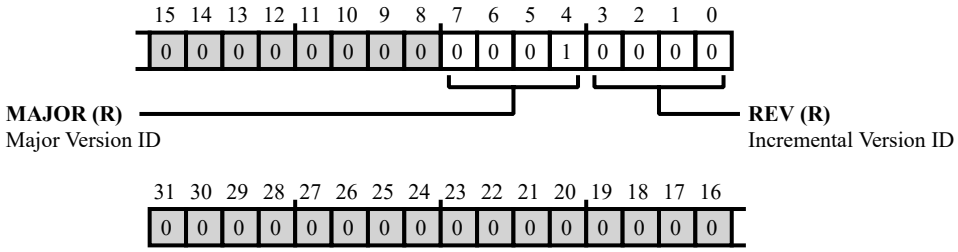

Figure 12-11: SMPU_REVID Register Diagram

Table 12-15: SMPU_REVID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:4 (R/NW)	MAJOR	Major Version ID.
3:0 (R/NW)	REV	Incremental Version ID.

Region n ID A Register

The SMPU_RIDA[n] register is used for ID comparison 'A'. This comparison is performed after a mask is applied to both the transaction ID (from either the read or write IDs) and the register value. An ID match means that the ID is the exception to the rule and the read or write is allowed even if the region is read or write-protected. For more detail, refer to the ID Comparison section.

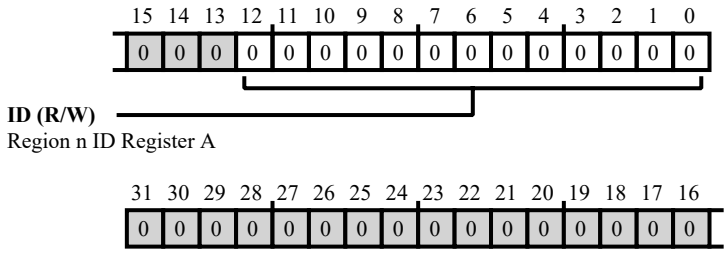

Figure 12-12: SMPU_RIDA[n] Register Diagram

Table 12-16: SMPU_RIDA[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12:0 (R/W)	ID	Region n ID Register A. The SMPU_RIDA[n].ID bit field, combined with the mask provides the means to bypass the configured memory protection for a region.

Region n ID B Register

The SMPU_RIDB[n] register is used for ID comparison 'B'. This comparison is performed after a mask is applied to both the transaction ID (from either the read or write IDs) and the register value. An ID match means that the ID is the exception to the rule and the read or write is allowed even if the region is read or write-protected. For more details, refer to the ID Comparison section.

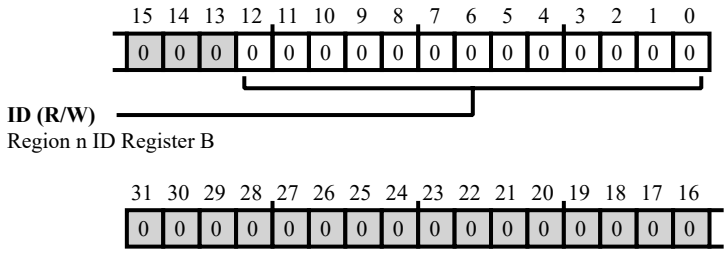

Figure 12-13: SMPU_RIDB[n] Register Diagram

Table 12-17: SMPU_RIDB[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12:0 (R/W)	ID	Region n ID Register B. The SMPU_RIDB[n].ID bit field, combined with the mask provides the means to bypass the configured memory protection for a region.

Region n ID Mask A Register

The SMPU_RIDMSKA[n] register is used for ID comparison 'A'. The mask allows or disallows certain IDs from affecting the final result of the ID match. For more details, refer to the ID Comparison section.

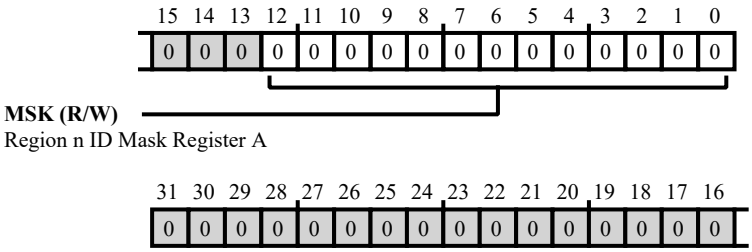

Figure 12-14: SMPU_RIDMSKA[n] Register Diagram

Table 12-18: SMPU_RIDMSKA[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12:0 (R/W)	MSK	Region n ID Mask Register A. The SMPU_RIDMSKA[n].MSK bit field, combined with the incoming transaction, provides the means to bypass the configured memory protection for a region.

Region n ID Mask B Register

The SMPU_RIDMSKB[n] register is used for ID comparison 'B'. The mask allows or disallows certain IDs from affecting the final result of the ID match. For more details, refer to the ID Comparison section.

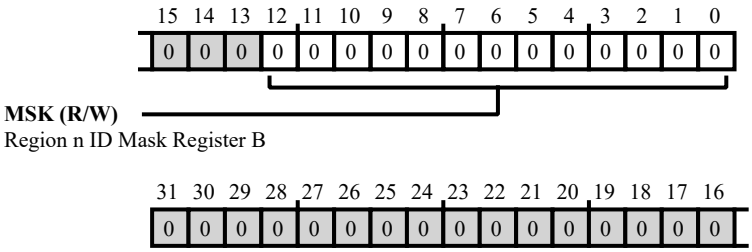

Figure 12-15: SMPU_RIDMSKB[n] Register Diagram

Table 12-19: SMPU_RIDMSKB[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
12:0 (R/W)	MSK	Region n ID Mask Register B. The SMPU_RIDMSKB[n].MSK bit field, combined with the incoming transaction provides the means to bypass the configured memory protection for a region.

SMPU Control Secure Accesses Register

The SMPU_SECURECTL register provides the bits required to set up the security settings for the processor. These settings includes error generation and read/write security.

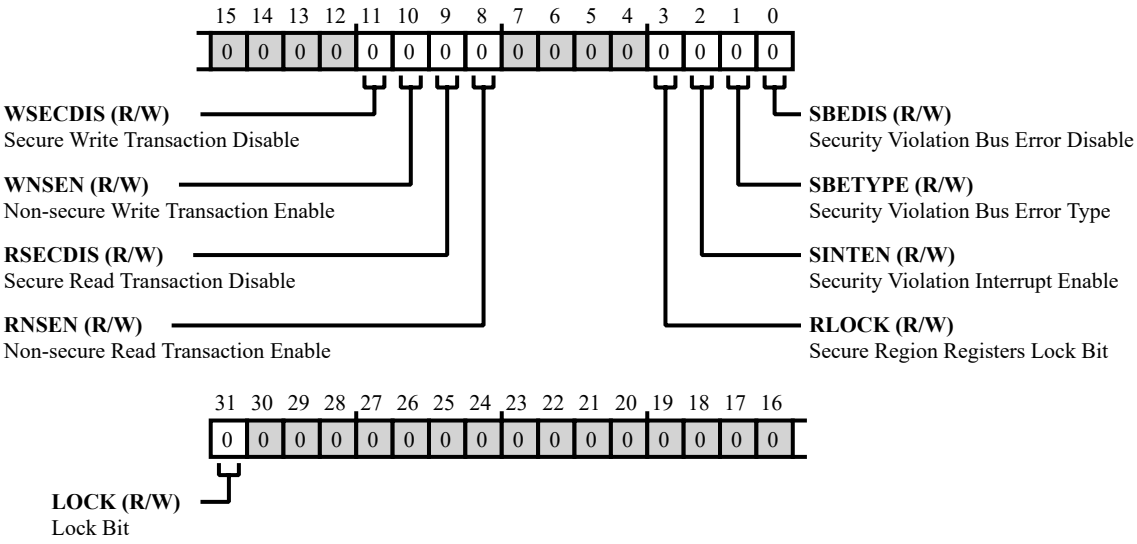

Figure 12-16: SMPU_SECURECTL Register Diagram

Table 12-20: SMPU_SECURECTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock Bit. When the SMPU_SECURECTL.LOCK bit is set and the global lock signal is asserted from the SPU, the SMPU_SECURECTL register is write-protected. Write-protection is disabled only when the global lock signal becomes deasserted again.	
		0	SMPU_SECURECTL is not write-protected
		1	SMPU_SECURECTL is write-protected
11 (R/W)	WSECDIS	Secure Write Transaction Disable. The SMPU_SECURECTL.WSECDIS bit disables secure write transactions.	
		0	Enable secure write transactions
		1	Disable secure write transactions
10 (R/W)	WNSEN	Non-secure Write Transaction Enable. The SMPU_SECURECTL.WNSEN bit enables non-secure write transactions.	
		0	Disable non-secure writes
		1	Enable non-secure writes

Table 12-20: SMPU_SECURECTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	RSECDIS	Secure Read Transaction Disable. The SMPU_SECURECTL.RSECDIS bit disables secure read transactions.	
		0	Enable secure read transactions
		1	Disable secure read transactions
8 (R/W)	RNSEN	Non-secure Read Transaction Enable. The SMPU_SECURECTL.RNSEN bit enables non-secure read transactions.	
		0	Disable non-secure read transactions
		1	Enable non-secure read transactions
3 (R/W)	RLOCK	Secure Region Registers Lock Bit. When the SMPU_SECURECTL.RLOCK bit is set, the secure region control registers, SMPU_SECURERCTL[n], are write-protected when the global lock signal is active from the SPU. When the global lock signal is deasserted, write access is allowed again.	
		0	Disable write-protection on secure region registers
		1	Enable write-protection on secure region registers
2 (R/W)	SINTEN	Security Violation Interrupt Enable. The SMPU_SECURECTL.SINTEN bit enables interrupt generation when a security violation occurs.	
		0	Disable security settings violation interrupt
		1	Enable security settings violation interrupt
1 (R/W)	SBETYPE	Security Violation Bus Error Type. The SMPU_SECURECTL.SBETYPE bit controls whether a decode error or a completer error is returned when a security violation occurs.	
		0	Decode error
		1	Completer error
0 (R/W)	SBEDIS	Security Violation Bus Error Disable. The SMPU_SECURECTL.SBEDIS bit controls whether or not a bus error is caused when a security violation occurs.	
		0	Enable bus error
		1	Disable bus error

Region n Control Secure Accesses Register

The SMPU_SECURERCTL[n] register contains bits that configure read/write security for a specific region.

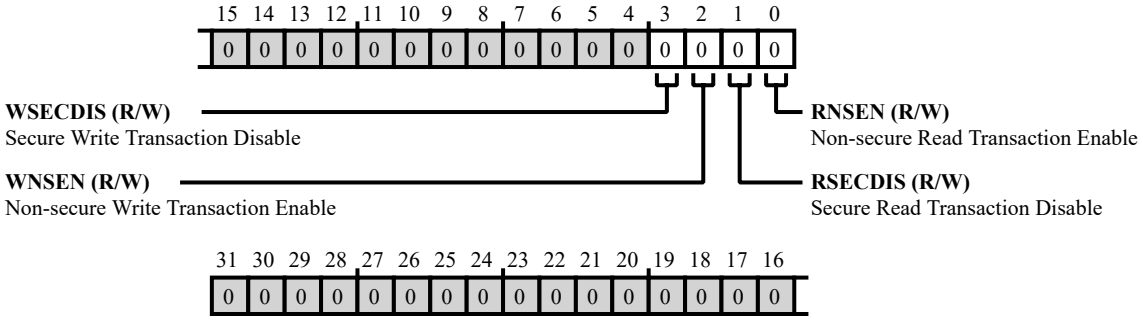

Figure 12-17: SMPU_SECURERCTL[n] Register Diagram

Table 12-21: SMPU_SECURERCTL[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	WSECDIS	Secure Write Transaction Disable. The SMPU_SECURERCTL[n].WSECDIS bit disables secure write transactions for the memory region.	
		0	Enable secure write transactions to this region
		1	Disable secure write transactions to this region
2 (R/W)	WNSEN	Non-secure Write Transaction Enable. This SMPU_SECURERCTL[n].WNSEN bit enables non-secure write transactions for the memory region.	
		0	Disable non-secure write transactions to this region
		1	Enable non-secure write transactions to this region
1 (R/W)	RSECDIS	Secure Read Transaction Disable. The SMPU_SECURERCTL[n].RSECDIS bit disables secure read transactions for the memory region.	
		0	Enable secure read transactions to this region
		1	Disable secure read transactions to this region
0 (R/W)	RNSEN	Non-secure Read Transaction Enable. The SMPU_SECURERCTL[n].RNSEN bit enables non-secure read transactions for the memory region.	
		0	Disable non-secure read transactions to this region
		1	Enable non-secure read transactions to this region

SMPU Status Register

The SMPU_STAT register provides the state of the SMPU and indicates various errors. All bits in this register are write 1 to clear.

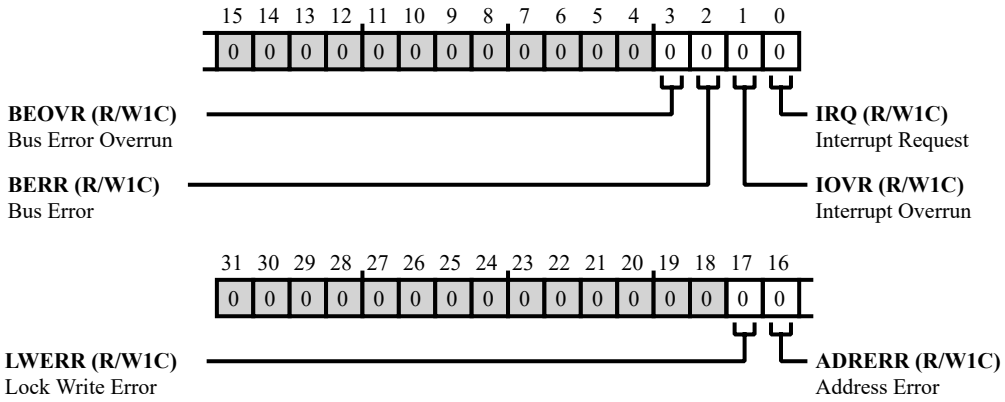

Figure 12-18: SMPU_STAT Register Diagram

Table 12-22: SMPU_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W1C)	LWERR	Lock Write Error. The SMPU_STAT.LWERR bit is set when SMPU_CTL.LOCK bit =1, the global lock signal is asserted from the SPU and a read or write attempt was made to the SMPU_CTL MMR.	
		0	No Lock Write Error
		1	Lock Write Error
16 (R/W1C)	ADRERR	Address Error. The SMPU_STAT.ADRERR bit is set when the SMPU MMR is accessed as an unaligned address, or when a read-only MMR is written to.	
		0	No Address Error
		1	Address Error
3 (R/W1C)	BEOVR	Bus Error Overrun. The SMPU_STAT.BEOVR bit indicates that another bus error had occurred. Any new information about the most recent violation which caused the bus error is not captured.	
		0	No Bus Error overrun
		1	Bus Error overrun has occurred

Table 12-22: SMPU_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W1C)	BERR	Bus Error. This `SMPU_STAT.BERR` bit indicates if a bus error was generated.	
		0	No Bus Error since this bit has been cleared
		1	Bus Error has been generated
1 (R/W1C)	IOVR	Interrupt Overrun. The `SMPU_STAT.IOVR` bit indicates if another violation occurred while the previous violation interrupt was not finished being serviced. Information about the most recent violation is then not captured.	
		0	No Interrupt overrun
		1	Interrupt overrun has occurred
0 (R/W1C)	IRQ	Interrupt Request. The `SMPU_STAT.IRQ` bit provides an indication that an interrupt has been generated.	
		0	No Interrupt since this bit has been cleared
		1	Interrupt has been generated

13 General-Purpose Ports (PORT)

This section describes general-purpose ports, pin multiplexing, general-purpose input/output (GPIO) functionality, and pin interrupts. The general-purpose ports provide the following three functions:

- Pin multiplexing scheme
- GPIO functionality
- Pin interrupt requests

NOTE: In this chapter, the naming convention for registers and bits omits the alphabetic group enumeration to refer to any and all of the ports. For example, `PORT_FER` represents registers `PORTA_FER`, `PORTB_FER`, and so on. Likewise `PORT_FER.PX1` represents bits PA1, PB1, and so on.

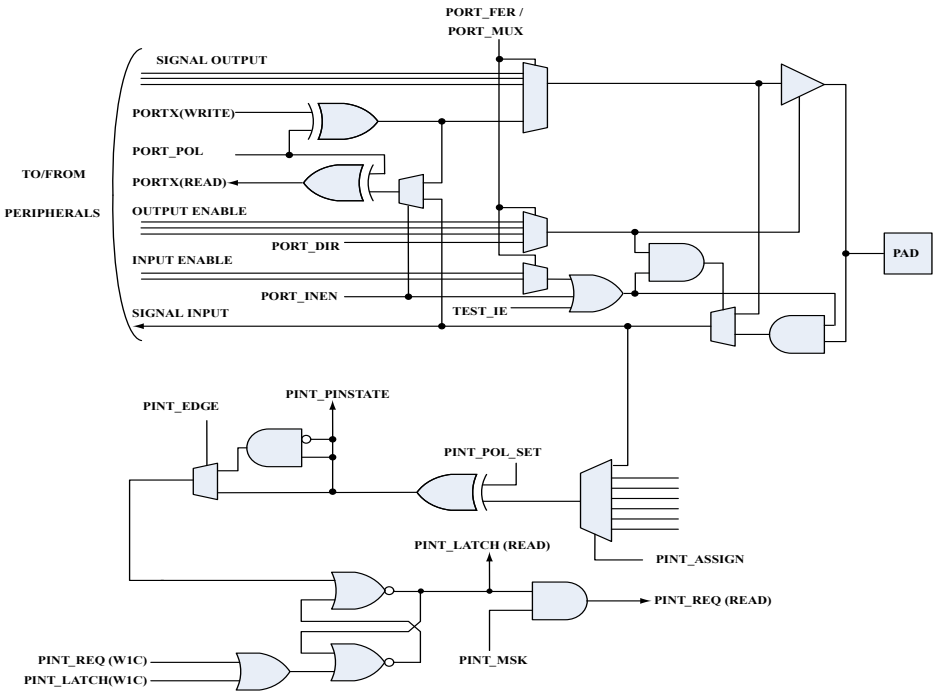

Figure 13-1: Simplified GPIO and Pin Interrupt Signal Flow

PORT Features

The PORTs include the following features:

- Input mode, output mode, and open-drain mode of GPIO operation
- Port multiplexing controlled on a pin-by-pin basis
- No external glue hardware required for unused pins
- All port pins provide interrupt request functionality
- Byte-wide pin-to-interrupt request assignment

PORT Functional Description

The number of ports and their composition is defined in the processor data sheet. Each port has a dedicated set of MMR registers that control pin functions and operates in general-purpose I/O (GPIO) mode by default, as controlled by the port-specific PORT_FER register. Each bit in this register, as well as the other PORT MMRs, represents a specific GPIO pin on the specified port.

Input Mode, Output Mode, and Open-Drain Mode of GPIO Operation

At reset, every GPIO pin defaults to input mode with the input drivers disabled. To enable any GPIO input driver, set the bits corresponding to the individual pins in the appropriate input enable register (PORT_INEN).

The GPIO output drivers are enabled by setting the corresponding bits in the direction registers (PORT_DIR).

The PORT can use every GPIO in open-drain mode by clearing the respective bit in the PORT_DATA register or setting the respective bit in the PORT_DATA_CLR register. Then, set the corresponding bit in the PORT_INEN register. Read from the PORT_DATA register to obtain the status from the pin.

Port Multiplexing Controlled on Pin-by-Pin Basis

Each port has two dedicated MMRs that control the port multiplexing, the 16-bit function enable (PORT_FER) registers and the 32-bit port multiplexing (PORT_MUX) registers.

All Port Pins Provide Interrupt Functionality

Pin interrupts are completely decoupled from GPIO functionality. Pins are connected directly via the PINTx modules, each of which is configurable in terms of which port pins are sensed for interrupt generation.

ADSP-2184x PORT Register List

The PORT module (PORT) regulates the use of the multiplexable processor pins. Every port pin can operate in general-purpose I/O (GPIO) mode or as an alternate function. This GPIO operation is the default after processor reset and is controlled by a set of registers that control GPIO functionality. Every bit in these registers represents a certain GPIO pin of a specific port. For more information on PORT functionality, see the PORT register descriptions.

Table 13-1: ADSP-2184x PORT Register List

ADSP-2184x PINT Register List

The Pin Interrupt module (PINT) controls the pin-to-interrupt assignment in a byte-wide manner. The pin-interrupt assignment registers do not consist of 32 individual bits. They consist of four control bytes, each functioning as a multiplexer control. For more information, see the PINT register descriptions.

All PINT registers are 32 bits wide and can be accessed by 32-bit load/store instructions. They also support 16-bit operation where the upper 16 bits are ignored and the application uses the lower 16 bits only. Consequently, all PINT registers support 32-bit accesses as well as 16-bit accesses for the lower half words. Applications may use faster 16-bit accesses as long as they do not require functionality of upper register halves.

Table 13-4: ADSP-2184x PINT Register List

Name	Description

PORT Architectural Concepts

These sections describe in more detail how the PORT module connects externally to pins and internally to the MMR bus. Ports are named alphabetically beginning with A.

- Internal Interfaces
- External Interfaces
- GPIO Pin Function
- Port Multiplexing Control

Internal Interfaces

All of the pin multiplexing, GPIO, and pin interrupt control block MMRs can be accessed through the MMR bus. There is no DMA support. Each of the pin interrupt (PINTx) modules has its own dedicated interrupt request output signal that connects directly to the system core.

External Interfaces

The pin multiplexing hardware can be seen as a layer between the on-chip peripherals and the silicon pads connecting to the physical pins/balls or the package, as controlled by the PORT unit.

GPIO Pin Function

By default, the PORT sets every GPIO pin to input mode. The input drivers are not enabled, which avoids the need for unnecessary current sinks and external termination resistors on unused pins.

Input Mode

The default mode of every GPIO pin after reset is input mode, but the input drivers are not enabled. To enable GPIO input drivers, set the bits corresponding to the PORT pins in the appropriate input enable register (PORT_INEN). When enabled, a read from the PORT_DATA register returns the logical state of the input pins. However, the input signal does not overwrite the state of the internal flip-flop used for providing output to the same pin. Only software can alter the state. If the input driver is enabled, a write to the PORT_DATA register can alter the state of the flip-flop, but the change cannot be read back.

Output Mode

Any GPIO pin can be configured for output mode. The GPIO output drivers are enabled by setting the bits corresponding to the PORT pins in the appropriate direction register. The PORT implements direction registers as a pair of write-1-to-set (W1S) and write-1-to-clear (W1C) MMRs called PORT_DIR_SET and PORT_DIR_CLR, respectively. As such, software can alter the direction of the signal flow on individual GPIO pins without impacting other GPIOs on the same port.

Both the PORT_DIR_SET and PORT_DIR_CLR registers return the same value when read, and a logical 1 indicates an enabled output. The PORT_DATA registers control the state of output pins. A logical 0 drives the output low while a logical 1 drives the output high.

While writes to the PORT_DATA register can alter all of the GPIOs on a specific port at once, there are also a pair of W1S and W1C MMRs called PORT_DATA_SET and PORT_DATA_CLR, respectively. These registers enable the manipulation of individual GPIO outputs. The state of the outputs can be obtained by reading the PORT_DATA registers. Because the state of the GPIO output can be controlled before the output driver is enabled, set or clear the internal flip-flop first by programming this register to avoid volatile levels on the output pin.

Trigger Toggle Mode

Any GPIO pin that has been configured for output mode can be toggled using a trigger input from the Trigger Routing Unit (TRU). To enable this functionality for a particular GPIO, set the appropriate bit in the PORT_TRIG_TGL register. Any subsequent trigger for the designated port causes all GPIO outputs set in the PORT_TRIG_TGL register to toggle.

To avoid unpredictable behavior, do not set, clear, or toggle the PORT_DATA, PORT_DATA_SET, PORT_DATA_CLR, or PORT_DATA_TGL registers when the GPIO output has the corresponding PORT_TRIG_TGL bit set. To change the state of the GPIO output using one of these registers, first clear the corresponding bit in the PORT_TRIG_TGL register.

Open-Drain Mode

Every GPIO can also be used in open-drain mode. First, either clear the respective bit in the PORT_DATA register or set the respective bit in the PORT_DATA_CLR register. Then, set the appropriate bit in the PORT_INEN register. Read from the PORT_DATA register to return the status from the pin rather than the state of the internal flip-flop.

By toggling the output driver through the PORT_DIR_SET and PORT_DIR_CLR register pair, the output signal can be pulled low or three-stated, as required. The polarity of the driven signal can be inverted when the internal flip-flop is set. When using a GPIO port in open-drain mode, take care to not exceed the V_{IH} operating condition associated with the respective pins.

Port Multiplexing Control

To configure pins properly, consult the processor data sheet to determine which bits in the PORT_FER and PORT_MUX register map to the pin of interest, and then set these registers appropriately for the desired function.

After reset, all port pins default to GPIO input mode with their output and input drivers disabled. As a result, all unused port pins can be left unconnected. Disabled pins appear as a high impedance to external circuits.

Each port has two dedicated MMRs that control the port multiplexing, the 16-bit function enable (PORT_FER) registers and the 32-bit port multiplexing (PORT_MUX) registers.

The function enable register specifies whether the pin is used as a GPIO pin or allocated for use by a specific peripheral, but it does not specify what the peripheral function is. Each bit in the 16-bit PORT_FER register corresponds to an individual port pin. For example, if bit 1 (PA1) of the PORTA_FER register is cleared, the PA_01 pin is configured as a GPIO. When set, one of the available peripheral functions becomes active on the PA_01 pin instead.

Pairs of bits in the PORT_MUX register control the multiplexing between the peripheral functions available to an individual pin, as some PORT pins provide up to four possible peripheral functions.

Refer to the Signal Muxing table in the data sheet for the specific PORT_MUX settings.

PORT Event Control

The following sections describe event generation in the PORT module.

PORT Interrupt Signals

The pin interrupts are decoupled from GPIO functionality, providing the following advantages.

- Flexible mapping scheme enables pins from up to four different ports to be grouped into one common interrupt scheme.

- Interrupt requests work on input and output pins regardless of whether the pin is functioning as a GPIO or a peripheral.

The processor has a number of interrupt channels dedicated to pin interrupts, managed by a set of pin interrupt (PINTx) blocks. Each PINTx block can sense up to 32 GPIO pins, as described in the following list and figure.

The processor supports both 32-bit and 16-bit peripheral bus accesses to PINTx registers.

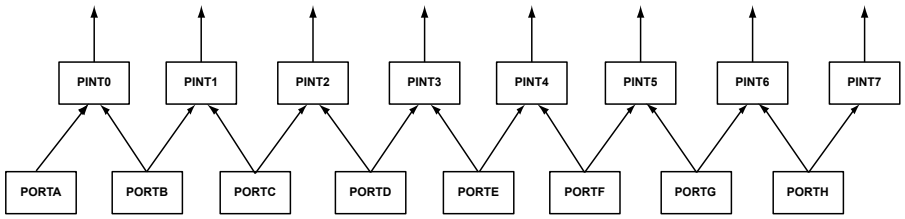

Figure 13-2: GPIO to PINTx Assignment

Pins connect to the PINTx module, as shown in the ***PINTx Block Diagram***.

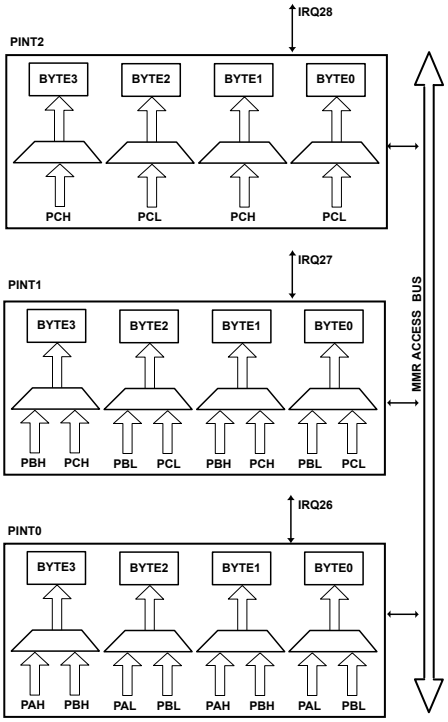

Figure 13-3: PINTx Block Diagram

As shown in the ***PINTx Block Diagram***, each port is subdivided into two 8-pin half ports, upper (`PxH`) and lower (`PxL`). The `PINT_ASSIGN` registers control the 8-bit multiplexers associated with these half ports, where the lower half units (eight pins) can be forwarded to either byte 0 or byte 2 of the PINTx blocks, and the upper half units (eight pins) can be forwarded to either byte 1 or byte 3 of the PINTx blocks.

When a half port is assigned to a byte in any PINTx block, the state of the eight pins appears in the PINT_PINSTATE register, regardless of whether the pin is enabled for GPIO or peripheral functions (input or output). When neither the input nor output drivers of the pin are enabled, the pin state is read as zero. The PINT_PINSTATE register reports the inverted state of the pin when the PINT_INV_SET register activates the signal inverter. The inverter can be enabled on an individual bit-by-bit basis. Each bit in the PINT_INV_SET/ PINT_INV_CLR register pair represents a pin signal.

By default, PORT interrupt request generation is level-sensitive, and an interrupt request occurs when the enabled pin is sensed as active high. Use the PINT_EDGE_SET register to change the interrupt request generation scheme to instead be edge-sensitive (rising edge generates the interrupt request). Use the PINT_INV_SET register to invert the polarity such that the PINTx block generates the interrupt request on active-low signals or falling edges.

The PINTx modules also assist when both signal edges must generate unique interrupt requests. If two different interrupt requests are required, the PINT_ASSIGN registers can route a single input signal to two different PINTx blocks, where one block inverts the signal in the PINT_INV_SET register and the other one does not. In this fashion, a unique software routine is associated with the hardware PINTx block that is generating the unique interrupt request for each signal edge. When both signal edges can be serviced by the same interrupt request, each half port can be routed to two separate bytes within a single PINTx block using the PINT_ASSIGN register, and then one of the half ports needs to have the inversion enabled in the PINT_INV_SET register. The servicing software routine can then detect from the PINT_LATCH register whether a falling, rising, or both edges have occurred.

Regardless of whether level-sensitive or edge-sensitive mode is used, the hardware always latches an interrupt request. Latched signals can be read from the PINT_LATCH registers. Only a software or hardware reset clears the latches. To clear the latch, a W1C operation must be performed to the PINT_REQ or PINT_LATCH register. When in level-sensitive mode, the interrupt request remains asserted if the pin state does not change by the time the interrupt service routine exits.

Because every PINTx block groups up to 32 pin signals, the PINT_MSK_SET/ PINT_MSK_CLR register pair can control which of the signals can request an interrupt at the system level. Software can interrogate the PINT_REQ register for signaling pins. The PINT_REQ bits represent a logical AND between the mask and the latch. When any of these bits is set, the block output interrupt request is asserted.

PORT Programming Model

The ***GPIO Programming Model Flow (Part 1)***, ***GPIO Programming Model Flow (Part 2)***, and ***GPIO Programming Model Flow (Part 3)*** figures show the programming model for the general-purpose ports. This programming includes the GPIO input and output operation, open-drain mode, and the pin interrupt PINTx modules.

NOTE: These process flow diagrams connect where call-out letters appear. For example, call-out A in the ***GPIO Programming Model Flow (Part 1)*** diagram connects to call-out A in the ***GPIO Programming Model Flow (Part 2)*** diagram.

The following flowcharts describe the processes for setting up pins for various functions. Begin the process from the start label in the ***GPIO Programming Model Flow (Part 1)*** figure. The first decision (GPIO or peripheral) determines how to program the PORT_FER register. Set the bit(s) corresponding to the pin(s) to 1 to enable peripheral functionality or to 0 to enable GPIO mode. For more information on setting up for peripheral functions, refer to Port Multiplexing Control.

If the pin is to be a GPIO pin, a subsequent series of decisions must be made that will impact how the PORT_DATA, PORT_POL, PORT_DIR, and PORT_INEN configuration registers must be programmed. Depending on the type of GPIO pin desired, some configurations do not apply and can have different meanings. The following paragraphs briefly describe the function of the different settings for each of the pin functions in the input, output, and open-drain GPIO modes. It is a best practice to use the SET or CLR versions of the PORT registers, where applicable, to effect changes on a pin-by-pin basis rather than on the full port.

For output mode, first clear the PORT_DATA register to set all the pins low. Then write the PORT_DIR register to define the direction of each pin (set the bits associated with the desired output pins to 1). In output mode, the other registers are not significant. The ***GPIO Programming Model Flow (Part 1)*** chart shows this flow starting at label 2.

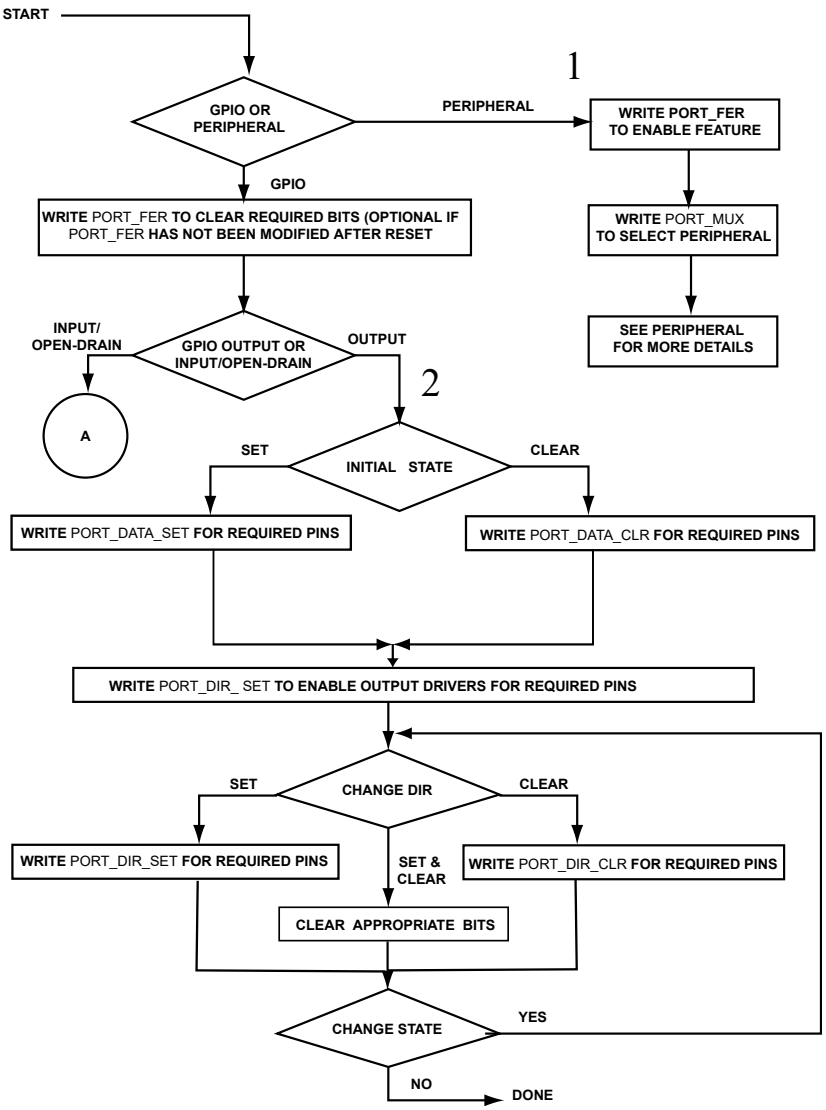

Figure 13-4: GPIO Programming Model Flow (Part 1)

For input mode, first decide the polarity for each pin using the PORT_POL register. Program the PORT_DIR register to define the appropriate pins as inputs (write a 0 to the bit location associated with the pin). If interrupt requests are desired, configure the PINT module as shown in the ***GPIO Programming Model Flow (Part 3)*** figure starting at label B. Finally, write the PORT_INEN register to enable the associated input drivers. The ***GPIO Programming Model Flow (Part 2)*** chart shows this entire flow starting at label 3.

For open-drain mode, set all pins low by clearing the PORT_DATA register. Then, use the PORT_INEN register to enable the appropriate input drivers. Set the PORT_DIR register in this mode to indicate whether the pin is in an active state or not (active being 0). The ***GPIO Programming Model Flow (Part 2)*** chart shows this flow starting at label 4.

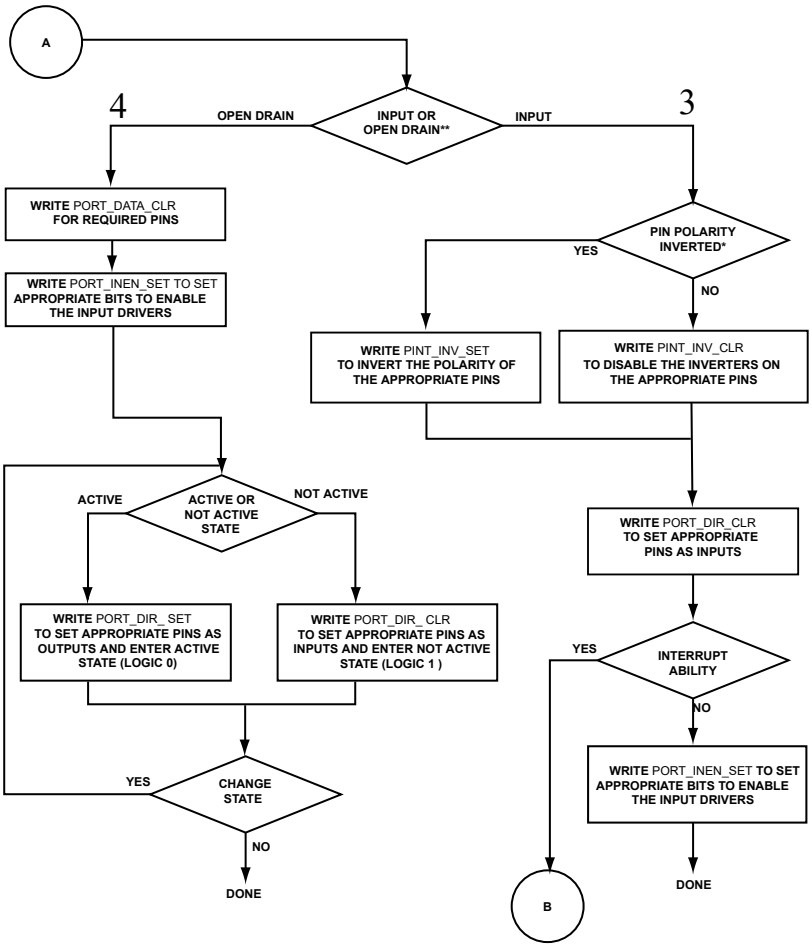

Figure 13-5: GPIO Programming Model Flow (Part 2)

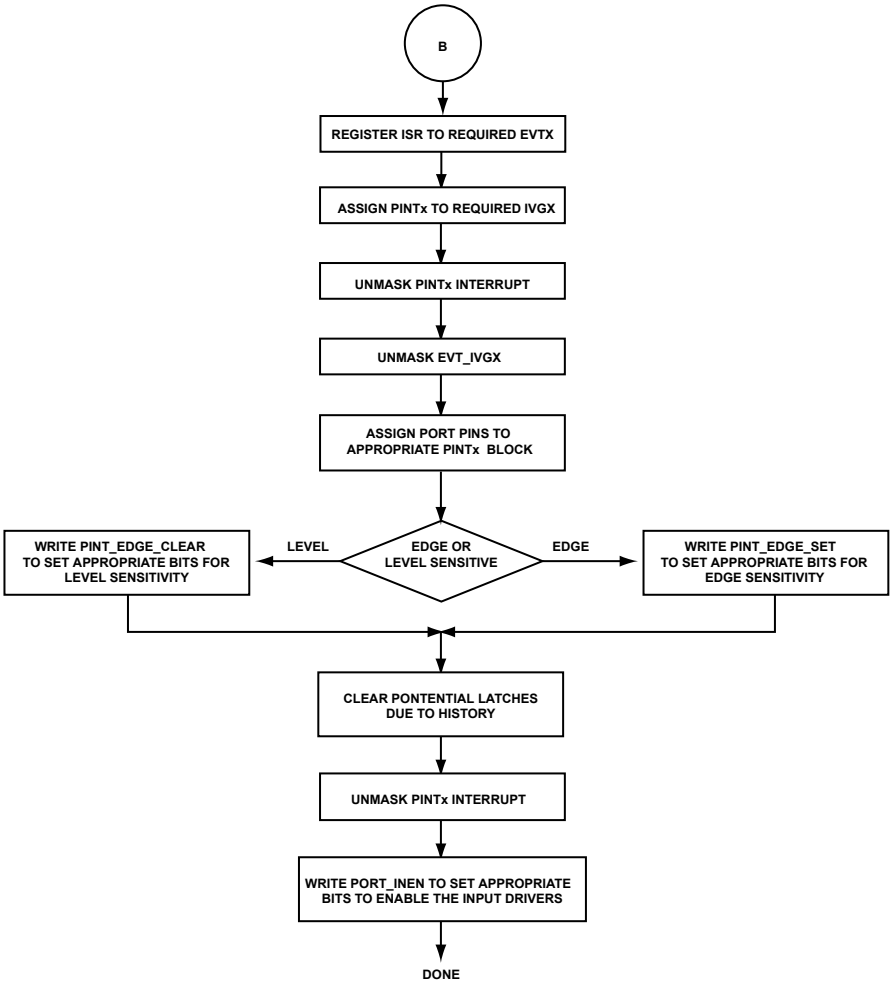

Figure 13-6: GPIO Programming Model Flow (Part 3)

Programmable Pull Enable and Pull Select Resistors for PORT and DAI

There are programmable weak pull-up resistors for DAI and PORT pins. These resistors can be enabled or disabled by configuring the PADS_PORT_AB_PE, PADS_PORT_CD_PE, PADS_PORT_EF_PE, PADS_PORT_GH_PE; PADS_PORT_AB_PS, PADS_PORT_CD_PS, PADS_PORT_EF_PS, PADS_PORT_GH_PS; PADS_DAI0_PE, PADS_DAI1_PE; and PADS_DAI0_PS, PADS_DAI1_PS registers.

Pull Enable (PE) and Pull Select (PS) Control

The GPIO pad provides optional internal pull resistors to define a stable logic level when the pin is not actively driven. The following controls are configurable:

- Pull Enable (PE): Determines whether a pull resistor is connected. When PE = 0, no pull is applied. When PE = 1, a pull resistor is enabled

- Pull Select (PS): Defines the type of pull resistor when PE is enabled. Setting PS = 0 applies a pull-down, while PS = 1 applies a pull-up.
- Strong Pull-Up (SPU): In input mode, enabling SPU forces the PAD strongly high, overriding weak pull configurations

NOTE: For unused PORT/DAI pins, ensure that any unused pin does not go into a floating state, by clearing (=0) the PE bit of that pin.

ADSP-2184x PORT Register Descriptions

The General-Purpose Input/Output Port (PORT) contains the following registers.

Table 13-9: ADSP-2184x PORT Register List

Name	Description
PORT_DATA	Port x GPIO Data Register

PORT_TRIG_TGL	Port x GPIO Trigger Toggle Register

Port x GPIO Data Register

The operation of the PORT_DATA register depends on whether the bit/pin is in output mode or input mode. In both modes, a set bit in the PORT_DATA register corresponds to a signal high on a GPIO pin. A cleared bit in the PORT_DATA register corresponds to a signal low on a GPIO pin.

The PORT_DATA, PORT_DATA_SET, and PORT_DATA_CLR registers control the state of GPIO pins in output mode. To enable output mode (and output drivers), use the PORT_DIR_SET and PORT_DIR_CLR registers.

Writes to the PORT_DATA register affect the state of all pins of the port that are in output mode. To set or clear specific pins without impacting other pins of the port, use the PORT_DATA_SET and PORT_DATA_CLR registers.

When the GPIO pins are in input mode (input driver is enabled with the PORT_INEN register), reads from the PORT_DATA, PORT_DATA_SET, and PORT_DATA_CLR registers return the state of the respective GPIO pins.

Note that when the input driver is not enabled, reads from the PORT_DATA, PORT_DATA_SET, and PORT_DATA_CLR registers return the value previously written to the registers.

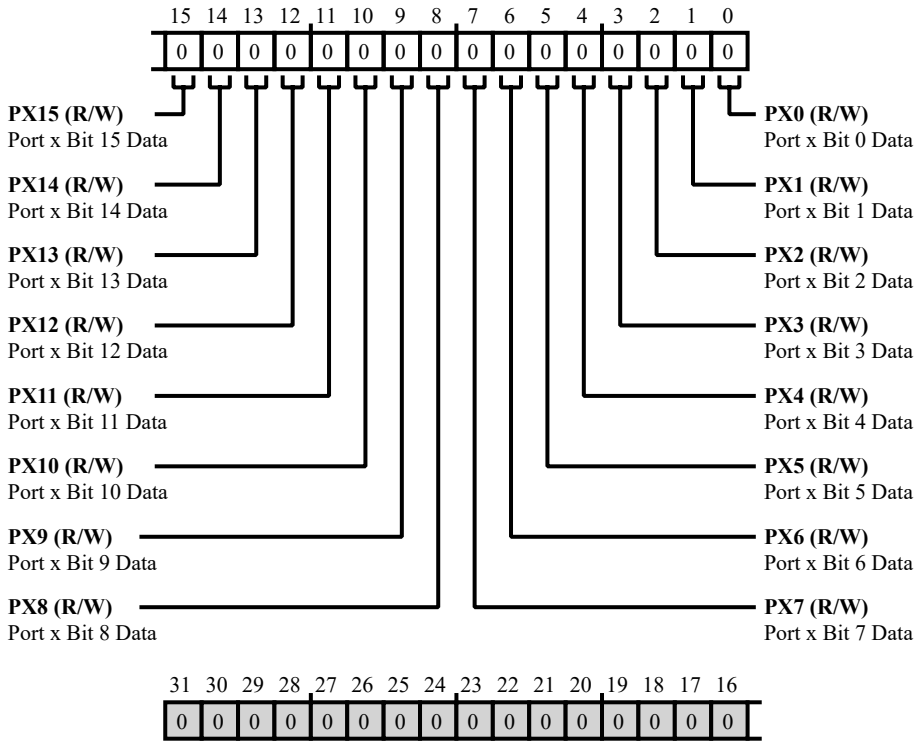

Figure 13-7: PORT_DATA Register Diagram

Table 13-10: PORT_DATA Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	PX15	Port x Bit 15 Data. The PORT_DATA.PX15 bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
14 (R/W)	PX14	Port x Bit 14 Data. The PORT_DATA.PX14 bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
13 (R/W)	PX13	Port x Bit 13 Data. The PORT_DATA.PX13 bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
12 (R/W)	PX12	Port x Bit 12 Data. The PORT_DATA.PX12 bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
11 (R/W)	PX11	Port x Bit 11 Data. The PORT_DATA.PX11 bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
10 (R/W)	PX10	Port x Bit 10 Data. The PORT_DATA.PX10 bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
9 (R/W)	PX9	Port x Bit 9 Data. The PORT_DATA.PX9 bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High

Table 13-10: PORT_DATA Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	PX8	Port x Bit 8 Data. The PORT_DATA.PX8 bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
7 (R/W)	PX7	Port x Bit 7 Data. The PORT_DATA.PX7 bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
6 (R/W)	PX6	Port x Bit 6 Data. The PORT_DATA.PX6 bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
5 (R/W)	PX5	Port x Bit 5 Data. The PORT_DATA.PX5 bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
4 (R/W)	PX4	Port x Bit 4 Data. The PORT_DATA.PX4 bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
3 (R/W)	PX3	Port x Bit 3 Data. The PORT_DATA.PX3 bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
2 (R/W)	PX2	Port x Bit 2 Data. The PORT_DATA.PX2 bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High

Table 13-10: PORT_DATA Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	PX1	Port x Bit 1 Data. The `PORT_DATA.PX1` bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High
0 (R/W)	PX0	Port x Bit 0 Data. The `PORT_DATA.PX0` bit indicates a signal on a GPIO pin.	
		0	Signal Low
		1	Signal High

Port x GPIO Data Clear Register

The PORT_DATA_CLR register operates differently for port bits/pins, depending on whether the bit/pin is output mode or input mode. For more information, see the PORT_DATA register description.

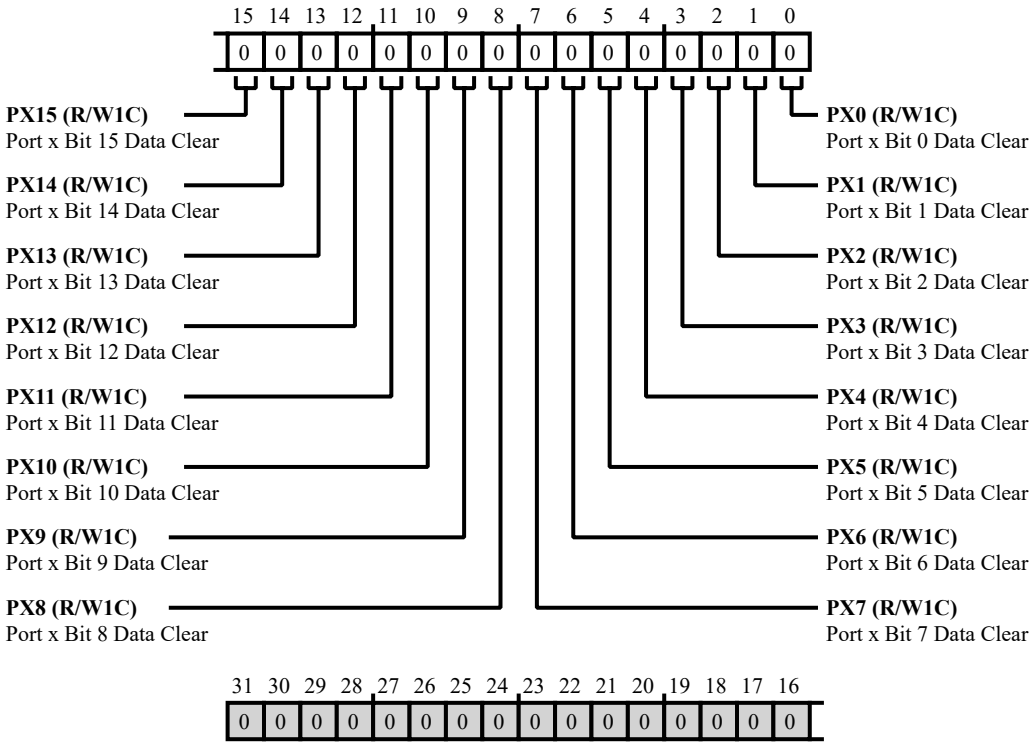

Figure 13-8: PORT_DATA_CLR Register Diagram

Table 13-11: PORT_DATA_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W1C)	PX15	Port x Bit 15 Data Clear. The PORT_DATA_CLR.PX15 bit clears the pin without impacting other pins of the port.	
		0	No Effect
		1	Clear Bit. Write 1 for signal low in output mode.
14 (R/W1C)	PX14	Port x Bit 14 Data Clear. The PORT_DATA_CLR.PX14 bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.

Table 13-11: PORT_DATA_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W1C)	PX13	Port x Bit 13 Data Clear. The PORT_DATA_CLR.PX13 bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.
12 (R/W1C)	PX12	Port x Bit 12 Data Clear. The PORT_DATA_CLR.PX12 bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.
11 (R/W1C)	PX11	Port x Bit 11 Data Clear. The PORT_DATA_CLR.PX11 bit clears the pin without impacting other pins of the port.	
		0	No Effect
		1	Clear Bit. Write 1 for signal low in output mode.
10 (R/W1C)	PX10	Port x Bit 10 Data Clear. The PORT_DATA_CLR.PX10 bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.
9 (R/W1C)	PX9	Port x Bit 9 Data Clear. The PORT_DATA_CLR.PX9 bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.
8 (R/W1C)	PX8	Port x Bit 8 Data Clear. The PORT_DATA_CLR.PX8 bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.

Table 13-11: PORT_DATA_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W1C)	PX7	Port x Bit 7 Data Clear. The PORT_DATA_CLR.PX7 bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.
6 (R/W1C)	PX6	Port x Bit 6 Data Clear. The PORT_DATA_CLR.PX6 bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.
5 (R/W1C)	PX5	Port x Bit 5 Data Clear. The PORT_DATA_CLR.PX5 bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.
4 (R/W1C)	PX4	Port x Bit 4 Data Clear. The PORT_DATA_CLR.PX4 bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.
3 (R/W1C)	PX3	Port x Bit 3 Data Clear. The PORT_DATA_CLR.PX3 bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.
2 (R/W1C)	PX2	Port x Bit 2 Data Clear. The PORT_DATA_CLR.PX2 bit clears the pin without impacting other pins of the port.	
		0	No Effect Write 0 has no effect in output mode.
		1	Clear Bit Write 1 for signal low in output mode.

Table 13-11: PORT_DATA_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W1C)	PX1	Port x Bit 1 Data Clear. The `PORT_DATA_CLR.PX1` bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.
0 (R/W1C)	PX0	Port x Bit 0 Data Clear. The `PORT_DATA_CLR.PX0` bit clears the pin without impacting other pins of the port.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Clear Bit. Write 1 for signal low in output mode.

Port x GPIO Data Set Register

The PORT_DATA_SET register operates differently for port bits/pins, depending on whether the bit/pin is output mode or input mode. For more information, see the PORT_DATA register description.

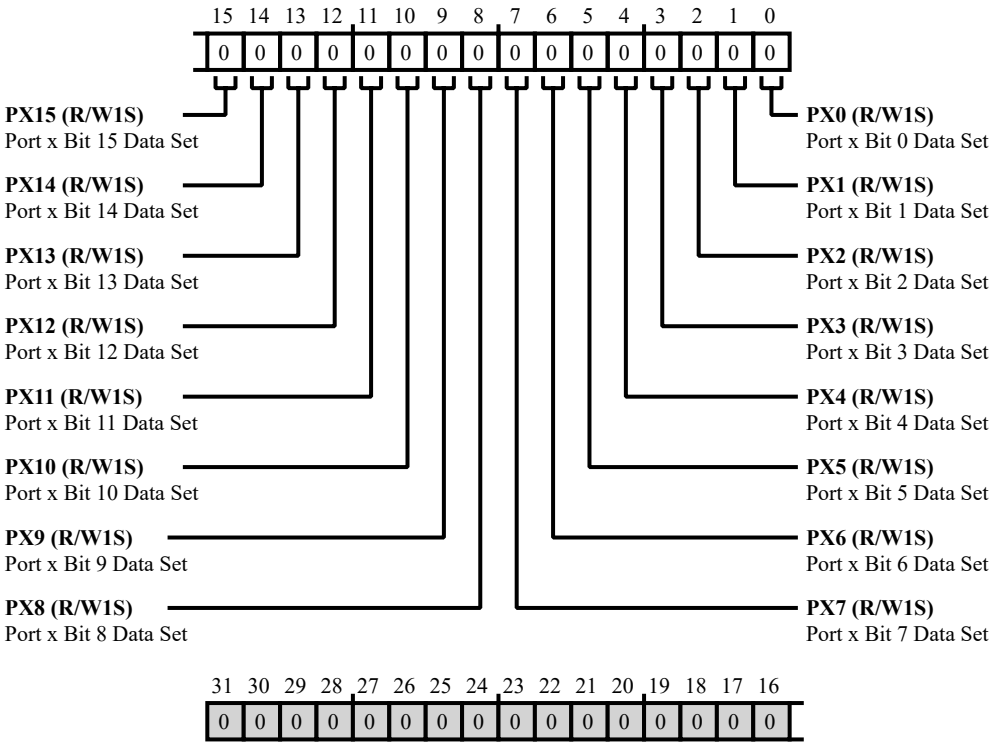

Figure 13-9: PORT_DATA_SET Register Diagram

Table 13-12: PORT_DATA_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W1S)	PX15	Port x Bit 15 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
14 (R/W1S)	PX14	Port x Bit 14 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
13 (R/W1S)	PX13	Port x Bit 13 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.

Table 13-12: PORT_DATA_SET Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W1S)	PX12	Port x Bit 12 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
11 (R/W1S)	PX11	Port x Bit 11 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit.
10 (R/W1S)	PX10	Port x Bit 10 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
9 (R/W1S)	PX9	Port x Bit 9 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
8 (R/W1S)	PX8	Port x Bit 8 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
7 (R/W1S)	PX7	Port x Bit 7 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
6 (R/W1S)	PX6	Port x Bit 6 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
5 (R/W1S)	PX5	Port x Bit 5 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
4 (R/W1S)	PX4	Port x Bit 4 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
3 (R/W1S)	PX3	Port x Bit 3 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.

Table 13-12: PORT_DATA_SET Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W1S)	PX2	Port x Bit 2 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
1 (R/W1S)	PX1	Port x Bit 1 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.
0 (R/W1S)	PX0	Port x Bit 0 Data Set.	
		0	No Effect. Write 0 has no effect in output mode.
		1	Set Bit. Write 1 for signal high in output mode.

Port x GPIO Output Toggle Register

The PORT_DATA_TGL register permits toggling the state of output GPIO pins. Setting bits in the PORT_DATA_TGL register affects the state of specific pins without impacting other pins of the port.

Reading the PORT_DATA_TGL returns the state of the PORT_DATA register output pin state, but does not return the input pin/signal state.

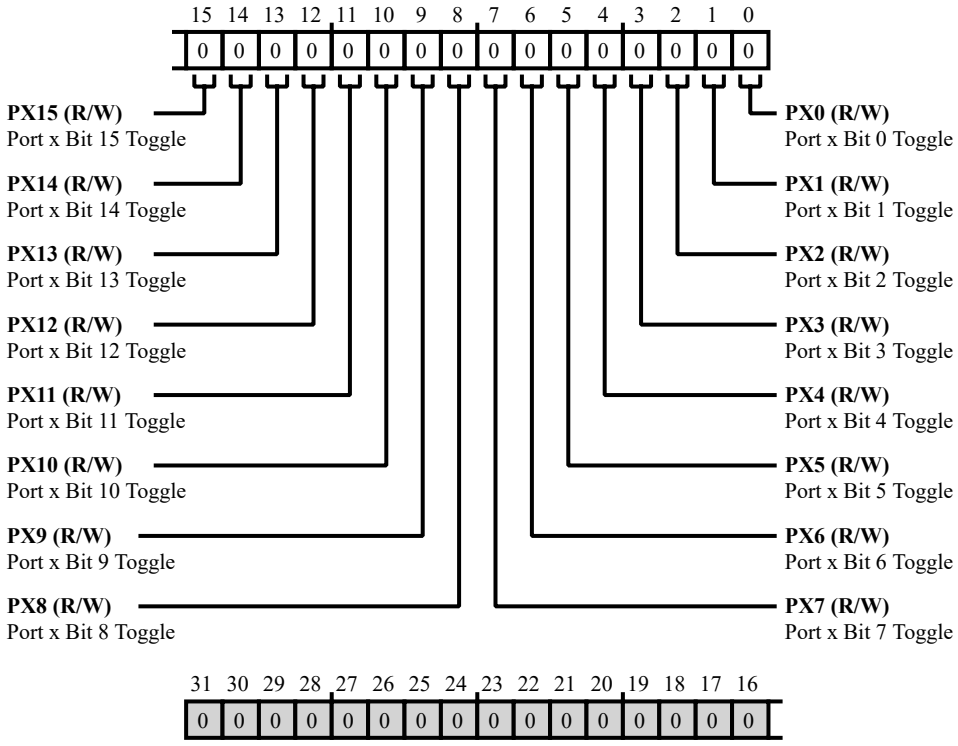

Figure 13-10: PORT_DATA_TGL Register Diagram

Table 13-13: PORT_DATA_TGL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	PX15	Port x Bit 15 Toggle. The PORT_DATA_TGL.PX15 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit.
14 (R/W)	PX14	Port x Bit 14 Toggle. The PORT_DATA_TGL.PX14 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit

Table 13-13: PORT_DATA_TGL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W)	PX13	Port x Bit 13 Toggle. The PORT_DATA_TGL.PX13 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit
12 (R/W)	PX12	Port x Bit 12 Toggle. The PORT_DATA_TGL.PX12 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit
11 (R/W)	PX11	Port x Bit 11 Toggle. The PORT_DATA_TGL.PX11 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit
10 (R/W)	PX10	Port x Bit 10 Toggle. The PORT_DATA_TGL.PX10 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit
9 (R/W)	PX9	Port x Bit 9 Toggle. The PORT_DATA_TGL.PX9 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit
8 (R/W)	PX8	Port x Bit 8 Toggle. The PORT_DATA_TGL.PX8 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit
7 (R/W)	PX7	Port x Bit 7 Toggle. The PORT_DATA_TGL.PX7 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit

Table 13-13: PORT_DATA_TGL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W)	PX6	Port x Bit 6 Toggle. The PORT_DATA_TGL.PX6 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit
5 (R/W)	PX5	Port x Bit 5 Toggle. The PORT_DATA_TGL.PX5 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit
4 (R/W)	PX4	Port x Bit 4 Toggle. The PORT_DATA_TGL.PX4 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit
3 (R/W)	PX3	Port x Bit 3 Toggle. The PORT_DATA_TGL.PX3 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit
2 (R/W)	PX2	Port x Bit 2 Toggle. The PORT_DATA_TGL.PX2 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit
1 (R/W)	PX1	Port x Bit 1 Toggle. The PORT_DATA_TGL.PX1 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit
0 (R/W)	PX0	Port x Bit 0 Toggle. The PORT_DATA_TGL.PX0 bit toggles the output GPIO bit/pin state.	
		0	No Effect
		1	Toggle Bit

Port x GPIO Direction Register

The PORT_DIR, PORT_DIR_SET, and PORT_DIR_CLR registers select output or input mode for GPIO pins and enable output drivers. Use the PORT_INEN, PORT_INEN_SET, and PORT_INEN_CLR registers to enable or disable input drivers.

Writes to the PORT_DIR register affect the state of all pins of the port. To select a direction for specific pins without impacting other pins of the port, use the PORT_DIR_SET and PORT_DIR_CLR registers.

Setting a bit in the PORT_DIR register enables output mode on the corresponding a GPIO pin. Clearing a bit in the PORT_DIR register disables output mode on the corresponding GPIO pin.

Input Mode - The default mode of every GPIO pin after reset is the input mode, but the input drivers are not enabled. To enable GPIO input drivers, set the corresponding bits in the PORT_INEN register. When enabled, a read from the PORT_DATA register returns the logical state of the input pin. The input signal does not overwrite the state of the bit used for the output case. That state can only be altered by software. If the input driver is enabled, a write to the PORT_DATA register can alter the state of the bit, but the change cannot be read back.

Output Mode - Any GPIO pin can be configured for output mode. The GPIO output drivers are enabled by setting the corresponding bits in the PORT_DIR, PORT_DIR_SET, or PORT_DIR_CLR registers. By using the PORT_DIR_SET and PORT_DIR_CLR registers, the direction of the signal flow of individual GPIO pins can be altered by separate software threads without mutually impacting other GPIOs on the same port. Both registers return the same value when read. Because the state of the GPIO output can already be controlled before the output driver is enabled, it is recommended to first set or clear the bit (using the PORT_DATA, PORT_DATA_SET, or PORT_DATA_CLR registers) to avoid any volatile levels on the output.

Open-Drain Mode - Every GPIO can also be used in open-drain mode. To accomplish this, first, clear the respective bit in the PORT_DATA or PORT_DATA_CLR register. Then, set the one bit in the PORT_INEN register. Reads from the PORT_DATA register then return the status from the pin and do not return the state of the internal flip-flop. By toggling the output driver through the PORT_DIR_SET and PORT_DIR_CLR register pair, the output signal can be pulled low or three-stated as required. Note that the polarity of the driven signal can be inverted when the internal flip-flop is set instead. When a GPIO port is used in open-drain mode, take care to not exceed the V_{IH} operating condition associated with the respective pin.

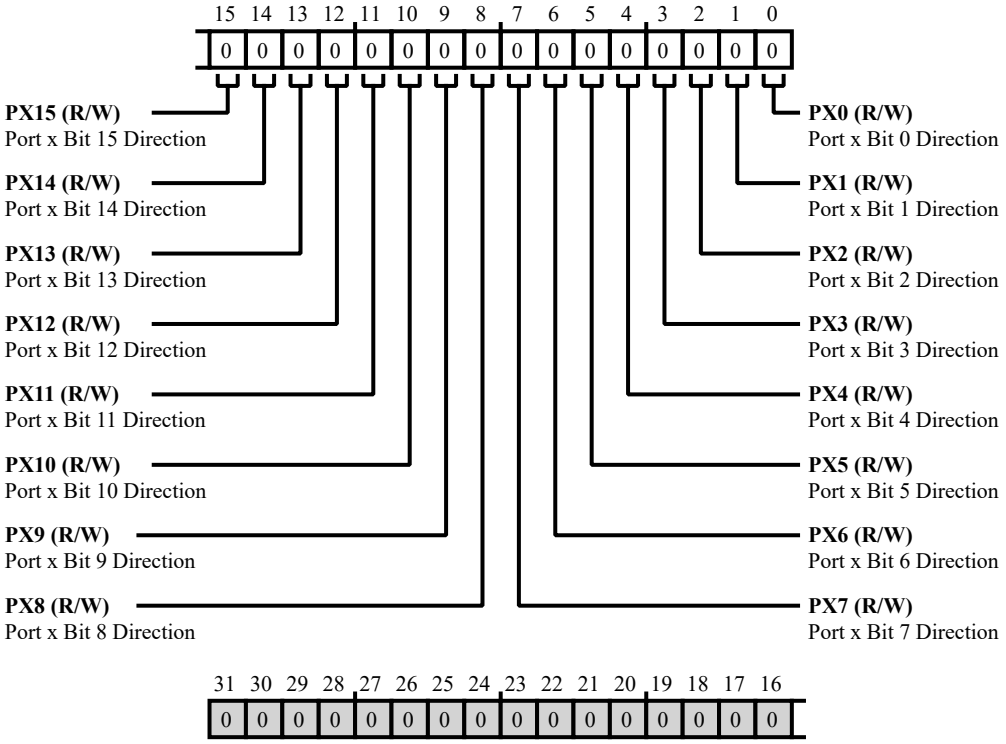

Figure 13-11: PORT_DIR Register Diagram

Table 13-14: PORT_DIR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	PX15	Port x Bit 15 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
14 (R/W)	PX14	Port x Bit 14 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
13 (R/W)	PX13	Port x Bit 13 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
12 (R/W)	PX12	Port x Bit 12 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.

Table 13-14: PORT_DIR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	PX11	Port x Bit 11 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
10 (R/W)	PX10	Port x Bit 10 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
9 (R/W)	PX9	Port x Bit 9 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
8 (R/W)	PX8	Port x Bit 8 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
7 (R/W)	PX7	Port x Bit 7 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
6 (R/W)	PX6	Port x Bit 6 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
5 (R/W)	PX5	Port x Bit 5 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
4 (R/W)	PX4	Port x Bit 4 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
3 (R/W)	PX3	Port x Bit 3 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
2 (R/W)	PX2	Port x Bit 2 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.

		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.
0 (R/W)	PX0	Port x Bit 0 Direction.	
		0	Input mode. The output driver is disabled.
		1	Output mode. The output driver is enabled.

Port x GPIO Direction Clear Register

The PORT_DIR_CLR register disables output mode and disables the output drivers for GPIO pins. For more information, see the PORT_DIR register description.

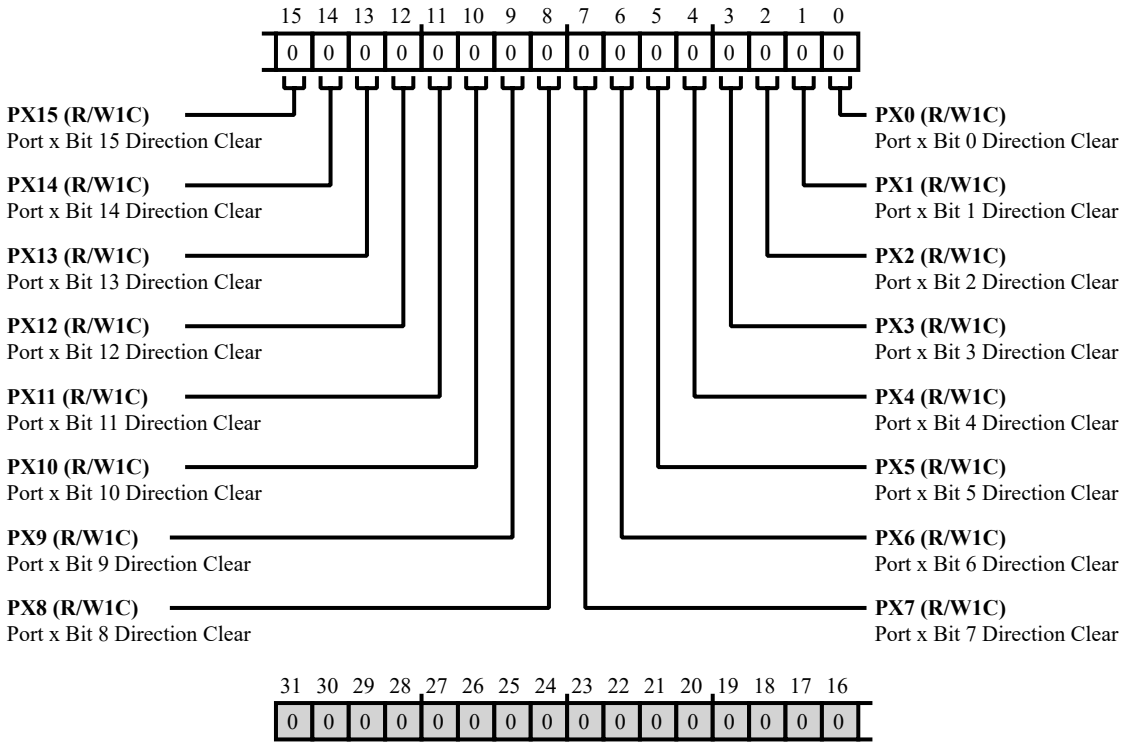

Figure 13-12: PORT_DIR_CLR Register Diagram

Table 13-15: PORT_DIR_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W1C)	PX15	Port x Bit 15 Direction Clear. The PORT_DIR_CLR.PX15 bit disables output mode and the output drivers for port x.	
		0	No Effect
		1	Disable output mode/driver
14 (R/W1C)	PX14	Port x Bit 14 Direction Clear. The PORT_DIR_CLR.PX14 bit disables output mode and the output drivers for port x.	
		0	No Effect
		1	Disable output mode/driver

Table 13-15: PORT_DIR_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W1C)	PX13	Port x Bit 13 Direction Clear. The PORT_DIR_CLR.PX13 bit disables output mode and the output drivers for port x.	
		0	No Effect
		1	Disable output mode/driver
12 (R/W1C)	PX12	Port x Bit 12 Direction Clear. The PORT_DIR_CLR.PX12 bit disables output mode and the output drivers for port x.	
		0	No Effect
		1	Disable output mode/driver
11 (R/W1C)	PX11	Port x Bit 11 Direction Clear. The PORT_DIR_CLR.PX11 bit disables output mode and the output drivers for port x.	
		0	No Effect
		1	Disable output mode/driver
10 (R/W1C)	PX10	Port x Bit 10 Direction Clear. The PORT_DIR_CLR.PX10 bit disables output mode and the output drivers for port x.	
		0	No Effect
		1	Disable output mode/driver
9 (R/W1C)	PX9	Port x Bit 9 Direction Clear. The PORT_DIR_CLR.PX9 bit disables output mode and the output drivers for port x.	
		0	No Effect
		1	Disable output mode/driver
8 (R/W1C)	PX8	Port x Bit 8 Direction Clear. The PORT_DIR_CLR.PX8 bit disables output mode and the output drivers for port x.	
		0	No Effect
		1	Disable output mode/driver

Table 13-15: PORT_DIR_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W1C)	PX7	Port x Bit 7 Direction Clear. The PORT_DIR_CLR.PX7 bit disables output mode and the output drivers for port x.	
		0	No Effect
		1	Disable output mode/driver
6 (R/W1C)	PX6	Port x Bit 6 Direction Clear. The PORT_DIR_CLR.PX6 bit disables output mode and the output drivers for port x.	
		0	No Effect
		1	Disable output mode/driver
5 (R/W1C)	PX5	Port x Bit 5 Direction Clear. The PORT_DIR_CLR.PX5 bit disables output mode and the output drivers for port x.	
		0	No Effect
		1	Disable output mode/driver
4 (R/W1C)	PX4	Port x Bit 4 Direction Clear. The PORT_DIR_CLR.PX4 bit disables output mode and the output drivers for port x.	
		0	No Effect
		1	Disable output mode/driver
3 (R/W1C)	PX3	Port x Bit 3 Direction Clear. The PORT_DIR_CLR.PX3 bit disables output mode and the output drivers for port x.	
		0	No Effect
		1	Disable output mode/driver
2 (R/W1C)	PX2	Port x Bit 2 Direction Clear. The PORT_DIR_CLR.PX2 bit disables output mode and the output drivers for port x.	
		0	No Effect
		1	Disable output mode/driver

Table 13-15: PORT_DIR_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W1C)	PX1	Port x Bit 1 Direction Clear. The `PORT_DIR_CLR.PX1` bit disables output mode and the output drivers for port x.	
		0	No Effect
		1	Disable output mode/driver
0 (R/W1C)	PX0	Port x Bit 0 Direction Clear. The `PORT_DIR_CLR.PX0` bit disables output mode and the output drivers for port x.	
		0	No Effect
		1	Disable output mode/driver

Port x GPIO Direction Set Register

The PORT_DIR_SET register enables output mode and output drivers for GPIO pins. For more information, see the PORT_DIR register description.

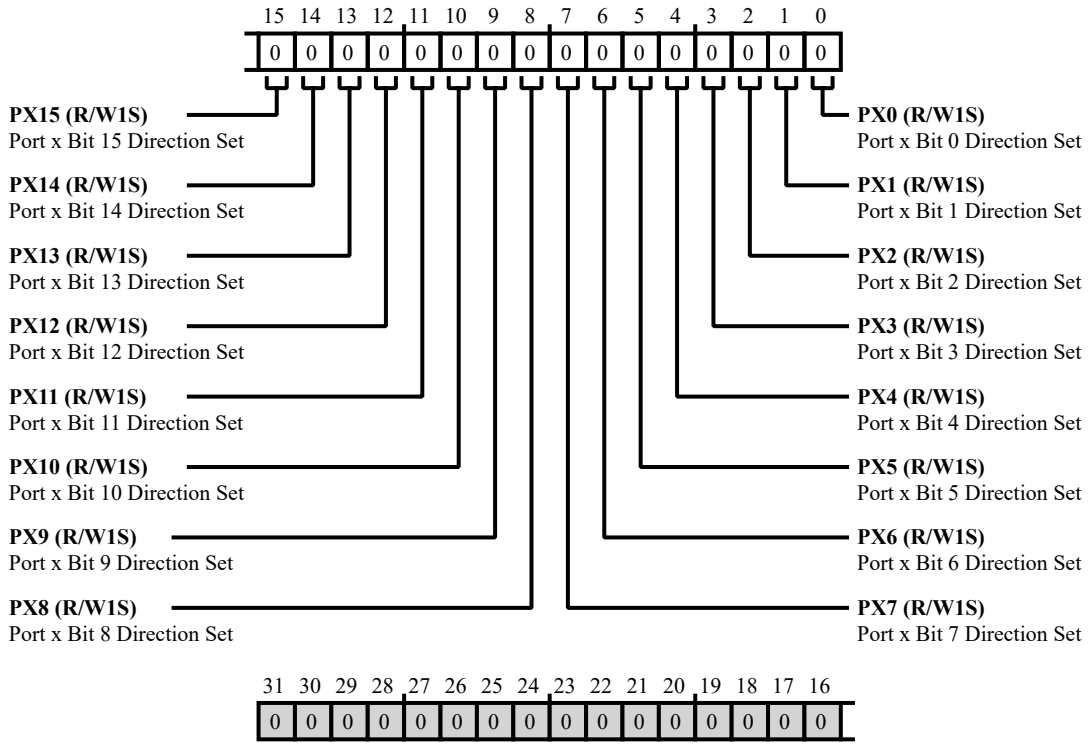

Figure 13-13: PORT_DIR_SET Register Diagram

Table 13-16: PORT_DIR_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W1S)	PX15	Port x Bit 15 Direction Set. The PORT_DIR_SET.PX15 bit enables the output mode/driver for port x.	
		0	No Effect
		1	Enable output mode/driver
14 (R/W1S)	PX14	Port x Bit 14 Direction Set. The PORT_DIR_SET.PX14 bit enables the output mode/driver for port x.	
		0	No Effect
		1	Enable output mode/driver

Table 13-16: PORT_DIR_SET Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W1S)	PX13	Port x Bit 13 Direction Set. The PORT_DIR_SET.PX13 bit enables the output mode/driver for port x.	
		0	No Effect
		1	Enable output mode/driver
12 (R/W1S)	PX12	Port x Bit 12 Direction Set. The PORT_DIR_SET.PX12 bit enables the output mode/driver for port x.	
		0	No Effect
		1	Enable output mode/driver
11 (R/W1S)	PX11	Port x Bit 11 Direction Set. The PORT_DIR_SET.PX11 bit enables the output mode/driver for port x.	
		0	No Effect
		1	Enable output mode/driver
10 (R/W1S)	PX10	Port x Bit 10 Direction Set. The PORT_DIR_SET.PX10 bit enables the output mode/driver for port x.	
		0	No Effect
		1	Enable output mode/driver
9 (R/W1S)	PX9	Port x Bit 9 Direction Set. The PORT_DIR_SET.PX9 bit enables the output mode/driver for port x.

6 (R/W1S)	PX6	Port x Bit 6 Direction Set. The PORT_DIR_SET.PX6 bit enables the output mode/driver for port x.	
		0	No Effect
		1	Enable output mode/driver
5 (R/W1S)	PX5	Port x Bit 5 Direction Set. The PORT_DIR_SET.PX5 bit enables the output mode/driver for port x.	
		0	No Effect
		1	Enable output mode/driver
4 (R/W1S)	PX4	Port x Bit 4 Direction Set. The PORT_DIR_SET.PX4 bit enables the output mode/driver for port x.	
		0	No Effect
		1	Enable output mode/driver
3 (R/W1S)	PX3	Port x Bit 3 Direction Set. The PORT_DIR_SET.PX3 bit enables the output mode/driver for port x.	
		0	No Effect
		1	Enable output mode/driver
2 (R/W1S)	PX2	Port x Bit 2 Direction Set. The PORT_DIR_SET.PX2 bit enables the output mode/driver for port x.	
		0	No Effect
		1	Enable output mode/driver
1 (R/W1S)	PX1	Port x Bit 1 Direction Set. The PORT_DIR_SET.PX1 bit enables the output mode/driver for port x.	
		0	No Effect
		1	Enable output mode/driver
0 (R/W1S)	PX0	Port x Bit 0 Direction Set. The PORT_DIR_SET.PX0 bit enables the output mode/driver for port x.	
		0	No Effect
		1	Enable output mode/driver

Port x Function Enable Register

The PORT_FER register bits indicate each port bit's operating mode: general purpose I/O mode or peripheral mode. After reset, all pins default to GPIO mode. Setting a bit in the PORT_FER registers enables a peripheral module to take ownership of the pin. The function enable bits impact output control only. Regardless of the setting of the function enable bits, both GPIO and peripherals can still sense the pin input. After a function is enabled, it is up to the PORT_MUX registers as to which peripheral takes control.

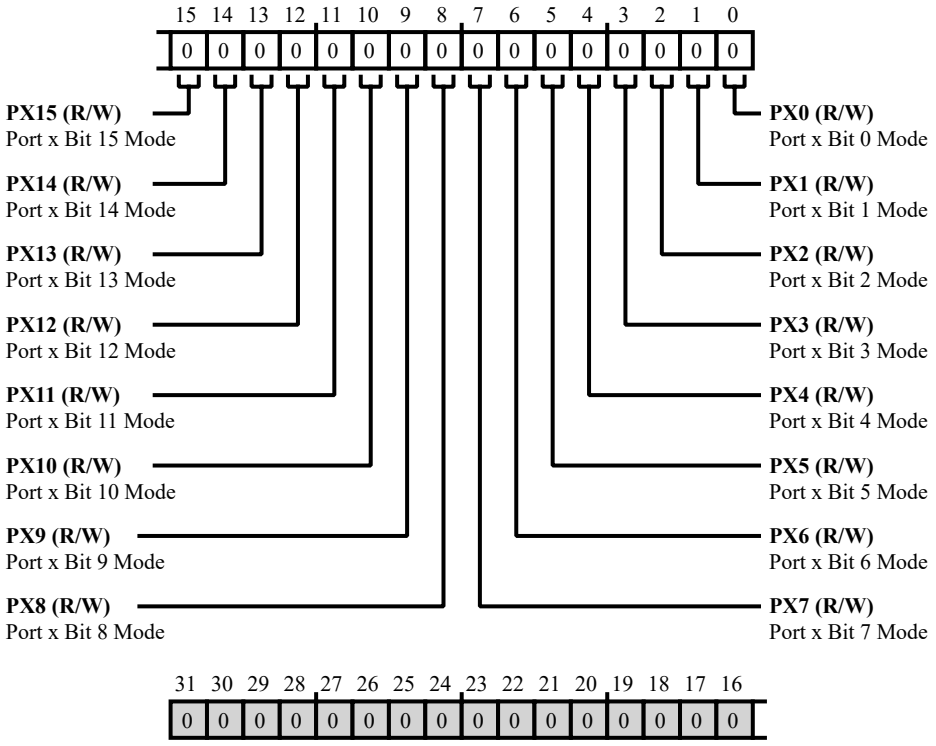

Figure 13-14: PORT_FER Register Diagram

Table 13-17: PORT_FER Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	PX15	Port x Bit 15 Mode. The PORT_FER.PX15 bit indicates the operating mode for port x.

		0	No Effect
		1	Set Bit for Peripheral Mode

Port x GPIO Input Enable Register

The PORT_INEN, PORT_INEN_SET, and PORT_INEN_CLR registers enable or disable input drivers, which are required for using a GPIO pin in input mode.

Writes to the PORT_INEN register affect the input drivers for all pins of the port. To set or clear specific pin drivers without impacting other pin drivers of the port, use the PORT_INEN_SET and PORT_INEN_CLR registers.

If the input is enabled, reads from the PORT_DATA, PORT_DATA_SET, or PORT_DATA_CLR registers return the state of the pins. However, the state of the output is not overwritten by the input. It is altered by software writes only. Input and output drivers can be enabled at the same time. In this case, a read of the data register returns the true value of the data register and not the pin state.

For more information, see the PORT_DATA register description and the PORT_DIR register description.

		1	Set Bit. Set to enable the input driver.

Port x GPIO Lock Register

The PORT_LOCK register enables (unlocks) or disables (locks) write access selectively for the PORT control registers.

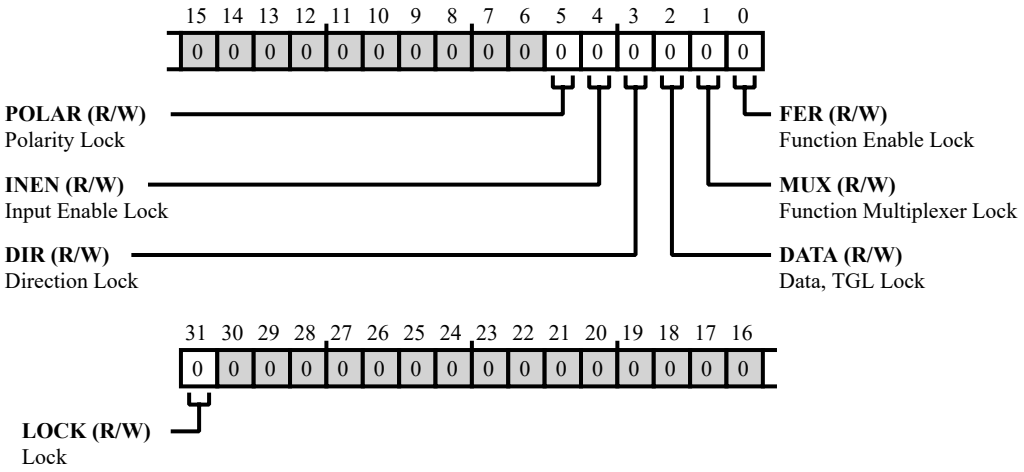

Figure 13-20: PORT_LOCK Register Diagram

Table 13-23: PORT_LOCK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock bit is set (SPU_CTL.GLCK bit =1) and the PORT_LOCK.LOCK bit is set, the PORT_LOCK register is read only (locked).	
		0	Unlock
		1	Lock
5 (R/W)	POLAR	Polarity Lock. The PORT_LOCK.POLAR disables write access to the PORT_POL, PORT_POL_SET, and PORT_POL_CLR registers.	
		0	Unlock POL
		1	Lock POL
4 (R/W)	INEN	Input Enable Lock. The PORT_LOCK.INEN disables write access to the PORT_INEN, PORT_INEN_SET, and PORT_INEN_CLR registers.	
		0	Unlock INEN
		1	Lock INEN

Table 13-23: PORT_LOCK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	DIR	Direction Lock. The PORT_LOCK.DIR disables write access to the PORT_DIR, PORT_DIR_SET, PORT_DIR_CLR registers.	
		0	Unlock DIR
		1	Lock DIR
2 (R/W)	DATA	Data, TGL Lock. The PORT_LOCK.DATA disables write access to the PORT_DATA, PORT_DATA_SET, PORT_DATA_CLR, and PORT_DATA_TGL registers.	
		0	Unlock DATA
		1	Lock DATA
1 (R/W)	MUX	Function Multiplexer Lock. The PORT_LOCK.MUX disables write accesses to the PORT_MUX register.	
		0	Unlock MUX
		1	Lock MUX
0 (R/W)	FER	Function Enable Lock. The PORT_LOCK.FER disables write access to the PORT_FER, PORT_FER_SET, and PORT_FER_CLR registers.	
		0	Unlock FER
		1	Lock FER

Port x Multiplexer Control Register

When a pin is in peripheral mode (not GPIO mode), the PORT_MUX register controls which peripheral takes ownership of a pin. Ports may have multiple, different peripheral functions. Two bits are required to describe every multiplexer on an individual pin-by-pin scheme. For example, bit 0 and bit 1 of the PORT_MUX register control the multiplexer of pin 0, bit 2 and bit 3 of PORT_MUX control the multiplexer of pin 1, and so on. The value of any PORT_MUX bit has no effect on the port pins when the associated bit in the PORT_FER register is 0 (selects GPIO mode). Even if a port has only one function, the PORT_MUX register is still present. For single function ports (no multiplexing is needed), leave the PORT_MUX bits at 0 (default). For all PORT_MUX bit fields: 00 = default/reset peripheral option, 01 = first alternate peripheral option, 10 = second alternate peripheral option, and 11 = third alternate peripheral option.

See the processor data sheet for details regarding the peripheral options associated with each port.

Table 13-24: PORT_MUX Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:30 (R/W)	MUX15	Mux for Port x Bit 15. The PORT_MUX.MUX15 bit provides multiplexer control for port x bit 15.

Table 13-24: PORT_MUX Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
29:28 (R/W)	MUX14	Mux for Port x Bit 14. The PORT_MUX.MUX14 bit provides multiplexer control for port x bit 14.
27:26 (R/W)	MUX13	Mux for Port x Bit 13. The PORT_MUX.MUX13 bit provides multiplexer control for port x bit 13.
25:24 (R/W)	MUX12	Mux for Port x Bit 12. The PORT_MUX.MUX12 bit provides multiplexer control for port x bit 12.
23:22 (R/W)	MUX11	Mux for Port x Bit 11. The PORT_MUX.MUX11 bit provides multiplexer control for port x bit 11.
21:20 (R/W)	MUX10	Mux for Port x Bit 10. The PORT_MUX.MUX10 bit provides multiplexer control for port x bit 10.
19:18 (R/W)	MUX9	Mux for Port x Bit 9. The PORT_MUX.MUX9 bit provides multiplexer control for port x bit 9.
17:16 (R/W)	MUX8	Mux for Port x Bit 8. The PORT_MUX.MUX8 bit provides multiplexer control for port x bit 8.
15:14 (R/W)	MUX7	Mux for Port x Bit 7. The PORT_MUX.MUX7 bit provides multiplexer control for port x bit 7.
13:12 (R/W)	MUX6	Mux for Port x Bit 6. The PORT_MUX.MUX6 bit provides multiplexer control for port x bit 6.
11:10 (R/W)	MUX5	Mux for Port x Bit 5. The PORT_MUX.MUX5 bit provides multiplexer control for port x bit 5.
9:8 (R/W)	MUX4	Mux for Port x Bit 4. The PORT_MUX.MUX4 bit provides multiplexer control for port x bit 4.
7:6 (R/W)	MUX3	Mux for Port x Bit 3. The PORT_MUX.MUX3 bit provides multiplexer control for port x bit 3.
5:4 (R/W)	MUX2	Mux for Port x Bit 2. The PORT_MUX.MUX2 bit provides multiplexer control for port x bit 2.
3:2 (R/W)	MUX1	Mux for Port x Bit 1. The PORT_MUX.MUX1 bit provides multiplexer control for port x bit 1.
1:0 (R/W)	MUX0	Mux for Port x Bit 0. The PORT_MUX.MUX0 bit provides multiplexer control for port x bit 0.

Port x GPIO Polarity Invert Register

The PORT_POL, PORT_POL_SET, and PORT_POL_CLR registers enable or disable inverting polarity of GPIO signals. To invert polarity of peripheral signals, use the inversion selection programming in the signal's corresponding module.

Writes to the PORT_POL register affect the polarity inversion selection of all pins of the port. To enable or disable polarity inversion for specific pins without impacting other pins of the port, use the PORT_POL_SET and PORT_POL_CLR registers.

Setting a bit in the PORT_POL register enables polarity inversion on the corresponding inversion GPIO pin, making the pin active-low or falling-edge sensitive. Clearing a bit in the PORT_POL register disables polarity (default state) on the corresponding GPIO pin, making it active-high or rising-edge sensitive.

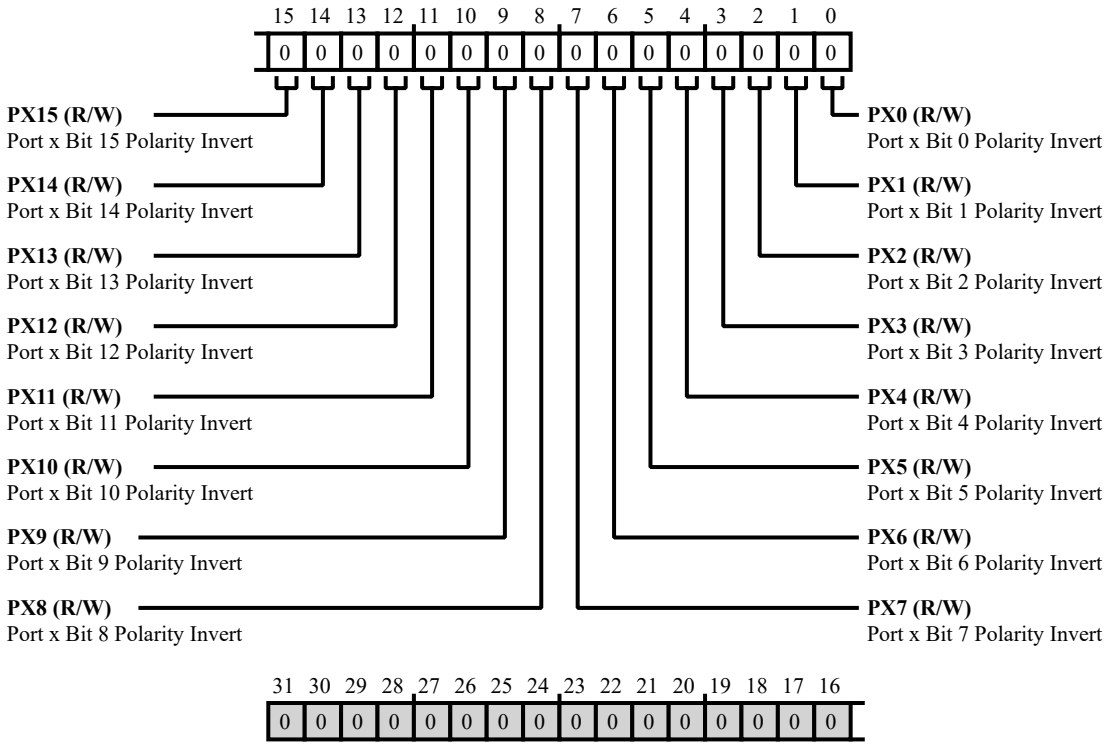

Figure 13-22: PORT_POL Register Diagram

Table 13-25: PORT_POL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	PX15	Port x Bit 15 Polarity Invert. The PORT_POL.PX15 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.

Table 13-25: PORT_POL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
14 (R/W)	PX14	Port x Bit 14 Polarity Invert. The PORT_POL.PX14 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
13 (R/W)	PX13	Port x Bit 13 Polarity Invert. The PORT_POL.PX13 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
12 (R/W)	PX12	Port x Bit 12 Polarity Invert. The PORT_POL.PX12 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
11 (R/W)	PX11	Port x Bit 11 Polarity Invert. The PORT_POL.PX11 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
10 (R/W)	PX10	Port x Bit 10 Polarity Invert. The PORT_POL.PX10 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
9 (R/W)	PX9	Port x Bit 9 Polarity Invert. The PORT_POL.PX9 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
8 (R/W)	PX8	Port x Bit 8 Polarity Invert. The PORT_POL.PX8 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.

Table 13-25: PORT_POL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	PX7	Port x Bit 7 Polarity Invert. The PORT_POL.PX7 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
6 (R/W)	PX6	Port x Bit 6 Polarity Invert. The PORT_POL.PX6 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
5 (R/W)	PX5	Port x Bit 5 Polarity Invert. The PORT_POL.PX5 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
4 (R/W)	PX4	Port x Bit 4 Polarity Invert. The PORT_POL.PX4 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
3 (R/W)	PX3	Port x Bit 3 Polarity Invert. The PORT_POL.PX3 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
2 (R/W)	PX2	Port x Bit 2 Polarity Invert. The PORT_POL.PX2 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.
1 (R/W)	PX1	Port x Bit 1 Polarity Invert. The PORT_POL.PX1 bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.

Table 13-25: PORT_POL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	PX0	Port x Bit 0 Polarity Invert. The `PORT_POL.PX0` bit enables polarity inversion.	
		0	No Invert. GPIO is active high or rising edge sensitive.
		1	Invert. GPIO is active low or falling edge sensitive.

Port x GPIO Polarity Invert Clear Register

The PORT_POL_CLR register disables polarity inversion for GPIO pins. For more information, see the PORT_POL register description.

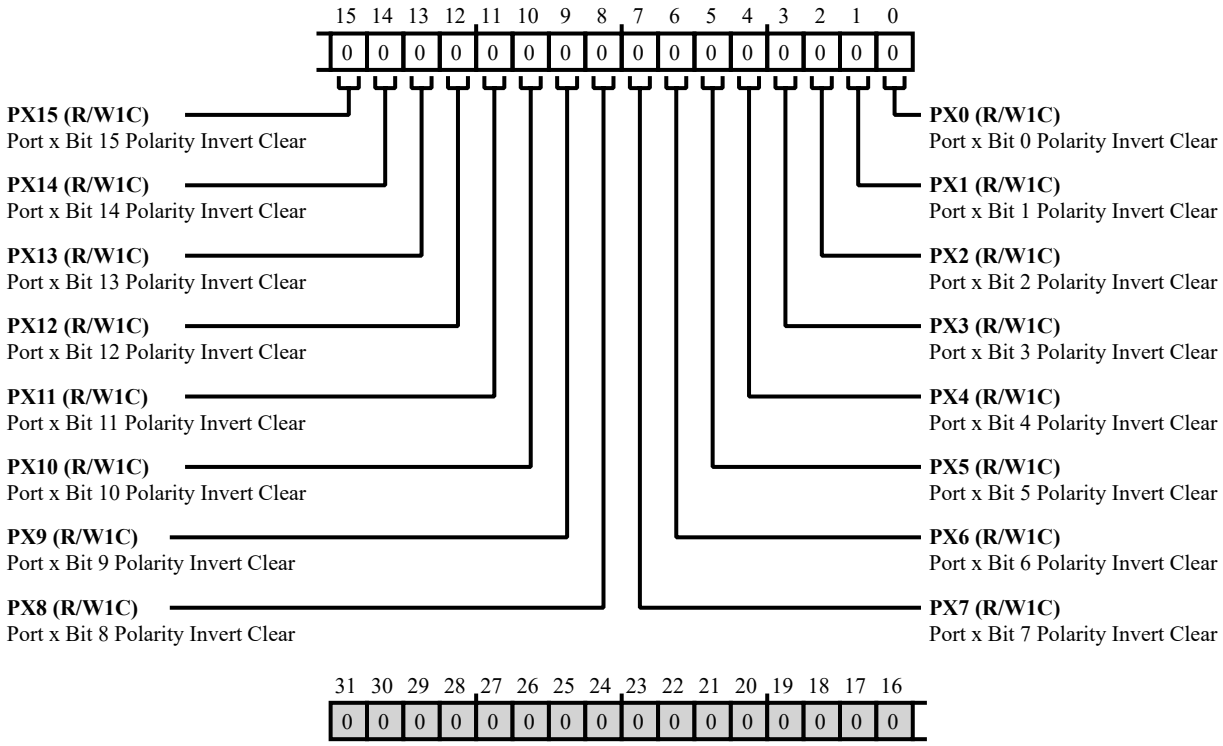

Figure 13-23: PORT_POL_CLR Register Diagram

Table 13-26: PORT_POL_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W1C)	PX15	Port x Bit 15 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
14 (R/W1C)	PX14	Port x Bit 14 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
13 (R/W1C)	PX13	Port x Bit 13 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.

Table 13-26: PORT_POL_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W1C)	PX12	Port x Bit 12 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
11 (R/W1C)	PX11	Port x Bit 11 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
10 (R/W1C)	PX10	Port x Bit 10 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
9 (R/W1C)	PX9	Port x Bit 9 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
8 (R/W1C)	PX8	Port x Bit 8 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
7 (R/W1C)	PX7	Port x Bit 7 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
6 (R/W1C)	PX6	Port x Bit 6 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
5 (R/W1C)	PX5	Port x Bit 5 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
4 (R/W1C)	PX4	Port x Bit 4 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
3 (R/W1C)	PX3	Port x Bit 3 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.

Table 13-26: PORT_POL_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W1C)	PX2	Port x Bit 2 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
1 (R/W1C)	PX1	Port x Bit 1 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.
0 (R/W1C)	PX0	Port x Bit 0 Polarity Invert Clear.	
		0	No Effect
		1	Clear Bit. Set to disable GPIO pin polarity invert.

Port x GPIO Polarity Invert Set Register

The PORT_POL_SET register enables polarity inversion for GPIO pins. For more information, see the PORT_POL register description.

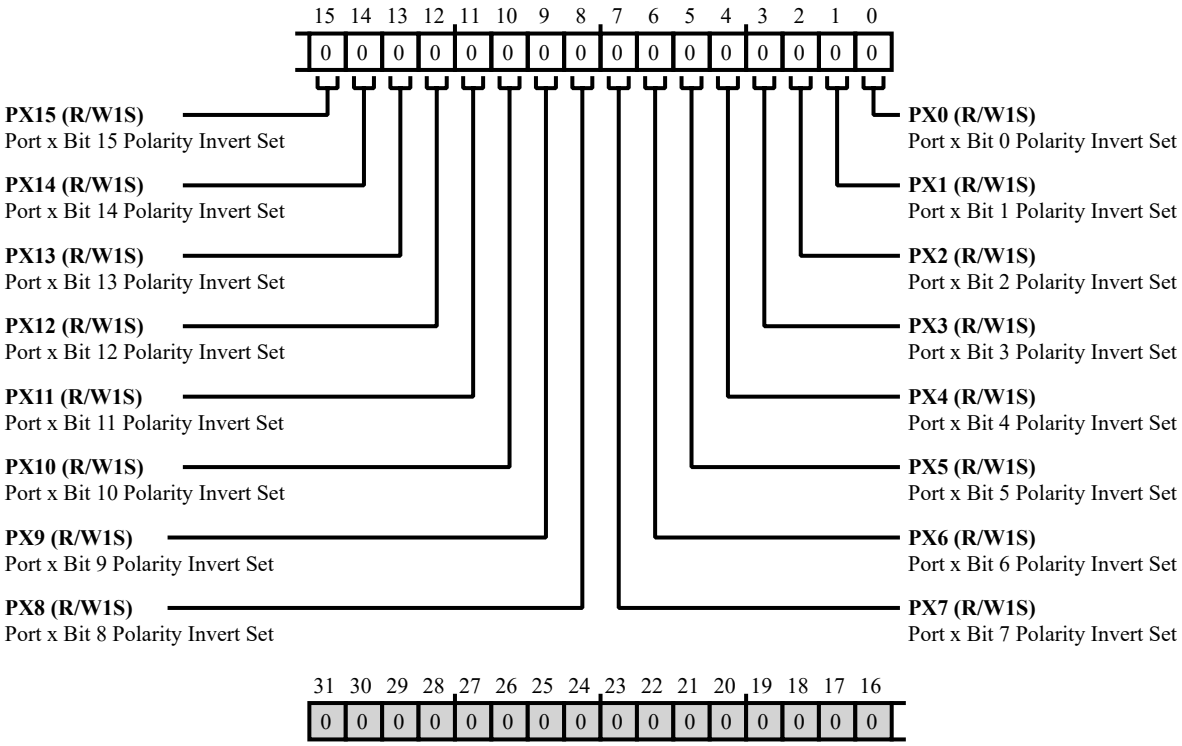

Figure 13-24: PORT_POL_SET Register Diagram

Table 13-27: PORT_POL_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W1S)	PX15	Port x Bit 15 Polarity Invert Set. The PORT_POL_SET.PX15 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
14 (R/W1S)	PX14	Port x Bit 14 Polarity Invert Set. The PORT_POL_SET.PX14 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.

Table 13-27: PORT_POL_SET Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W1S)	PX13	Port x Bit 13 Polarity Invert Set. The PORT_POL_SET.PX13 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
12 (R/W1S)	PX12	Port x Bit 12 Polarity Invert Set. The PORT_POL_SET.PX12 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
11 (R/W1S)	PX11	Port x Bit 11 Polarity Invert Set. The PORT_POL_SET.PX11 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
10 (R/W1S)	PX10	Port x Bit 10 Polarity Invert Set. The PORT_POL_SET.PX10 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
9 (R/W1S)	PX9	Port x Bit 9 Polarity Invert Set. The PORT_POL_SET.PX9 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
8 (R/W1S)	PX8	Port x Bit 8 Polarity Invert Set. The PORT_POL_SET.PX8 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
7 (R/W1S)	PX7	Port x Bit 7 Polarity Invert Set. The PORT_POL_SET.PX7 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.

Table 13-27: PORT_POL_SET Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W1S)	PX6	Port x Bit 6 Polarity Invert Set. The PORT_POL_SET.PX6 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
5 (R/W1S)	PX5	Port x Bit 5 Polarity Invert Set. The PORT_POL_SET.PX5 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
4 (R/W1S)	PX4	Port x Bit 4 Polarity Invert Set. The PORT_POL_SET.PX4 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
3 (R/W1S)	PX3	Port x Bit 3 Polarity Invert Set. The PORT_POL_SET.PX3 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
2 (R/W1S)	PX2	Port x Bit 2 Polarity Invert Set. The PORT_POL_SET.PX2 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
1 (R/W1S)	PX1	Port x Bit 1 Polarity Invert Set. The PORT_POL_SET.PX1 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.
0 (R/W1S)	PX0	Port x Bit 0 Polarity Invert Set. The PORT_POL_SET.PX0 bit enables pin polarity inversion.	
		0	No Effect
		1	Set Bit. Set to enable GPIO pin polarity invert.

Port x GPIO Trigger Toggle Register

The PORT_TRIG_TGL register permits toggling the state of output GPIO pins in response to a trigger from the TRU for the corresponding port. Setting bits in the PORT_TRIG_TGL register enables triggers to toggle the state of those specific pins without impacting other pins of the port.

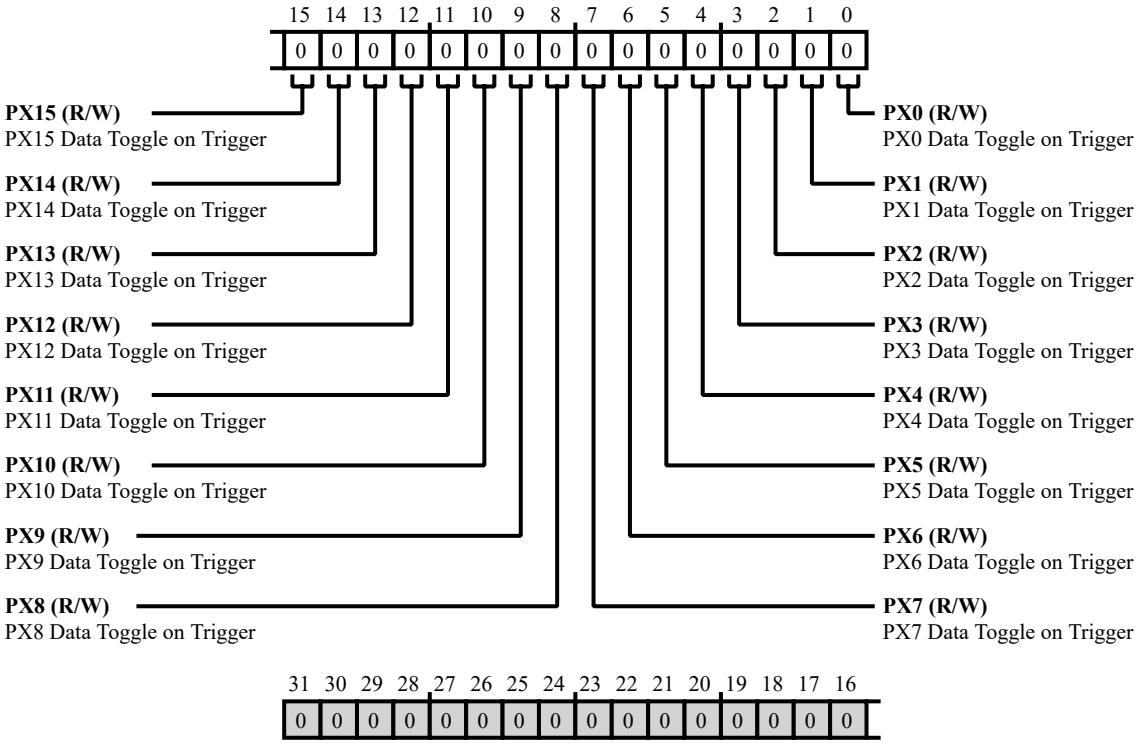

Figure 13-25: PORT_TRIG_TGL Register Diagram

Table 13-28: PORT_TRIG_TGL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W)	PX15	PX15 Data Toggle on Trigger. The PORT_TRIG_TGL.PX15 bit enables triggers to toggle the state of the pin.
14 (R/W)	PX14	PX14 Data Toggle on Trigger. The PORT_TRIG_TGL.PX14 bit enables triggers to toggle the state of the pin.
13 (R/W)	PX13	PX13 Data Toggle on Trigger. The PORT_TRIG_TGL.PX13 bit enables triggers to toggle the state of the pin.
12 (R/W)	PX12	PX12 Data Toggle on Trigger. The PORT_TRIG_TGL.PX12 bit enables triggers to toggle the state of the pin.
11 (R/W)	PX11	PX11 Data Toggle on Trigger. The PORT_TRIG_TGL.PX11 bit enables triggers to toggle the state of the pin.

Table 13-28: PORT_TRIG_TGL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
10 (R/W)	PX10	PX10 Data Toggle on Trigger. The PORT_TRIG_TGL.PX10 bit enables triggers to toggle the state of the pin.
9 (R/W)	PX9	PX9 Data Toggle on Trigger. The PORT_TRIG_TGL.PX9 bit enables triggers to toggle the state of the pin.
8 (R/W)	PX8	PX8 Data Toggle on Trigger. The PORT_TRIG_TGL.PX8 bit enables triggers to toggle the state of the pin.
7 (R/W)	PX7	PX7 Data Toggle on Trigger. The PORT_TRIG_TGL.PX7 bit enables triggers to toggle the state of the pin.
6 (R/W)	PX6	PX6 Data Toggle on Trigger. The PORT_TRIG_TGL.PX6 bit enables triggers to toggle the state of the pin.
5 (R/W)	PX5	PX5 Data Toggle on Trigger. The PORT_TRIG_TGL.PX5 bit enables triggers to toggle the state of the pin.
4 (R/W)	PX4	PX4 Data Toggle on Trigger. The PORT_TRIG_TGL.PX4 bit enables triggers to toggle the state of the pin.
3 (R/W)	PX3	PX3 Data Toggle on Trigger. The PORT_TRIG_TGL.PX3 bit enables triggers to toggle the state of the pin.
2 (R/W)	PX2	PX2 Data Toggle on Trigger. The PORT_TRIG_TGL.PX2 bit enables triggers to toggle the state of the pin.
1 (R/W)	PX1	PX1 Data Toggle on Trigger. The PORT_TRIG_TGL.PX1 bit enables triggers to toggle the state of the pin.
0 (R/W)	PX0	PX0 Data Toggle on Trigger. The PORT_TRIG_TGL.PX0 bit enables triggers to toggle the state of the pin.

ADSP-2184x PINT Register Descriptions

The Pin Interrupt module (PINT) contains the following registers.

Table 13-29: ADSP-2184x PINT Register List

Name	Description
PINT_ASSIGN	PINT Assign Register
PINT_EDGE_CLR	PINT Edge Clear Register
PINT_EDGE_SET	PINT Edge Set Register
PINT_INV_CLR	PINT Invert Clear Register

Table 13-29: ADSP-2184x PINT Register List (Continued)

Name	Description
PINT_INV_SET	PINT Invert Set Register
PINT_LATCH	PINT Latch Register
PINT_MSK_CLR	PINT Mask Clear Register
PINT_MSK_SET	PINT Mask Set Register
PINT_PINSTATE	PINT Pin State Register
PINT_REQ	PINT Request Register

PINT Assign Register

The PINT_ASSIGN register controls the pin-to-interrupt request assignment in a byte-wide manner. This register consists of four control bytes that each function as a multiplexer control.

The PINT ports are subdivided into 8-bit half ports, resulting in lower and upper half 8-bit units. Using the multiplexers controlled by the PINT_ASSIGN register, the lower half units of eight pins can be forwarded to either byte 0 or byte 2 of either associated PINT block. The upper half units can be forwarded to either byte 1 or byte 3 of the PINT block, without further restrictions.

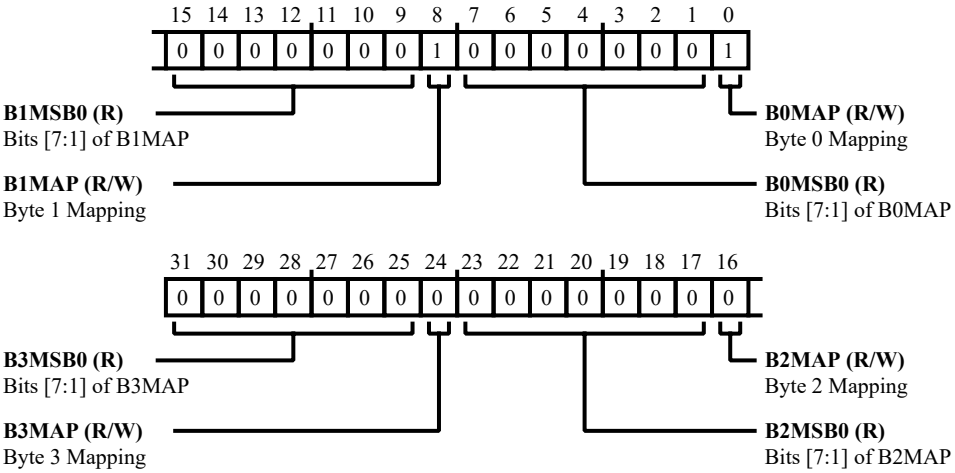

Figure 13-26: PINT_ASSIGN Register Diagram

Table 13-30: PINT_ASSIGN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:25 (R/NW)	B3MSB0	Bits [7:1] of B3MAP.	
24 (R/W)	B3MAP	Byte 3 Mapping.	
		0	B3MAP_PAH. Byte 3 = PA.H
		1	B3MAP_PBH. Byte 3 = PB.H
23:17 (R/NW)	B2MSB0	Bits [7:1] of B2MAP.	
16 (R/W)	B2MAP	Byte 2 Mapping.	
		0	B2MAP_PAL. Byte 2 = PA.L
		1	B2MAP_PBL. Byte 2 = PB.L
15:9 (R/NW)	B1MSB0	Bits [7:1] of B1MAP.	

Table 13-30: PINT_ASSIGN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	B1MAP	Byte 1 Mapping.	
		0	B1MAP_PAH. Byte 1 = PA.H
		1	B1MAP_PBH. Byte 1 = PB.H
7:1 (R/NW)	B0MSB0	Bits [7:1] of B0MAP.	
0 (R/W)	B0MAP	Byte 0 Mapping.	
		0	B0MAP_PAL. Byte 0 = PA.L
		1	B0MAP_PBL. Byte 0 = PB.L

PINT Edge Clear Register

The PINT_EDGE_CLR register permits selecting level-sensitive interrupts. Writing 1 to a bit in PINT_EDGE_CLR enables level sensitivity for the corresponding pin interrupt.

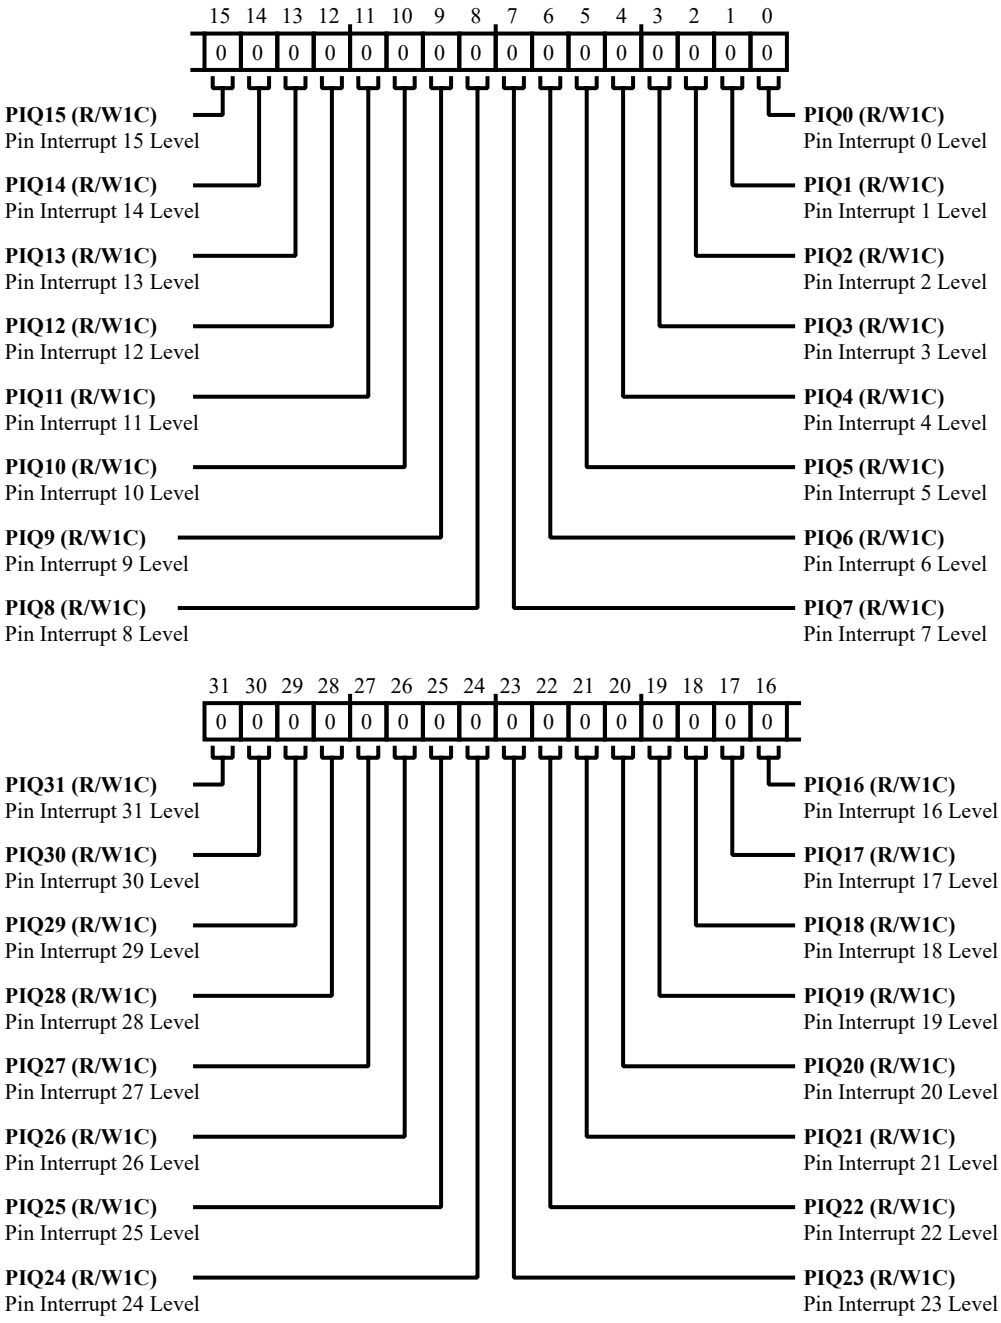

Figure 13-27: PINT_EDGE_CLR Register Diagram

Table 13-31: PINT_EDGE_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1C)	PIQ31	Pin Interrupt 31 Level. Set the PINT_EDGE_CLR.PIQ31 bit to enable level sensitivity.
30 (R/W1C)	PIQ30	Pin Interrupt 30 Level. Set the PINT_EDGE_CLR.PIQ30 bit to enable level sensitivity.
29 (R/W1C)	PIQ29	Pin Interrupt 29 Level. Set the PINT_EDGE_CLR.PIQ29 bit to enable level sensitivity.
28 (R/W1C)	PIQ28	Pin Interrupt 28 Level. Set the PINT_EDGE_CLR.PIQ28 bit to enable level sensitivity.
27 (R/W1C)	PIQ27	Pin Interrupt 27 Level. Set the PINT_EDGE_CLR.PIQ27 bit to enable level sensitivity.
26 (R/W1C)	PIQ26	Pin Interrupt 26 Level. Set the PINT_EDGE_CLR.PIQ26 bit to enable level sensitivity.
25 (R/W1C)	PIQ25	Pin Interrupt 25 Level. Set the PINT_EDGE_CLR.PIQ25 bit to enable level sensitivity.
24 (R/W1C)	PIQ24	Pin Interrupt 24 Level. Set the PINT_EDGE_CLR.PIQ24 bit to enable level sensitivity.
23 (R/W1C)	PIQ23	Pin Interrupt 23 Level. Set the PINT_EDGE_CLR.PIQ23 bit to enable level sensitivity.
22 (R/W1C)	PIQ22	Pin Interrupt 22 Level. Set the PINT_EDGE_CLR.PIQ22 bit to enable level sensitivity.
21 (R/W1C)	PIQ21	Pin Interrupt 21 Level. Set the PINT_EDGE_CLR.PIQ21 bit to enable level sensitivity.
20 (R/W1C)	PIQ20	Pin Interrupt 20 Level. Set the PINT_EDGE_CLR.PIQ20 bit to enable level sensitivity.
19 (R/W1C)	PIQ19	Pin Interrupt 19 Level. Set the PINT_EDGE_CLR.PIQ19 bit to enable level sensitivity.
18 (R/W1C)	PIQ18	Pin Interrupt 18 Level. Set the PINT_EDGE_CLR.PIQ18 bit to enable level sensitivity.
17 (R/W1C)	PIQ17	Pin Interrupt 17 Level. Set the PINT_EDGE_CLR.PIQ17 bit to enable level sensitivity.
16 (R/W1C)	PIQ16	Pin Interrupt 16 Level. Set the PINT_EDGE_CLR.PIQ16 bit to enable level sensitivity.

Table 13-31: PINT_EDGE_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W1C)	PIQ15	Pin Interrupt 15 Level. Set the PINT_EDGE_CLR.PIQ15 bit to enable level sensitivity.
14 (R/W1C)	PIQ14	Pin Interrupt 14 Level. Set the PINT_EDGE_CLR.PIQ14 bit to enable level sensitivity.
13 (R/W1C)	PIQ13	Pin Interrupt 13 Level. Set the PINT_EDGE_CLR.PIQ13 bit to enable level sensitivity.
12 (R/W1C)	PIQ12	Pin Interrupt 12 Level. Set the PINT_EDGE_CLR.PIQ12 bit to enable level sensitivity.
11 (R/W1C)	PIQ11	Pin Interrupt 11 Level. Set the PINT_EDGE_CLR.PIQ11 bit to enable level sensitivity.
10 (R/W1C)	PIQ10	Pin Interrupt 10 Level. Set the PINT_EDGE_CLR.PIQ10 bit to enable level sensitivity.
9 (R/W1C)	PIQ9	Pin Interrupt 9 Level. Set the PINT_EDGE_CLR.PIQ9 bit to enable level sensitivity.
8 (R/W1C)	PIQ8	Pin Interrupt 8 Level. Set the PINT_EDGE_CLR.PIQ8 bit to enable level sensitivity.
7 (R/W1C)	PIQ7	Pin Interrupt 7 Level. Set the PINT_EDGE_CLR.PIQ7 bit to enable level sensitivity.
6 (R/W1C)	PIQ6	Pin Interrupt 6 Level. Set the PINT_EDGE_CLR.PIQ6 bit to enable level sensitivity.
5 (R/W1C)	PIQ5	Pin Interrupt 5 Level. Set the PINT_EDGE_CLR.PIQ5 bit to enable level sensitivity.
4 (R/W1C)	PIQ4	Pin Interrupt 4 Level. Set the PINT_EDGE_CLR.PIQ4 bit to enable level sensitivity.
3 (R/W1C)	PIQ3	Pin Interrupt 3 Level. Set the PINT_EDGE_CLR.PIQ3 bit to enable level sensitivity.
2 (R/W1C)	PIQ2	Pin Interrupt 2 Level. Set the PINT_EDGE_CLR.PIQ2 bit to enable level sensitivity.
1 (R/W1C)	PIQ1	Pin Interrupt 1 Level. Set the PINT_EDGE_CLR.PIQ1 bit to enable level sensitivity.
0 (R/W1C)	PIQ0	Pin Interrupt 0 Level. Set the PINT_EDGE_CLR.PIQ0 bit to enable level sensitivity.

PINT Edge Set Register

The PINT_EDGE_SET register permits selecting edge-sensitive interrupts. Writing 1 to a bit in PINT_EDGE_SET enables edge sensitivity for the corresponding pin interrupt.

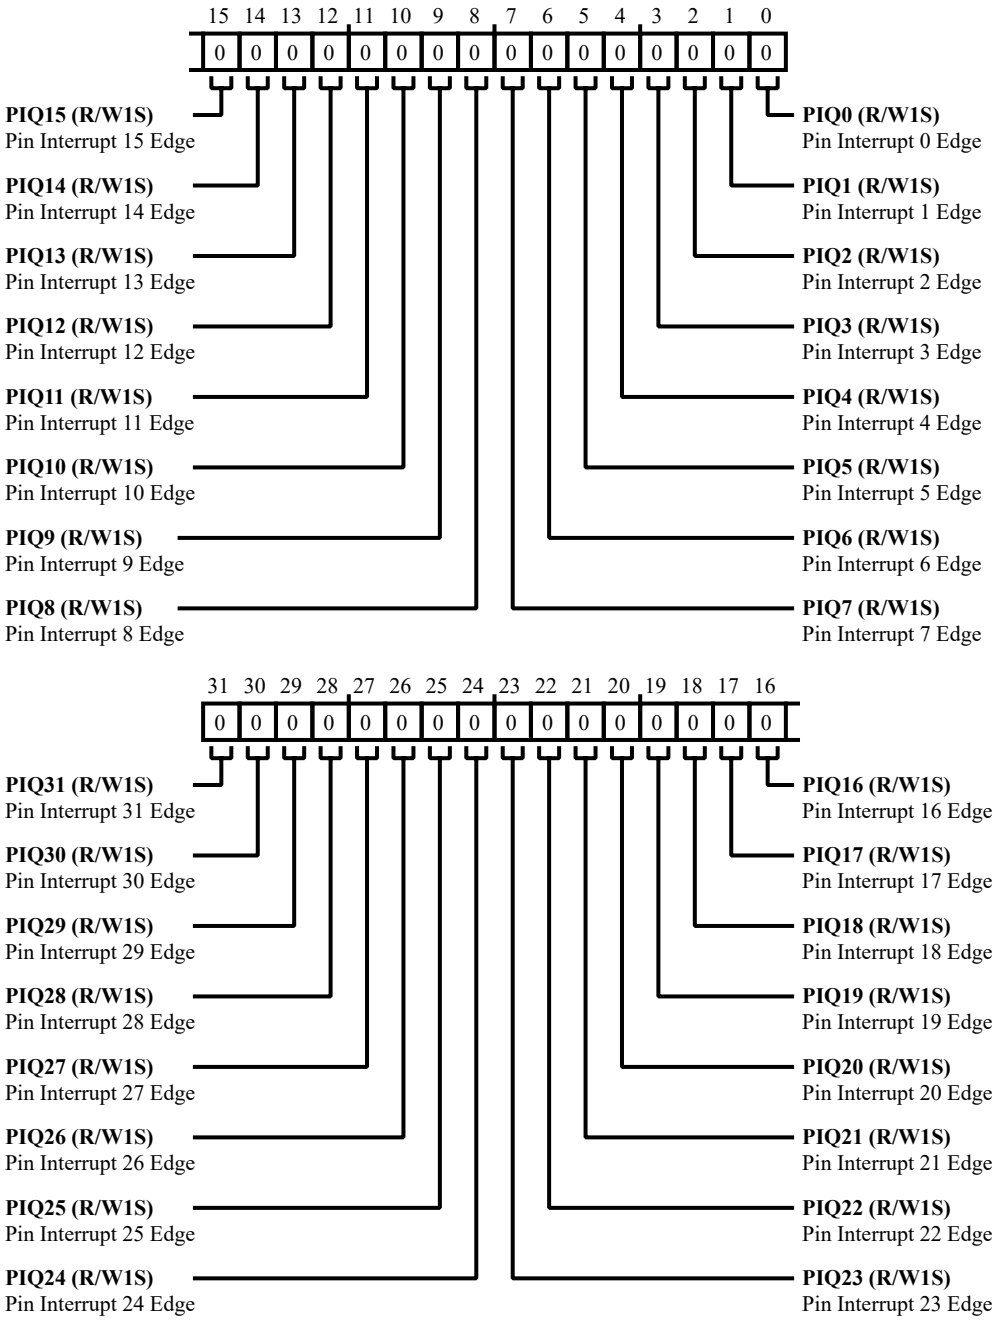

Figure 13-28: PINT_EDGE_SET Register Diagram

Table 13-32: PINT_EDGE_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1S)	PIQ31	Pin Interrupt 31 Edge. Set the PINT_EDGE_SET.PIQ31 bit to enable edge sensitivity.
30 (R/W1S)	PIQ30	Pin Interrupt 30 Edge. Set the PINT_EDGE_SET.PIQ30 bit to enable edge sensitivity.
29 (R/W1S)	PIQ29	Pin Interrupt 29 Edge. Set the PINT_EDGE_SET.PIQ29 bit to enable edge sensitivity.
28 (R/W1S)	PIQ28	Pin Interrupt 28 Edge. Set the PINT_EDGE_SET.PIQ28 bit to enable edge sensitivity.
27 (R/W1S)	PIQ27	Pin Interrupt 27 Edge. Set the PINT_EDGE_SET.PIQ27 bit to enable edge sensitivity.
26 (R/W1S)	PIQ26	Pin Interrupt 26 Edge. Set the PINT_EDGE_SET.PIQ26 bit to enable edge sensitivity.
25 (R/W1S)	PIQ25	Pin Interrupt 25 Edge. Set the PINT_EDGE_SET.PIQ25 bit to enable edge sensitivity.
24 (R/W1S)	PIQ24	Pin Interrupt 24 Edge. Set the PINT_EDGE_SET.PIQ24 bit to enable edge sensitivity.
23 (R/W1S)	PIQ23	Pin Interrupt 23 Edge. Set the PINT_EDGE_SET.PIQ23 bit to enable edge sensitivity.
22 (R/W1S)	PIQ22	Pin Interrupt 22 Edge. Set the PINT_EDGE_SET.PIQ22 bit to enable edge sensitivity.
21 (R/W1S)	PIQ21	Pin Interrupt 21 Edge. Set the PINT_EDGE_SET.PIQ21 bit to enable edge sensitivity.
20 (R/W1S)	PIQ20	Pin Interrupt 20 Edge. Set the PINT_EDGE_SET.PIQ20 bit to enable edge sensitivity.
19 (R/W1S)	PIQ19	Pin Interrupt 19 Edge. Set the PINT_EDGE_SET.PIQ19 bit to enable edge sensitivity.
18 (R/W1S)	PIQ18	Pin Interrupt 18 Edge. Set the PINT_EDGE_SET.PIQ18 bit to enable edge sensitivity.
17 (R/W1S)	PIQ17	Pin Interrupt 17 Edge. Set the PINT_EDGE_SET.PIQ17 bit to enable edge sensitivity.
16 (R/W1S)	PIQ16	Pin Interrupt 16 Edge. Set the PINT_EDGE_SET.PIQ16 bit to enable edge sensitivity.

Table 13-32: PINT_EDGE_SET Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W1S)	PIQ15	Pin Interrupt 15 Edge. Set the PINT_EDGE_SET.PIQ15 bit to enable edge sensitivity.
14 (R/W1S)	PIQ14	Pin Interrupt 14 Edge. Set the PINT_EDGE_SET.PIQ14 bit to enable edge sensitivity.
13 (R/W1S)	PIQ13	Pin Interrupt 13 Edge. Set the PINT_EDGE_SET.PIQ13 bit to enable edge sensitivity.
12 (R/W1S)	PIQ12	Pin Interrupt 12 Edge. Set the PINT_EDGE_SET.PIQ12 bit to enable edge sensitivity.
11 (R/W1S)	PIQ11	Pin Interrupt 11 Edge. Set the PINT_EDGE_SET.PIQ11 bit to enable edge sensitivity.
10 (R/W1S)	PIQ10	Pin Interrupt 10 Edge. Set the PINT_EDGE_SET.PIQ10 bit to enable edge sensitivity.
9 (R/W1S)	PIQ9	Pin Interrupt 9 Edge. Set the PINT_EDGE_SET.PIQ9 bit to enable edge sensitivity.
8 (R/W1S)	PIQ8	Pin Interrupt 8 Edge. Set the PINT_EDGE_SET.PIQ8 bit to enable edge sensitivity.
7 (R/W1S)	PIQ7	Pin Interrupt 7 Edge. Set the PINT_EDGE_SET.PIQ7 bit to enable edge sensitivity.
6 (R/W1S)	PIQ6	Pin Interrupt 6 Edge. Set the PINT_EDGE_SET.PIQ6 bit to enable edge sensitivity.
5 (R/W1S)	PIQ5	Pin Interrupt 5 Edge. Set the PINT_EDGE_SET.PIQ5 bit to enable edge sensitivity.
4 (R/W1S)	PIQ4	Pin Interrupt 4 Edge. Set the PINT_EDGE_SET.PIQ4 bit to enable edge sensitivity.
3 (R/W1S)	PIQ3	Pin Interrupt 3 Edge. Set the PINT_EDGE_SET.PIQ3 bit to enable edge sensitivity.
2 (R/W1S)	PIQ2	Pin Interrupt 2 Edge. Set the PINT_EDGE_SET.PIQ2 bit to enable edge sensitivity.
1 (R/W1S)	PIQ1	Pin Interrupt 1 Edge. Set the PINT_EDGE_SET.PIQ1 bit to enable edge sensitivity.
0 (R/W1S)	PIQ0	Pin Interrupt 0 Edge. Set the PINT_EDGE_SET.PIQ0 bit to enable edge sensitivity.

PINT Invert Clear Register

The PINT_INV_CLR register disables inverting input polarity. Writing 1 to a bit in PINT_INV_CLR disables an inverter for input on the corresponding pin.

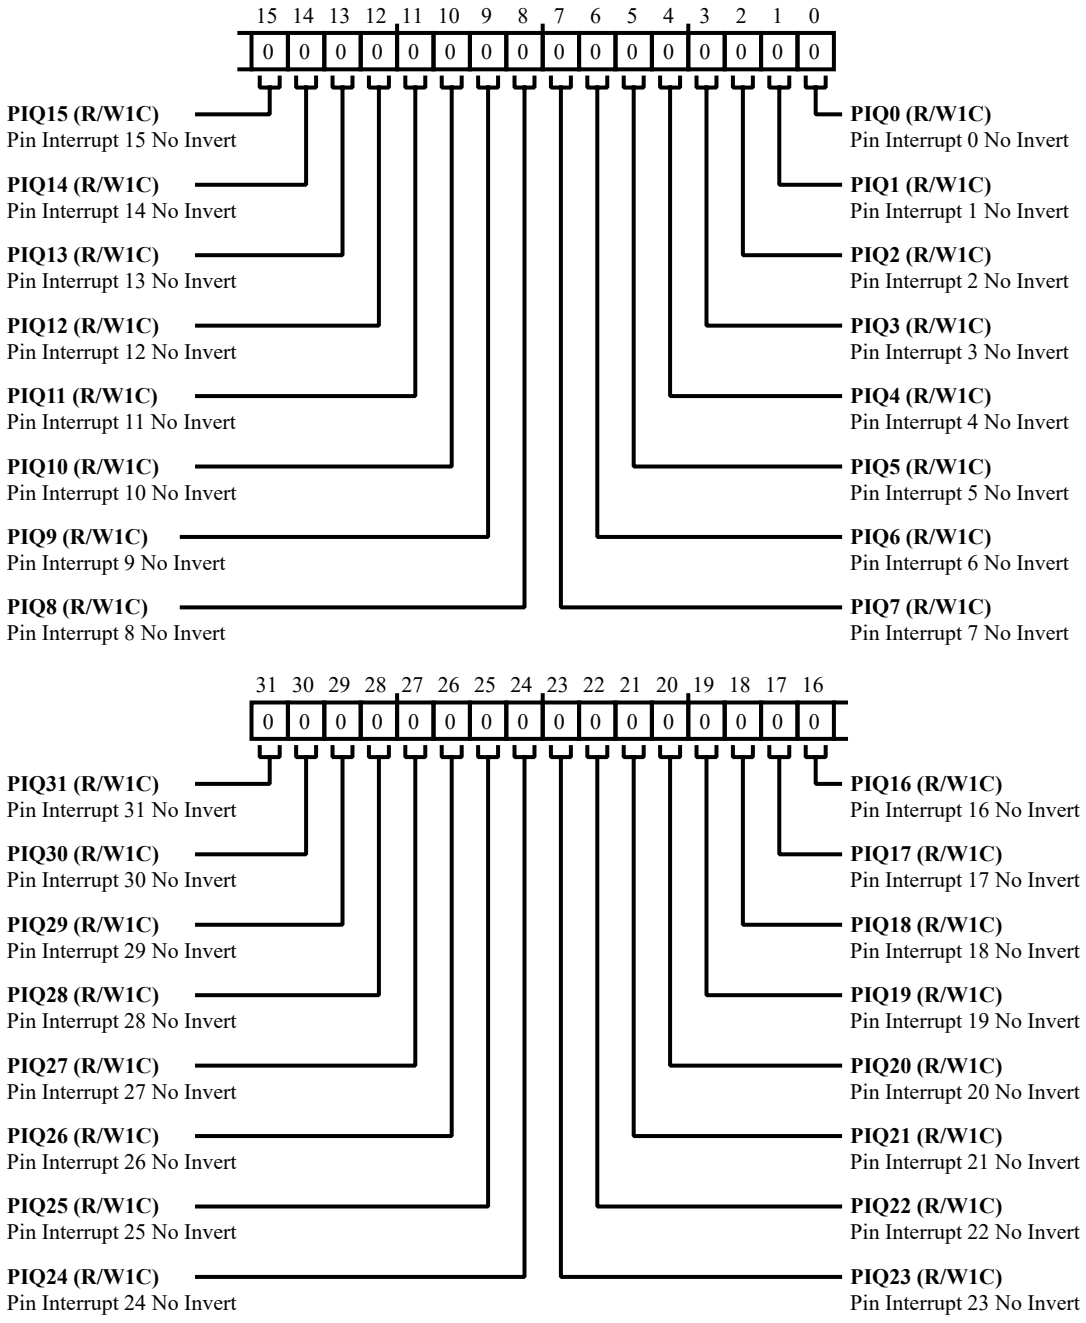

Figure 13-29: PINT_INV_CLR Register Diagram

Table 13-33: PINT_INV_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1C)	PIQ31	Pin Interrupt 31 No Invert. Set the PINT_INV_CLR.PIQ31 bit to disable inverted input.
30 (R/W1C)	PIQ30	Pin Interrupt 30 No Invert. Set the PINT_INV_CLR.PIQ30 bit to disable inverted input.
29 (R/W1C)	PIQ29	Pin Interrupt 29 No Invert. Set the PINT_INV_CLR.PIQ29 bit to disable inverted input.
28 (R/W1C)	PIQ28	Pin Interrupt 28 No Invert. Set the PINT_INV_CLR.PIQ28 bit to disable inverted input.
27 (R/W1C)	PIQ27	Pin Interrupt 27 No Invert. Set the PINT_INV_CLR.PIQ27 bit to disable inverted input.
26 (R/W1C)	PIQ26	Pin Interrupt 26 No Invert. Set the PINT_INV_CLR.PIQ26 bit to disable inverted input.
25 (R/W1C)	PIQ25	Pin Interrupt 25 No Invert. Set the PINT_INV_CLR.PIQ25 bit to disable inverted input.
24 (R/W1C)	PIQ24	Pin Interrupt 24 No Invert. Set the PINT_INV_CLR.PIQ24 bit to disable inverted input.
23 (R/W1C)	PIQ23	Pin Interrupt 23 No Invert. Set the PINT_INV_CLR.PIQ23 bit to disable inverted input.
22 (R/W1C)	PIQ22	Pin Interrupt 22 No Invert. Set the PINT_INV_CLR.PIQ22 bit to disable inverted input.
21 (R/W1C)	PIQ21	Pin Interrupt 21 No Invert. Set the PINT_INV_CLR.PIQ21 bit to disable inverted input.
20 (R/W1C)	PIQ20	Pin Interrupt 20 No Invert. Set the PINT_INV_CLR.PIQ20 bit to disable inverted input.
19 (R/W1C)	PIQ19	Pin Interrupt 19 No Invert. Set the PINT_INV_CLR.PIQ19 bit to disable inverted input.
18 (R/W1C)	PIQ18	Pin Interrupt 18 No Invert. Set the PINT_INV_CLR.PIQ18 bit to disable inverted input.
17 (R/W1C)	PIQ17	Pin Interrupt 17 No Invert. Set the PINT_INV_CLR.PIQ17 bit to disable inverted input.
16 (R/W1C)	PIQ16	Pin Interrupt 16 No Invert. Set the PINT_INV_CLR.PIQ16 bit to disable inverted input.

Table 13-33: PINT_INV_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W1C)	PIQ15	Pin Interrupt 15 No Invert. Set the PINT_INV_CLR.PIQ15 bit to disable inverted input.
14 (R/W1C)	PIQ14	Pin Interrupt 14 No Invert. Set the PINT_INV_CLR.PIQ14 bit to disable inverted input.
13 (R/W1C)	PIQ13	Pin Interrupt 13 No Invert. Set the PINT_INV_CLR.PIQ13 bit to disable inverted input.
12 (R/W1C)	PIQ12	Pin Interrupt 12 No Invert. Set the PINT_INV_CLR.PIQ12 bit to disable inverted input.
11 (R/W1C)	PIQ11	Pin Interrupt 11 No Invert. Set the PINT_INV_CLR.PIQ11 bit to disable inverted input.
10 (R/W1C)	PIQ10	Pin Interrupt 10 No Invert. Set the PINT_INV_CLR.PIQ10 bit to disable inverted input.
9 (R/W1C)	PIQ9	Pin Interrupt 9 No Invert. Set the PINT_INV_CLR.PIQ9 bit to disable inverted input.
8 (R/W1C)	PIQ8	Pin Interrupt 8 No Invert. Set the PINT_INV_CLR.PIQ8 bit to disable inverted input.
7 (R/W1C)	PIQ7	Pin Interrupt 7 No Invert. Set the PINT_INV_CLR.PIQ7 bit to disable inverted input.
6 (R/W1C)	PIQ6	Pin Interrupt 6 No Invert. Set the PINT_INV_CLR.PIQ6 bit to disable inverted input.
5 (R/W1C)	PIQ5	Pin Interrupt 5 No Invert. Set the PINT_INV_CLR.PIQ5 bit to disable inverted input.
4 (R/W1C)	PIQ4	Pin Interrupt 4 No Invert. Set the PINT_INV_CLR.PIQ4 bit to disable inverted input.
3 (R/W1C)	PIQ3	Pin Interrupt 3 No Invert. Set the PINT_INV_CLR.PIQ3 bit to disable inverted input.
2 (R/W1C)	PIQ2	Pin Interrupt 2 No Invert. Set the PINT_INV_CLR.PIQ2 bit to disable inverted input.
1 (R/W1C)	PIQ1	Pin Interrupt 1 No Invert. Set the PINT_INV_CLR.PIQ1 bit to disable inverted input.
0 (R/W1C)	PIQ0	Pin Interrupt 0 No Invert. Set the PINT_INV_CLR.PIQ0 bit to disable inverted input.

PINT Invert Set Register

The PINT_INV_SET register enables inverting input polarity. Writing 1 to a bit in PINT_INV_SET enables an inverter for input on the corresponding pin.

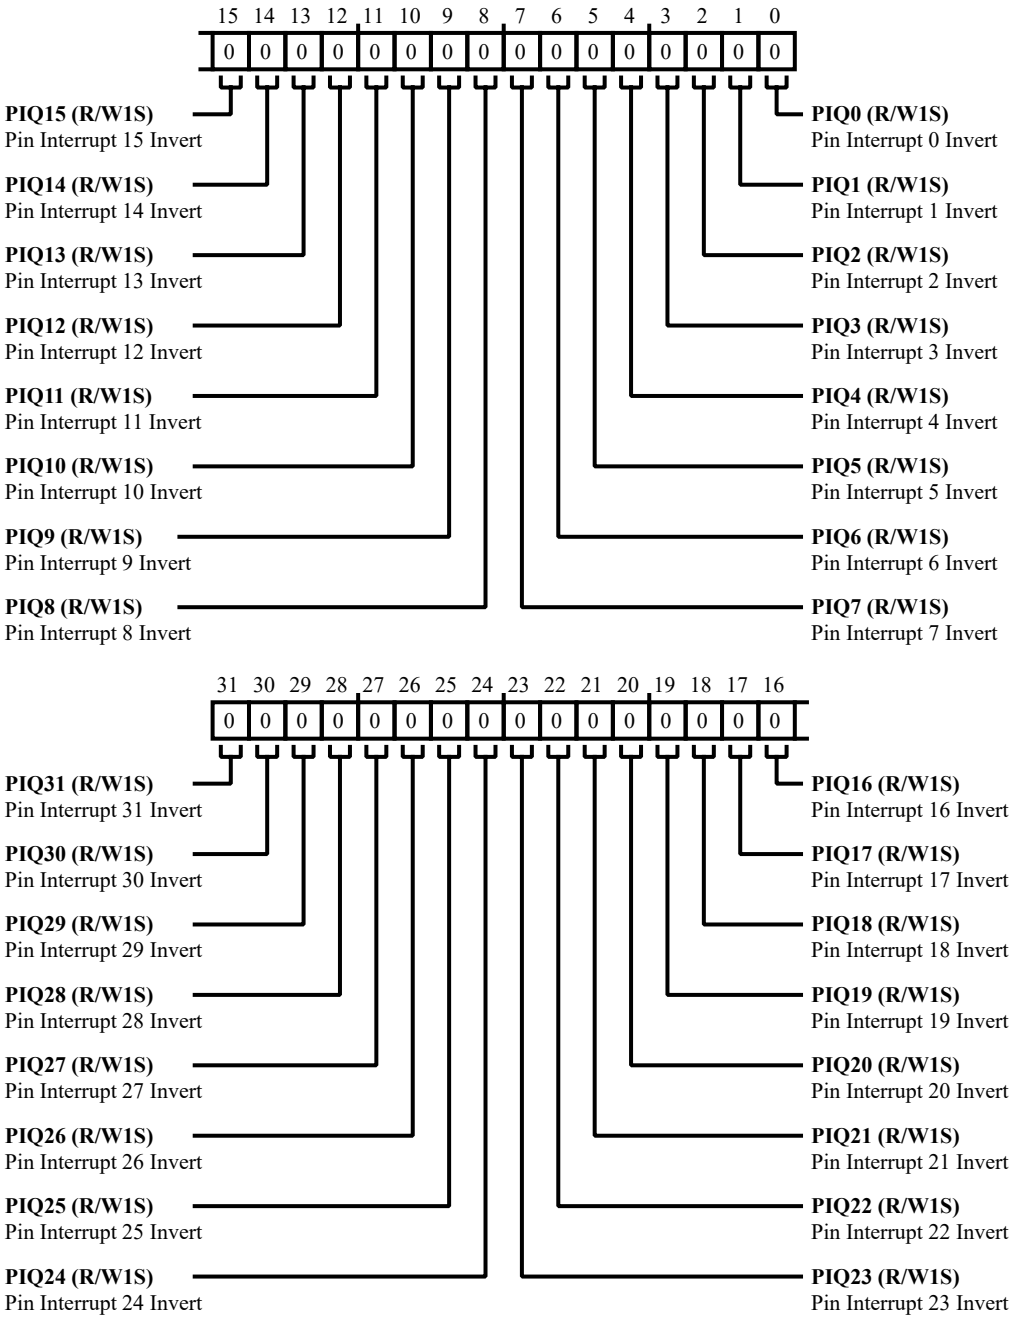

Figure 13-30: PINT_INV_SET Register Diagram

Table 13-34: PINT_INV_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1S)	PIQ31	Pin Interrupt 31 Invert. Set the PINT_INV_SET.PIQ31 bit to enable inverted input.
30 (R/W1S)	PIQ30	Pin Interrupt 30 Invert. Set the PINT_INV_SET.PIQ30 bit to enable inverted input.
29 (R/W1S)	PIQ29	Pin Interrupt 29 Invert. Set the PINT_INV_SET.PIQ29 bit to enable inverted input.
28 (R/W1S)	PIQ28	Pin Interrupt 28 Invert. Set the PINT_INV_SET.PIQ28 bit to enable inverted input.
27 (R/W1S)	PIQ27	Pin Interrupt 27 Invert. Set the PINT_INV_SET.PIQ27 bit to enable inverted input.
26 (R/W1S)	PIQ26	Pin Interrupt 26 Invert. Set the PINT_INV_SET.PIQ26 bit to enable inverted input.
25 (R/W1S)	PIQ25	Pin Interrupt 25 Invert. Set the PINT_INV_SET.PIQ25 bit to enable inverted input.
24 (R/W1S)	PIQ24	Pin Interrupt 24 Invert. Set the PINT_INV_SET.PIQ24 bit to enable inverted input.
23 (R/W1S)	PIQ23	Pin Interrupt 23 Invert. Set the PINT_INV_SET.PIQ23 bit to enable inverted input.
22 (R/W1S)	PIQ22	Pin Interrupt 22 Invert. Set the PINT_INV_SET.PIQ22 bit to enable inverted input.
21 (R/W1S)	PIQ21	Pin Interrupt 21 Invert. Set the PINT_INV_SET.PIQ21 bit to enable inverted input.
20 (R/W1S)	PIQ20	Pin Interrupt 20 Invert. Set the PINT_INV_SET.PIQ20 bit to enable inverted input.
19 (R/W1S)	PIQ19	Pin Interrupt 19 Invert. Set the PINT_INV_SET.PIQ19 bit to enable inverted input.
18 (R/W1S)	PIQ18	Pin Interrupt 18 Invert. Set the PINT_INV_SET.PIQ18 bit to enable inverted input.
17 (R/W1S)	PIQ17	Pin Interrupt 17 Invert. Set the PINT_INV_SET.PIQ17 bit to enable inverted input.
16 (R/W1S)	PIQ16	Pin Interrupt 16 Invert. Set the PINT_INV_SET.PIQ16 bit to enable inverted input.

Table 13-34: PINT_INV_SET Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W1S)	PIQ15	Pin Interrupt 15 Invert. Set the PINT_INV_SET.PIQ15 bit to enable inverted input.
14 (R/W1S)	PIQ14	Pin Interrupt 14 Invert. Set the PINT_INV_SET.PIQ14 bit to enable inverted input.
13 (R/W1S)	PIQ13	Pin Interrupt 13 Invert. Set the PINT_INV_SET.PIQ13 bit to enable inverted input.
12 (R/W1S)	PIQ12	Pin Interrupt 12 Invert. Set the PINT_INV_SET.PIQ12 bit to enable inverted input.
11 (R/W1S)	PIQ11	Pin Interrupt 11 Invert. Set the PINT_INV_SET.PIQ11 bit to enable inverted input.
10 (R/W1S)	PIQ10	Pin Interrupt 10 Invert. Set the PINT_INV_SET.PIQ10 bit to enable inverted input.
9 (R/W1S)	PIQ9	Pin Interrupt 9 Invert. Set the PINT_INV_SET.PIQ9 bit to enable inverted input.
8 (R/W1S)	PIQ8	Pin Interrupt 8 Invert. Set the PINT_INV_SET.PIQ8 bit to enable inverted input.
7 (R/W1S)	PIQ7	Pin Interrupt 7 Invert. Set the PINT_INV_SET.PIQ7 bit to enable inverted input.
6 (R/W1S)	PIQ6	Pin Interrupt 6 Invert. Set the PINT_INV_SET.PIQ6 bit to enable inverted input.
5 (R/W1S)	PIQ5	Pin Interrupt 5 Invert. Set the PINT_INV_SET.PIQ5 bit to enable inverted input.
4 (R/W1S)	PIQ4	Pin Interrupt 4 Invert. Set the PINT_INV_SET.PIQ4 bit to enable inverted input.
3 (R/W1S)	PIQ3	Pin Interrupt 3 Invert. Set the PINT_INV_SET.PIQ3 bit to enable inverted input.
2 (R/W1S)	PIQ2	Pin Interrupt 2 Invert. Set the PINT_INV_SET.PIQ2 bit to enable inverted input.
1 (R/W1S)	PIQ1	Pin Interrupt 1 Invert. Set the PINT_INV_SET.PIQ1 bit to enable inverted input.
0 (R/W1S)	PIQ0	Pin Interrupt 0 Invert. Set the PINT_INV_SET.PIQ0 bit to enable inverted input.

PINT Latch Register

The PINT_LATCH register indicates the interrupt latch status for pin interrupts. When set, an interrupt request is latched. When cleared, there is no interrupt request latched.

Both the PINT_REQ and PINT_LATCH registers indicate whether an interrupt request is latched on the respective pin. The PINT_LATCH register is a latch that operates regardless of the interrupt masks. Bits of the PINT_REQ register depend on the mask register. The PINT_REQ register is a logical AND of the PINT_LATCH register and the interrupt mask.

Having two separate registers here enables the user to interrogate certain pins in polling mode while others work in interrupt mode. The PINT_LATCH registers can be used for edge detection or pin activity detection.

Both registers have W1C behavior. Writing a 1 to either register clears the respective bits in both registers. For interrupt operation, the user may prefer to W1C the PINT_REQ register (address still loaded in Px pointer). In polling mode, it might be cleaner to W1C the PINT_LATCH register.

Whether in edge-sensitive mode or level-sensitive mode, PINT_LATCH bits are never cleared by hardware except at system reset. Even in level-sensitive mode, the PINT_LATCH register functions as latch.

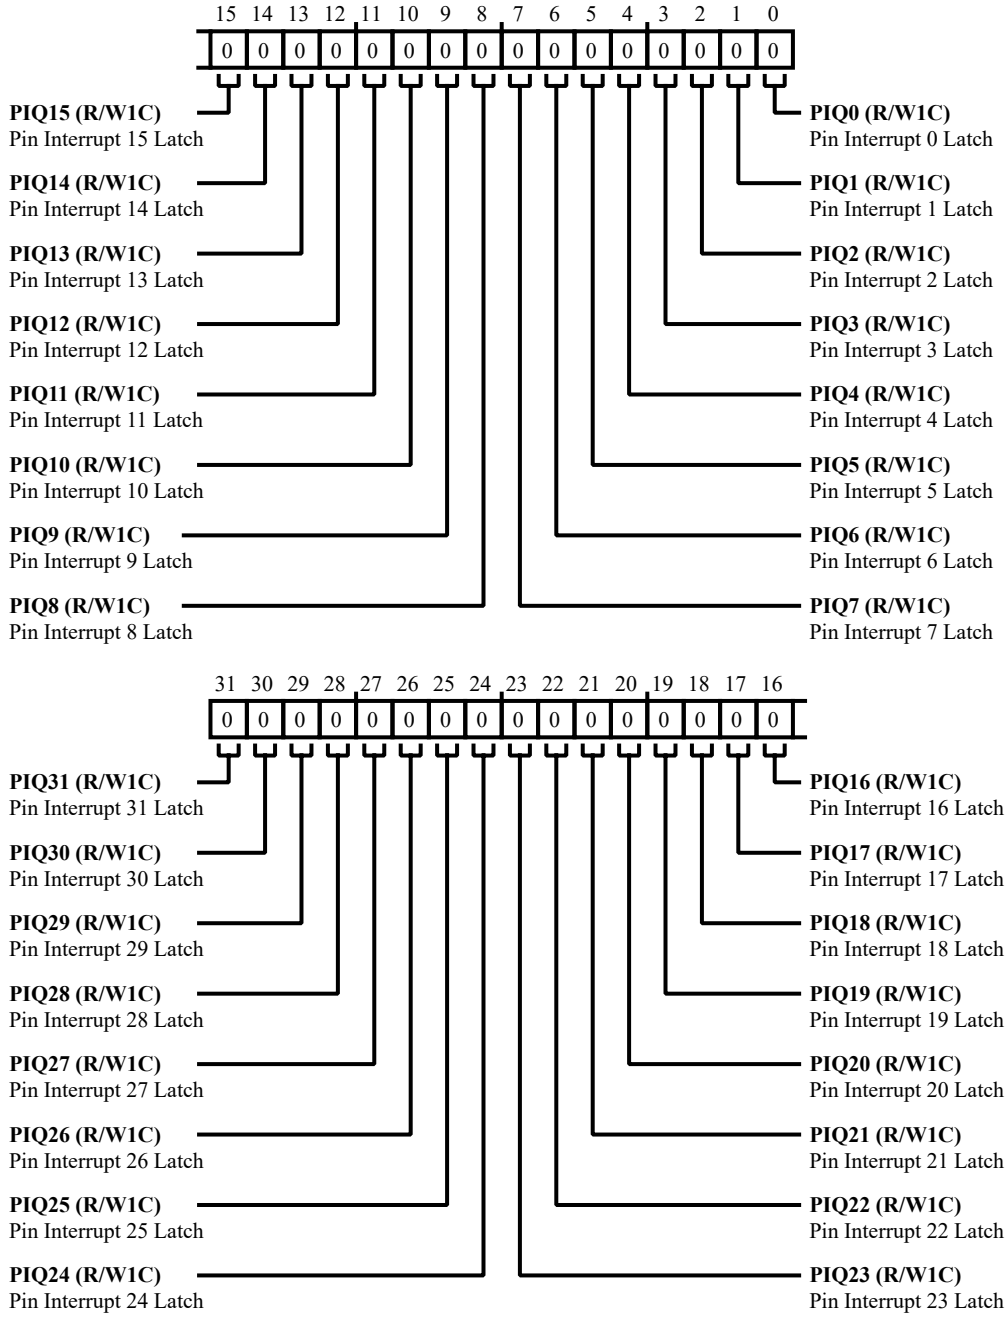

Figure 13-31: PINT_LATCH Register Diagram

Table 13-35: PINT_LATCH Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1C)	PIQ31	Pin Interrupt 31 Latch. If the `PINT_LATCH.PIQ31` bit is set, the request is latched.

Table 13-35: PINT_LATCH Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
30 (R/W1C)	PIQ30	Pin Interrupt 30 Latch. If the `PINT_LATCH.PIQ30` bit is set, the request is latched.
29 (R/W1C)	PIQ29	Pin Interrupt 29 Latch. If the `PINT_LATCH.PIQ29` bit is set, the request is latched.
28 (R/W1C)	PIQ28	Pin Interrupt 28 Latch. If the `PINT_LATCH.PIQ28` bit is set, the request is latched.
27 (R/W1C)	PIQ27	Pin Interrupt 27 Latch. If the `PINT_LATCH.PIQ27` bit is set, the request is latched.
26 (R/W1C)	PIQ26	Pin Interrupt 26 Latch. If the `PINT_LATCH.PIQ26` bit is set, the request is latched.
25 (R/W1C)	PIQ25	Pin Interrupt 25 Latch. If the `PINT_LATCH.PIQ25` bit is set, the request is latched.
24 (R/W1C)	PIQ24	Pin Interrupt 24 Latch. If the `PINT_LATCH.PIQ24` bit is set, the request is latched.
23 (R/W1C)	PIQ23	Pin Interrupt 23 Latch. If the `PINT_LATCH.PIQ23` bit is set, the request is latched.
22 (R/W1C)	PIQ22	Pin Interrupt 22 Latch. If the `PINT_LATCH.PIQ22` bit is set, the request is latched.
21 (R/W1C)	PIQ21	Pin Interrupt 21 Latch. If the `PINT_LATCH.PIQ21` bit is set, the request is latched.
20 (R/W1C)	PIQ20	Pin Interrupt 20 Latch. If the `PINT_LATCH.PIQ20` bit is set, the request is latched.
19 (R/W1C)	PIQ19	Pin Interrupt 19 Latch. If the `PINT_LATCH.PIQ19` bit is set, the request is latched.
18 (R/W1C)	PIQ18	Pin Interrupt 18 Latch. If the `PINT_LATCH.PIQ18` bit is set, the request is latched.
17 (R/W1C)	PIQ17	Pin Interrupt 17 Latch. If the `PINT_LATCH.PIQ17` bit is set, the request is latched.
16 (R/W1C)	PIQ16	Pin Interrupt 16 Latch. If the `PINT_LATCH.PIQ16` bit is set, the request is latched.
15 (R/W1C)	PIQ15	Pin Interrupt 15 Latch. If the `PINT_LATCH.PIQ15` bit is set, the request is latched.

Table 13-35: PINT_LATCH Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/W1C)	PIQ14	Pin Interrupt 14 Latch. If the `PINT_LATCH.PIQ14` bit is set, the request is latched.
13 (R/W1C)	PIQ13	Pin Interrupt 13 Latch. If the `PINT_LATCH.PIQ13` bit is set, the request is latched.
12 (R/W1C)	PIQ12	Pin Interrupt 12 Latch. If the `PINT_LATCH.PIQ12` bit is set, the request is latched.
11 (R/W1C)	PIQ11	Pin Interrupt 11 Latch. If the `PINT_LATCH.PIQ11` bit is set, the request is latched.
10 (R/W1C)	PIQ10	Pin Interrupt 10 Latch. If the `PINT_LATCH.PIQ10` bit is set, the request is latched.
9 (R/W1C)	PIQ9	Pin Interrupt 9 Latch. If the `PINT_LATCH.PIQ9` bit is set, the request is latched.
8 (R/W1C)	PIQ8	Pin Interrupt 8 Latch. If the `PINT_LATCH.PIQ8` bit is set, the request is latched.
7 (R/W1C)	PIQ7	Pin Interrupt 7 Latch. If the `PINT_LATCH.PIQ7` bit is set, the request is latched.
6 (R/W1C)	PIQ6	Pin Interrupt 6 Latch. If the `PINT_LATCH.PIQ6` bit is set, the request is latched.
5 (R/W1C)	PIQ5	Pin Interrupt 5 Latch. If the `PINT_LATCH.PIQ5` bit is set, the request is latched.
4 (R/W1C)	PIQ4	Pin Interrupt 4 Latch. If the `PINT_LATCH.PIQ4` bit is set, the request is latched.
3 (R/W1C)	PIQ3	Pin Interrupt 3 Latch. If the `PINT_LATCH.PIQ3` bit is set, the request is latched.
2 (R/W1C)	PIQ2	Pin Interrupt 2 Latch. If the `PINT_LATCH.PIQ2` bit is set, the request is latched.
1 (R/W1C)	PIQ1	Pin Interrupt 1 Latch. If the `PINT_LATCH.PIQ1` bit is set, the request is latched.
0 (R/W1C)	PIQ0	Pin Interrupt 0 Latch. If the `PINT_LATCH.PIQ0` bit is set, the request is latched.

PINT Mask Clear Register

The PINT_MSK_CLR register permits masking (disabling) of interrupt requests. Writing 1 to a bit in PINT_MSK_CLR masks the corresponding pin interrupt.

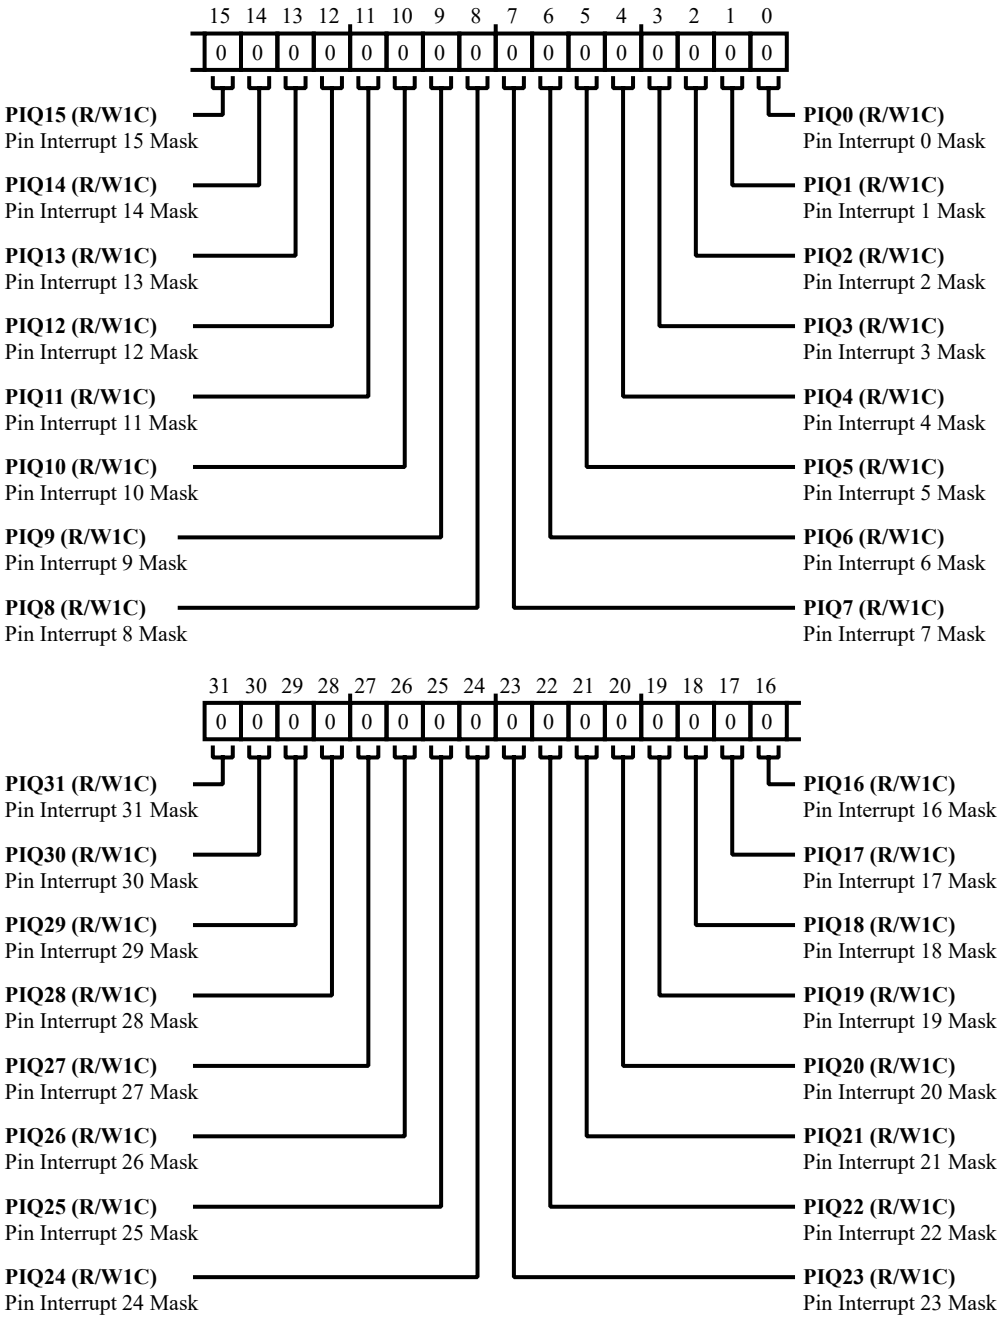

Figure 13-32: PINT_MSK_CLR Register Diagram

Table 13-36: PINT_MSK_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1C)	PIQ31	Pin Interrupt 31 Mask. Set the PINT_MSK_CLR.PIQ31 bit to disable the interrupt.
30 (R/W1C)	PIQ30	Pin Interrupt 30 Mask. Set the PINT_MSK_CLR.PIQ30 bit to disable the interrupt.
29 (R/W1C)	PIQ29	Pin Interrupt 29 Mask. Set the PINT_MSK_CLR.PIQ29 bit to disable the interrupt.
28 (R/W1C)	PIQ28	Pin Interrupt 28 Mask. Set the PINT_MSK_CLR.PIQ28 bit to disable the interrupt.
27 (R/W1C)	PIQ27	Pin Interrupt 27 Mask. Set the PINT_MSK_CLR.PIQ27 bit to disable the interrupt.
26 (R/W1C)	PIQ26	Pin Interrupt 26 Mask. Set the PINT_MSK_CLR.PIQ26 bit to disable the interrupt.
25 (R/W1C)	PIQ25	Pin Interrupt 25 Mask. Set the PINT_MSK_CLR.PIQ25 bit to disable the interrupt.
24 (R/W1C)	PIQ24	Pin Interrupt 24 Mask. Set the PINT_MSK_CLR.PIQ24 bit to disable the interrupt.
23 (R/W1C)	PIQ23	Pin Interrupt 23 Mask. Set the PINT_MSK_CLR.PIQ23 bit to disable the interrupt.
22 (R/W1C)	PIQ22	Pin Interrupt 22 Mask. Set the PINT_MSK_CLR.PIQ22 bit to disable the interrupt.
21 (R/W1C)	PIQ21	Pin Interrupt 21 Mask. Set the PINT_MSK_CLR.PIQ21 bit to disable the interrupt.
20 (R/W1C)	PIQ20	Pin Interrupt 20 Mask. Set the PINT_MSK_CLR.PIQ20 bit to disable the interrupt.
19 (R/W1C)	PIQ19	Pin Interrupt 19 Mask. Set the PINT_MSK_CLR.PIQ19 bit to disable the interrupt.
18 (R/W1C)	PIQ18	Pin Interrupt 18 Mask. Set the PINT_MSK_CLR.PIQ18 bit to disable the interrupt.
17 (R/W1C)	PIQ17	Pin Interrupt 17 Mask. Set the PINT_MSK_CLR.PIQ17 bit to disable the interrupt.
16 (R/W1C)	PIQ16	Pin Interrupt 16 Mask. Set the PINT_MSK_CLR.PIQ16 bit to disable the interrupt.

Table 13-36: PINT_MSK_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W1C)	PIQ15	Pin Interrupt 15 Mask. Set the PINT_MSK_CLR.PIQ15 bit to disable the interrupt.
14 (R/W1C)	PIQ14	Pin Interrupt 14 Mask. Set the PINT_MSK_CLR.PIQ14 bit to disable the interrupt.
13 (R/W1C)	PIQ13	Pin Interrupt 13 Mask. Set the PINT_MSK_CLR.PIQ13 bit to disable the interrupt.
12 (R/W1C)	PIQ12	Pin Interrupt 12 Mask. Set the PINT_MSK_CLR.PIQ12 bit to disable the interrupt.
11 (R/W1C)	PIQ11	Pin Interrupt 11 Mask. Set the PINT_MSK_CLR.PIQ11 bit to disable the interrupt.
10 (R/W1C)	PIQ10	Pin Interrupt 10 Mask. Set the PINT_MSK_CLR.PIQ10 bit to disable the interrupt.
9 (R/W1C)	PIQ9	Pin Interrupt 9 Mask. Set the PINT_MSK_CLR.PIQ9 bit to disable the interrupt.
8 (R/W1C)	PIQ8	Pin Interrupt 8 Mask. Set the PINT_MSK_CLR.PIQ8 bit to disable the interrupt.
7 (R/W1C)	PIQ7	Pin Interrupt 7 Mask. Set the PINT_MSK_CLR.PIQ7 bit to disable the interrupt.
6 (R/W1C)	PIQ6	Pin Interrupt 6 Mask. Set the PINT_MSK_CLR.PIQ6 bit to disable the interrupt.
5 (R/W1C)	PIQ5	Pin Interrupt 5 Mask. Set the PINT_MSK_CLR.PIQ5 bit to disable the interrupt.
4 (R/W1C)	PIQ4	Pin Interrupt 4 Mask. Set the PINT_MSK_CLR.PIQ4 bit to disable the interrupt.
3 (R/W1C)	PIQ3	Pin Interrupt 3 Mask. Set the PINT_MSK_CLR.PIQ3 bit to disable the interrupt.
2 (R/W1C)	PIQ2	Pin Interrupt 2 Mask. Set the PINT_MSK_CLR.PIQ2 bit to disable the interrupt.
1 (R/W1C)	PIQ1	Pin Interrupt 1 Mask. Set the PINT_MSK_CLR.PIQ1 bit to disable the interrupt.
0 (R/W1C)	PIQ0	Pin Interrupt 0 Mask. Set the PINT_MSK_CLR.PIQ0 bit to disable the interrupt.

PINT Mask Set Register

The PINT_MSK_SET register permits unmasking (enabling) of interrupt requests. Writing 1 to a bit in PINT_MSK_SET unmasks the corresponding pin interrupt.

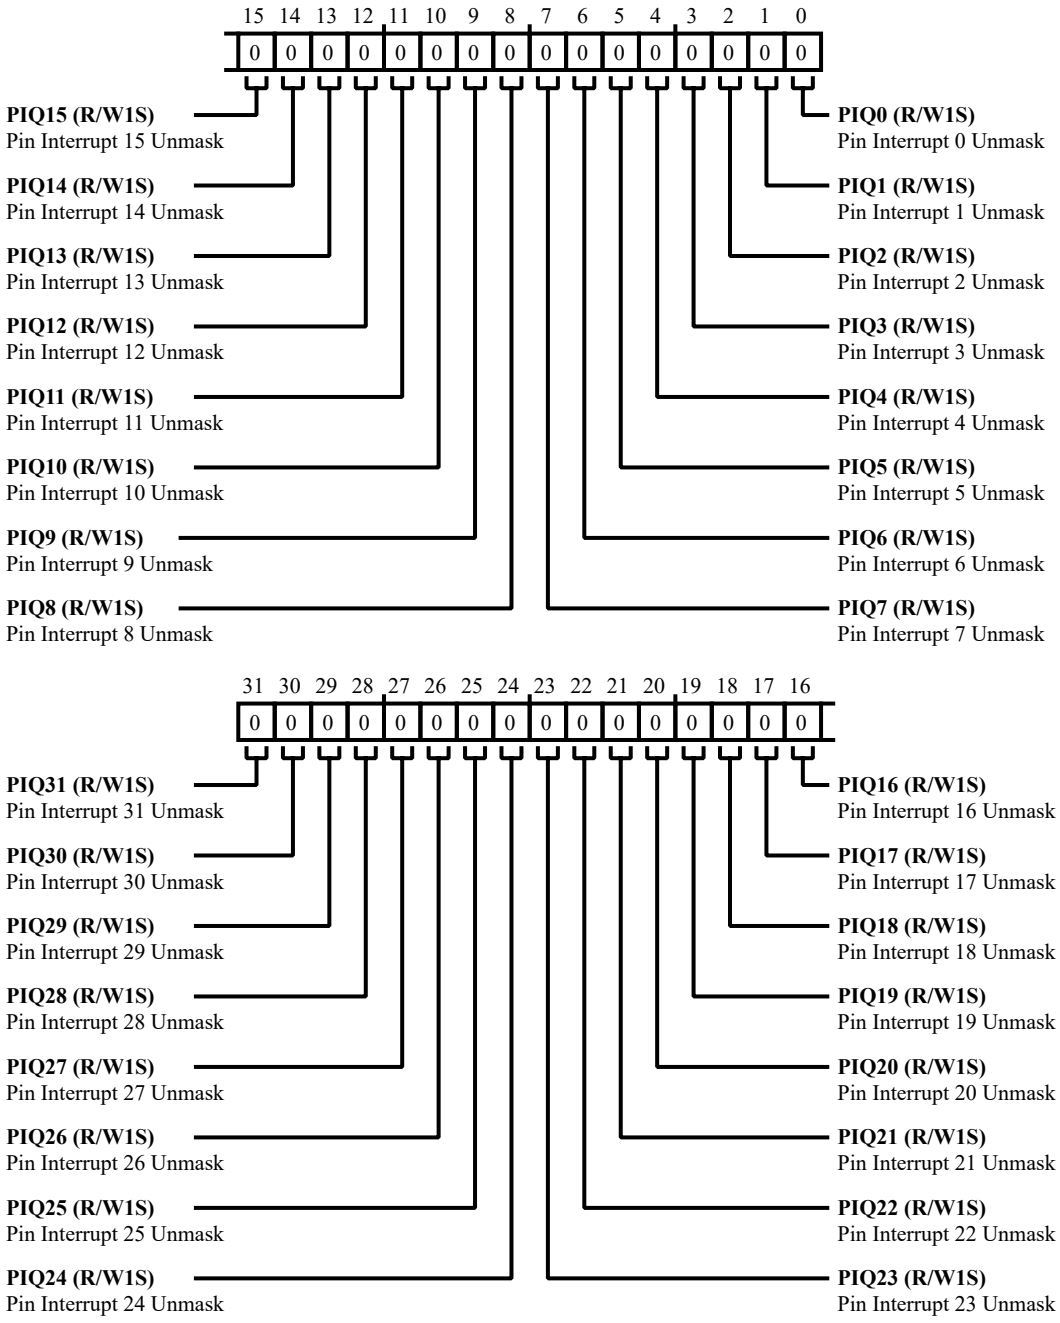

Figure 13-33: PINT_MSK_SET Register Diagram

Table 13-37: PINT_MSK_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1S)	PIQ31	Pin Interrupt 31 Unmask. Set the PINT_MSK_SET.PIQ31 bit to enable the interrupt.
30 (R/W1S)	PIQ30	Pin Interrupt 30 Unmask. Set the PINT_MSK_SET.PIQ30 bit to enable the interrupt.
29 (R/W1S)	PIQ29	Pin Interrupt 29 Unmask. Set the PINT_MSK_SET.PIQ29 bit to enable the interrupt.
28 (R/W1S)	PIQ28	Pin Interrupt 28 Unmask. Set the PINT_MSK_SET.PIQ28 bit to enable the interrupt.
27 (R/W1S)	PIQ27	Pin Interrupt 27 Unmask. Set the PINT_MSK_SET.PIQ27 bit to enable the interrupt.
26 (R/W1S)	PIQ26	Pin Interrupt 26 Unmask. Set the PINT_MSK_SET.PIQ26 bit to enable the interrupt.
25 (R/W1S)	PIQ25	Pin Interrupt 25 Unmask. Set the PINT_MSK_SET.PIQ25 bit to enable the interrupt.
24 (R/W1S)	PIQ24	Pin Interrupt 24 Unmask. Set the PINT_MSK_SET.PIQ24 bit to enable the interrupt.
23 (R/W1S)	PIQ23	Pin Interrupt 23 Unmask. Set the PINT_MSK_SET.PIQ23 bit to enable the interrupt.
22 (R/W1S)	PIQ22	Pin Interrupt 22 Unmask. Set the PINT_MSK_SET.PIQ22 bit to enable the interrupt.
21 (R/W1S)	PIQ21	Pin Interrupt 21 Unmask. Set the PINT_MSK_SET.PIQ21 bit to enable the interrupt.
20 (R/W1S)	PIQ20	Pin Interrupt 20 Unmask. Set the PINT_MSK_SET.PIQ20 bit to enable the interrupt.
19 (R/W1S)	PIQ19	Pin Interrupt 19 Unmask. Set the PINT_MSK_SET.PIQ19 bit to enable the interrupt.
18 (R/W1S)	PIQ18	Pin Interrupt 18 Unmask. Set the PINT_MSK_SET.PIQ18 bit to enable the interrupt.
17 (R/W1S)	PIQ17	Pin Interrupt 17 Unmask. Set the PINT_MSK_SET.PIQ17 bit to enable the interrupt.
16 (R/W1S)	PIQ16	Pin Interrupt 16 Unmask. Set the PINT_MSK_SET.PIQ16 bit to enable the interrupt.

Table 13-37: PINT_MSK_SET Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W1S)	PIQ15	Pin Interrupt 15 Unmask. Set the `PINT_MSK_SET.PIQ15` bit to enable the interrupt.
14 (R/W1S)	PIQ14	Pin Interrupt 14 Unmask. Set the `PINT_MSK_SET.PIQ14` bit to enable the interrupt.
13 (R/W1S)	PIQ13	Pin Interrupt 13 Unmask. Set the `PINT_MSK_SET.PIQ13` bit to enable the interrupt.
12 (R/W1S)	PIQ12	Pin Interrupt 12 Unmask. Set the `PINT_MSK_SET.PIQ12` bit to enable the interrupt.
11 (R/W1S)	PIQ11	Pin Interrupt 11 Unmask. Set the `PINT_MSK_SET.PIQ11` bit to enable the interrupt.
10 (R/W1S)	PIQ10	Pin Interrupt 10 Unmask. Set the `PINT_MSK_SET.PIQ10` bit to enable the interrupt.
9 (R/W1S)	PIQ9	Pin Interrupt 9 Unmask. Set the `PINT_MSK_SET.PIQ9` bit to enable the interrupt.
8 (R/W1S)	PIQ8	Pin Interrupt 8 Unmask. Set the `PINT_MSK_SET.PIQ8` bit to enable the interrupt.
7 (R/W1S)	PIQ7	Pin Interrupt 7 Unmask. Set the `PINT_MSK_SET.PIQ7` bit to enable the interrupt.
6 (R/W1S)	PIQ6	Pin Interrupt 6 Unmask. Set the `PINT_MSK_SET.PIQ6` bit to enable the interrupt.
5 (R/W1S)	PIQ5	Pin Interrupt 5 Unmask. Set the `PINT_MSK_SET.PIQ5` bit to enable the interrupt.
4 (R/W1S)	PIQ4	Pin Interrupt 4 Unmask. Set the `PINT_MSK_SET.PIQ4` bit to enable the interrupt.
3 (R/W1S)	PIQ3	Pin Interrupt 3 Unmask. Set the `PINT_MSK_SET.PIQ3` bit to enable the interrupt.
2 (R/W1S)	PIQ2	Pin Interrupt 2 Unmask. Set the `PINT_MSK_SET.PIQ2` bit to enable the interrupt.
1 (R/W1S)	PIQ1	Pin Interrupt 1 Unmask. Set the `PINT_MSK_SET.PIQ1` bit to enable the interrupt.
0 (R/W1S)	PIQ0	Pin Interrupt 0 Unmask. Set the `PINT_MSK_SET.PIQ0` bit to enable the interrupt.

PINT Pin State Register

When a half port is assigned to a byte in any PINT block, the state of the eight pins (regardless of GPIO or function, input or output) can be seen in the PINT_PINSTATE register. While neither input nor output drivers of the pin are enabled, reads of the pin state in PINT_PINSTATE return zero. The PINT_PINSTATE register reports the inverted state of the pin if the signal inverter is activated by the PINT_INV_SET register. The inverter can be enabled on an individual bit-by-bit basis. Every bit in the PINT_INV_SET and PINT_INV_CLR register pair represents a pin signal.

The pin interrupt pin state registers enable the service routine to read the current state of the pin without reading from GPIO space. If there was an edge-sensitive interrupt, the service routine can check whether the state of the pin is still high or turned low.

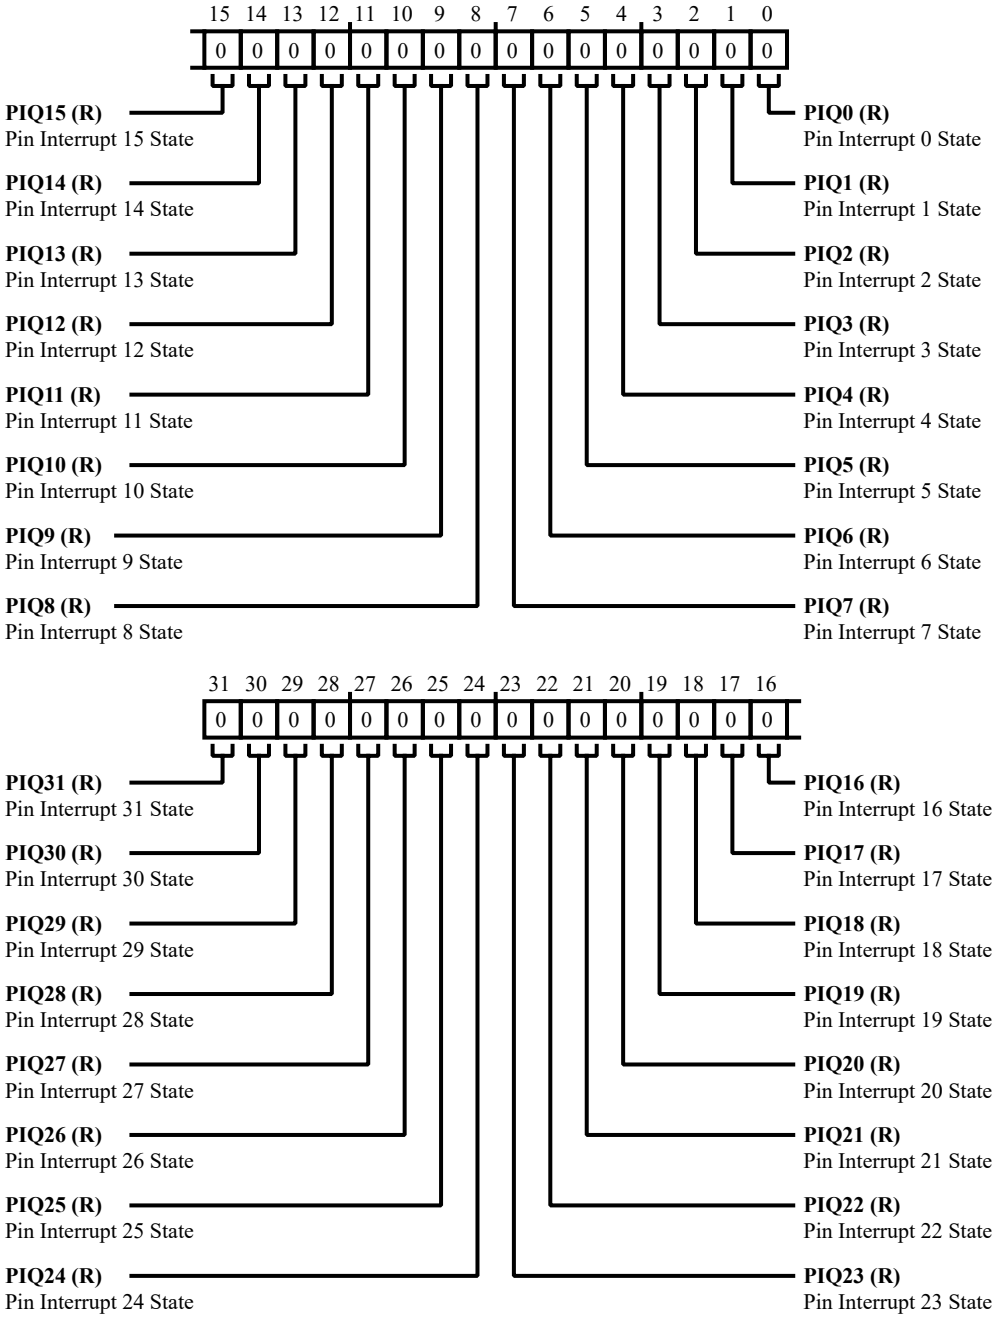

Figure 13-34: PINT_PINSTATE Register Diagram

Table 13-38: PINT_PINSTATE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/NW)	PIQ31	Pin Interrupt 31 State. A read of the `PINT_PINSTATE.PIQ31` bit returns the pin state.

Table 13-38: PINT_PINSTATE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
30 (R/NW)	PIQ30	Pin Interrupt 30 State. A read of the PINT_PINSTATE.PIQ30 bit returns the pin state.
29 (R/NW)	PIQ29	Pin Interrupt 29 State. A read of the PINT_PINSTATE.PIQ29 bit returns the pin state.
28 (R/NW)	PIQ28	Pin Interrupt 28 State. A read of the PINT_PINSTATE.PIQ28 bit returns the pin state.
27 (R/NW)	PIQ27	Pin Interrupt 27 State. A read of the PINT_PINSTATE.PIQ27 bit returns the pin state.
26 (R/NW)	PIQ26	Pin Interrupt 26 State. A read of the PINT_PINSTATE.PIQ26 bit returns the pin state.
25 (R/NW)	PIQ25	Pin Interrupt 25 State. A read of the PINT_PINSTATE.PIQ25 bit returns the pin state.
24 (R/NW)	PIQ24	Pin Interrupt 24 State. A read of the PINT_PINSTATE.PIQ24 bit returns the pin state.
23 (R/NW)	PIQ23	Pin Interrupt 23 State. A read of the PINT_PINSTATE.PIQ23 bit returns the pin state.
22 (R/NW)	PIQ22	Pin Interrupt 22 State. A read of the PINT_PINSTATE.PIQ22 bit returns the pin state.
21 (R/NW)	PIQ21	Pin Interrupt 21 State. A read of the PINT_PINSTATE.PIQ21 bit returns the pin state.
20 (R/NW)	PIQ20	Pin Interrupt 20 State. A read of the PINT_PINSTATE.PIQ20 bit returns the pin state.
19 (R/NW)	PIQ19	Pin Interrupt 19 State. A read of the PINT_PINSTATE.PIQ19 bit returns the pin state.
18 (R/NW)	PIQ18	Pin Interrupt 18 State. A read of the PINT_PINSTATE.PIQ18 bit returns the pin state.
17 (R/NW)	PIQ17	Pin Interrupt 17 State. A read of the PINT_PINSTATE.PIQ17 bit returns the pin state.
16 (R/NW)	PIQ16	Pin Interrupt 16 State. A read of the PINT_PINSTATE.PIQ16 bit returns the pin state.
15 (R/NW)	PIQ15	Pin Interrupt 15 State. A read of the PINT_PINSTATE.PIQ15 bit returns the pin state.

Table 13-38: PINT_PINSTATE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/NW)	PIQ14	Pin Interrupt 14 State. A read of the PINT_PINSTATE.PIQ14 bit returns the pin state.
13 (R/NW)	PIQ13	Pin Interrupt 13 State. A read of the PINT_PINSTATE.PIQ13 bit returns the pin state.
12 (R/NW)	PIQ12	Pin Interrupt 12 State. A read of the PINT_PINSTATE.PIQ12 bit returns the pin state.
11 (R/NW)	PIQ11	Pin Interrupt 11 State. A read of the PINT_PINSTATE.PIQ11 bit returns the pin state.
10 (R/NW)	PIQ10	Pin Interrupt 10 State. A read of the PINT_PINSTATE.PIQ10 bit returns the pin state.
9 (R/NW)	PIQ9	Pin Interrupt 9 State. A read of the PINT_PINSTATE.PIQ9 bit returns the pin state.
8 (R/NW)	PIQ8	Pin Interrupt 8 State. A read of the PINT_PINSTATE.PIQ8 bit returns the pin state.
7 (R/NW)	PIQ7	Pin Interrupt 7 State. A read of the PINT_PINSTATE.PIQ7 bit returns the pin state.
6 (R/NW)	PIQ6	Pin Interrupt 6 State. A read of the PINT_PINSTATE.PIQ6 bit returns the pin state.
5 (R/NW)	PIQ5	Pin Interrupt 5 State. A read of the PINT_PINSTATE.PIQ5 bit returns the pin state.
4 (R/NW)	PIQ4	Pin Interrupt 4 State. A read of the PINT_PINSTATE.PIQ4 bit returns the pin state.
3 (R/NW)	PIQ3	Pin Interrupt 3 State. A read of the PINT_PINSTATE.PIQ3 bit returns the pin state.
2 (R/NW)	PIQ2	Pin Interrupt 2 State. A read of the PINT_PINSTATE.PIQ2 bit returns the pin state.
1 (R/NW)	PIQ1	Pin Interrupt 1 State. A read of the PINT_PINSTATE.PIQ1 bit returns the pin state.
0 (R/NW)	PIQ0	Pin Interrupt 0 State. A read of the PINT_PINSTATE.PIQ0 bit returns the pin state.

PINT Request Register

The PINT_REQ register indicates the interrupt request status for pin interrupts. When set, an interrupt request is pending. When cleared, there is no interrupt request pending.

Both the PINT_REQ and PINT_LATCH registers indicate whether an interrupt request is latched on the respective pin. The PINT_LATCH register is a latch that operates regardless of the interrupt masks. Bits of the PINT_REQ register depend on the mask register. The PINT_REQ register is a logical AND of the PINT_LATCH register and the interrupt mask.

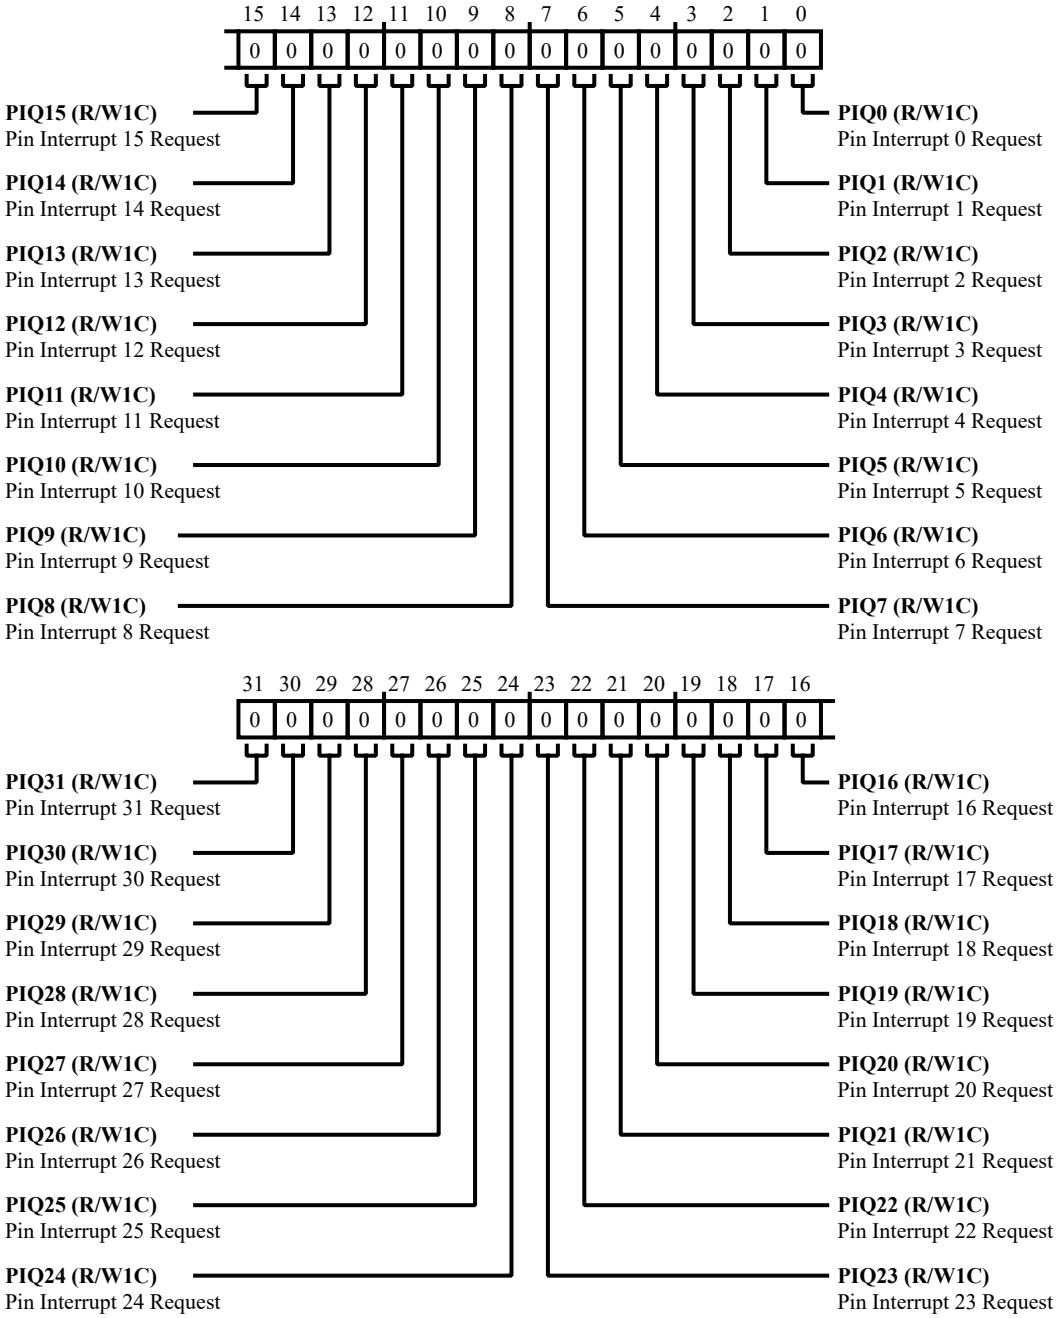

Figure 13-35: PINT_REQ Register Diagram

Table 13-39: PINT_REQ Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1C)	PIQ31	Pin Interrupt 31 Request. If the `PINT_REQ.PIQ31` bit is set, a request is pending.

Table 13-39: PINT_REQ Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
30 (R/W1C)	PIQ30	Pin Interrupt 30 Request. If the PINT_REQ.PIQ30 bit is set, a request is pending.
29 (R/W1C)	PIQ29	Pin Interrupt 29 Request. If the PINT_REQ.PIQ29 bit is set, a request is pending.
28 (R/W1C)	PIQ28	Pin Interrupt 28 Request. If the PINT_REQ.PIQ28 bit is set, a request is pending.
27 (R/W1C)	PIQ27	Pin Interrupt 27 Request. If the PINT_REQ.PIQ27 bit is set, a request is pending.
26 (R/W1C)	PIQ26	Pin Interrupt 26 Request. If the PINT_REQ.PIQ26 bit is set, a request is pending.
25 (R/W1C)	PIQ25	Pin Interrupt 25 Request. If the PINT_REQ.PIQ25 bit is set, a request is pending.
24 (R/W1C)	PIQ24	Pin Interrupt 24 Request. If the PINT_REQ.PIQ24 bit is set, a request is pending.
23 (R/W1C)	PIQ23	Pin Interrupt 23 Request. If the PINT_REQ.PIQ23 bit is set, a request is pending.
22 (R/W1C)	PIQ22	Pin Interrupt 22 Request. If the PINT_REQ.PIQ22 bit is set, a request is pending.
21 (R/W1C)	PIQ21	Pin Interrupt 21 Request. If the PINT_REQ.PIQ21 bit is set, a request is pending.
20 (R/W1C)	PIQ20	Pin Interrupt 20 Request. If the PINT_REQ.PIQ20 bit is set, a request is pending.
19 (R/W1C)	PIQ19	Pin Interrupt 19 Request. If the PINT_REQ.PIQ19 bit is set, a request is pending.
18 (R/W1C)	PIQ18	Pin Interrupt 18 Request. If the PINT_REQ.PIQ18 bit is set, a request is pending.
17 (R/W1C)	PIQ17	Pin Interrupt 17 Request. If the PINT_REQ.PIQ17 bit is set, a request is pending.
16 (R/W1C)	PIQ16	Pin Interrupt 16 Request. If the PINT_REQ.PIQ16 bit is set, a request is pending.
15 (R/W1C)	PIQ15	Pin Interrupt 15 Request. If the PINT_REQ.PIQ15 bit is set, a request is pending.

Table 13-39: PINT_REQ Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/W1C)	PIQ14	Pin Interrupt 14 Request. If the `PINT_REQ.PIQ14` bit is set, a request is pending.
13 (R/W1C)	PIQ13	Pin Interrupt 13 Request. If the `PINT_REQ.PIQ13` bit is set, a request is pending.
12 (R/W1C)	PIQ12	Pin Interrupt 12 Request. If the `PINT_REQ.PIQ12` bit is set, a request is pending.
11 (R/W1C)	PIQ11	Pin Interrupt 11 Request. If the `PINT_REQ.PIQ11` bit is set, a request is pending.
10 (R/W1C)	PIQ10	Pin Interrupt 10 Request. If the `PINT_REQ.PIQ10` bit is set, a request is pending.
9 (R/W1C)	PIQ9	Pin Interrupt 9 Request. If the `PINT_REQ.PIQ9` bit is set, a request is pending.
8 (R/W1C)	PIQ8	Pin Interrupt 8 Request. If the `PINT_REQ.PIQ8` bit is set, a request is pending.
7 (R/W1C)	PIQ7	Pin Interrupt 7 Request. If the `PINT_REQ.PIQ7` bit is set, a request is pending.
6 (R/W1C)	PIQ6	Pin Interrupt 6 Request. If the `PINT_REQ.PIQ6` bit is set, a request is pending.
5 (R/W1C)	PIQ5	Pin Interrupt 5 Request. If the `PINT_REQ.PIQ5` bit is set, a request is pending.
4 (R/W1C)	PIQ4	Pin Interrupt 4 Request. If the `PINT_REQ.PIQ4` bit is set, a request is pending.
3 (R/W1C)	PIQ3	Pin Interrupt 3 Request. If the `PINT_REQ.PIQ3` bit is set, a request is pending.
2 (R/W1C)	PIQ2	Pin Interrupt 2 Request. If the `PINT_REQ.PIQ2` bit is set, a request is pending.
1 (R/W1C)	PIQ1	Pin Interrupt 1 Request. If the `PINT_REQ.PIQ1` bit is set, a request is pending.
0 (R/W1C)	PIQ0	Pin Interrupt 0 Request. If the `PINT_REQ.PIQ0` bit is set, a request is pending.

ADSP-2184x PADS Register Descriptions

Pads Controller (PADS) contains the following registers.

Table 13-40: ADSP-2184x PADS Register List

Name	Description
PADS_DAI0_0_DS	DAI0 Pins 1 to 8 Drive Strength Control Register
PADS_DAI0_1_DS	DAI0 Pins 9 to 16 Drive Strength Control Register
PADS_DAI0_2_DS	DAI0 Pins 17 to 20 Drive Strength Control Register
PADS_DAI0_IE	DAI0 Port Input Enable Control Register
PADS_DAI0_PE	DAI0 Pull Enable Register
PADS_DAI0_PS	DAI0 Pull Selector Register
PADS_DAI0_SL	DAI0 Slew Rate Control Register
PADS_DAI0_SPU	DAI0 Strong Pull Up Control Register
PADS_DAI1_0_DS	DAI1 Pins 1 to 8 Drive Strength Control Register
PADS_DAI1_1_DS	DAI1 Pins 9 to 16 Drive Strength Control Register
PADS_DAI1_2_DS	DAI1 Pins 17 to 20 Drive Strength Control Register
PADS_DAI1_IE	DAI1 Port Input Enable Control Register
PADS_DAI1_PE	DAI1 Pull Enable Register
PADS_DAI1_PS	DAI1 Pull Selector Register
PADS_DAI1_SL	DAI1 Slew Rate Control Register
PADS_DAI1_SPU	DAI1 Strong Pull up Control Register
PADS_NONPORTS_CTL	Non-GPIO Control Register
PADS_NONPORTS_DS	Non-GPIO Drive Strength Register
PADS_NONPORTS_DS_1	EMAC Non-GPIO Drive Strength Register
PADS_OTPC_BOOT_STAT	OTPC Boot Status Register
PADS_PCFG0	Peripheral PAD Configuration 0 Register
PADS_PCFG1	Peripheral Configuration 1 Register
PADS_PORTA0_DS	PORTA Pins 0 to 7 Drive Strength Control Register
PADS_PORTA1_DS	PORTA Pins 8 to 15 Drive Strength Control Register
PADS_PORTB0_DS	PORTB Pins 0 to 7 Drive Strength Control Register
PADS_PORTB1_DS	PORTB Pins 8 to 15 Drive Strength Control Register
PADS_PORTC0_DS	PORTC Pins 0 to 7 Drive Strength Control Register
PADS_PORTC1_DS	PORTC Pins 8 to 15 Drive Strength Control Register
PADS_PORTD0_DS	PORTD Pins 0 to 7 Drive Strength Control Register

Table 13-40: ADSP-2184x PADS Register List (Continued)

Name	Description
PADS_PORTD1_DS	PORTD Pins 8 to 15 Drive Strength Control Register
PADS_PORTE0_DS	PORTE Pins 0 to 7 Drive Strength Control Register
PADS_PORTE1_DS	PORTE Pins 8 to 15 Drive Strength Control Register
PADS_PORTF0_DS	PORTF Pins 0 to 7 Drive Strength Control Register
PADS_PORTF1_DS	PORTF Pins 8 to 15 Drive Strength Control Register
PADS_PORTG0_DS	PORTG Pins 0 to 7 Drive Strength Control Register
PADS_PORTG1_DS	PORTG Pins 8 to 15 Drive Strength Control Register
PADS_PORTH0_DS	PORTH Pins 0 to 7 Drive Strength Control Register
PADS_PORTH1_DS	PORTH Pins 8 and 9 Drive Strength Control Register
PADS_PORT_AB_PE	PORTA and PORTB Pull Enable Register
PADS_PORT_AB_PS	PORTA and PORTB Pull Selector Register
PADS_PORT_AB_SL	PORTA and PORTB Slew Rate Control Register
PADS_PORT_AB_SPU	PORTA and PORTB Strong Pull Up Control Register
PADS_PORT_CD_PE	PORTC and PORTD Pull Enable Register
PADS_PORT_CD_PS	PORTC and PORTD Pull Selector Register
PADS_PORT_CD_SL	PORTC and PORTD Slew Rate Control Register
PADS_PORT_CD_SPU	PORTC and PORTD Strong Pull Up Control Register
PADS_PORT_EF_PE	PORTE and PORTF Pull Enable Register
PADS_PORT_EF_PS	PORTE and PORTF Pull Selector Register
PADS_PORT_EF_SL	PORTE and PORTF Slew Rate Control Register
PADS_PORT_EF_SPU	PORTE and PORTF Strong Pull Up Control Register
PADS_PORT_GH_PE	PORTG and PORTH Pull Enable Register
PADS_PORT_GH_PS	PORTG and PORTH Pull Selector Register
PADS_PORT_GH_SL	PORTG and PORTH Slew Rate Control Register
PADS_PORT_GH_SPU	PORTG and PORTH Strong Pull Up Control Register
PADS_STAT	Status Register

DAI0 Pins 1 to 8 Drive Strength Control Register

The default drive strength is 1001. Do not change this value.

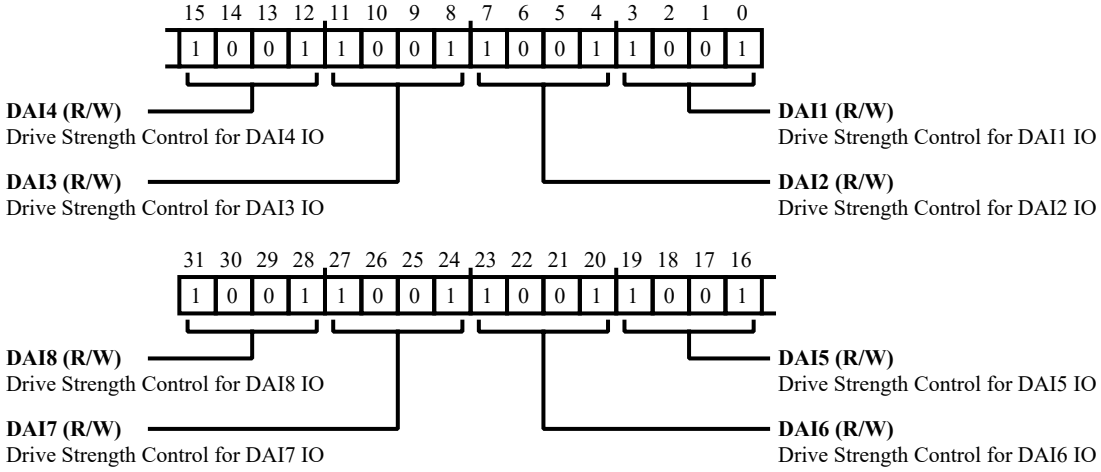

Figure 13-36: PADS_DAI0_0_DS Register Diagram

Table 13-41: PADS_DAI0_0_DS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:28 (R/W)	DAI8	Drive Strength Control for DAI8 IO.
27:24 (R/W)	DAI7	Drive Strength Control for DAI7 IO.
23:20 (R/W)	DAI6	Drive Strength Control for DAI6 IO.
19:16 (R/W)	DAI5	Drive Strength Control for DAI5 IO.
15:12 (R/W)	DAI4	Drive Strength Control for DAI4 IO.
11:8 (R/W)	DAI3	Drive Strength Control for DAI3 IO.
7:4 (R/W)	DAI2	Drive Strength Control for DAI2 IO.
3:0 (R/W)	DAI1	Drive Strength Control for DAI1 IO.

DAI0 Pins 9 to 16 Drive Strength Control Register

The default drive strength is 1001. Do not change this value.

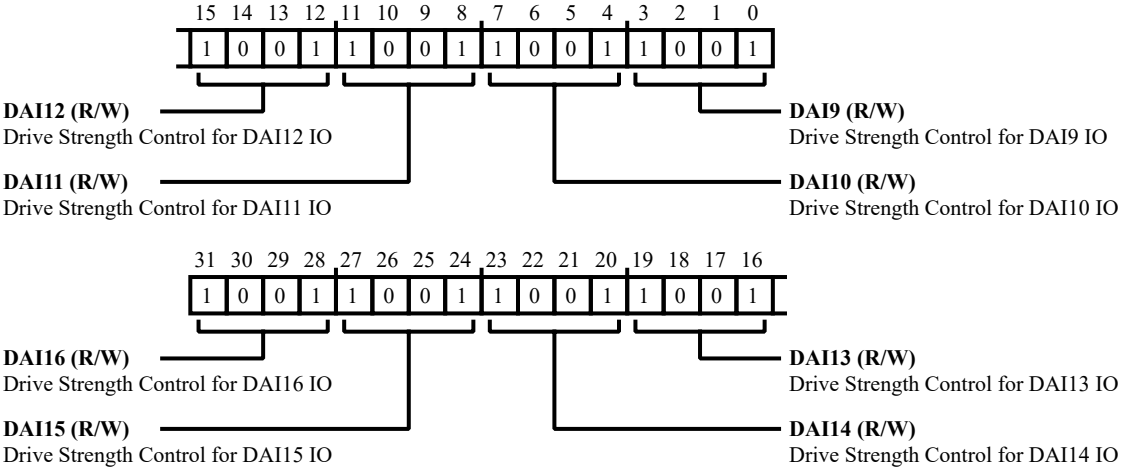

Figure 13-37: PADS_DAI0_1_DS Register Diagram

Table 13-42: PADS_DAI0_1_DS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:28 (R/W)	DAI16	Drive Strength Control for DAI16 IO.
27:24 (R/W)	DAI15	Drive Strength Control for DAI15 IO.
23:20 (R/W)	DAI14	Drive Strength Control for DAI14 IO.
19:16 (R/W)	DAI13	Drive Strength Control for DAI13 IO.
15:12 (R/W)	DAI12	Drive Strength Control for DAI12 IO.
11:8 (R/W)	DAI11	Drive Strength Control for DAI11 IO.
7:4 (R/W)	DAI10	Drive Strength Control for DAI10 IO.
3:0 (R/W)	DAI9	Drive Strength Control for DAI9 IO.

DAI0 Pins 17 to 20 Drive Strength Control Register

The default drive strength is 1001. Do not change this value.

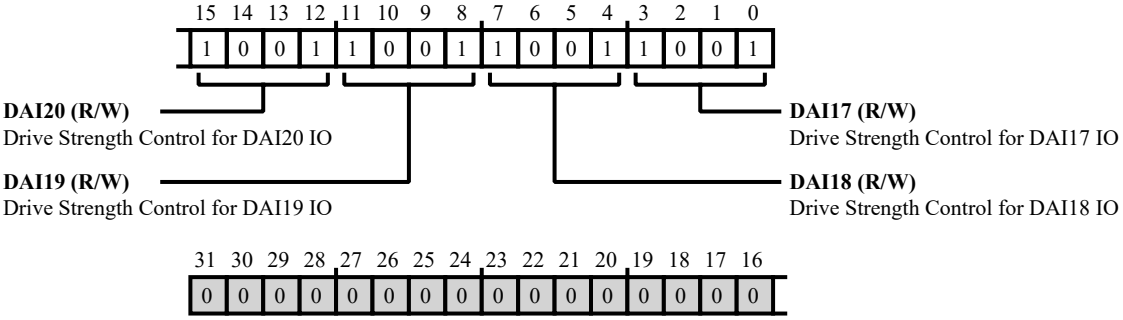

Figure 13-38: PADS_DAI0_2_DS Register Diagram

Table 13-43: PADS_DAI0_2_DS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:12 (R/W)	DAI20	Drive Strength Control for DAI20 IO.
11:8 (R/W)	DAI19	Drive Strength Control for DAI19 IO.
7:4 (R/W)	DAI18	Drive Strength Control for DAI18 IO.
3:0 (R/W)	DAI17	Drive Strength Control for DAI17 IO.

DAI0 Port Input Enable Control Register

The PADS_DAI0_IE register configures input enable control of the DAI0 (20 pins) pads. If =0 implies input buffer disable and if =1 implies enable.

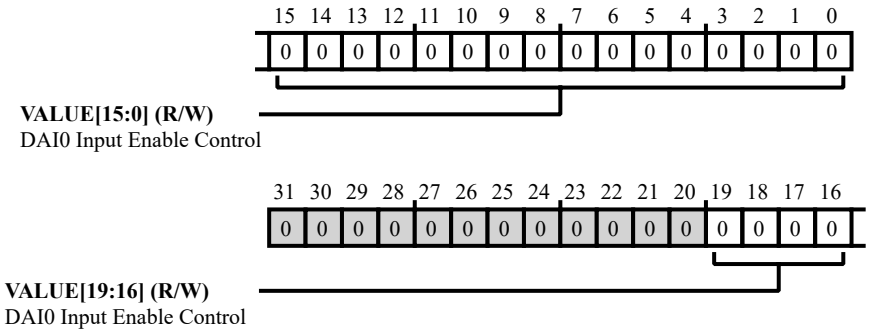

Figure 13-39: PADS_DAI0_IE Register Diagram

Table 13-54: PADS_DAI1_PS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19 (R/W)	DAI20_PS	Pull Selector for DAI20 IO.
18 (R/W)	DAI19_PS	Pull Selector for DAI19 IO.
17 (R/W)	DAI18_PS	Pull Selector for DAI18 IO.
16 (R/W)	DAI17_PS	Pull Selector for DAI17 IO.

Table 13-54: PADS_DAI1_PS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W)	DAI16_PS	Pull Selector for DAI16 IO.
14 (R/W)	DAI15_PS	Pull Selector for DAI15 IO.
13 (R/W)	DAI14_PS	Pull Selector for DAI14 IO.
12 (R/W)	DAI13_PS	Pull Selector for DAI13 IO.
11 (R/W)	DAI12_PS	Pull Selector for DAI12 IO.
10 (R/W)	DAI11_PS	Pull Selector for DAI11 IO.
9 (R/W)	DAI10_PS	Pull Selector for DAI10 IO.
8 (R/W)	DAI9_PS	Pull Selector for DAI9 IO.
7 (R/W)	DAI8_PS	Pull Selector for DAI8 IO.
6 (R/W)	DAI7_PS	Pull Selector for DAI7 IO.
5 (R/W)	DAI6_PS	Pull Selector for DAI6 IO.
4 (R/W)	DAI5_PS	Pull Selector for DAI5 IO.
3 (R/W)	DAI4_PS	Pull Selector for DAI4 IO.
2 (R/W)	DAI3_PS	Pull Selector for DAI3 IO.
1 (R/W)	DAI2_PS	Pull Selector for DAI2 IO.
0 (R/W)	DAI1_PS	Pull Selector for DAI1 IO.

DAI1 Slew Rate Control Register

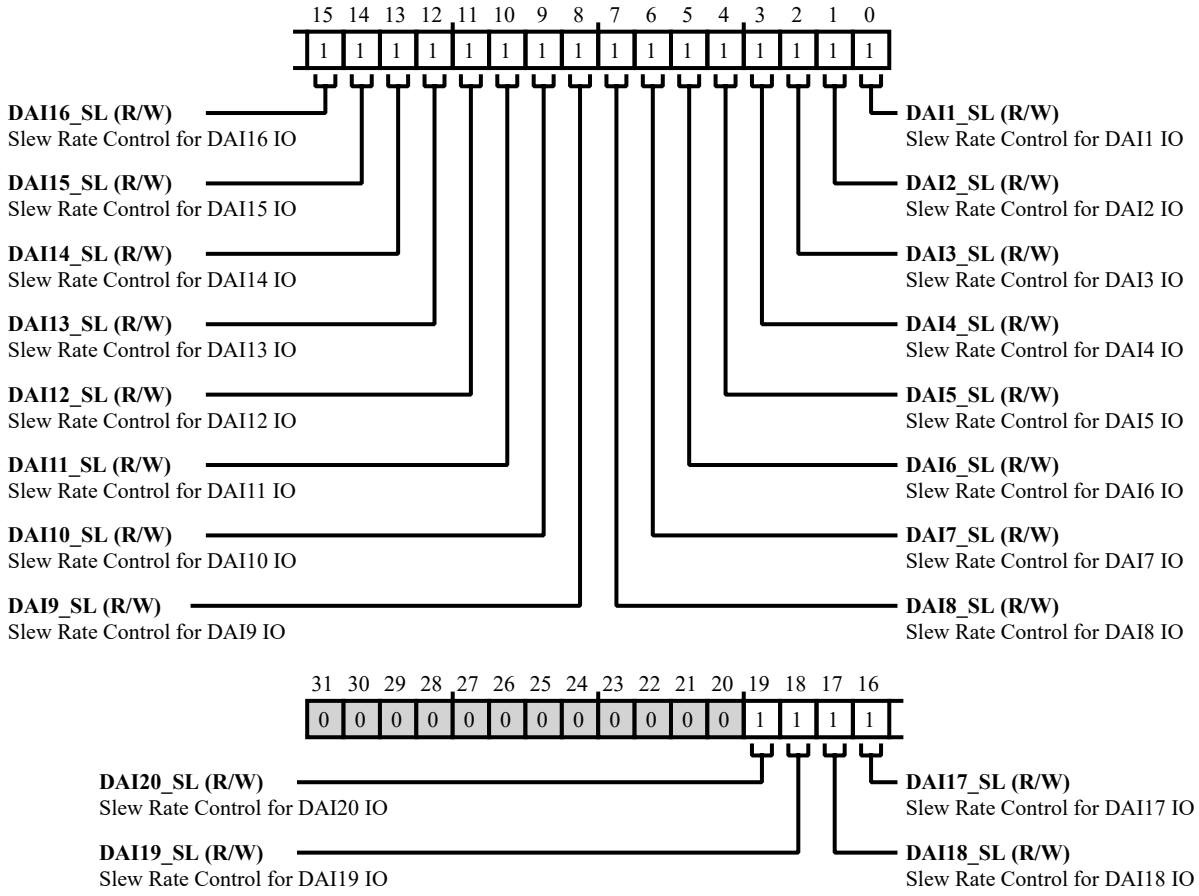

Figure 13-50: PADS_DAI1_SL Register Diagram

Table 13-55: PADS_DAI1_SL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19 (R/W)	DAI20_SL	Slew Rate Control for DAI20 IO.
18 (R/W)	DAI19_SL	Slew Rate Control for DAI19 IO.
17 (R/W)	DAI18_SL	Slew Rate Control for DAI18 IO.
16 (R/W)	DAI17_SL	Slew Rate Control for DAI17 IO.

Table 13-55: PADS_DAI1_SL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W)	DAI16_SL	Slew Rate Control for DAI16 IO.
14 (R/W)	DAI15_SL	Slew Rate Control for DAI15 IO.
13 (R/W)	DAI14_SL	Slew Rate Control for DAI14 IO.
12 (R/W)	DAI13_SL	Slew Rate Control for DAI13 IO.
11 (R/W)	DAI12_SL	Slew Rate Control for DAI12 IO.
10 (R/W)	DAI11_SL	Slew Rate Control for DAI11 IO.
9 (R/W)	DAI10_SL	Slew Rate Control for DAI10 IO.
8 (R/W)	DAI9_SL	Slew Rate Control for DAI9 IO.
7 (R/W)	DAI8_SL	Slew Rate Control for DAI8 IO.
6 (R/W)	DAI7_SL	Slew Rate Control for DAI7 IO.
5 (R/W)	DAI6_SL	Slew Rate Control for DAI6 IO.
4 (R/W)	DAI5_SL	Slew Rate Control for DAI5 IO.
3 (R/W)	DAI4_SL	Slew Rate Control for DAI4 IO.
2 (R/W)	DAI3_SL	Slew Rate Control for DAI3 IO.
1 (R/W)	DAI2_SL	Slew Rate Control for DAI2 IO.
0 (R/W)	DAI1_SL	Slew Rate Control for DAI1 IO.

DAI1 Strong Pull up Control Register

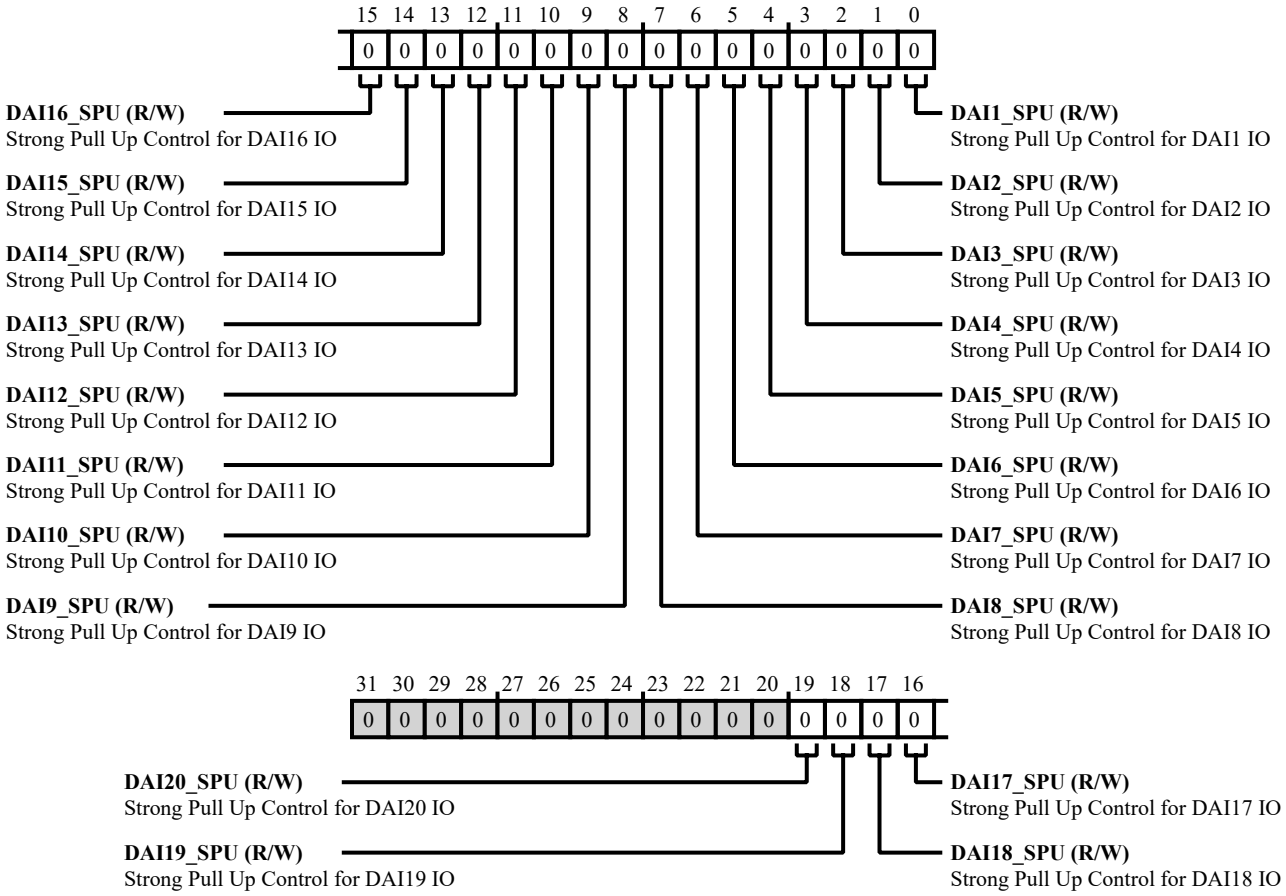

Figure 13-51: PADS_DAI1_SPU Register Diagram

Table 13-56: PADS_DAI1_SPU Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19 (R/W)	DAI20_SPU	Strong Pull Up Control for DAI20 IO.
18 (R/W)	DAI19_SPU	Strong Pull Up Control for DAI19 IO.
17 (R/W)	DAI18_SPU	Strong Pull Up Control for DAI18 IO.
16 (R/W)	DAI17_SPU	Strong Pull Up Control for DAI17 IO.

Table 13-56: PADS_DAI1_SPU Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W)	DAI16_SPU	Strong Pull Up Control for DAI16 IO.
14 (R/W)	DAI15_SPU	Strong Pull Up Control for DAI15 IO.
13 (R/W)	DAI14_SPU	Strong Pull Up Control for DAI14 IO.
12 (R/W)	DAI13_SPU	Strong Pull Up Control for DAI13 IO.
11 (R/W)	DAI12_SPU	Strong Pull Up Control for DAI12 IO.
10 (R/W)	DAI11_SPU	Strong Pull Up Control for DAI11 IO.
9 (R/W)	DAI10_SPU	Strong Pull Up Control for DAI10 IO.
8 (R/W)	DAI9_SPU	Strong Pull Up Control for DAI9 IO.
7 (R/W)	DAI8_SPU	Strong Pull Up Control for DAI8 IO.
6 (R/W)	DAI7_SPU	Strong Pull Up Control for DAI7 IO.
5 (R/W)	DAI6_SPU	Strong Pull Up Control for DAI6 IO.
4 (R/W)	DAI5_SPU	Strong Pull Up Control for DAI5 IO.
3 (R/W)	DAI4_SPU	Strong Pull Up Control for DAI4 IO.
2 (R/W)	DAI3_SPU	Strong Pull Up Control for DAI3 IO.
1 (R/W)	DAI2_SPU	Strong Pull Up Control for DAI2 IO.
0 (R/W)	DAI1_SPU	Strong Pull Up Control for DAI1 IO.

Non-GPIO Control Register

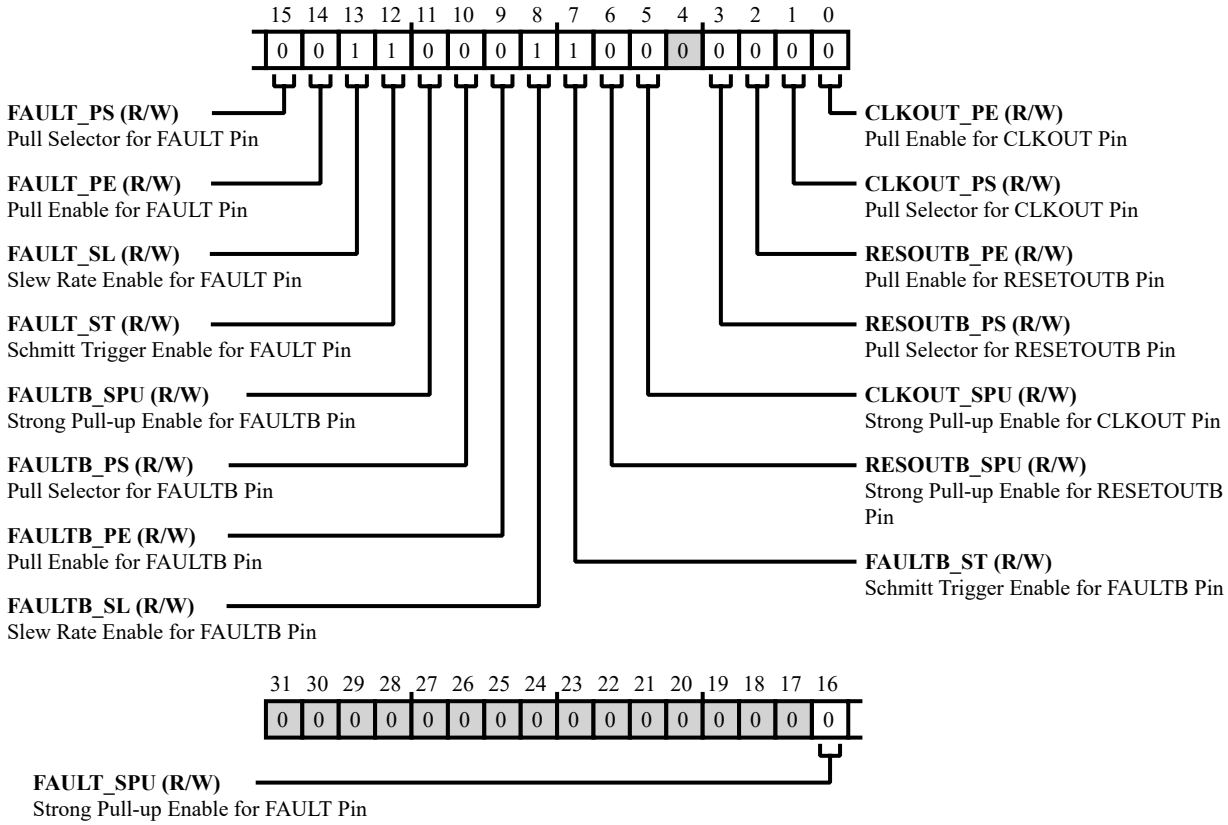

Figure 13-52: PADS_NONPORTS_CTL Register Diagram

Table 13-57: PADS_NONPORTS_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
16 (R/W)	FAULT_SPU	Strong Pull-up Enable for FAULT Pin.
15 (R/W)	FAULT_PS	Pull Selector for FAULT Pin.
14 (R/W)	FAULT_PE	Pull Enable for FAULT Pin.
13 (R/W)	FAULT_SL	Slew Rate Enable for FAULT Pin.
12 (R/W)	FAULT_ST	Schmitt Trigger Enable for FAULT Pin.

Table 13-57: PADS_NONPORTS_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
11 (R/W)	FAULTB_SPU	Strong Pull-up Enable for FAULTB Pin.
10 (R/W)	FAULTB_PS	Pull Selector for FAULTB Pin.
9 (R/W)	FAULTB_PE	Pull Enable for FAULTB Pin.
8 (R/W)	FAULTB_SL	Slew Rate Enable for FAULTB Pin.
7 (R/W)	FAULTB_ST	Schmitt Trigger Enable for FAULTB Pin.
6 (R/W)	RESOUTB_SPU	Strong Pull-up Enable for RESETOUTB Pin.
5 (R/W)	CLKOUT_SPU	Strong Pull-up Enable for CLKOUT Pin.
3 (R/W)	RESOUTB_PS	Pull Selector for RESETOUTB Pin.
2 (R/W)	RESOUTB_PE	Pull Enable for RESETOUTB Pin.
1 (R/W)	CLKOUT_PS	Pull Selector for CLKOUT Pin.
0 (R/W)	CLKOUT_PE	Pull Enable for CLKOUT Pin.

Non-GPIO Drive Strength Register

The PADS_NONPORTS_DS register sets the drive strength and tolerance for the non-GPIO pins. The drive strength is only controlled for pin groups classified by the interface type.

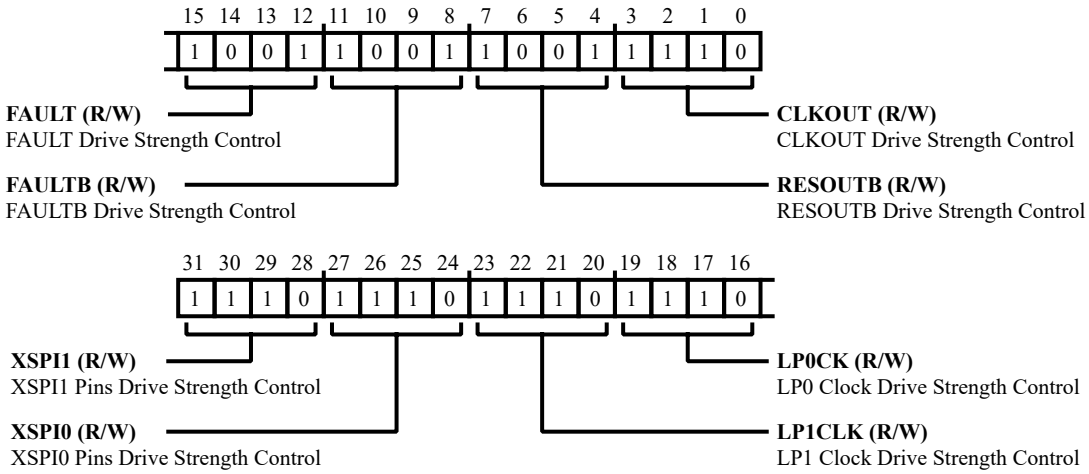

Figure 13-53: PADS_NONPORTS_DS Register Diagram

Table 13-58: PADS_NONPORTS_DS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:28 (R/W)	XSPI1	XSPI1 Pins Drive Strength Control.
27:24 (R/W)	XSPI0	XSPI0 Pins Drive Strength Control.
23:20 (R/W)	LP1CLK	LP1 Clock Drive Strength Control.
19:16 (R/W)	LP0CK	LP0 Clock Drive Strength Control.
15:12 (R/W)	FAULT	FAULT Drive Strength Control.
11:8 (R/W)	FAULTB	FAULTB Drive Strength Control.
7:4 (R/W)	RESOUTB	RESOUTB Drive Strength Control.
3:0 (R/W)	CLKOUT	CLKOUT Drive Strength Control.

EMAC Non-GPIO Drive Strength Register

The PADS_NONPORTS_DS_1 register sets the drive strength and tolerance for the non-GPIO pins. The drive strength is only controlled for pin groups classified by the interface type.

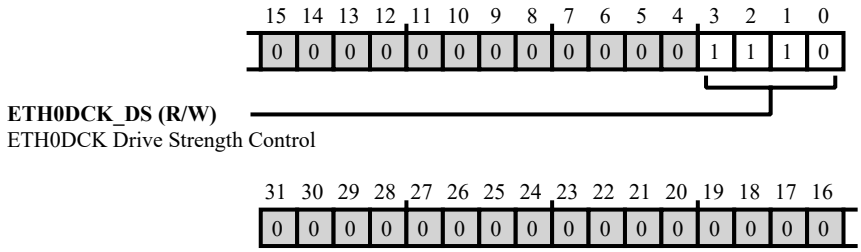

Figure 13-54: PADS_NONPORTS_DS_1 Register Diagram

Table 13-59: PADS_NONPORTS_DS_1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
3:0 (R/W)	ETH0DCK_DS	ETH0DCK Drive Strength Control. The default drive strength is 1001. Do not change this value.

OTPC Boot Status Register

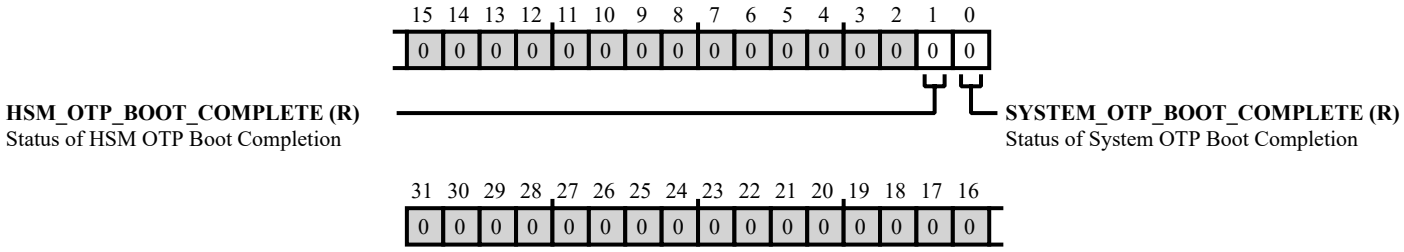

Figure 13-55: PADS_OTPC_BOOT_STAT Register Diagram

Table 13-60: PADS_OTPC_BOOT_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
1 (R/NW)	HSM_OTP_BOOT_COMPLETE	Status of HSM OTP Boot Completion. 1> Success 0> Failure
0 (R/NW)	SYSTEM_OTP_BOOT_COMPLETE	Status of System OTP Boot Completion. 1> Success 0> Failure

Peripheral PAD Configuration 0 Register

The PADS_PCFG0 register provides several configuration options for the pads and multiplexing for peripherals.

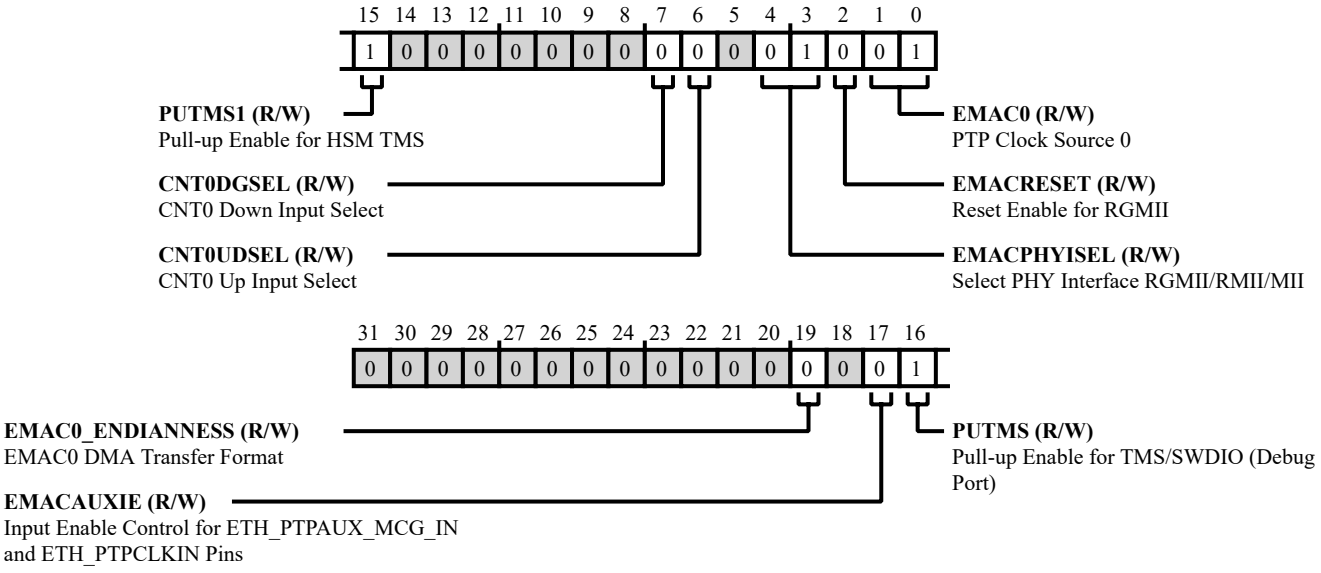

Figure 13-56: PADS_PCFG0 Register Diagram

Table 13-61: PADS_PCFG0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
19 (R/W)	EMAC0_ENDIANNESS	EMAC0 DMA Transfer Format. Configure the PADS_PCFG0.EMAC0_ENDIANNESS bit field to set the EMAC0 DMA transfers to use big-endian or little-endian format.	
		0	Little-Endian
		1	Big-Endian
17 (R/W)	EMACAUXIE	Input Enable Control for ETH_PTPAUX_MCG_IN and ETH_PTPCLKIN Pins.	
		0	Disable input
		1	Enable input
16 (R/W)	PUTMS	Pull-up Enable for TMS/SWDIO (Debug Port).	
		0	Disable pull-up
		1	Enable pull-up
15 (R/W)	PUTMS1	Pull-up Enable for HSM TMS.	
		0	Disable pull-up
		1	Enable pull-up

Table 13-61: PADS_PCFG0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	CNT0DGSEL	CNT0 Down Input Select. The PADS_PCFG0 bit selects the input for the CNT0 counter down and gate.	
		0	GPIO port pins
		1	Trigger connection
6 (R/W)	CNT0UDSEL	CNT0 Up Input Select. The PADS_PCFG0 bit selects the input for the CNT0 counter up and direction.	
		0	GPIO port pins
		1	Trigger connection
4:3 (R/W)	EMACPHYISEL	Select PHY Interface RGMII/RMII/MII.	
		0	MII Interface Selects PHY Interface MII
		1	RGMII Interface Selects PHY Interface RGMII
		2	RMII Interface Selects PHY Interface RMII
		3	Reserved
2 (R/W)	EMACRESET	Reset Enable for RGMII. The PADS_PCFG0.EMACRESET bit asserts the reset on the RGMII interface. To select the PHY interface (RGMII or RMII), set the EMACPHYISEL bit as required and then set PADS_PCFG0.EMACRESET.	
		0	RGMII reset is asserted
		1	RGMII reset reset is deasserted
1:0 (R/W)	EMAC0	PTP Clock Source 0. The PADS_PCFG0.EMAC0 selects the clock source for the PTP Block in EMAC0.	
		0	REFCLK (MII or RMII) or CLKO7 (RGMII)
		1	SCLK0
		2	External PTP clock
		3	SCLK0

Peripheral Configuration 1 Register

The PADS_PCFG1 register provides bits to configure PWM secondary inputs to timers and enable inputs from the TRU.

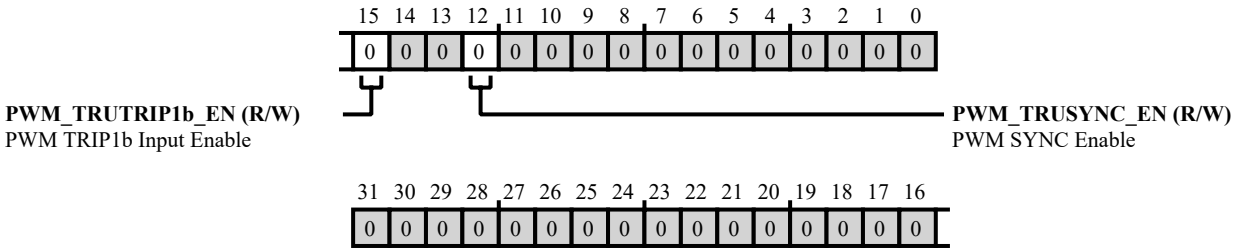

Figure 13-57: PADS_PCFG1 Register Diagram

Table 13-62: PADS_PCFG1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W)	PWM_TRUTRIP1B_EN	PWM TRIP1b Input Enable. The PADS_PCFG1.PWM_TRUTRIP1B_EN bit enables the PWM TRIP1b input from the TRU. 0> TRU Trip1b input to PWM disabled 1>TRU Trip1b input to PWM enabled
12 (R/W)	PWM_TRUSYNC_EN	PWM SYNC Enable. The PADS_PCFG1.PWM_TRUSYNC_EN bit enables the PWM SYNC input from the TRU. 0> Disable, PWM sync input is from external pin 1> Enable, PWM sync input is from the TRU

PORTA Pins 0 to 7 Drive Strength Control Register

The default drive strength is 1001. Do not change this value.

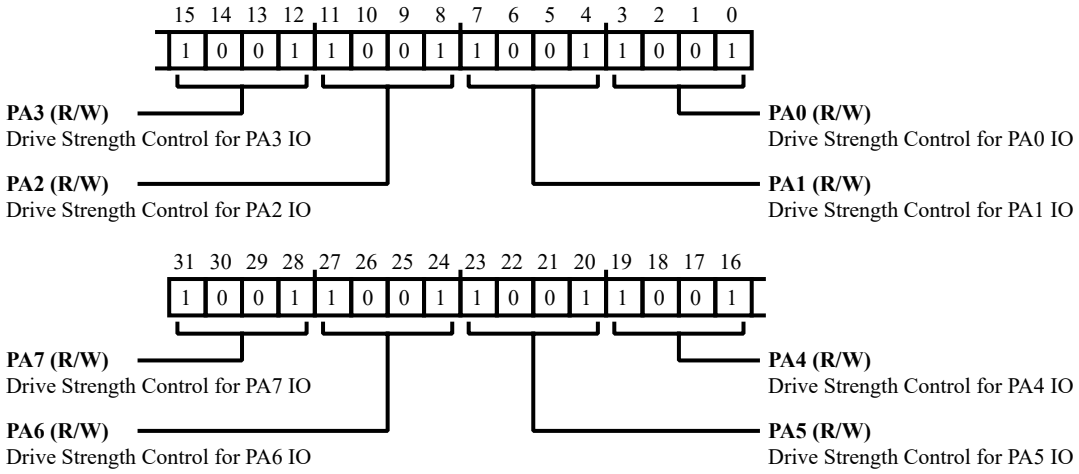

Figure 13-58: PADS_PORTA0_DS Register Diagram

Table 13-63: PADS_PORTA0_DS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:28 (R/W)	PA7	Drive Strength Control for PA7 IO.
27:24 (R/W)	PA6	Drive Strength Control for PA6 IO.
23:20 (R/W)	PA5	Drive Strength Control for PA5 IO.
19:16 (R/W)	PA4	Drive Strength Control for PA4 IO.
15:12 (R/W)	PA3	Drive Strength Control for PA3 IO.
11:8 (R/W)	PA2	Drive Strength Control for PA2 IO.
7:4 (R/W)	PA1	Drive Strength Control for PA1 IO.
3:0 (R/W)	PA0	Drive Strength Control for PA0 IO.

PORTA Pins 8 to 15 Drive Strength Control Register

The default drive strength is 1001. Do not change this value.

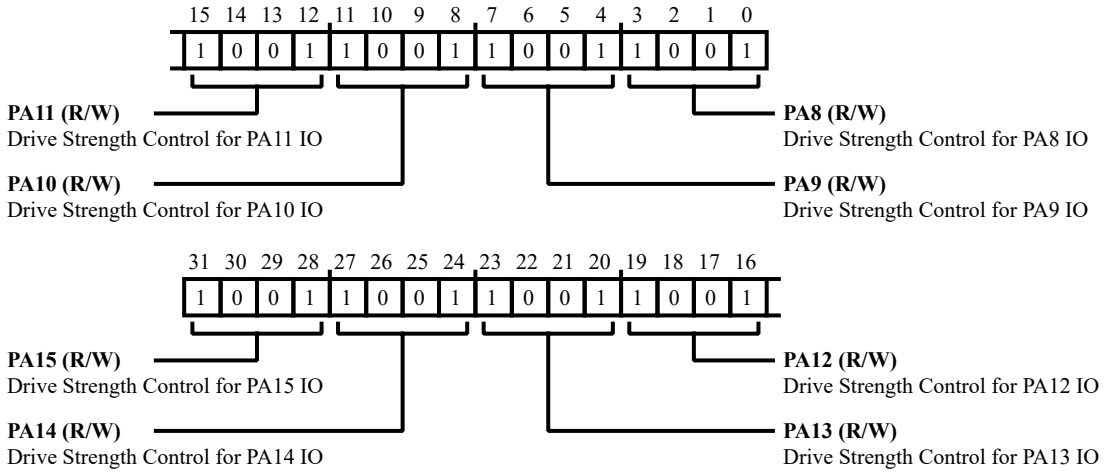

Figure 13-59: PADS_PORTA1_DS Register Diagram

Table 13-64: PADS_PORTA1_DS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:28 (R/W)	PA15	Drive Strength Control for PA15 IO.
27:24 (R/W)	PA14	Drive Strength Control for PA14 IO.
23:20 (R/W)	PA13	Drive Strength Control for PA13 IO.
19:16 (R/W)	PA12	Drive Strength Control for PA12 IO.
15:12 (R/W)	PA11	Drive Strength Control for PA11 IO.
11:8 (R/W)	PA10	Drive Strength Control for PA10 IO.
7:4 (R/W)	PA9	Drive Strength Control for PA9 IO.
3:0 (R/W)	PA8	Drive Strength Control for PA8 IO.

PORTB Pins 0 to 7 Drive Strength Control Register

The default drive strength is 1001. Do not change this value.

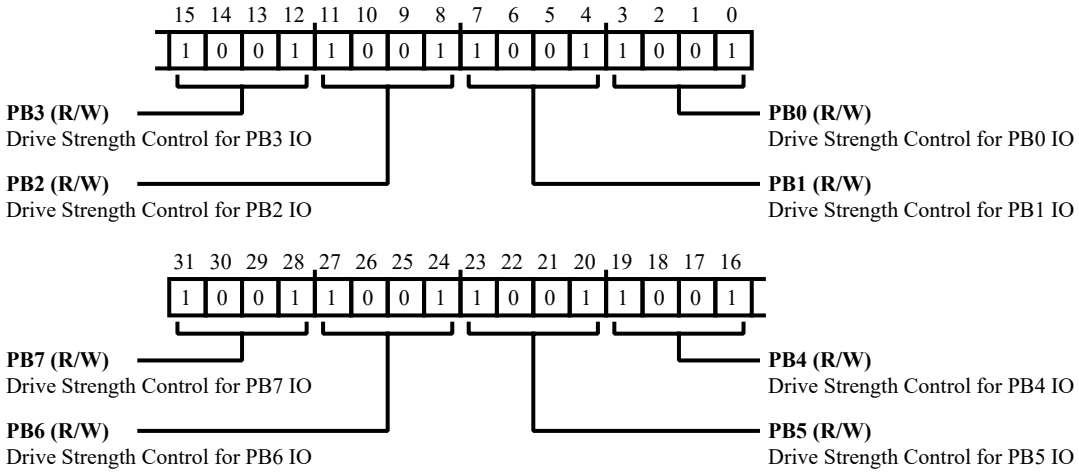

Figure 13-60: PADS_PORTB0_DS Register Diagram

Table 13-65: PADS_PORTB0_DS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:28 (R/W)	PB7	Drive Strength Control for PB7 IO.
27:24 (R/W)	PB6	Drive Strength Control for PB6 IO.
23:20 (R/W)	PB5	Drive Strength Control for PB5 IO.
19:16 (R/W)	PB4	Drive Strength Control for PB4 IO.
15:12 (R/W)	PB3	Drive Strength Control for PB3 IO.
11:8 (R/W)	PB2	Drive Strength Control for PB2 IO.
7:4 (R/W)	PB1	Drive Strength Control for PB1 IO.
3:0 (R/W)	PB0	Drive Strength Control for PB0 IO.

PORTB Pins 8 to 15 Drive Strength Control Register

The default drive strength is 1001. Do not change this value.

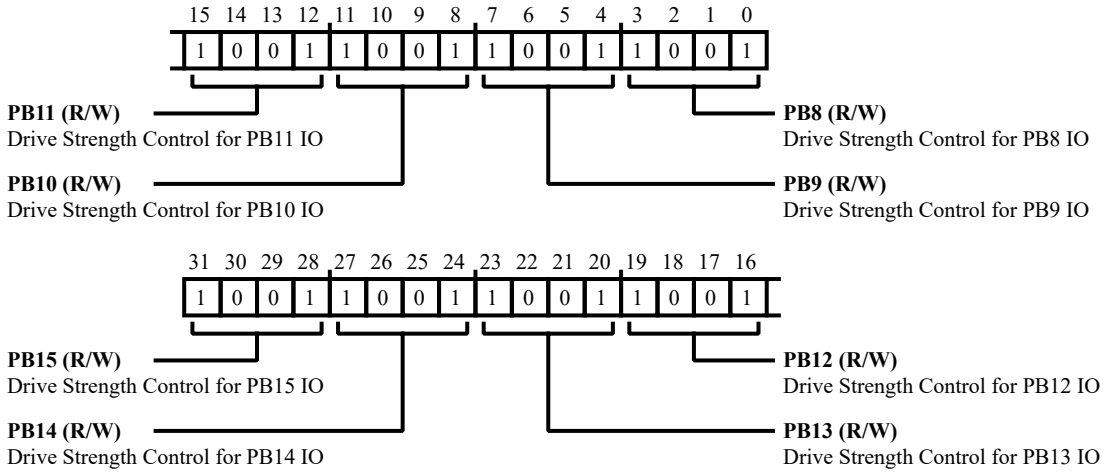

Figure 13-61: PADS_PORTB1_DS Register Diagram

19:16 (R/W)	PD4	Drive Strength Control for PD4 IO.
15:12 (R/W)	PD3	Drive Strength Control for PD3 IO.
11:8 (R/W)	PD2	Drive Strength Control for PD2 IO.
7:4 (R/W)	PD1	Drive Strength Control for PD1 IO.
3:0 (R/W)	PD0	Drive Strength Control for PD0 IO.

PORTD Pins 8 to 15 Drive Strength Control Register

The default drive strength is 1001. Do not change this value.

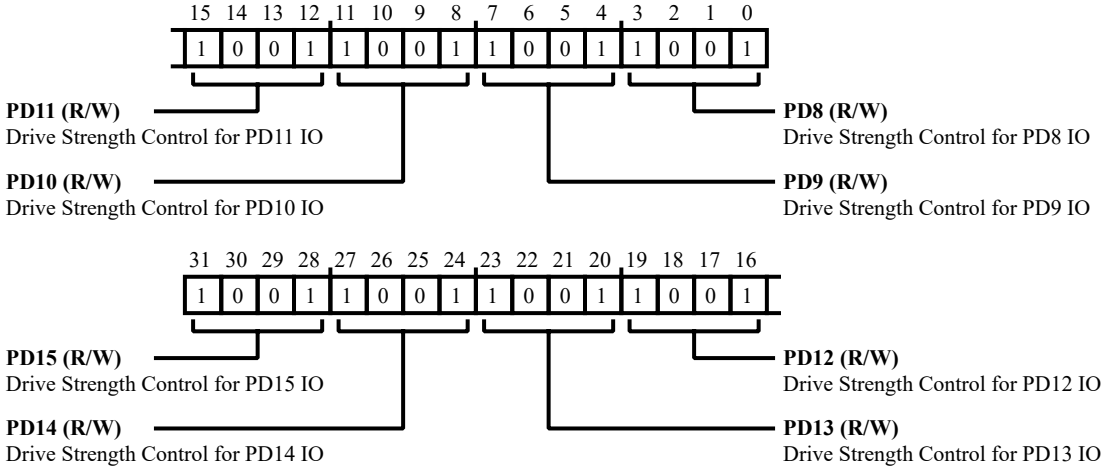

Figure 13-65: PADS_PORTD1_DS Register Diagram

Table 13-70: PADS_PORTD1_DS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:28 (R/W)	PD15	Drive Strength Control for PD15 IO.
27:24 (R/W)	PD14	Drive Strength Control for PD14 IO.
23:20 (R/W)	PD13	Drive Strength Control for PD13 IO.
19:16 (R/W)	PD12	Drive Strength Control for PD12 IO.
15:12 (R/W)	PD11	Drive Strength Control for PD11 IO.
11:8 (R/W)	PD10	Drive Strength Control for PD10 IO.
7:4 (R/W)	PD9	Drive Strength Control for PD9 IO.
3:0 (R/W)	PD8	Drive Strength Control for PD8 IO.

PORTE Pins 0 to 7 Drive Strength Control Register

The default drive strength is 1001. Do not change this value.

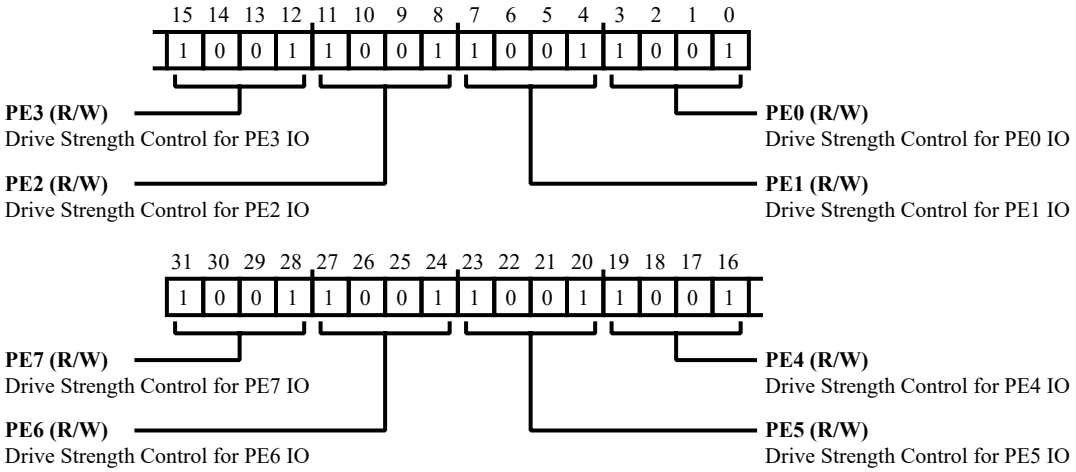

Figure 13-66: PADS_PORTE0_DS Register Diagram

Table 13-71: PADS_PORTE0_DS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:28 (R/W)	PE7	Drive Strength Control for PE7 IO.
27:24 (R/W)	PE6	Drive Strength Control for PE6 IO.
23:20 (R/W)	PE5	Drive Strength Control for PE5 IO.
19:16 (R/W)	PE4	Drive Strength Control for PE4 IO.
15:12 (R/W)	PE3	Drive Strength Control for PE3 IO.
11:8 (R/W)	PE2	Drive Strength Control for PE2 IO.
7:4 (R/W)	PE1	Drive Strength Control for PE1 IO.
3:0 (R/W)	PE0	Drive Strength Control for PE0 IO.

PORTE Pins 8 to 15 Drive Strength Control Register

The default drive strength is 1001. Do not change this value.

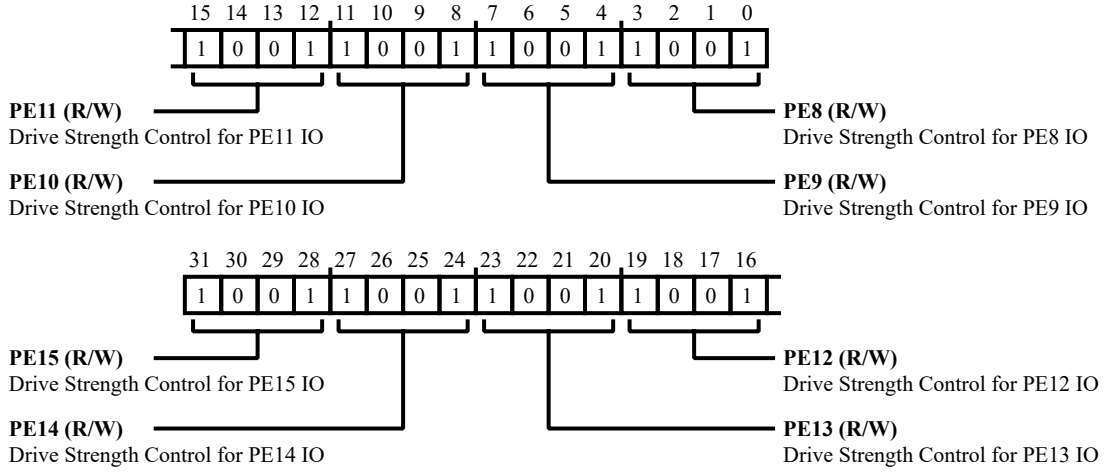

Figure 13-67: PADS_PORTE1_DS Register Diagram

Table 13-72: PADS_PORTE1_DS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:28 (R/W)	PE15	Drive Strength Control for PE15 IO.
27:24 (R/W)	PE14	Drive Strength Control for PE14 IO.
23:20 (R/W)	PE13	Drive Strength Control for PE13 IO.
19:16 (R/W)	PE12	Drive Strength Control for PE12 IO.
15:12 (R/W)	PE11	Drive Strength Control for PE11 IO.
11:8 (R/W)	PE10	Drive Strength Control for PE10 IO.
7:4 (R/W)	PE9	Drive Strength Control for PE9 IO.
3:0 (R/W)	PE8	Drive Strength Control for PE8 IO.

PORTF Pins 0 to 7 Drive Strength Control Register

The default drive strength is 1001. Do not change this value.

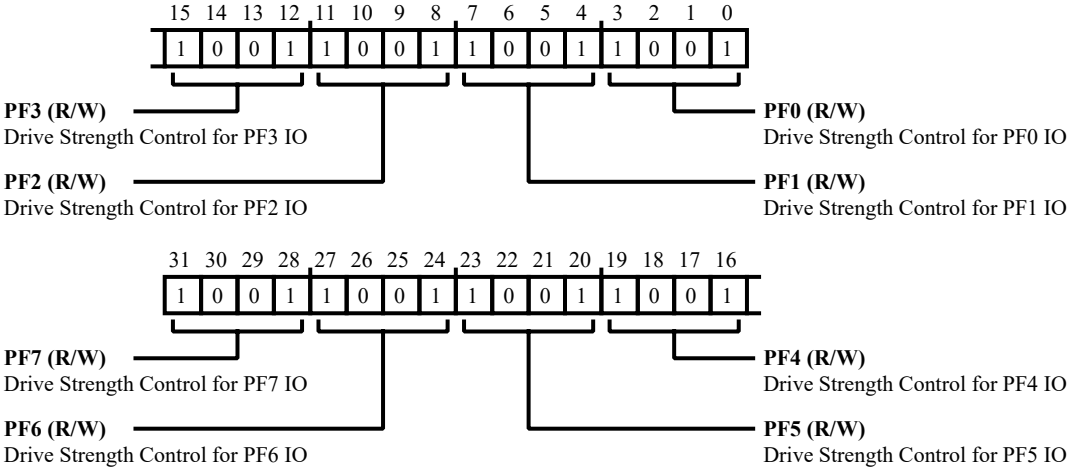

Figure 13-68: PADS_PORTF0_DS Register Diagram

Table 13-73: PADS_PORTF0_DS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:28 (R/W)	PF7	Drive Strength Control for PF7 IO.
27:24 (R/W)	PF6	Drive Strength Control for PF6 IO.
23:20 (R/W)	PF5	Drive Strength Control for PF5 IO.
19:16 (R/W)	PF4	Drive Strength Control for PF4 IO.
15:12 (R/W)	PF3	Drive Strength Control for PF3 IO.
11:8 (R/W)	PF2	Drive Strength Control for PF2 IO.
7:4 (R/W)	PF1	Drive Strength Control for PF1 IO.
3:0 (R/W)	PF0	Drive Strength Control for PF0 IO.

PORTF Pins 8 to 15 Drive Strength Control Register

The default drive strength is 1001. Do not change this value.

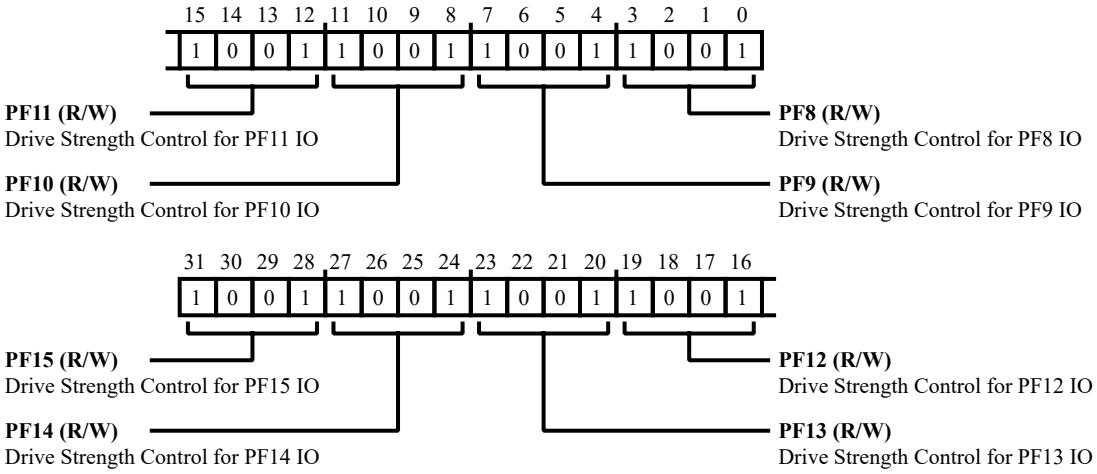

Figure 13-69: PADS_PORTF1_DS Register Diagram

Table 13-74: PADS_PORTF1_DS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:28 (R/W)	PF15	Drive Strength Control for PF15 IO.
27:24 (R/W)	PF14	Drive Strength Control for PF14 IO.
23:20 (R/W)	PF13	Drive Strength Control for PF13 IO.
19:16 (R/W)	PF12	Drive Strength Control for PF12 IO.
15:12 (R/W)	PF11	Drive Strength Control for PF11 IO.
11:8 (R/W)	PF10	Drive Strength Control for PF10 IO.
7:4 (R/W)	PF9	Drive Strength Control for PF9 IO.
3:0 (R/W)	PF8	Drive Strength Control for PF8 IO.

PORTG Pins 0 to 7 Drive Strength Control Register

The default drive strength is 1001. Do not change this value.

Bit No. (Access)	Bit Name	Description/Enumeration
31:28 (R/W)	PH15	DS control for PH15 IO.
27:24 (R/W)	PH14	DS control for PH14 IO.
23:20 (R/W)	PH13	DS control for PH13 IO.
19:16 (R/W)	PH12	DS control for PH12 IO.
15:12 (R/W)	PH11	DS control for PH11 IO.
11:8 (R/W)	PH10	DS control for PH10 IO.
7:4 (R/W)	PH9	Drive Strength Control for PH9 IO.
3:0 (R/W)	PH8	Drive Strength Control for PH8 IO.

PORTA and PORTB Pull Enable Register

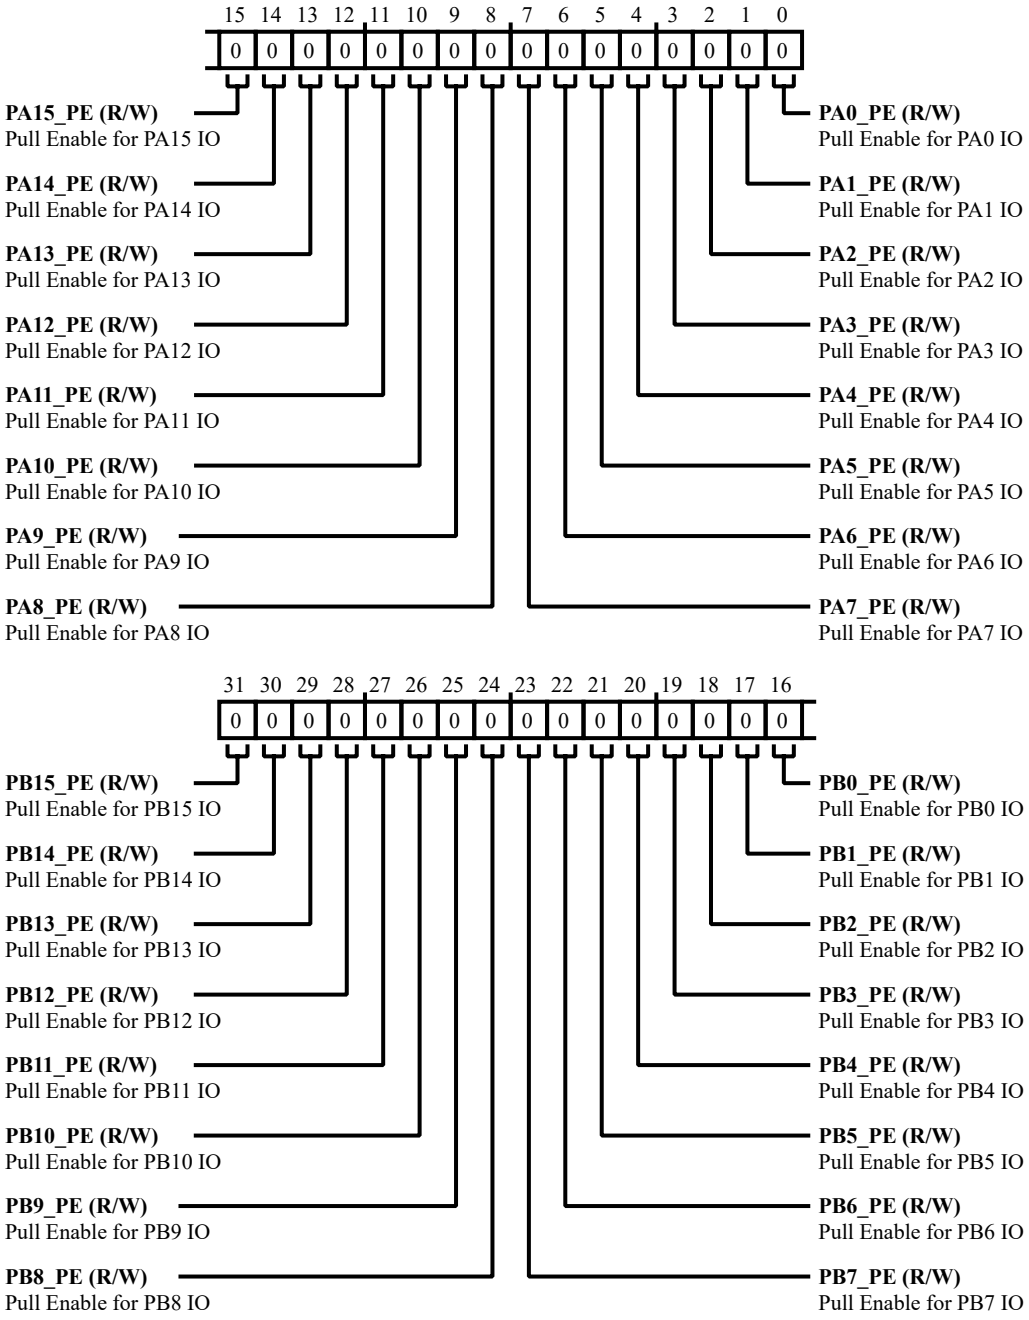

Figure 13-74: PADS_PORT_AB_PE Register Diagram

Table 13-79: PADS_PORT_AB_PE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	PB15_PE	Pull Enable for PB15 IO.
30 (R/W)	PB14_PE	Pull Enable for PB14 IO.
29 (R/W)	PB13_PE	Pull Enable for PB13 IO.
28 (R/W)	PB12_PE	Pull Enable for PB12 IO.
27 (R/W)	PB11_PE	Pull Enable for PB11 IO.
26 (R/W)	PB10_PE	Pull Enable for PB10 IO.
25 (R/W)	PB9_PE	Pull Enable for PB9 IO.
24 (R/W)	PB8_PE	Pull Enable for PB8 IO.
23 (R/W)	PB7_PE	Pull Enable for PB7 IO.
22 (R/W)	PB6_PE	Pull Enable for PB6 IO.
21 (R/W)	PB5_PE	Pull Enable for PB5 IO.
20 (R/W)	PB4_PE	Pull Enable for PB4 IO.
19 (R/W)	PB3_PE	Pull Enable for PB3 IO.
18 (R/W)	PB2_PE	Pull Enable for PB2 IO.
17 (R/W)	PB1_PE	Pull Enable for PB1 IO.
16 (R/W)	PB0_PE	Pull Enable for PB0 IO.

Table 13-79: PADS_PORT_AB_PE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W)	PA15_PE	Pull Enable for PA15 IO.
14 (R/W)	PA14_PE	Pull Enable for PA14 IO.
13 (R/W)	PA13_PE	Pull Enable for PA13 IO.
12 (R/W)	PA12_PE	Pull Enable for PA12 IO.
11 (R/W)	PA11_PE	Pull Enable for PA11 IO.
10 (R/W)	PA10_PE	Pull Enable for PA10 IO.
9 (R/W)	PA9_PE	Pull Enable for PA9 IO.
8 (R/W)	PA8_PE	Pull Enable for PA8 IO.
7 (R/W)	PA7_PE	Pull Enable for PA7 IO.
6 (R/W)	PA6_PE	Pull Enable for PA6 IO.
5 (R/W)	PA5_PE	Pull Enable for PA5 IO.
4 (R/W)	PA4_PE	Pull Enable for PA4 IO.
3 (R/W)	PA3_PE	Pull Enable for PA3 IO.
2 (R/W)	PA2_PE	Pull Enable for PA2 IO.
1 (R/W)	PA1_PE	Pull Enable for PA1 IO.
0 (R/W)	PA0_PE	Pull Enable for PA0 IO.

PORTA and PORTB Pull Selector Register

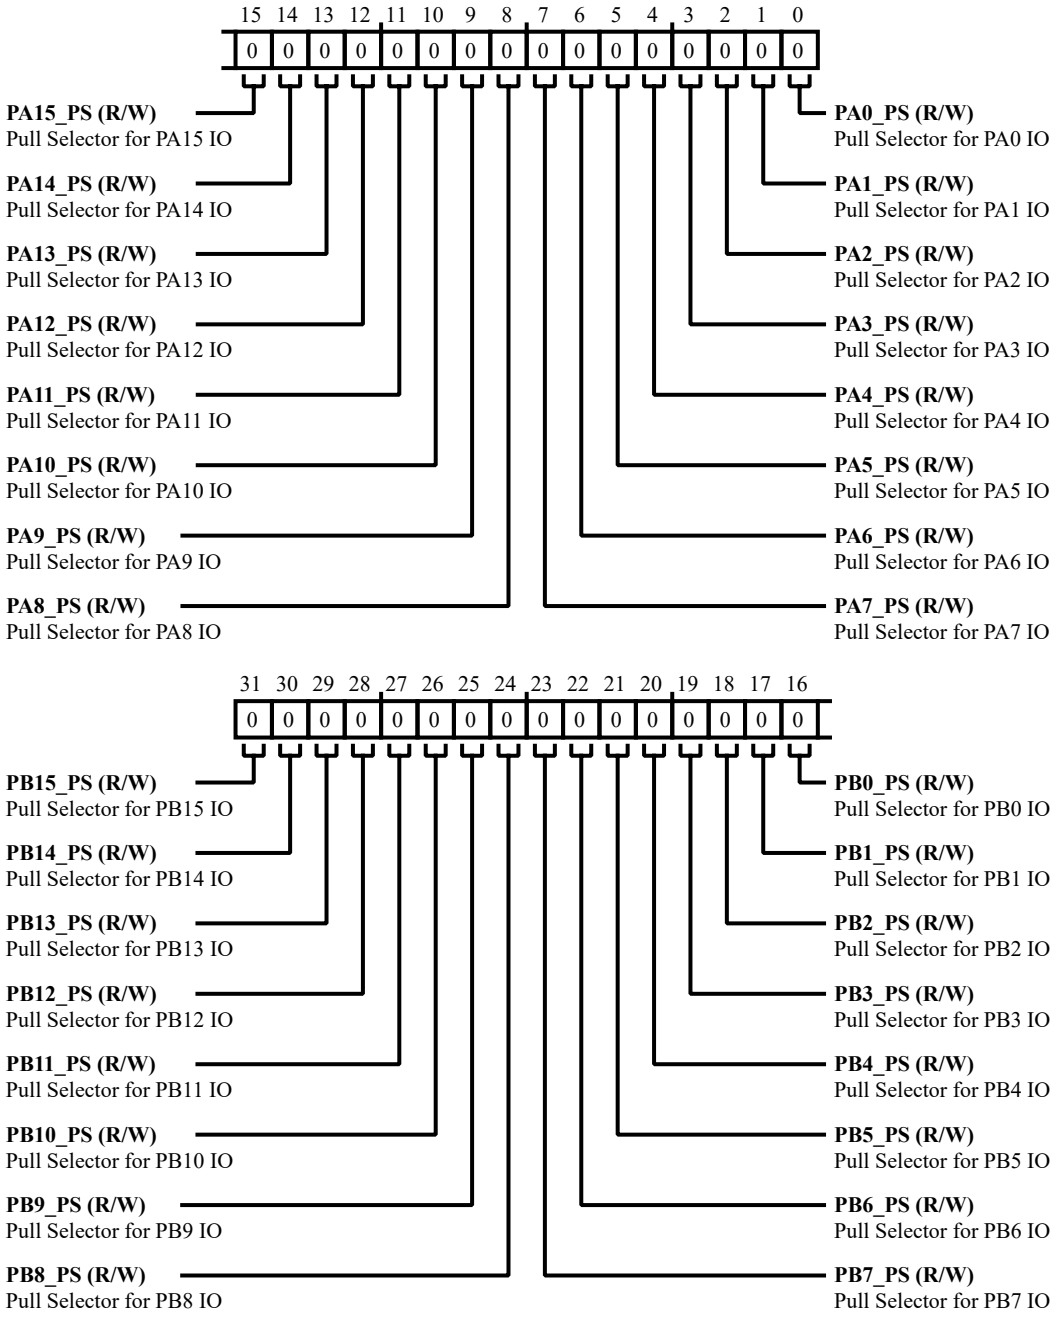

Figure 13-75: PADS_PORT_AB_PS Register Diagram

Table 13-80: PADS_PORT_AB_PS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	PB15_PS	Pull Selector for PB15 IO.
30 (R/W)	PB14_PS	Pull Selector for PB14 IO.
29 (R/W)	PB13_PS	Pull Selector for PB13 IO.
28 (R/W)	PB12_PS	Pull Selector for PB12 IO.
27 (R/W)	PB11_PS	Pull Selector for PB11 IO.
26 (R/W)	PB10_PS	Pull Selector for PB10 IO.
25 (R/W)	PB9_PS	Pull Selector for PB9 IO.
24 (R/W)	PB8_PS	Pull Selector for PB8 IO.
23 (R/W)	PB7_PS	Pull Selector for PB7 IO.
22 (R/W)	PB6_PS	Pull Selector for PB6 IO.
21 (R/W)	PB5_PS	Pull Selector for PB5 IO.
20 (R/W)	PB4_PS	Pull Selector for PB4 IO.
19 (R/W)	PB3_PS	Pull Selector for PB3 IO.
18 (R/W)	PB2_PS	Pull Selector for PB2 IO.
17 (R/W)	PB1_PS	Pull Selector for PB1 IO.
16 (R/W)	PB0_PS	Pull Selector for PB0 IO.

Table 13-80: PADS_PORT_AB_PS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W)	PA15_PS	Pull Selector for PA15 IO.
14 (R/W)	PA14_PS	Pull Selector for PA14 IO.
13 (R/W)	PA13_PS	Pull Selector for PA13 IO.
12 (R/W)	PA12_PS	Pull Selector for PA12 IO.
11 (R/W)	PA11_PS	Pull Selector for PA11 IO.
10 (R/W)	PA10_PS	Pull Selector for PA10 IO.
9 (R/W)	PA9_PS	Pull Selector for PA9 IO.
8 (R/W)	PA8_PS	Pull Selector for PA8 IO.
7 (R/W)	PA7_PS	Pull Selector for PA7 IO.
6 (R/W)	PA6_PS	Pull Selector for PA6 IO.
5 (R/W)	PA5_PS	Pull Selector for PA5 IO.
4 (R/W)	PA4_PS	Pull Selector for PA4 IO.
3 (R/W)	PA3_PS	Pull Selector for PA3 IO.
2 (R/W)	PA2_PS	Pull Selector for PA2 IO.
1 (R/W)	PA1_PS	Pull Selector for PA1 IO.
0 (R/W)	PA0_PS	Pull Selector for PA0 IO.

PORTA and PORTB Slew Rate Control Register

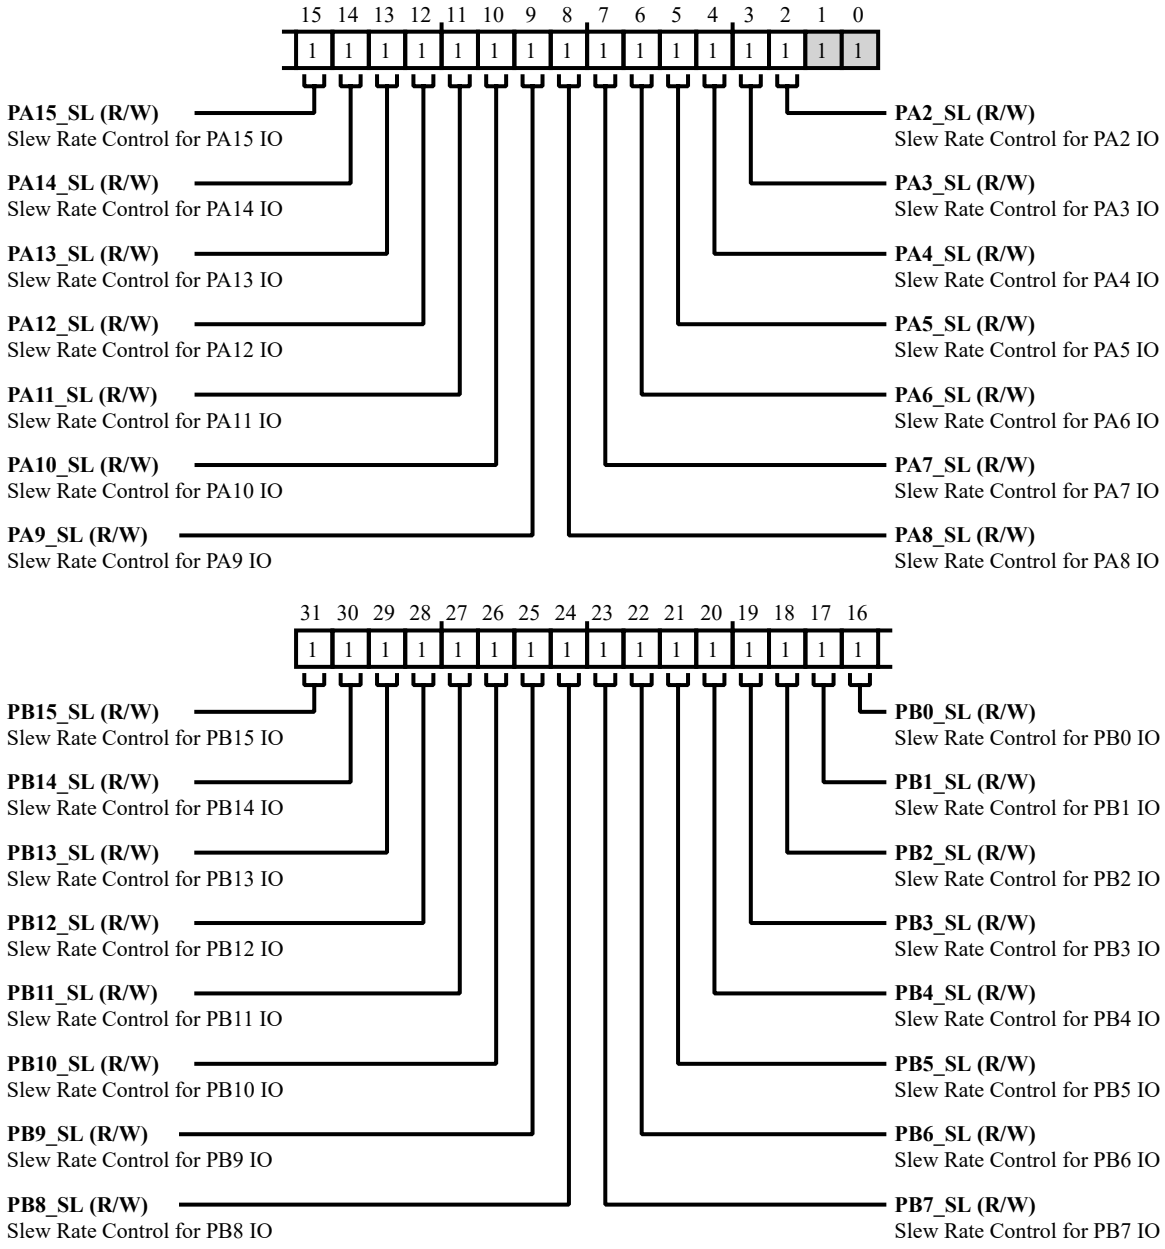

Figure 13-76: PADS_PORT_AB_SL Register Diagram

Table 13-81: PADS_PORT_AB_SL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	PB15_SL	Slew Rate Control for PB15 IO.

Table 13-81: PADS_PORT_AB_SL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
30 (R/W)	PB14_SL	Slew Rate Control for PB14 IO.
29 (R/W)	PB13_SL	Slew Rate Control for PB13 IO.
28 (R/W)	PB12_SL	Slew Rate Control for PB12 IO.
27 (R/W)	PB11_SL	Slew Rate Control for PB11 IO.
26 (R/W)	PB10_SL	Slew Rate Control for PB10 IO.
25 (R/W)	PB9_SL	Slew Rate Control for PB9 IO.
24 (R/W)	PB8_SL	Slew Rate Control for PB8 IO.
23 (R/W)	PB7_SL	Slew Rate Control for PB7 IO.
22 (R/W)	PB6_SL	Slew Rate Control for PB6 IO.
21 (R/W)	PB5_SL	Slew Rate Control for PB5 IO.
20 (R/W)	PB4_SL	Slew Rate Control for PB4 IO.
19 (R/W)	PB3_SL	Slew Rate Control for PB3 IO.
18 (R/W)	PB2_SL	Slew Rate Control for PB2 IO.
17 (R/W)	PB1_SL	Slew Rate Control for PB1 IO.
16 (R/W)	PB0_SL	Slew Rate Control for PB0 IO.
15 (R/W)	PA15_SL	Slew Rate Control for PA15 IO.

Table 13-81: PADS_PORT_AB_SL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/W)	PA14_SL	Slew Rate Control for PA14 IO.
13 (R/W)	PA13_SL	Slew Rate Control for PA13 IO.
12 (R/W)	PA12_SL	Slew Rate Control for PA12 IO.
11 (R/W)	PA11_SL	Slew Rate Control for PA11 IO.
10 (R/W)	PA10_SL	Slew Rate Control for PA10 IO.
9 (R/W)	PA9_SL	Slew Rate Control for PA9 IO.
8 (R/W)	PA8_SL	Slew Rate Control for PA8 IO.
7 (R/W)	PA7_SL	Slew Rate Control for PA7 IO.
6 (R/W)	PA6_SL	Slew Rate Control for PA6 IO.
5 (R/W)	PA5_SL	Slew Rate Control for PA5 IO.
4 (R/W)	PA4_SL	Slew Rate Control for PA4 IO.
3 (R/W)	PA3_SL	Slew Rate Control for PA3 IO.
2 (R/W)	PA2_SL	Slew Rate Control for PA2 IO.

PORTA and PORTB Strong Pull Up Control Register

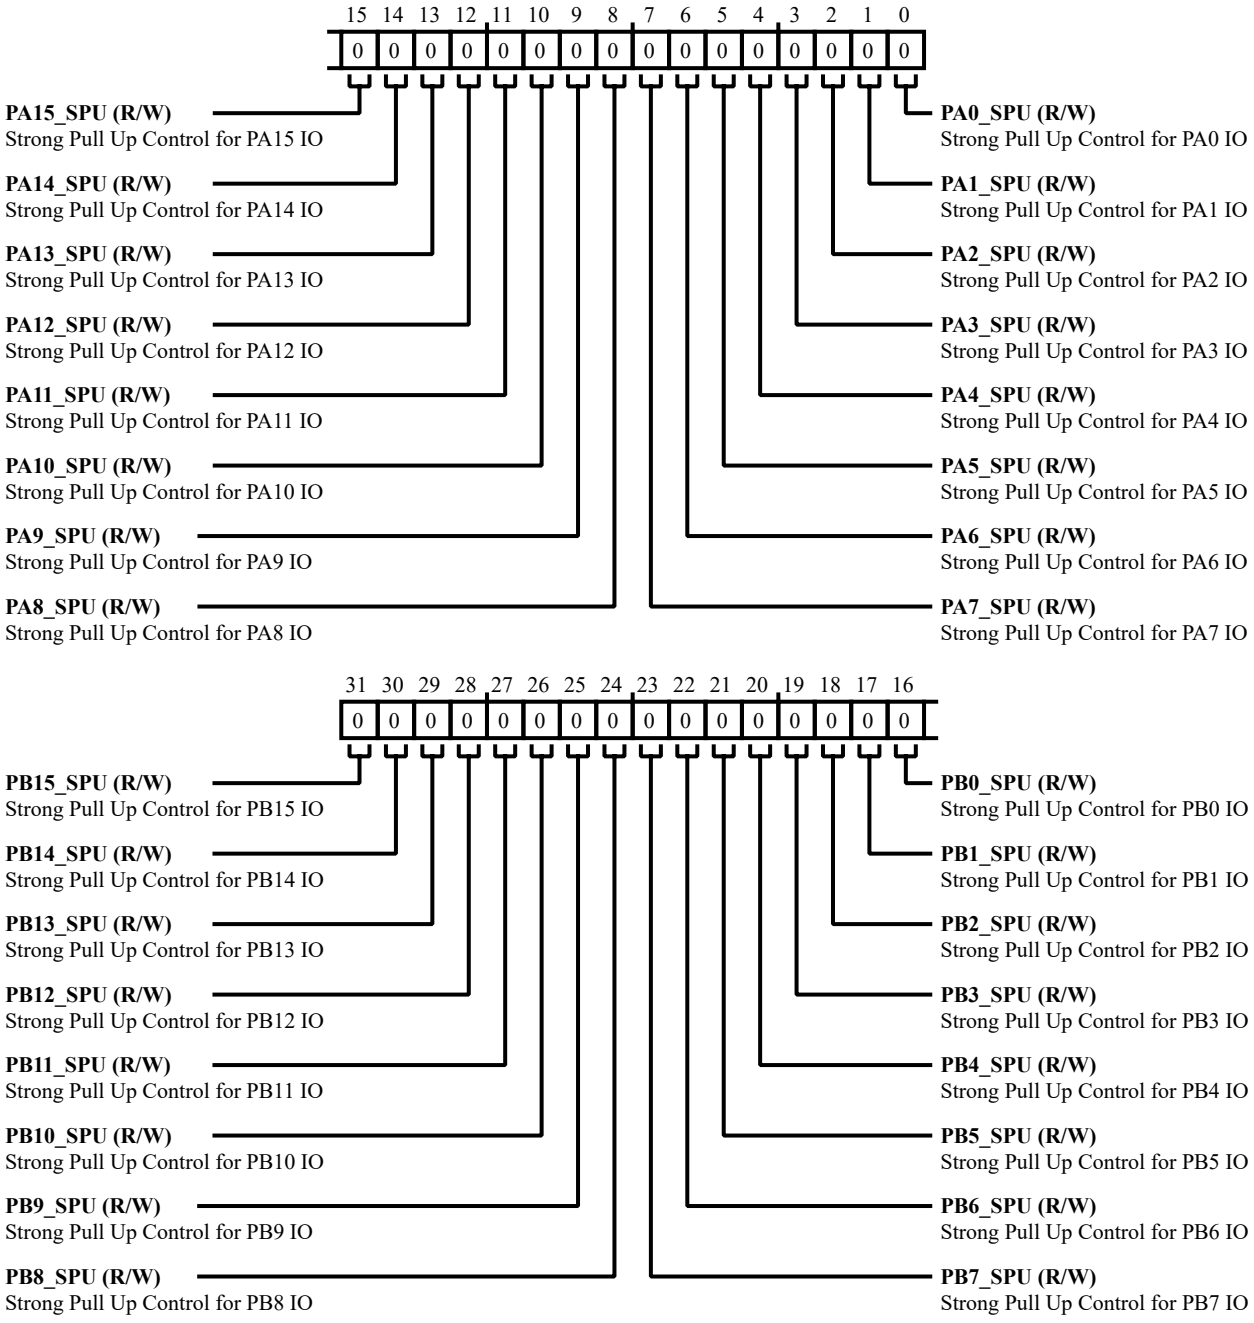

Figure 13-77: PADS_PORT_AB_SPU Register Diagram

Table 13-82: PADS_PORT_AB_SPU Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	PB15_SPU	Strong Pull Up Control for PB15 IO.
30 (R/W)	PB14_SPU	Strong Pull Up Control for PB14 IO.
29 (R/W)	PB13_SPU	Strong Pull Up Control for PB13 IO.
28 (R/W)	PB12_SPU	Strong Pull Up Control for PB12 IO.
27 (R/W)	PB11_SPU	Strong Pull Up Control for PB11 IO.
26 (R/W)	PB10_SPU	Strong Pull Up Control for PB10 IO.
25 (R/W)	PB9_SPU	Strong Pull Up Control for PB9 IO.
24 (R/W)	PB8_SPU	Strong Pull Up Control for PB8 IO.
23 (R/W)	PB7_SPU	Strong Pull Up Control for PB7 IO.
22 (R/W)	PB6_SPU	Strong Pull Up Control for PB6 IO.
21 (R/W)	PB5_SPU	Strong Pull Up Control for PB5 IO.
20 (R/W)	PB4_SPU	Strong Pull Up Control for PB4 IO.
19 (R/W)	PB3_SPU	Strong Pull Up Control for PB3 IO.
18 (R/W)	PB2_SPU	Strong Pull Up Control for PB2 IO.
17 (R/W)	PB1_SPU	Strong Pull Up Control for PB1 IO.
16 (R/W)	PB0_SPU	Strong Pull Up Control for PB0 IO.

Table 13-82: PADS_PORT_AB_SPU Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W)	PA15_SPU	Strong Pull Up Control for PA15 IO.
14 (R/W)	PA14_SPU	Strong Pull Up Control for PA14 IO.
13 (R/W)	PA13_SPU	Strong Pull Up Control for PA13 IO.
12 (R/W)	PA12_SPU	Strong Pull Up Control for PA12 IO.
11 (R/W)	PA11_SPU	Strong Pull Up Control for PA11 IO.
10 (R/W)	PA10_SPU	Strong Pull Up Control for PA10 IO.
9 (R/W)	PA9_SPU	Strong Pull Up Control for PA9 IO.
8 (R/W)	PA8_SPU	Strong Pull Up Control for PA8 IO.
7 (R/W)	PA7_SPU	Strong Pull Up Control for PA7 IO.
6 (R/W)	PA6_SPU	Strong Pull Up Control for PA6 IO.
5 (R/W)	PA5_SPU	Strong Pull Up Control for PA5 IO.
4 (R/W)	PA4_SPU	Strong Pull Up Control for PA4 IO.
3 (R/W)	PA3_SPU	Strong Pull Up Control for PA3 IO.
2 (R/W)	PA2_SPU	Strong Pull Up Control for PA2 IO.
1 (R/W)	PA1_SPU	Strong Pull Up Control for PA1 IO.
0 (R/W)	PA0_SPU	Strong Pull Up Control for PA0 IO.

PORTC and PORTD Pull Enable Register

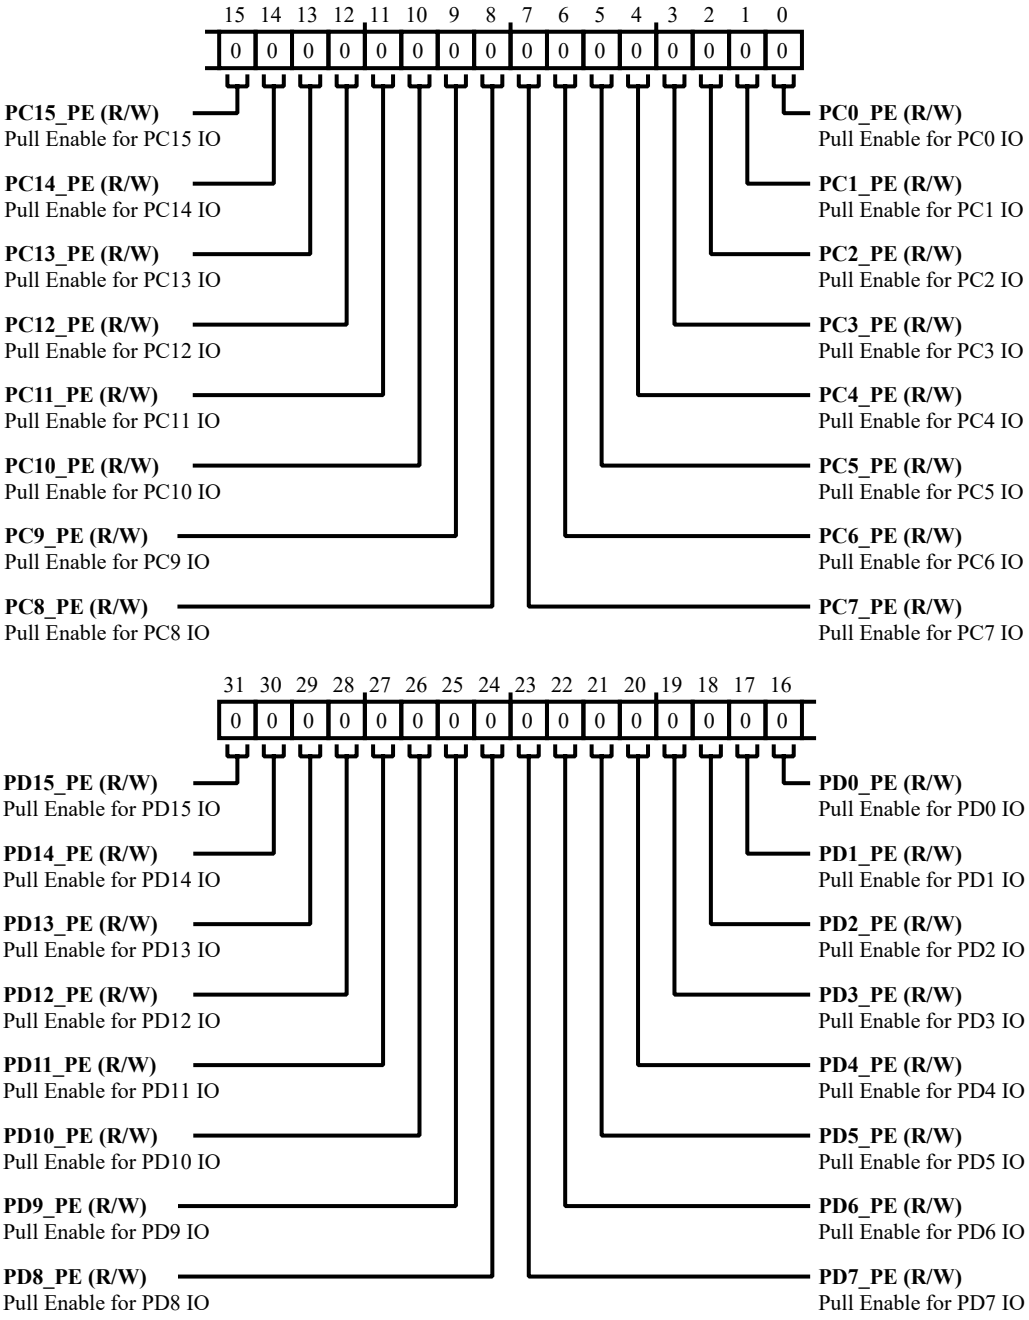

Figure 13-78: PADS_PORT_CD_PE Register Diagram

Table 13-83: PADS_PORT_CD_PE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	PD15_PE	Pull Enable for PD15 IO.
30 (R/W)	PD14_PE	Pull Enable for PD14 IO.
29 (R/W)	PD13_PE	Pull Enable for PD13 IO.
28 (R/W)	PD12_PE	Pull Enable for PD12 IO.
27 (R/W)	PD11_PE	Pull Enable for PD11 IO.
26 (R/W)	PD10_PE	Pull Enable for PD10 IO.
25 (R/W)	PD9_PE	Pull Enable for PD9 IO.
24 (R/W)	PD8_PE	Pull Enable for PD8 IO.
23 (R/W)	PD7_PE	Pull Enable for PD7 IO.
22 (R/W)	PD6_PE	Pull Enable for PD6 IO.
21 (R/W)	PD5_PE	Pull Enable for PD5 IO.
20 (R/W)	PD4_PE	Pull Enable for PD4 IO.
19 (R/W)	PD3_PE	Pull Enable for PD3 IO.
18 (R/W)	PD2_PE	Pull Enable for PD2 IO.
17 (R/W)	PD1_PE	Pull Enable for PD1 IO.
16 (R/W)	PD0_PE	Pull Enable for PD0 IO.

Table 13-83: PADS_PORT_CD_PE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W)	PC15_PE	Pull Enable for PC15 IO.
14 (R/W)	PC14_PE	Pull Enable for PC14 IO.
13 (R/W)	PC13_PE	Pull Enable for PC13 IO.
12 (R/W)	PC12_PE	Pull Enable for PC12 IO.
11 (R/W)	PC11_PE	Pull Enable for PC11 IO.
10 (R/W)	PC10_PE	Pull Enable for PC10 IO.
9 (R/W)	PC9_PE	Pull Enable for PC9 IO.
8 (R/W)	PC8_PE	Pull Enable for PC8 IO.
7 (R/W)	PC7_PE	Pull Enable for PC7 IO.
6 (R/W)	PC6_PE	Pull Enable for PC6 IO.
5 (R/W)	PC5_PE	Pull Enable for PC5 IO.
4 (R/W)	PC4_PE	Pull Enable for PC4 IO.
3 (R/W)	PC3_PE	Pull Enable for PC3 IO.
2 (R/W)	PC2_PE	Pull Enable for PC2 IO.
1 (R/W)	PC1_PE	Pull Enable for PC1 IO.
0 (R/W)	PC0_PE	Pull Enable for PC0 IO.

PORTC and PORTD Pull Selector Register

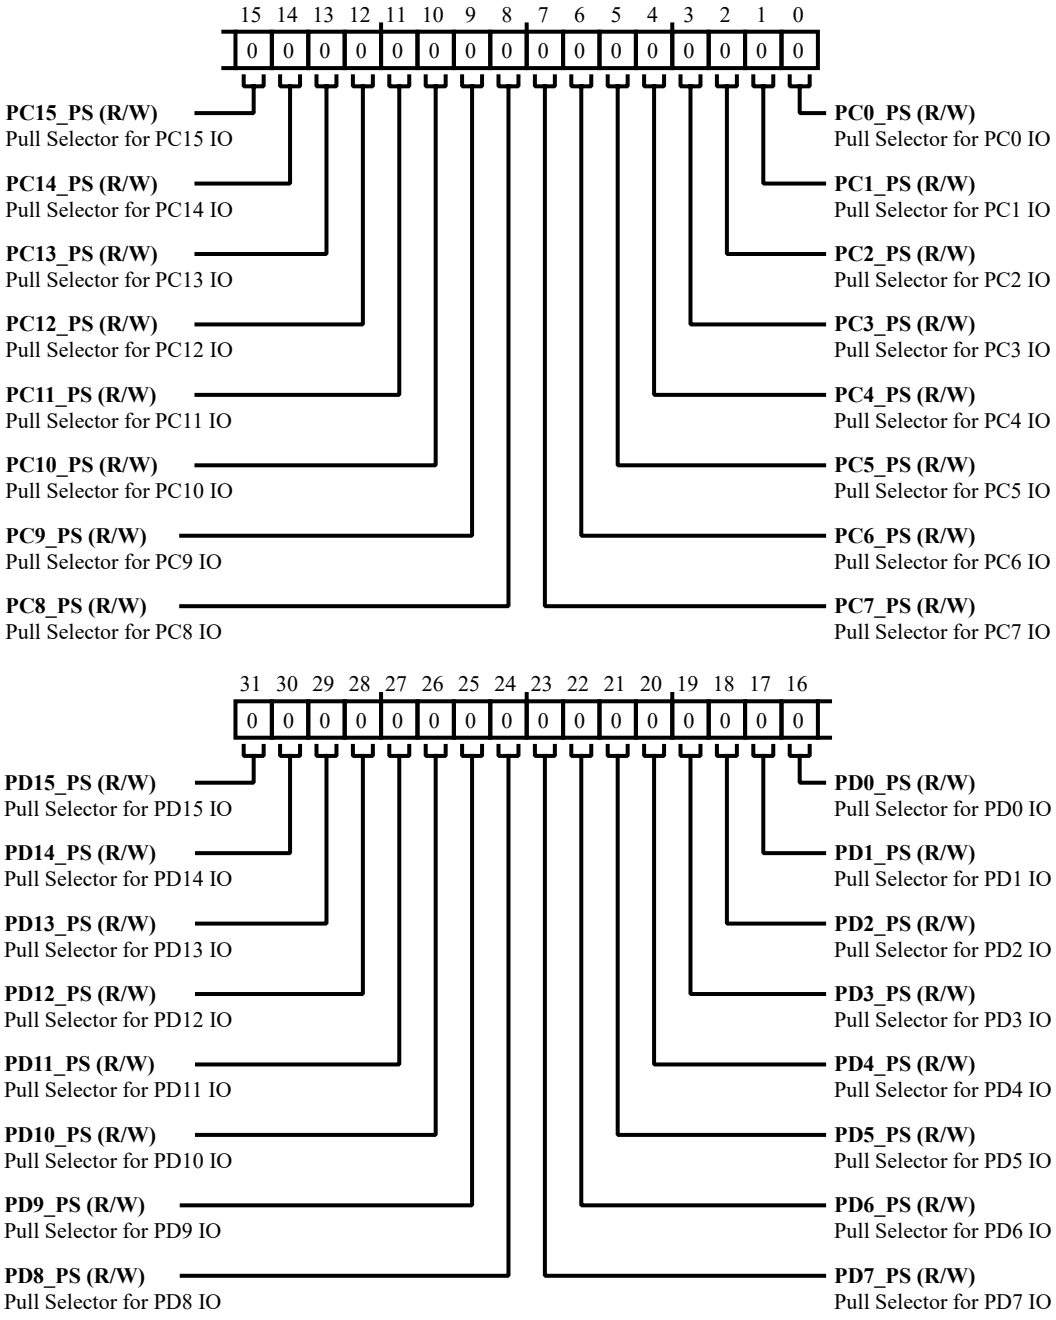

Figure 13-79: PADS_PORT_CD_PS Register Diagram

Table 13-84: PADS_PORT_CD_PS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	PD15_PS	Pull Selector for PD15 IO.
30 (R/W)	PD14_PS	Pull Selector for PD14 IO.
29 (R/W)	PD13_PS	Pull Selector for PD13 IO.
28 (R/W)	PD12_PS	Pull Selector for PD12 IO.
27 (R/W)	PD11_PS	Pull Selector for PD11 IO.
26 (R/W)	PD10_PS	Pull Selector for PD10 IO.
25 (R/W)	PD9_PS	Pull Selector for PD9 IO.
24 (R/W)	PD8_PS	Pull Selector for PD8 IO.
23 (R/W)	PD7_PS	Pull Selector for PD7 IO.
22 (R/W)	PD6_PS	Pull Selector for PD6 IO.
21 (R/W)	PD5_PS	Pull Selector for PD5 IO.
20 (R/W)	PD4_PS	Pull Selector for PD4 IO.
19 (R/W)	PD3_PS	Pull Selector for PD3 IO.
18 (R/W)	PD2_PS	Pull Selector for PD2 IO.
17 (R/W)	PD1_PS	Pull Selector for PD1 IO.
16 (R/W)	PD0_PS	Pull Selector for PD0 IO.

Table 13-84: PADS_PORT_CD_PS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W)	PC15_PS	Pull Selector for PC15 IO.
14 (R/W)	PC14_PS	Pull Selector for PC14 IO.
13 (R/W)	PC13_PS	Pull Selector for PC13 IO.
12 (R/W)	PC12_PS	Pull Selector for PC12 IO.
11 (R/W)	PC11_PS	Pull Selector for PC11 IO.
10 (R/W)	PC10_PS	Pull Selector for PC10 IO.
9 (R/W)	PC9_PS	Pull Selector for PC9 IO.
8 (R/W)	PC8_PS	Pull Selector for PC8 IO.
7 (R/W)	PC7_PS	Pull Selector for PC7 IO.
6 (R/W)	PC6_PS	Pull Selector for PC6 IO.
5 (R/W)	PC5_PS	Pull Selector for PC5 IO.
4 (R/W)	PC4_PS	Pull Selector for PC4 IO.
3 (R/W)	PC3_PS	Pull Selector for PC3 IO.
2 (R/W)	PC2_PS	Pull Selector for PC2 IO.
1 (R/W)	PC1_PS	Pull Selector for PC1 IO.
0 (R/W)	PC0_PS	Pull Selector for PC0 IO.

PORTC and PORTD Slew Rate Control Register

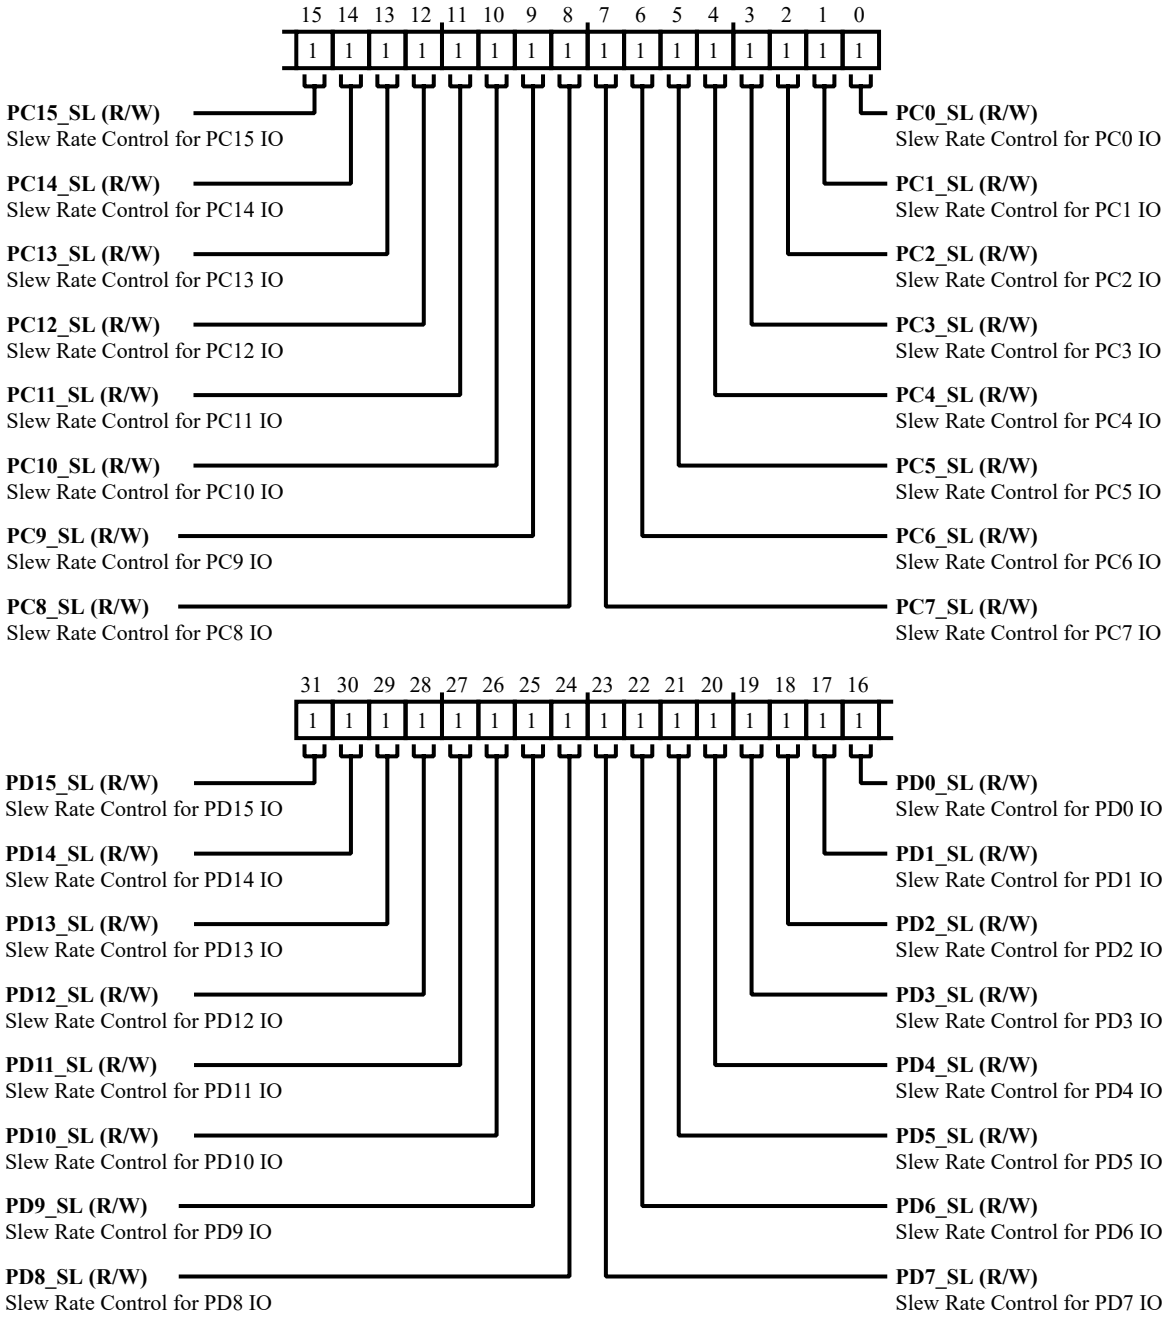

Figure 13-80: PADS_PORT_CD_SL Register Diagram

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	PD15_SL	Slew Rate Control for PD15 IO.
30 (R/W)	PD14_SL	Slew Rate Control for PD14 IO.
29 (R/W)	PD13_SL	Slew Rate Control for PD13 IO.
28 (R/W)	PD12_SL	Slew Rate Control for PD12 IO.
27 (R/W)	PD11_SL	Slew Rate Control for PD11 IO.
26 (R/W)	PD10_SL	Slew Rate Control for PD10 IO.
25 (R/W)	PD9_SL	Slew Rate Control for PD9 IO.
24 (R/W)	PD8_SL	Slew Rate Control for PD8 IO.
23 (R/W)	PD7_SL	Slew Rate Control for PD7 IO.
22 (R/W)	PD6_SL	Slew Rate Control for PD6 IO.
21 (R/W)	PD5_SL	Slew Rate Control for PD5 IO.
20 (R/W)	PD4_SL	Slew Rate Control for PD4 IO.
19 (R/W)	PD3_SL	Slew Rate Control for PD3 IO.
18 (R/W)	PD2_SL	Slew Rate Control for PD2 IO.
17 (R/W)	PD1_SL	Slew Rate Control for PD1 IO.
16 (R/W)	PD0_SL	Slew Rate Control for PD0 IO.

Table 13-85: PADS_PORT_CD_SL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W)	PC15_SL	Slew Rate Control for PC15 IO.
14 (R/W)	PC14_SL	Slew Rate Control for PC14 IO.
13 (R/W)	PC13_SL	Slew Rate Control for PC13 IO.
12 (R/W)	PC12_SL	Slew Rate Control for PC12 IO.
11 (R/W)	PC11_SL	Slew Rate Control for PC11 IO.
10 (R/W)	PC10_SL	Slew Rate Control for PC10 IO.
9 (R/W)	PC9_SL	Slew Rate Control for PC9 IO.
8 (R/W)	PC8_SL	Slew Rate Control for PC8 IO.
7 (R/W)	PC7_SL	Slew Rate Control for PC7 IO.
6 (R/W)	PC6_SL	Slew Rate Control for PC6 IO.
5 (R/W)	PC5_SL	Slew Rate Control for PC5 IO.
4 (R/W)	PC4_SL	Slew Rate Control for PC4 IO.
3 (R/W)	PC3_SL	Slew Rate Control for PC3 IO.
2 (R/W)	PC2_SL	Slew Rate Control for PC2 IO.
1 (R/W)	PC1_SL	Slew Rate Control for PC1 IO.
0 (R/W)	PC0_SL	Slew Rate Control for PC0 IO.

PORTC and PORTD Strong Pull Up Control Register

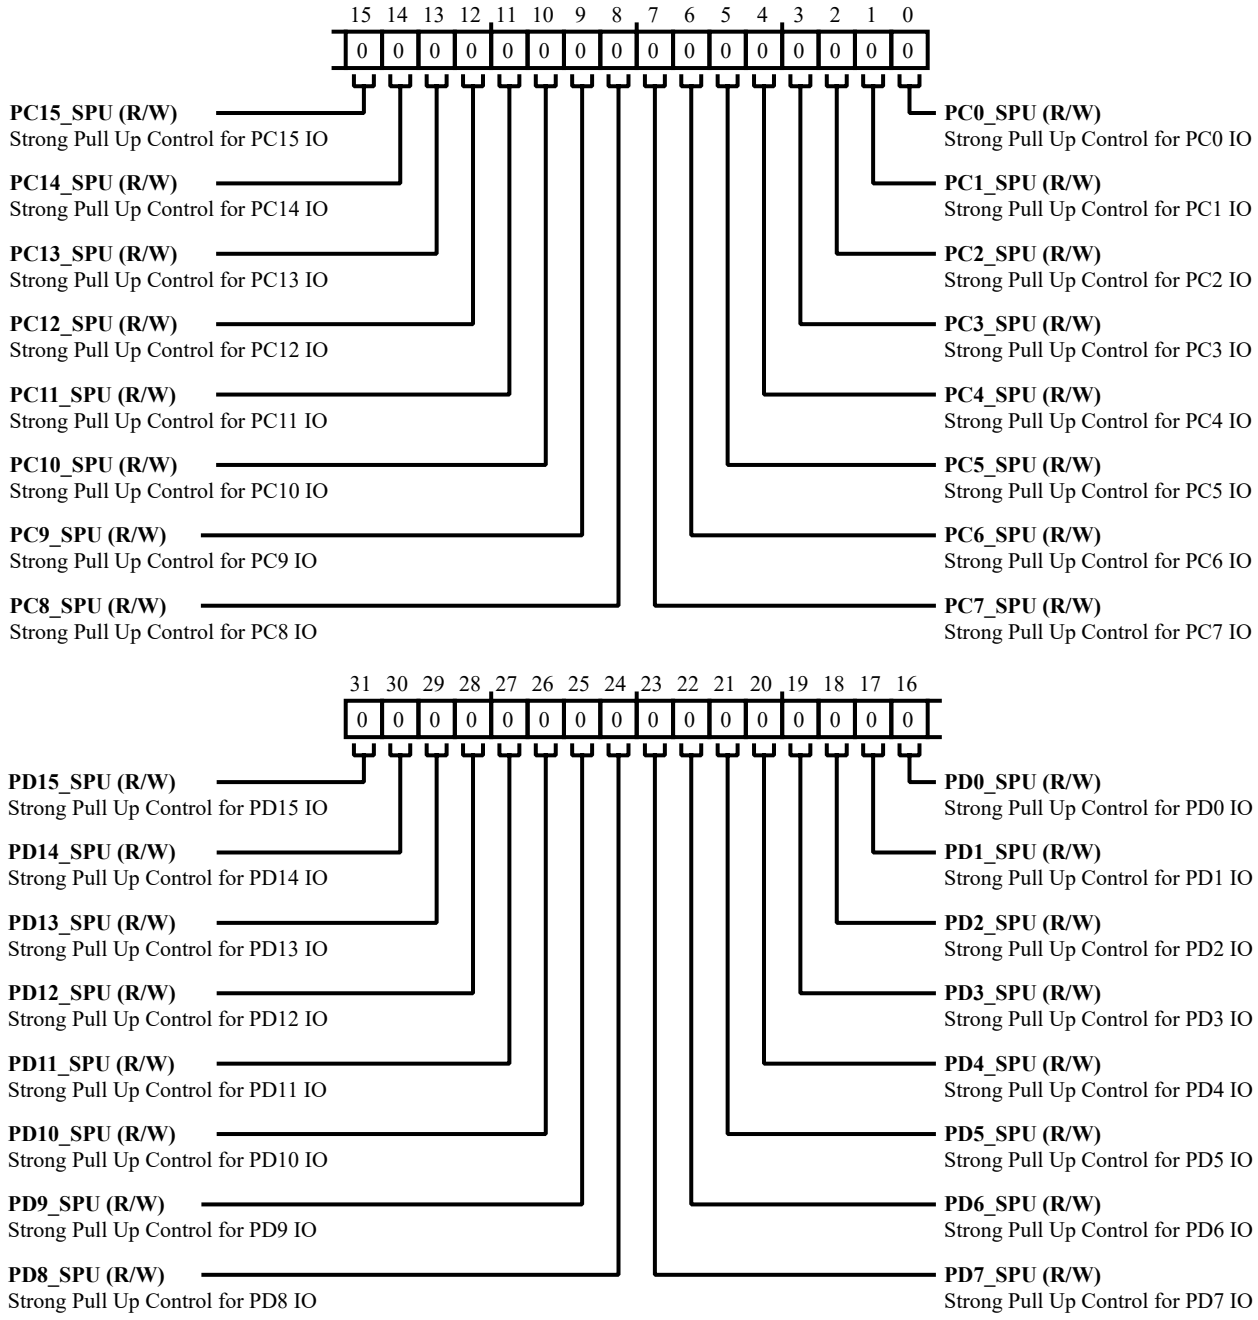

Figure 13-81: PADS_PORT_CD_SPU Register Diagram

Table 13-86: PADS_PORT_CD_SPU Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	PD15_SPU	Strong Pull Up Control for PD15 IO.
30 (R/W)	PD14_SPU	Strong Pull Up Control for PD14 IO.
29 (R/W)	PD13_SPU	Strong Pull Up Control for PD13 IO.
28 (R/W)	PD12_SPU	Strong Pull Up Control for PD12 IO.
27 (R/W)	PD11_SPU	Strong Pull Up Control for PD11 IO.
26 (R/W)	PD10_SPU	Strong Pull Up Control for PD10 IO.
25 (R/W)	PD9_SPU	Strong Pull Up Control for PD9 IO.
24 (R/W)	PD8_SPU	Strong Pull Up Control for PD8 IO.
23 (R/W)	PD7_SPU	Strong Pull Up Control for PD7 IO.
22 (R/W)	PD6_SPU	Strong Pull Up Control for PD6 IO.
21 (R/W)	PD5_SPU	Strong Pull Up Control for PD5 IO.
20 (R/W)	PD4_SPU	Strong Pull Up Control for PD4 IO.
19 (R/W)	PD3_SPU	Strong Pull Up Control for PD3 IO.
18 (R/W)	PD2_SPU	Strong Pull Up Control for PD2 IO.
17 (R/W)	PD1_SPU	Strong Pull Up Control for PD1 IO.
16 (R/W)	PD0_SPU	Strong Pull Up Control for PD0 IO.

Table 13-86: PADS_PORT_CD_SPU Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W)	PC15_SPU	Strong Pull Up Control for PC15 IO.
14 (R/W)	PC14_SPU	Strong Pull Up Control for PC14 IO.
13 (R/W)	PC13_SPU	Strong Pull Up Control for PC13 IO.
12 (R/W)	PC12_SPU	Strong Pull Up Control for PC12 IO.
11 (R/W)	PC11_SPU	Strong Pull Up Control for PC11 IO.
10 (R/W)	PC10_SPU	Strong Pull Up Control for PC10 IO.
9 (R/W)	PC9_SPU	Strong Pull Up Control for PC9 IO.
8 (R/W)	PC8_SPU	Strong Pull Up Control for PC8 IO.
7 (R/W)	PC7_SPU	Strong Pull Up Control for PC7 IO.
6 (R/W)	PC6_SPU	Strong Pull Up Control for PC6 IO.
5 (R/W)	PC5_SPU	Strong Pull Up Control for PC5 IO.
4 (R/W)	PC4_SPU	Strong Pull Up Control for PC4 IO.
3 (R/W)	PC3_SPU	Strong Pull Up Control for PC3 IO.
2 (R/W)	PC2_SPU	Strong Pull Up Control for PC2 IO.
1 (R/W)	PC1_SPU	Strong Pull Up Control for PC1 IO.
0 (R/W)	PC0_SPU	Strong Pull Up Control for PC0 IO.

PORTE and PORTF Pull Enable Register

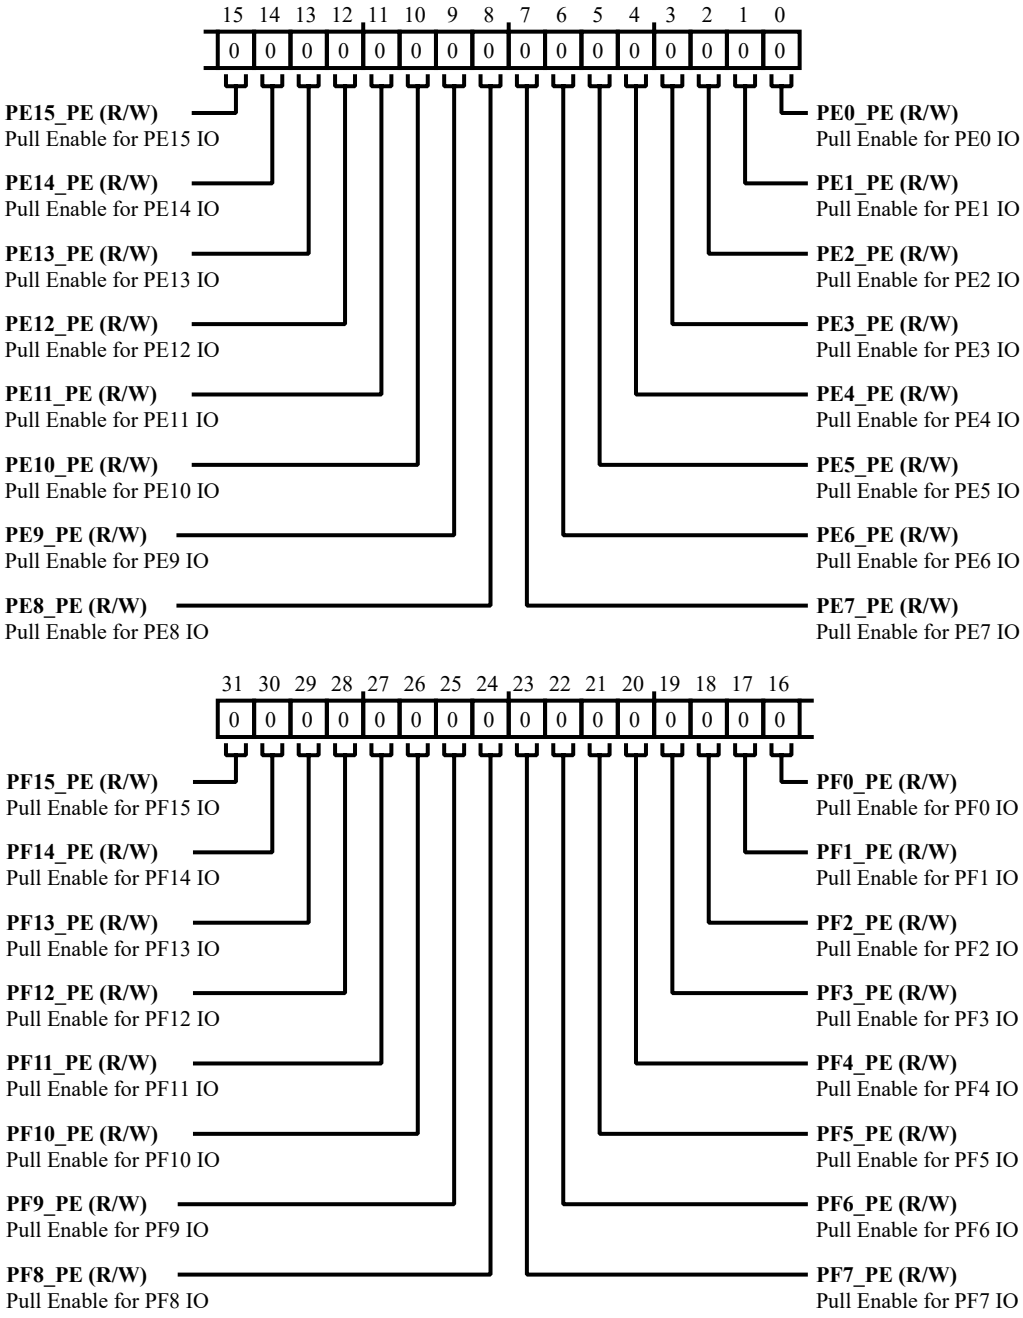

Figure 13-82: PADS_PORT_EF_PE Register Diagram

Table 13-87: PADS_PORT_EF_PE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	PF15_PE	Pull Enable for PF15 IO.
30 (R/W)	PF14_PE	Pull Enable for PF14 IO.
29 (R/W)	PF13_PE	Pull Enable for PF13 IO.
28 (R/W)	PF12_PE	Pull Enable for PF12 IO.
27 (R/W)	PF11_PE	Pull Enable for PF11 IO.
26 (R/W)	PF10_PE	Pull Enable for PF10 IO.
25 (R/W)	PF9_PE	Pull Enable for PF9 IO.
24 (R/W)	PF8_PE	Pull Enable for PF8 IO.
23 (R/W)	PF7_PE	Pull Enable for PF7 IO.
22 (R/W)	PF6_PE	Pull Enable for PF6 IO.
21 (R/W)	PF5_PE	Pull Enable for PF5 IO.
20 (R/W)	PF4_PE	Pull Enable for PF4 IO.
19 (R/W)	PF3_PE	Pull Enable for PF3 IO.
18 (R/W)	PF2_PE	Pull Enable for PF2 IO.
17 (R/W)	PF1_PE	Pull Enable for PF1 IO.
16 (R/W)	PF0_PE	Pull Enable for PF0 IO.

Table 13-87: PADS_PORT_EF_PE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W)	PE15_PE	Pull Enable for PE15 IO.
14 (R/W)	PE14_PE	Pull Enable for PE14 IO.
13 (R/W)	PE13_PE	Pull Enable for PE13 IO.
12 (R/W)	PE12_PE	Pull Enable for PE12 IO.
11 (R/W)	PE11_PE	Pull Enable for PE11 IO.
10 (R/W)	PE10_PE	Pull Enable for PE10 IO.
9 (R/W)	PE9_PE	Pull Enable for PE9 IO.
8 (R/W)	PE8_PE	Pull Enable for PE8 IO.
7 (R/W)	PE7_PE	Pull Enable for PE7 IO.
6 (R/W)	PE6_PE	Pull Enable for PE6 IO.
5 (R/W)	PE5_PE	Pull Enable for PE5 IO.
4 (R/W)	PE4_PE	Pull Enable for PE4 IO.
3 (R/W)	PE3_PE	Pull Enable for PE3 IO.
2 (R/W)	PE2_PE	Pull Enable for PE2 IO.
1 (R/W)	PE1_PE	Pull Enable for PE1 IO.
0 (R/W)	PE0_PE	Pull Enable for PE0 IO.

PORTE and PORTF Pull Selector Register

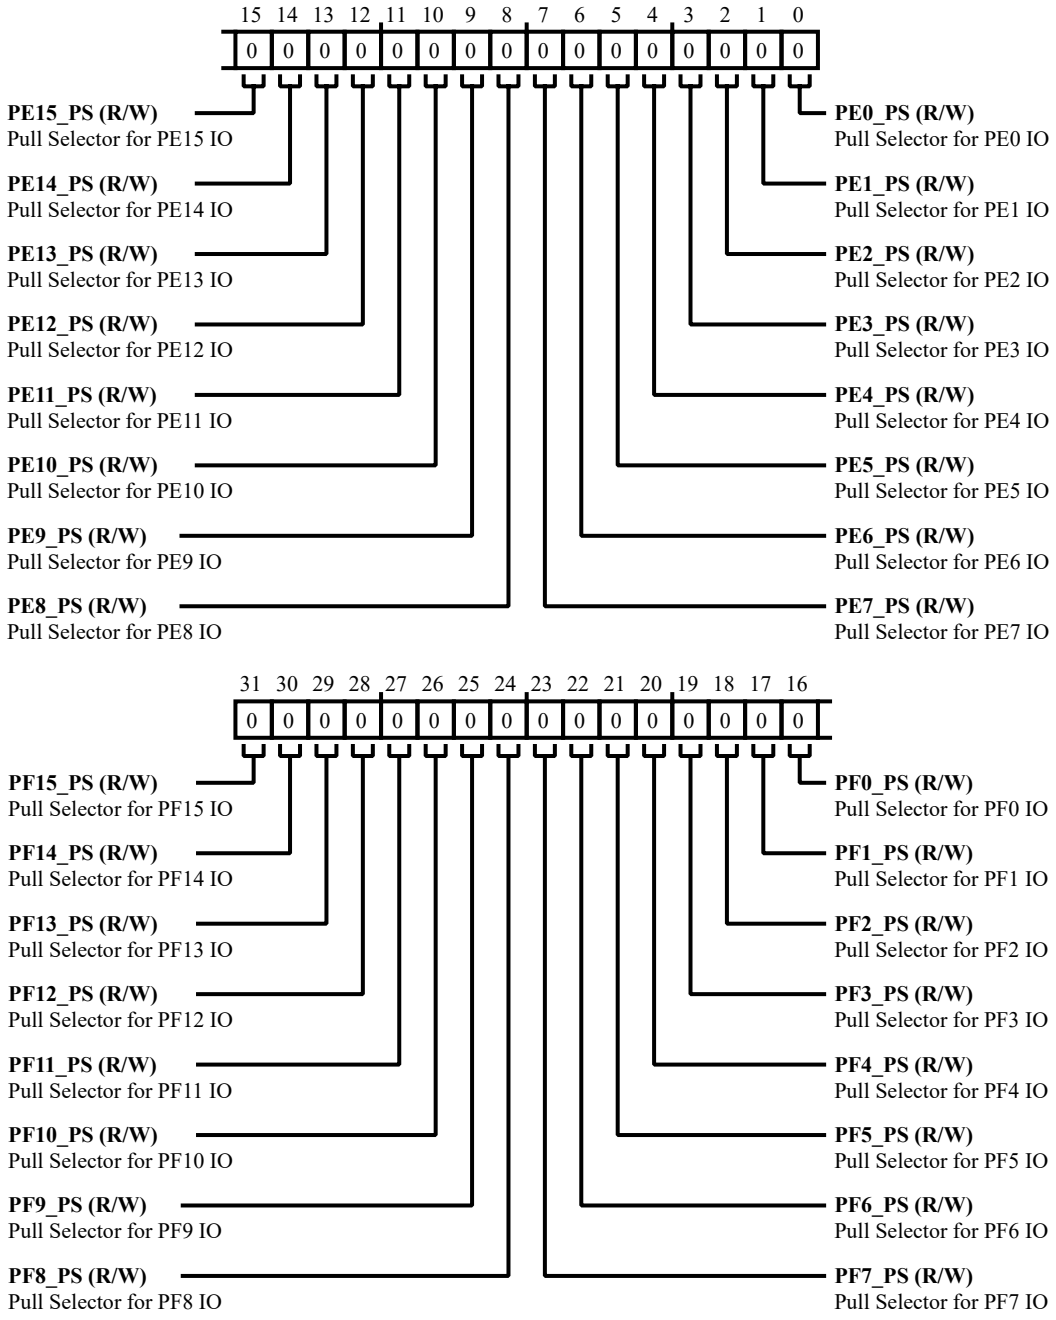

Figure 13-83: PADS_PORT_EF_PS Register Diagram

Table 13-88: PADS_PORT_EF_PS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	PF15_PS	Pull Selector for PF15 IO.
30 (R/W)	PF14_PS	Pull Selector for PF14 IO.
29 (R/W)	PF13_PS	Pull Selector for PF13 IO.
28 (R/W)	PF12_PS	Pull Selector for PF12 IO.
27 (R/W)	PF11_PS	Pull Selector for PF11 IO.
26 (R/W)	PF10_PS	Pull Selector for PF10 IO.
25 (R/W)	PF9_PS	Pull Selector for PF9 IO.
24 (R/W)	PF8_PS	Pull Selector for PF8 IO.
23 (R/W)	PF7_PS	Pull Selector for PF7 IO.
22 (R/W)	PF6_PS	Pull Selector for PF6 IO.
21 (R/W)	PF5_PS	Pull Selector for PF5 IO.
20 (R/W)	PF4_PS	Pull Selector for PF4 IO.
19 (R/W)	PF3_PS	Pull Selector for PF3 IO.
18 (R/W)	PF2_PS	Pull Selector for PF2 IO.
17 (R/W)	PF1_PS	Pull Selector for PF1 IO.
16 (R/W)	PF0_PS	Pull Selector for PF0 IO.

Table 13-88: PADS_PORT_EF_PS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W)	PE15_PS	Pull Selector for PE15 IO.
14 (R/W)	PE14_PS	Pull Selector for PE14 IO.
13 (R/W)	PE13_PS	Pull Selector for PE13 IO.
12 (R/W)	PE12_PS	Pull Selector for PE12 IO.
11 (R/W)	PE11_PS	Pull Selector for PE11 IO.
10 (R/W)	PE10_PS	Pull Selector for PE10 IO.
9 (R/W)	PE9_PS	Pull Selector for PE9 IO.
8 (R/W)	PE8_PS	Pull Selector for PE8 IO.
7 (R/W)	PE7_PS	Pull Selector for PE7 IO.
6 (R/W)	PE6_PS	Pull Selector for PE6 IO.
5 (R/W)	PE5_PS	Pull Selector for PE5 IO.
4 (R/W)	PE4_PS	Pull Selector for PE4 IO.
3 (R/W)	PE3_PS	Pull Selector for PE3 IO.
2 (R/W)	PE2_PS	Pull Selector for PE2 IO.
1 (R/W)	PE1_PS	Pull Selector for PE1 IO.
0 (R/W)	PE0_PS	Pull Selector for PE0 IO.

PORTE and PORTF Slew Rate Control Register

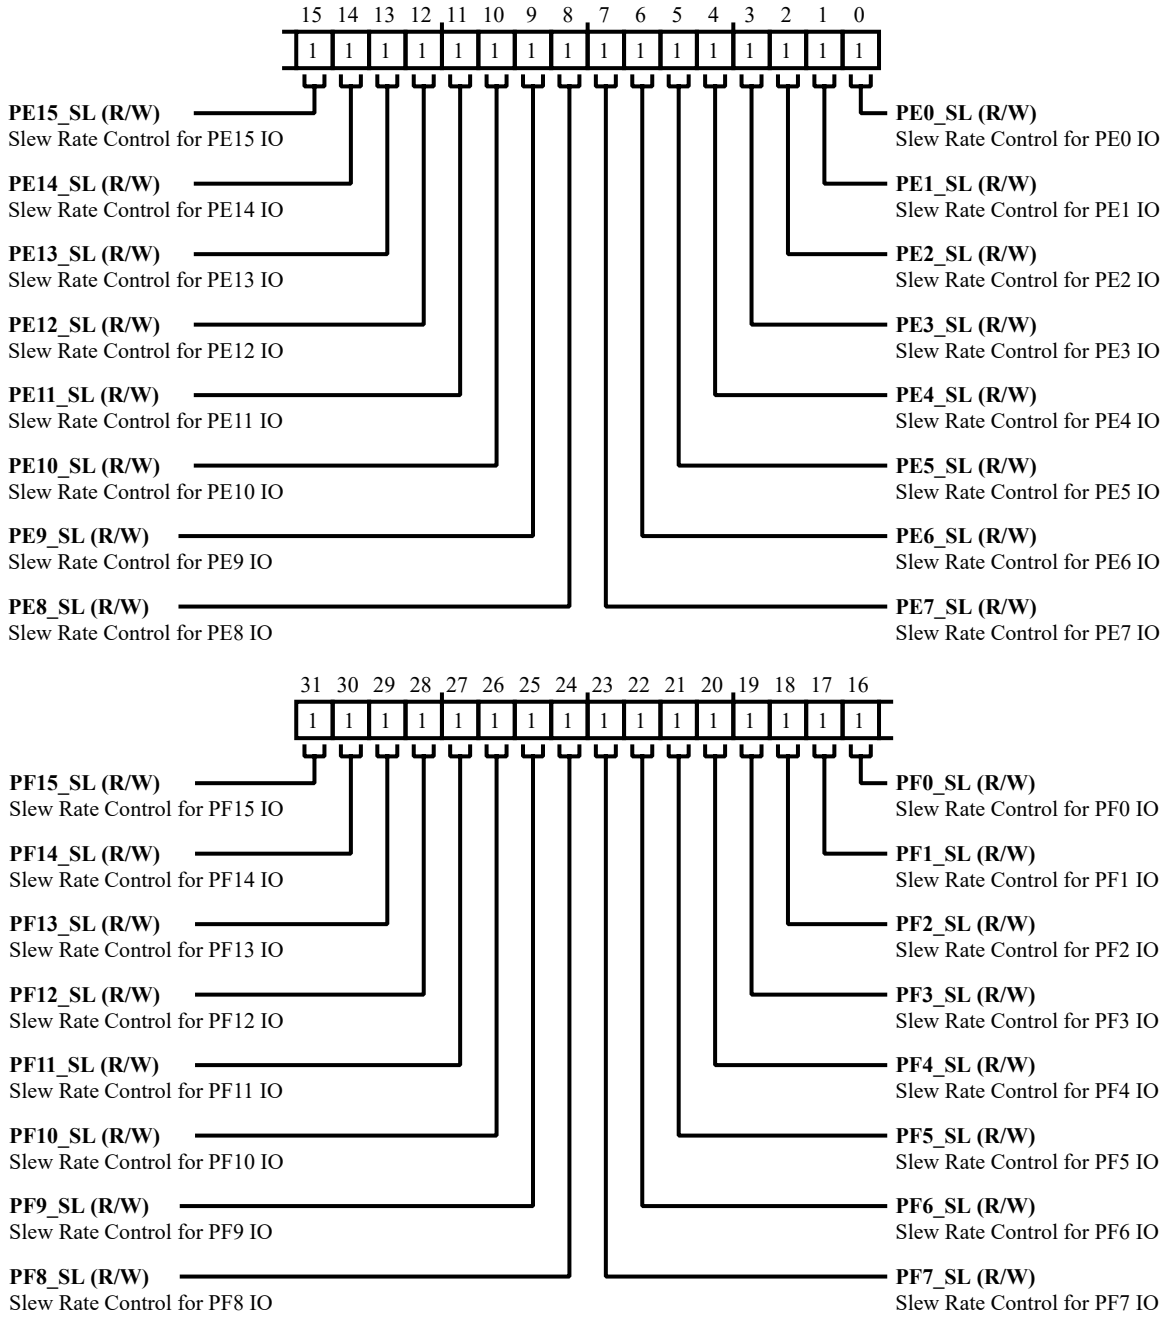

Figure 13-84: PADS_PORT_EF_SL Register Diagram

Table 13-89: PADS_PORT_EF_SL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	PF15_SL	Slew Rate Control for PF15 IO.
30 (R/W)	PF14_SL	Slew Rate Control for PF14 IO.
29 (R/W)	PF13_SL	Slew Rate Control for PF13 IO.
28 (R/W)	PF12_SL	Slew Rate Control for PF12 IO.
27 (R/W)	PF11_SL	Slew Rate Control for PF11 IO.
26 (R/W)	PF10_SL	Slew Rate Control for PF10 IO.
25 (R/W)	PF9_SL	Slew Rate Control for PF9 IO.
24 (R/W)	PF8_SL	Slew Rate Control for PF8 IO.
23 (R/W)	PF7_SL	Slew Rate Control for PF7 IO.
22 (R/W)	PF6_SL	Slew Rate Control for PF6 IO.
21 (R/W)	PF5_SL	Slew Rate Control for PF5 IO.
20 (R/W)	PF4_SL	Slew Rate Control for PF4 IO.
19 (R/W)	PF3_SL	Slew Rate Control for PF3 IO.
18 (R/W)	PF2_SL	Slew Rate Control for PF2 IO.
17 (R/W)	PF1_SL	Slew Rate Control for PF1 IO.
16 (R/W)	PF0_SL	Slew Rate Control for PF0 IO.

Table 13-89: PADS_PORT_EF_SL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W)	PE15_SL	Slew Rate Control for PE15 IO.
14 (R/W)	PE14_SL	Slew Rate Control for PE14 IO.
13 (R/W)	PE13_SL	Slew Rate Control for PE13 IO.
12 (R/W)	PE12_SL	Slew Rate Control for PE12 IO.
11 (R/W)	PE11_SL	Slew Rate Control for PE11 IO.
10 (R/W)	PE10_SL	Slew Rate Control for PE10 IO.
9 (R/W)	PE9_SL	Slew Rate Control for PE9 IO.
8 (R/W)	PE8_SL	Slew Rate Control for PE8 IO.
7 (R/W)	PE7_SL	Slew Rate Control for PE7 IO.
6 (R/W)	PE6_SL	Slew Rate Control for PE6 IO.
5 (R/W)	PE5_SL	Slew Rate Control for PE5 IO.
4 (R/W)	PE4_SL	Slew Rate Control for PE4 IO.
3 (R/W)	PE3_SL	Slew Rate Control for PE3 IO.
2 (R/W)	PE2_SL	Slew Rate Control for PE2 IO.
1 (R/W)	PE1_SL	Slew Rate Control for PE1 IO.
0 (R/W)	PE0_SL	Slew Rate Control for PE0 IO.

PORTE and PORTF Strong Pull Up Control Register

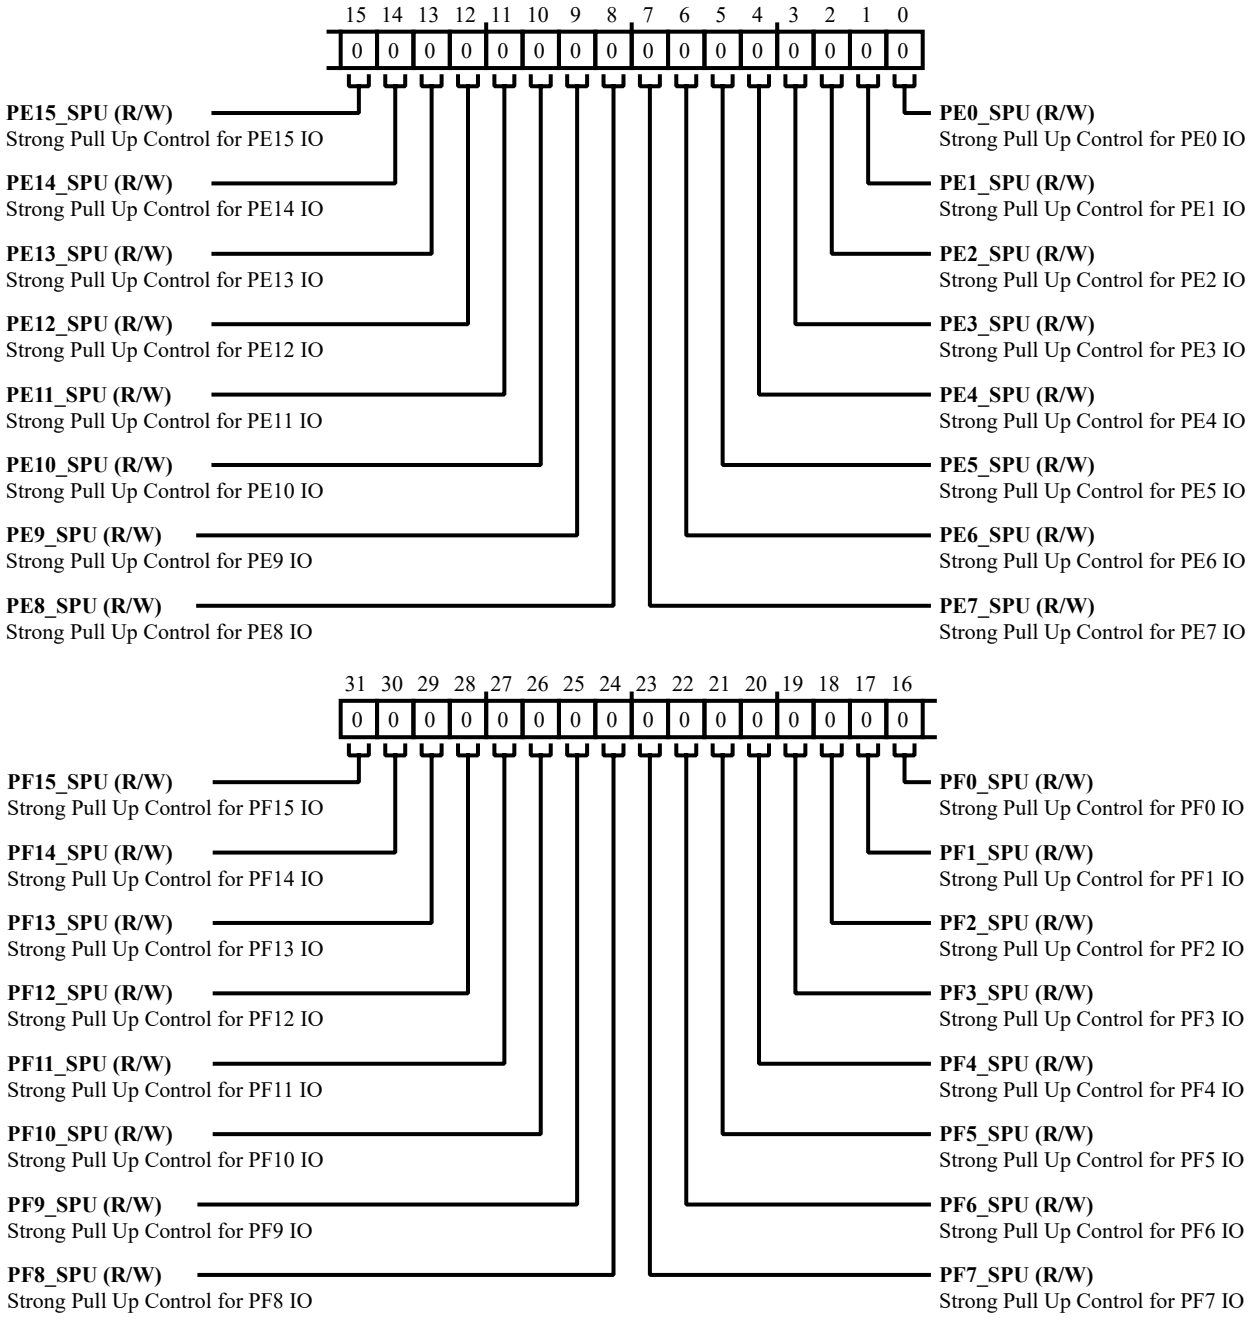

Figure 13-85: PADS_PORT_EF_SPU Register Diagram

Table 13-90: PADS_PORT_EF_SPU Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	PF15_SPU	Strong Pull Up Control for PF15 IO.
30 (R/W)	PF14_SPU	Strong Pull Up Control for PF14 IO.
29 (R/W)	PF13_SPU	Strong Pull Up Control for PF13 IO.
28 (R/W)	PF12_SPU	Strong Pull Up Control for PF12 IO.
27 (R/W)	PF11_SPU	Strong Pull Up Control for PF11 IO.
26 (R/W)	PF10_SPU	Strong Pull Up Control for PF10 IO.
25 (R/W)	PF9_SPU	Strong Pull Up Control for PF9 IO.
24 (R/W)	PF8_SPU	Strong Pull Up Control for PF8 IO.
23 (R/W)	PF7_SPU	Strong Pull Up Control for PF7 IO.
22 (R/W)	PF6_SPU	Strong Pull Up Control for PF6 IO.
21 (R/W)	PF5_SPU	Strong Pull Up Control for PF5 IO.
20 (R/W)	PF4_SPU	Strong Pull Up Control for PF4 IO.
19 (R/W)	PF3_SPU	Strong Pull Up Control for PF3 IO.
18 (R/W)	PF2_SPU	Strong Pull Up Control for PF2 IO.
17 (R/W)	PF1_SPU	Strong Pull Up Control for PF1 IO.
16 (R/W)	PF0_SPU	Strong Pull Up Control for PF0 IO.

Table 13-90: PADS_PORT_EF_SPU Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W)	PE15_SPU	Strong Pull Up Control for PE15 IO.
14 (R/W)	PE14_SPU	Strong Pull Up Control for PE14 IO.
13 (R/W)	PE13_SPU	Strong Pull Up Control for PE13 IO.
12 (R/W)	PE12_SPU	Strong Pull Up Control for PE12 IO.
11 (R/W)	PE11_SPU	Strong Pull Up Control for PE11 IO.
10 (R/W)	PE10_SPU	Strong Pull Up Control for PE10 IO.
9 (R/W)	PE9_SPU	Strong Pull Up Control for PE9 IO.
8 (R/W)	PE8_SPU	Strong Pull Up Control for PE8 IO.
7 (R/W)	PE7_SPU	Strong Pull Up Control for PE7 IO.
6 (R/W)	PE6_SPU	Strong Pull Up Control for PE6 IO.
5 (R/W)	PE5_SPU	Strong Pull Up Control for PE5 IO.
4 (R/W)	PE4_SPU	Strong Pull Up Control for PE4 IO.
3 (R/W)	PE3_SPU	Strong Pull Up Control for PE3 IO.
2 (R/W)	PE2_SPU	Strong Pull Up Control for PE2 IO.
1 (R/W)	PE1_SPU	Strong Pull Up Control for PE1 IO.
0 (R/W)	PE0_SPU	Strong Pull Up Control for PE0 IO.

PORTG and PORTH Pull Enable Register

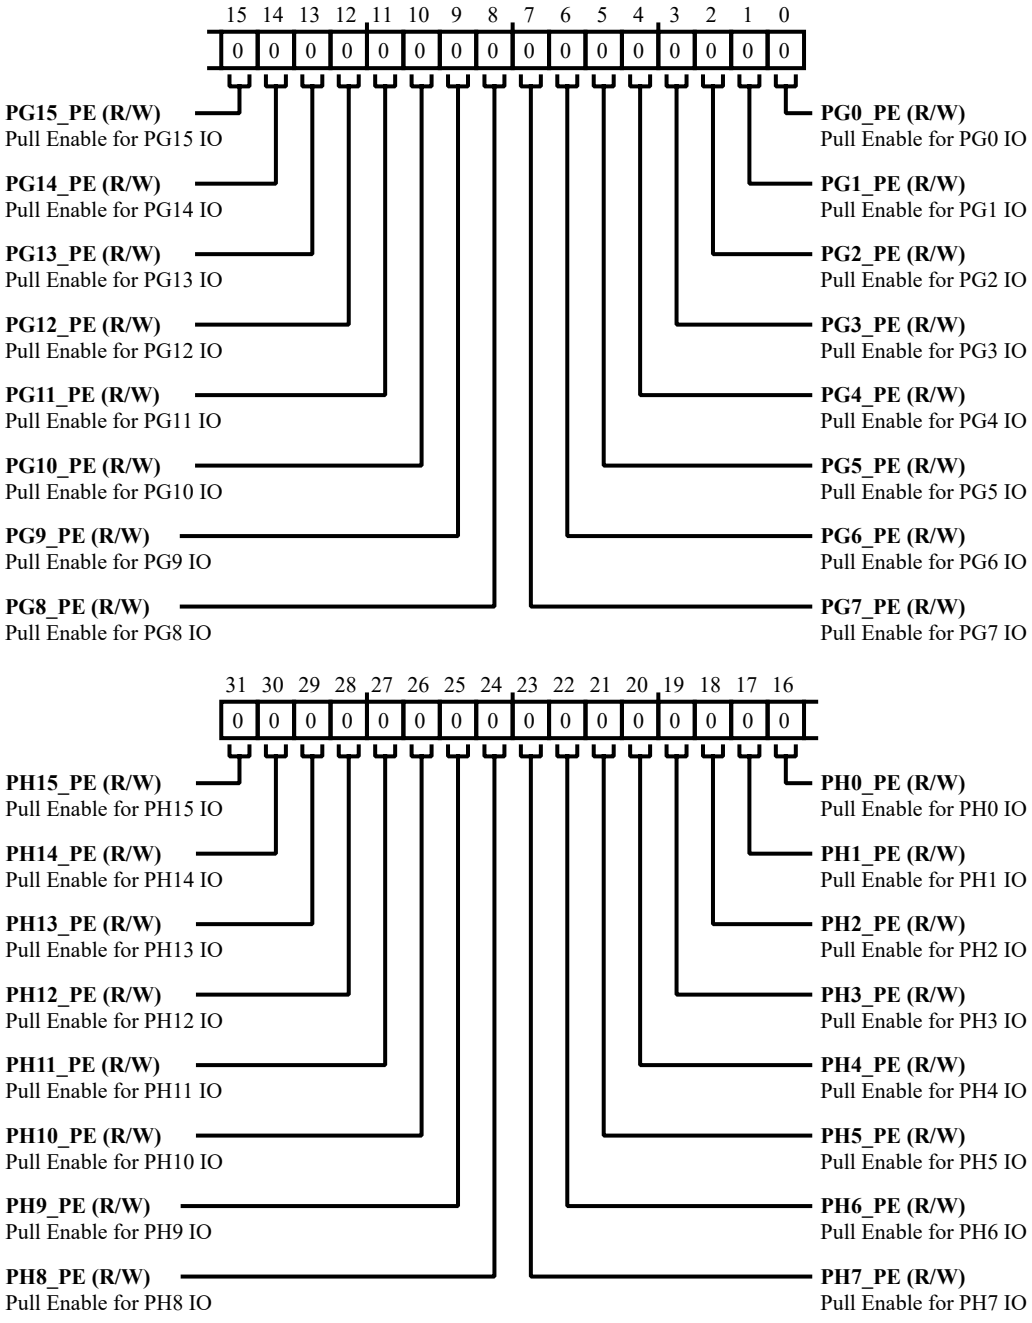

Figure 13-86: PADS_PORT_GH_PE Register Diagram

Table 13-91: PADS_PORT_GH_PE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	PH15_PE	Pull Enable for PH15 IO.
30 (R/W)	PH14_PE	Pull Enable for PH14 IO.
29 (R/W)	PH13_PE	Pull Enable for PH13 IO.
28 (R/W)	PH12_PE	Pull Enable for PH12 IO.
27 (R/W)	PH11_PE	Pull Enable for PH11 IO.
26 (R/W)	PH10_PE	Pull Enable for PH10 IO.
25 (R/W)	PH9_PE	Pull Enable for PH9 IO.
24 (R/W)	PH8_PE	Pull Enable for PH8 IO.
23 (R/W)	PH7_PE	Pull Enable for PH7 IO.
22 (R/W)	PH6_PE	Pull Enable for PH6 IO.
21 (R/W)	PH5_PE	Pull Enable for PH5 IO.
20 (R/W)	PH4_PE	Pull Enable for PH4 IO.
19 (R/W)	PH3_PE	Pull Enable for PH3 IO.
18 (R/W)	PH2_PE	Pull Enable for PH2 IO.
17 (R/W)	PH1_PE	Pull Enable for PH1 IO.
16 (R/W)	PH0_PE	Pull Enable for PH0 IO.

Table 13-91: PADS_PORT_GH_PE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W)	PG15_PE	Pull Enable for PG15 IO.
14 (R/W)	PG14_PE	Pull Enable for PG14 IO.
13 (R/W)	PG13_PE	Pull Enable for PG13 IO.
12 (R/W)	PG12_PE	Pull Enable for PG12 IO.
11 (R/W)	PG11_PE	Pull Enable for PG11 IO.
10 (R/W)	PG10_PE	Pull Enable for PG10 IO.
9 (R/W)	PG9_PE	Pull Enable for PG9 IO.
8 (R/W)	PG8_PE	Pull Enable for PG8 IO.
7 (R/W)	PG7_PE	Pull Enable for PG7 IO.
6 (R/W)	PG6_PE	Pull Enable for PG6 IO.
5 (R/W)	PG5_PE	Pull Enable for PG5 IO.
4 (R/W)	PG4_PE	Pull Enable for PG4 IO.
3 (R/W)	PG3_PE	Pull Enable for PG3 IO.
2 (R/W)	PG2_PE	Pull Enable for PG2 IO.
1 (R/W)	PG1_PE	Pull Enable for PG1 IO.
0 (R/W)	PG0_PE	Pull Enable for PG0 IO.

PORTG and PORTH Pull Selector Register

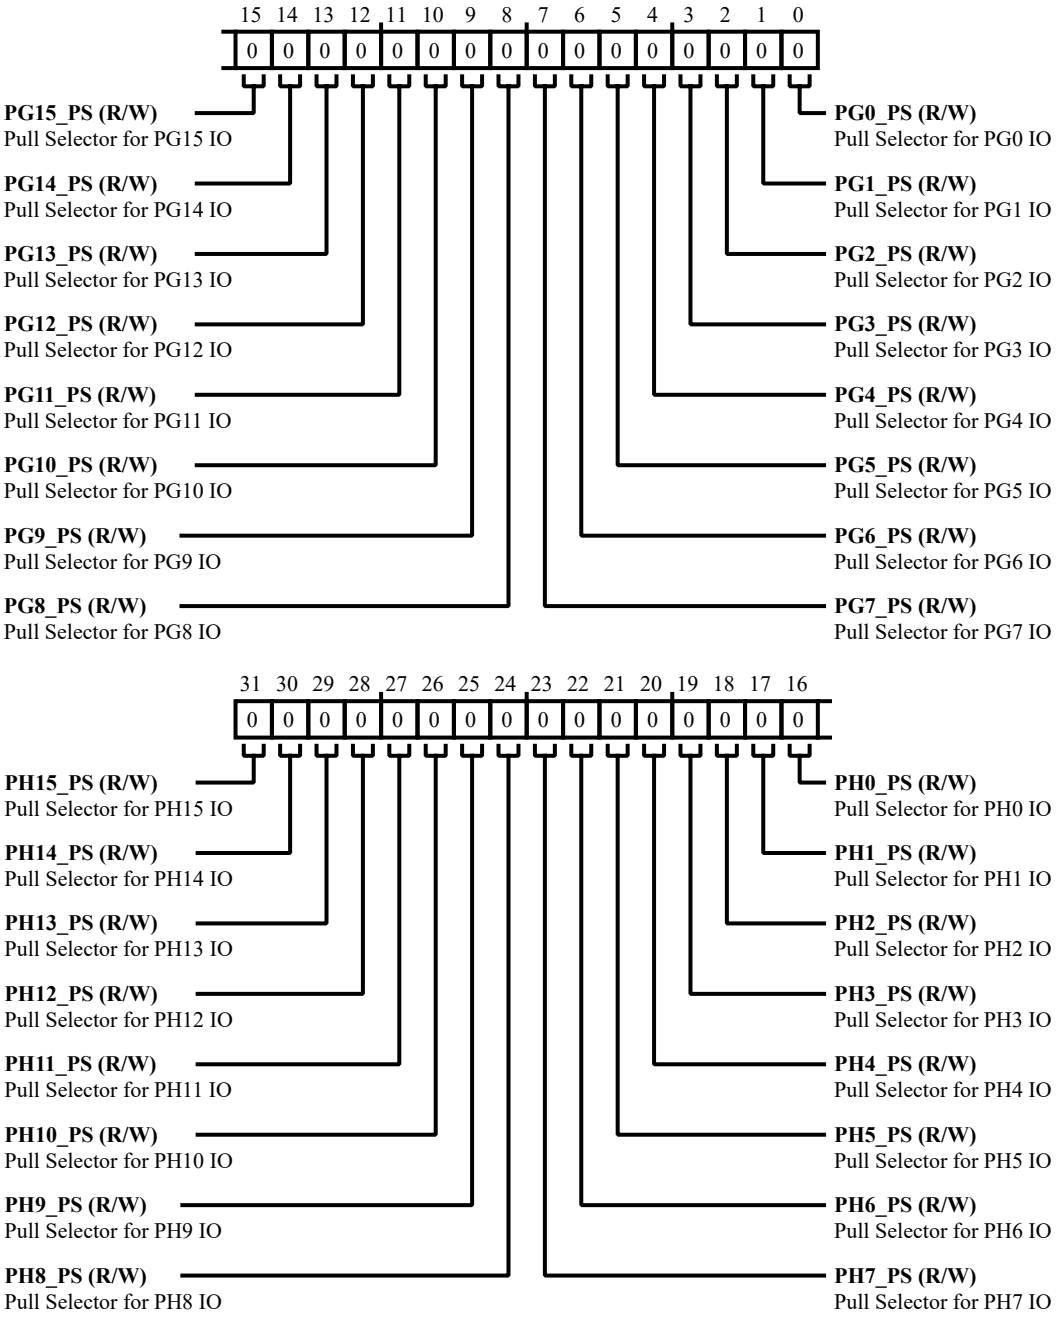

Figure 13-87: PADS_PORT_GH_PS Register Diagram

Table 13-92: PADS_PORT_GH_PS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	PH15_PS	Pull Selector for PH15 IO.
30 (R/W)	PH14_PS	Pull Selector for PH14 IO.
29 (R/W)	PH13_PS	Pull Selector for PH13 IO.
28 (R/W)	PH12_PS	Pull Selector for PH12 IO.
27 (R/W)	PH11_PS	Pull Selector for PH11 IO.
26 (R/W)	PH10_PS	Pull Selector for PH10 IO.
25 (R/W)	PH9_PS	Pull Selector for PH9 IO.
24 (R/W)	PH8_PS	Pull Selector for PH8 IO.
23 (R/W)	PH7_PS	Pull Selector for PH7 IO.
22 (R/W)	PH6_PS	Pull Selector for PH6 IO.
21 (R/W)	PH5_PS	Pull Selector for PH5 IO.
20 (R/W)	PH4_PS	Pull Selector for PH4 IO.
19 (R/W)	PH3_PS	Pull Selector for PH3 IO.
18 (R/W)	PH2_PS	Pull Selector for PH2 IO.
17 (R/W)	PH1_PS	Pull Selector for PH1 IO.
16 (R/W)	PH0_PS	Pull Selector for PH0 IO.

Table 13-92: PADS_PORT_GH_PS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W)	PG15_PS	Pull Selector for PG15 IO.
14 (R/W)	PG14_PS	Pull Selector for PG14 IO.
13 (R/W)	PG13_PS	Pull Selector for PG13 IO.
12 (R/W)	PG12_PS	Pull Selector for PG12 IO.
11 (R/W)	PG11_PS	Pull Selector for PG11 IO.
10 (R/W)	PG10_PS	Pull Selector for PG10 IO.
9 (R/W)	PG9_PS	Pull Selector for PG9 IO.
8 (R/W)	PG8_PS	Pull Selector for PG8 IO.
7 (R/W)	PG7_PS	Pull Selector for PG7 IO.
6 (R/W)	PG6_PS	Pull Selector for PG6 IO.
5 (R/W)	PG5_PS	Pull Selector for PG5 IO.
4 (R/W)	PG4_PS	Pull Selector for PG4 IO.
3 (R/W)	PG3_PS	Pull Selector for PG3 IO.
2 (R/W)	PG2_PS	Pull Selector for PG2 IO.
1 (R/W)	PG1_PS	Pull Selector for PG1 IO.
0 (R/W)	PG0_PS	Pull Selector for PG0 IO.

PORTG and PORTH Slew Rate Control Register

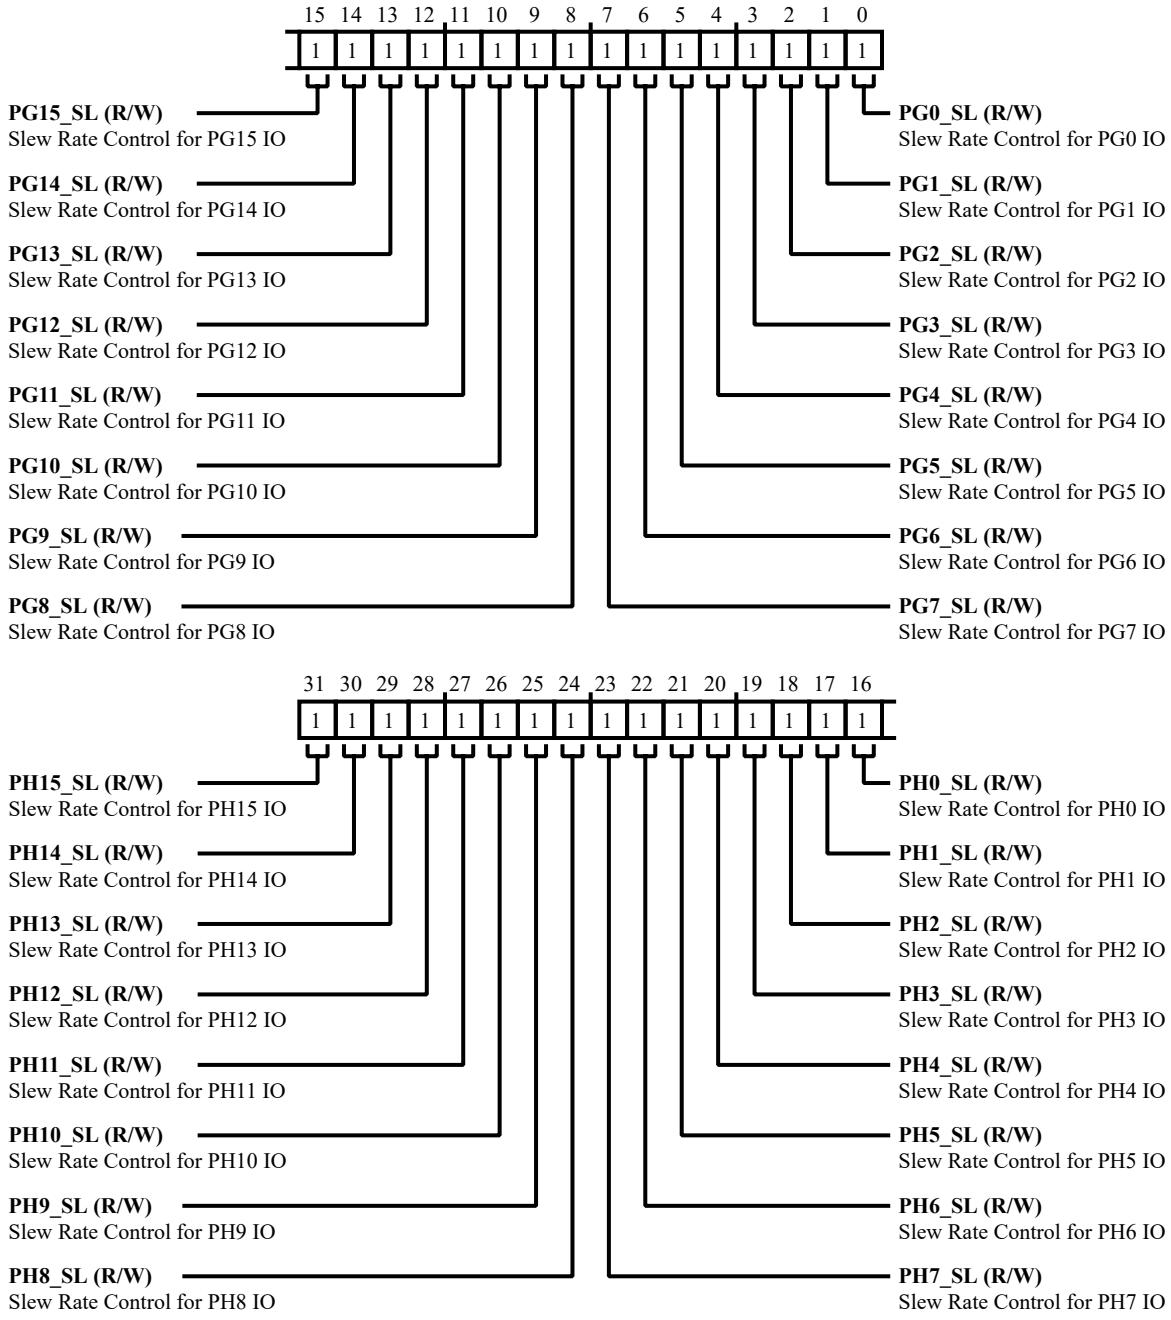

Figure 13-88: PADS_PORT_GH_SL Register Diagram

Table 13-93: PADS_PORT_GH_SL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	PH15_SL	Slew Rate Control for PH15 IO.
30 (R/W)	PH14_SL	Slew Rate Control for PH14 IO.
29 (R/W)	PH13_SL	Slew Rate Control for PH13 IO.
28 (R/W)	PH12_SL	Slew Rate Control for PH12 IO.
27 (R/W)	PH11_SL	Slew Rate Control for PH11 IO.
26 (R/W)	PH10_SL	Slew Rate Control for PH10 IO.
25 (R/W)	PH9_SL	Slew Rate Control for PH9 IO.
24 (R/W)	PH8_SL	Slew Rate Control for PH8 IO.
23 (R/W)	PH7_SL	Slew Rate Control for PH7 IO.
22 (R/W)	PH6_SL	Slew Rate Control for PH6 IO.
21 (R/W)	PH5_SL	Slew Rate Control for PH5 IO.
20 (R/W)	PH4_SL	Slew Rate Control for PH4 IO.
19 (R/W)	PH3_SL	Slew Rate Control for PH3 IO.
18 (R/W)	PH2_SL	Slew Rate Control for PH2 IO.
17 (R/W)	PH1_SL	Slew Rate Control for PH1 IO.
16 (R/W)	PH0_SL	Slew Rate Control for PH0 IO.

Table 13-93: PADS_PORT_GH_SL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W)	PG15_SL	Slew Rate Control for PG15 IO.
14 (R/W)	PG14_SL	Slew Rate Control for PG14 IO.
13 (R/W)	PG13_SL	Slew Rate Control for PG13 IO.
12 (R/W)	PG12_SL	Slew Rate Control for PG12 IO.
11 (R/W)	PG11_SL	Slew Rate Control for PG11 IO.
10 (R/W)	PG10_SL	Slew Rate Control for PG10 IO.
9 (R/W)	PG9_SL	Slew Rate Control for PG9 IO.
8 (R/W)	PG8_SL	Slew Rate Control for PG8 IO.
7 (R/W)	PG7_SL	Slew Rate Control for PG7 IO.
6 (R/W)	PG6_SL	Slew Rate Control for PG6 IO.
5 (R/W)	PG5_SL	Slew Rate Control for PG5 IO.
4 (R/W)	PG4_SL	Slew Rate Control for PG4 IO.
3 (R/W)	PG3_SL	Slew Rate Control for PG3 IO.
2 (R/W)	PG2_SL	Slew Rate Control for PG2 IO.
1 (R/W)	PG1_SL	Slew Rate Control for PG1 IO.
0 (R/W)	PG0_SL	Slew Rate Control for PG0 IO.

PORTG and PORTH Strong Pull Up Control Register

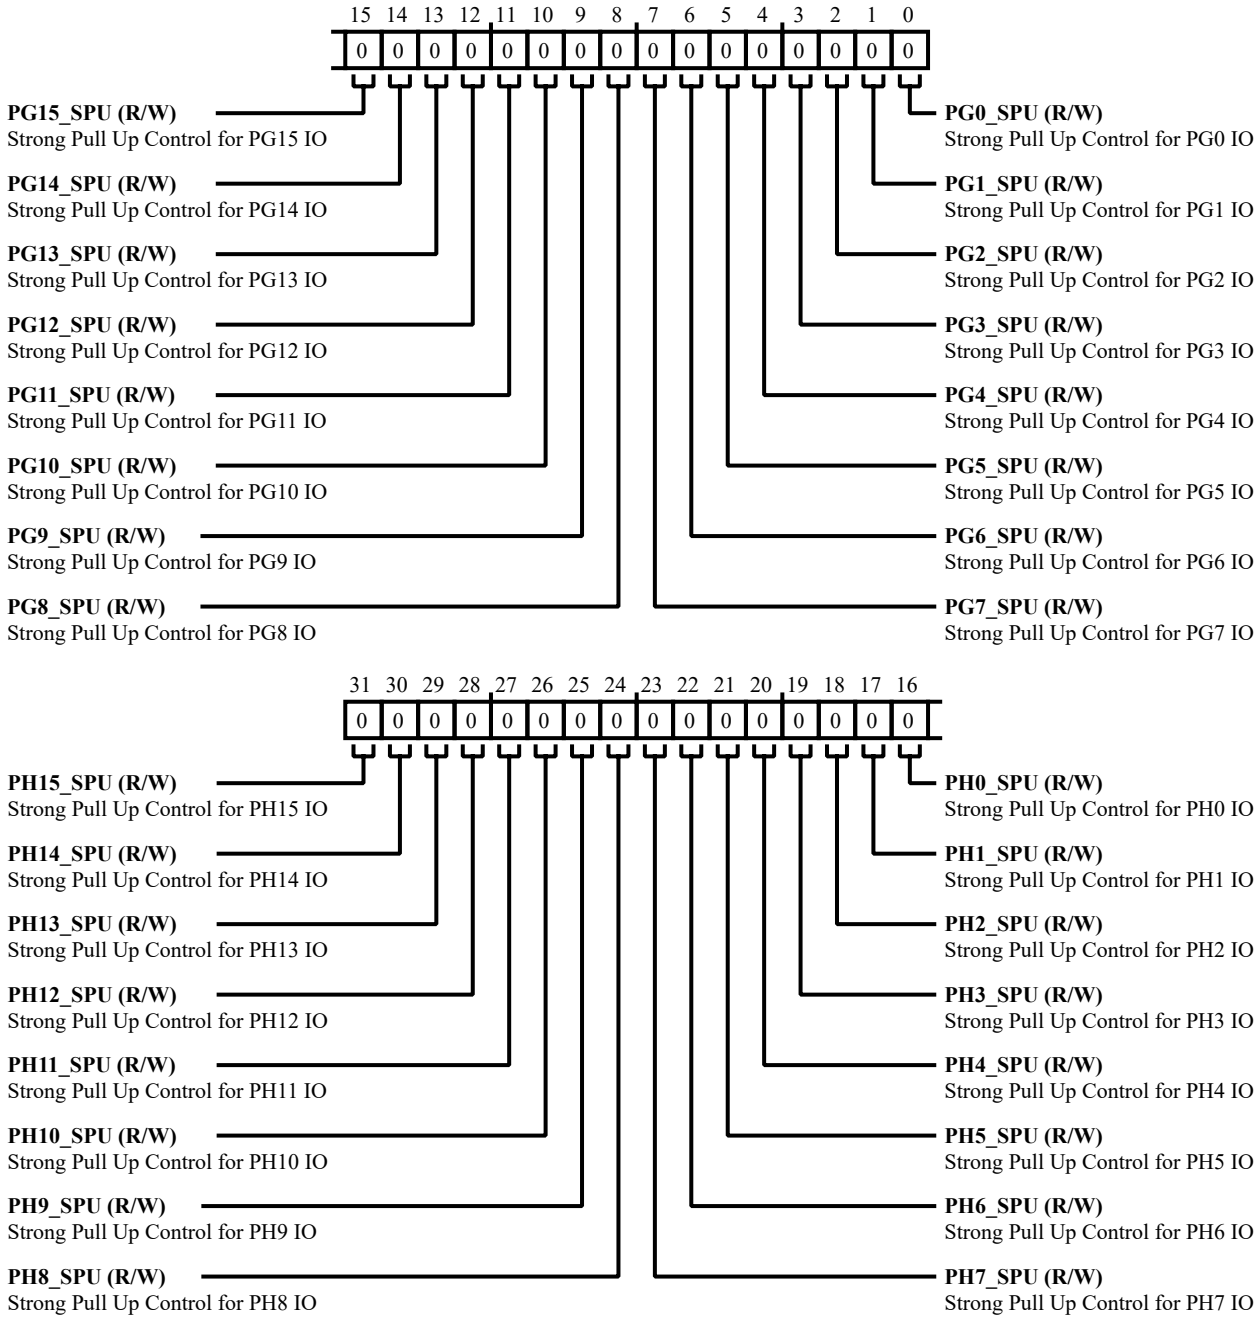

Figure 13-89: PADS_PORT_GH_SPU Register Diagram

Table 13-94: PADS_PORT_GH_SPU Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	PH15_SPU	Strong Pull Up Control for PH15 IO.
30 (R/W)	PH14_SPU	Strong Pull Up Control for PH14 IO.
29 (R/W)	PH13_SPU	Strong Pull Up Control for PH13 IO.

14 Thermal Monitoring Unit (TMU)

The TMU provides on-chip temperature measurement which is important in applications that have substantial power consumption. The TMU is integrated into the processor die and digital infrastructure using an MMR-based system access to measure the die temperature variations in real-time.

TMU Features

The TMU supports the following features:

- On-chip temperature sensing
- Programmable over-temperature and under-temperature limits
- Programmable conversion rate
- Averaging feature available
- Temperature gain and offset correction options
- Uses dedicated channel of HADC for conversion
- Programmable blanking and refresh period for TMU conversion

TMU Functional Description

Following sections provide the functional description of TMU.

TMU Definitions

The following definitions are helpful when using the TMU module.

Thermal Diode

A special type of diode whose electrical properties change with the temperature in a defined way.

DTM

Dynamic thermal management is a set of techniques that adapt the run-time behavior of a processor to achieve the highest performance under thermal constraints.

TMU Block Diagram

The ***Thermal Monitoring Unit Block Diagram*** shows the main block inside TMU.

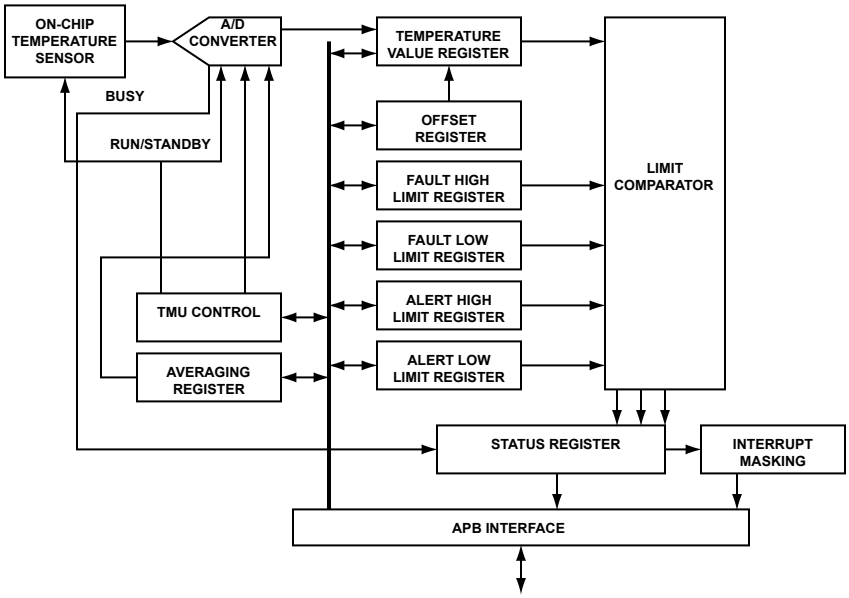

Figure 14-1: Thermal Monitoring Unit Block Diagram

TMU Architectural Concepts

The following sections provide information on the architecture and system integration of the TMU.

System Integration

Dynamic thermal management (DTM) techniques adapt the run-time behavior of a processor to achieve the highest performance under thermal constraints. One of the most important aspects of DTM is to capture the run-time variations in the temperature caused by power consumption variations due to workload changes.

The accuracy of thermal measurements directly affects the efficiency of thermal management as well as the performance of the processor. Temperature estimations lower or higher than the actual temperature may cause late or early activation of DTM techniques.

- Late activation of DTM can result in degraded reliability because the temperature may exceed the designated thresholds.
- Early activation of DTM can have significant impact on performance.

The TMU is an analog thermal sensor that consists of a temperature-sensing diode, a calibrated reference current source, and a current comparator. The sensor placement error is one of the most important sources of inaccuracy in values obtained from thermal sensors.

The TMU module provides the temperature monitoring capability to the chip and implements thermal management in the end system. It provides many features which ensure the minimum load on the software and also minimal or no external components for a flexible temperature monitoring system.

Digital Thermometer

The TMU functions as a digital thermometer with an MMR-based system access. The on-die temperature value is measured and digitized through an A/D converter. The temperature value is stored and updated periodically in an MMR register. The TMU can be configured to generate an interrupt as it crosses the upper temperature limit (`TMU_FLT_LIM_HI` register). A thermal event is also routed to the interrupt port of the sensor. The event is then routed to the SEC, to ensure that core intervention is not required in the event of overheating.

Temperature Sensor Averaging

The temperature sensor averaging feature enhances the accuracy of the temperature measurements. This feature is enabled by default after power-up. In this mode, the averaging reduces the effect of noise on the temperature result. The temperature is measured each time a conversion is performed. A moving average method is used to determine the result in the temperature value register. The total time to measure a temperature channel is typically 1 ms.

TMU and HADC

The TMU modules uses one of the ADC channels to digitize the temperature reading. Therefore, the HADC module is shared by the TMU. If the TMU is not enabled, the HADC operates at its full throughput. TMU can be enabled periodically or permanently. In periodic enable mode, it is enabled once in a specific refresh period. After enabling, the TMU measures the temperature for a specific blanking period. During the blanking period, the TMU uses the ADC for temperature measurement, so that the ADC is not available for data conversion.

The typical value of blanking period is 1.1×10^6 system clock (SCLK) cycles.

The typical value of refresh period is 21×10^6 SCLK cycles.

So, for every 21×10^6 cycles, 1.1×10^6 cycles are used for temperature measurement. Program these values for blanking period and refresh period through the TMU registers.

When TMU is enabled, the HADC modules is not available for external input conversion. This state is indicated by the `HADC_STAT.TMUHADC_BUSY` status bit. All the requests for HADC conversion are ignored when `HADC_STAT.TMUHADC_BUSY` bit is high.

In the periodic enable mode, the ongoing HADC conversion is completed activating the TMU to measure temperature as shown. If HADC is in autoscan mode, the TMU is activated after completing the ongoing sequence. If HADC is in fixed-conversion mode, all the fixed conversions are completed and followed by TMU activation.

TMU Event Control

The TMU generates different events depending on the state of the TMU temperature measurement and the different thresholds set in thresh hold registers. These events are reported in the TMU_STAT register as shown below. It can generate an event for each of following conditions.

- The fault high limit is configured in the TMU_FLT_LIM_HI register. The interrupt is generated when the temperature value is greater than or equal to this value.
- The alert high limit (0,1,2) is configured in the TMU_ALRT_LIM_HI register. The interrupt is generated when the temperature value is greater than or equal to these value.
- The fault low limit is configured in the TMU_FLT_LIM_LO register. The TMU_STAT.FLTLO status bit is set when the temperature value is less than or equal to this value.
- The alert low limit is configured in the TMU_ALRT_LIM_LO register. The TMU_STAT.FLTLO status bit is set when the temperature value is less than or equal to this value.

Interrupts and status conditions can be masked (disabled) or unmasked (enabled) by setting and clearing bits in the TMU_IMSK register.

NOTE: Only TMU_FLT_LIM_HI and TMU_ALRT_LIM_HI generate an interrupt to core. Other events only result in status change in the TMU_STAT register.

Status and Error Signals

When the measured temperature value exceeds the high or low limits that are configured in the TMU_FLT_LIM_HI/TMU_FLT_LIM_LO and the TMU_ALRT_LIM_HI/TMU_ALRT_LIM_LO registers, corresponding thermal events are triggered.

The fault and alert events are sent to the core through the status register (TMU_STAT). Both the TMU_STAT.FLTHI and the TMU_STAT.ALRT1HI/TMU_STAT.ALRT2HI/TMU_STAT.ALRT3HI bits are sticky bits and are cleared by a W1C operation by the core.

The alert and fault registers can be programmed through the MMR bus interface as shown in the TMU block diagram. A write into the TMU_FLT_LIM_HI/TMU_FLT_LIM_LO and TMU_ALRT_LIM_HI/TMU_ALRT_LIM_LO registers or the TMU_TEMP register is not allowed when the events are being triggered.

TMU Programming Guidelines

The following section provides basic programming information for the TMU module.

To get the best performance and accuracy from the TMU, initialize the TMU_GAIN and TMU_OFFSET registers before enabling the module. After the registers are programmed, the rest of TMU initialization can take place. This includes setting up the fault and alert limits and then enabling the TMU.

Reading Temperature Data

After enabling the TMU, the temperature data can only be read after a finite period of time referred to as startup time.

If the HADC module is used, apply the following mechanism:

1. Initialize the HADC module.
2. Wait for the ADC ready interrupt.
3. Perform TMU conversions.

The minimum time required before reading the first valid data is ~100us for a typical SCLK frequency of 125Mhz and using the default register values.

If the HADC module is not used, complete the following steps

1. Initialize the HADC module (dummy initialization).
2. Wait for the ADC ready interrupt.
3. Perform TMU conversions.

TMU Calibration

Calibration settings are comprised of gain and offset settings. These settings must be programmed into the corresponding device registers before the temperature is read from the TMU temperature value register. The calibration setting ensures that the reported temperature approximates the actual die temperature (within the error specified in the data sheet). The specified accuracy of the reported temperature cannot be met if gain and offset settings are not used.

The TMU configuration software programs gain and offset values as part of the TMU initialization process. The gain value is programmed in the `TMU_GAIN.VALUE` field. The offset value is programmed in the `TMU_OFFSET.VALUE` bit field. The *TMU Calibration Settings* table provides the calibration setting for the processor.

Table 14-5: TMU Calibration Settings

Bit Field	Programmed Value
`TMU_GAIN.VALUE`	TBD
`TMU_OFFSET.VALUE`	TBD

NOTE: Refer to the product data sheet for the expected TMU accuracy achieved using the settings.

NOTE: The calibration settings provide expected TMU performance at temperatures above room temperature. The accuracy is not guaranteed for temperatures below room temperature.

ADSP-2184x TMU Register Descriptions

Thermal monitoring unit (TMU) contains the following registers.

Table 14-6: ADSP-2184x TMU Register List

Name	Description
TMU_ALRT_LIM_HI	Alert High Limit Register
TMU_ALRT_LIM_LO	Alert Low Limit Register
TMU_AVG	Averaging Register
TMU_CNV_BLANK	Temperature Conversion Blank Register
TMU_CTL	TMU Control Register
TMU_FLT_LIM_HI	Fault High Limit Register
TMU_FLT_LIM_LO	Fault Low Limit Register
TMU_GAIN	Gain Value Register
TMU_IMSK	Interrupt Mask Register
TMU_OFFSET	Offset Register
TMU_REFR_CNTR	Temperature Refresh Counter
TMU_STAT	Status Register
TMU_TEMP	Temperature Value Register

Alert High Limit Register

The TMU_ALRT_LIM_HI register configures the alert temperature high limit.

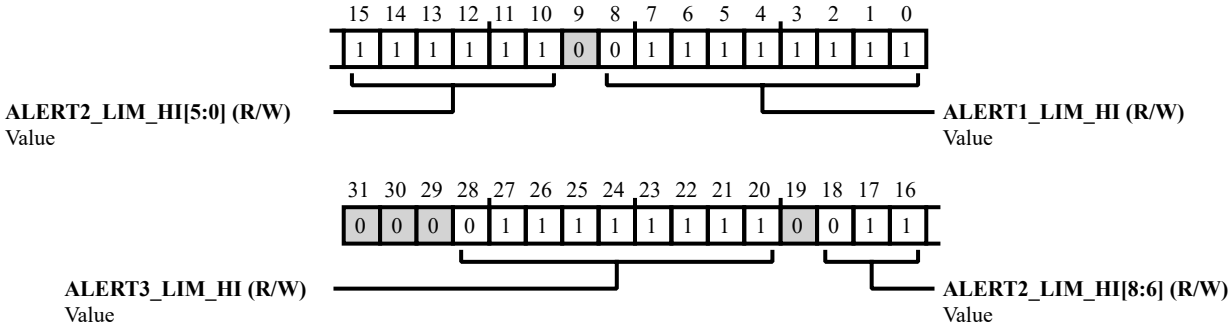

Figure 14-2: TMU_ALRT_LIM_HI Register Diagram

Table 14-7: TMU_ALRT_LIM_HI Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
28:20 (R/W)	ALERT3_LIM_HI	Value. The TMU_ALRT_LIM_HI.ALERT3_LIM_HI bit field configures the alert temperature high limit as an integer value stored in two's complement format. If the temperature value is greater than or equal to the high limit, the TMU_STAT.ALRT3HI bit is set.
18:10 (R/W)	ALERT2_LIM_HI	Value. The TMU_ALRT_LIM_HI.ALERT2_LIM_HI bit field configures the alert temperature high limit as an integer value stored in two's complement format. If the temperature value is greater than or equal to the high limit, the TMU_STAT.ALRT2HI bit is set.
8:0 (R/W)	ALERT1_LIM_HI	Value. The TMU_ALRT_LIM_HI.ALERT1_LIM_HI bit field configures the alert temperature high limit as an integer value stored in two's complement format. If the temperature value is greater than or equal to the high limit, the TMU_STAT.ALRT1HI bit is set.

Alert Low Limit Register

The TMU_ALRT_LIM_LO register configures the alert temperature low limit.

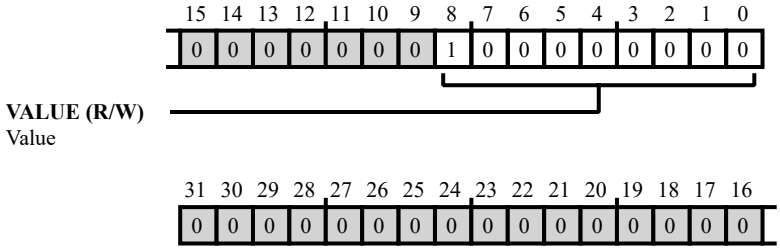

Figure 14-3: TMU_ALRT_LIM_LO Register Diagram

Table 14-8: TMU_ALRT_LIM_LO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
8:0 (R/W)	VALUE	Value. The TMU_ALRT_LIM_LO.VALUE bit field configures the alert temperature low limit as an integer value stored in two's complement format. If the temperature value is less than or equal to the low limit the TMU_STAT.ALRTLO bit is set.

Averaging Register

The TMU_AVG register enables averaging on the TMU.

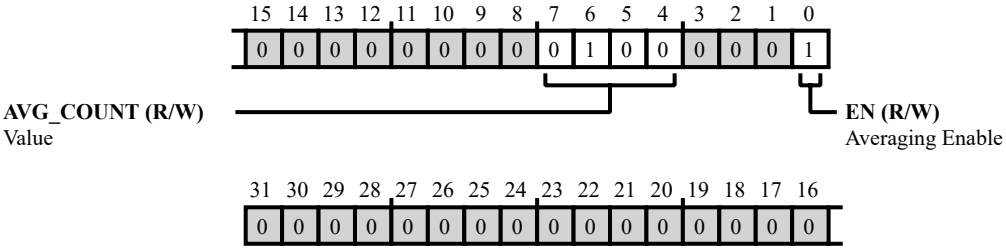

Figure 14-4: TMU_AVG Register Diagram

Table 14-9: TMU_AVG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:4 (R/W)	AVG_COUNT	Value. The TMU_AVG.AVG_COUNT bit field indicates the number of values (N) to be averaged where N = 2^{AVG_COUNT}. The minimum value of TMU_AVG.AVG_COUNT is 1 and maximum value is 12. The fault value is 5, hence 2^5 = 32 values are averaged, by default. A maximum 2^{12}=4096 values can be averaged.
0 (R/W)	EN	Averaging Enable. The TMU_AVG.EN bit enables averaging on the TMU. Moving average is calculated for the past N values, where N is a power of 2. N value can be programmed by a register. N is defined by the TMU_AVG.AVG_COUNT register The average value is calculated using the equation: {(N-1)*previous_average+current_sampe}/N. The first N samples are summed and divided by N to calculate the first average value. Hence, the temperature value will not be updated for the first N conversions, when averaging is enabled. Averaging is enabled by default. It can be disabled when it is not needed.

Temperature Conversion Blank Register

The TMU_CNV_BLANK register specifies blanking period in which TMU utilizes HADC for temperature conversion.

The conversion time is calculated as: (VALUE+1)*50k SCLK cycles. So, the minimum conversion time is 50k SCLK cycles. Default conversion time is 200k SCLK cycles. For this duration, the system cannot use HADC for data conversion and HADC does take input for data-conversion. The status is indicated by TMUHADC_BUSY bit of the HADC block.

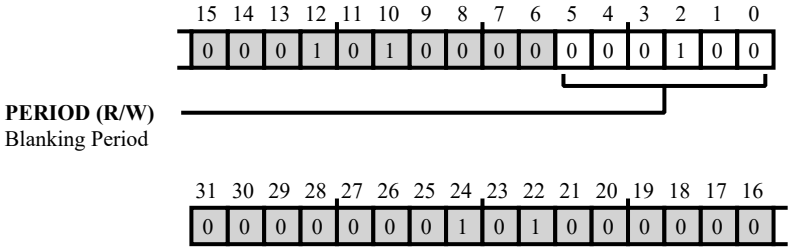

Figure 14-5: TMU_CNV_BLANK Register Diagram

Table 14-10: TMU_CNV_BLANK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
5:0 (R/W)	PERIOD	Blanking Period. Blanking period is (CNV_BLANK+1)*150k SCLK cycles. So the minimum blanking period is 150k SCLK cycles. Default blanking period is 1650k (1.65 million) SCLK cycles. For this duration, The system cannot use HADC for data conversion and HADC will not take input for data-conversion. The status will be indicated by TMHADC_BUSY bit of HADC block. More details can be found in TMU Programming model section.

TMU Control Register

The TMU_CTL register contains bits that allow programs to configure and enable the TMU.

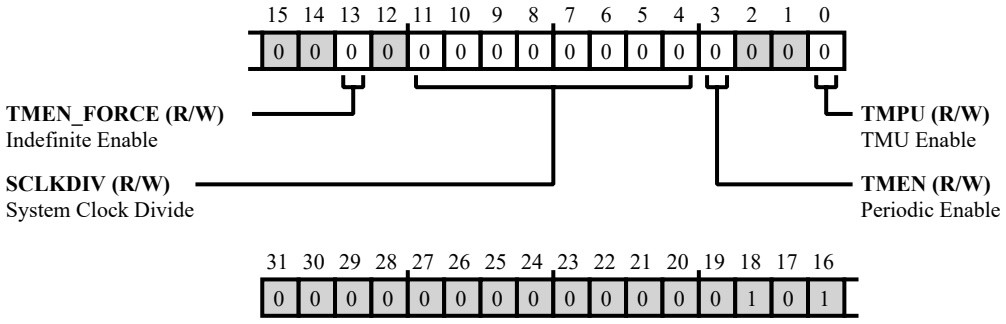

Figure 14-6: TMU_CTL Register Diagram

Table 14-11: TMU_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
13 (R/W)	TMEN_FORCE	Indefinite Enable. Asserting the TMU_CTL.TMEN_FORCE bit enables the TMU indefinitely. HADC is always used by the TMU, so the HADC cannot be used to convert channel inputs.
11:4 (R/W)	SCLKDIV	System Clock Divide. The TMU_CTL.SCLKDIV bit selects the division ratio for the system clock (SCLK). SCLK is divided by (11+2*SCLKDIV). Thus, by default the SCLK is divided by 11.
3 (R/W)	TMEN	Periodic Enable. Asserting the TMU_CTL.TMEN bit enables the TMU periodically. TMU is enabled once in every refresh period defined by the TMU_REFR_CNTR register. And in each refresh period, TMU measures temperature for the blanking period (Tblank). It is defined by CNV_BLANK bit.
0 (R/W)	TMPU	TMU Enable. The TMU_CTL.TMPU bit enables the TMU. By default, the module is in power-down mode. The peripheral interface is active even in power-down mode (the TMU registers can be read/written).

Fault High Limit Register

The TMU_FLT_LIM_HI register sets the temperature fault high limit as an integer value. The value is stored in two's complement format. Asserts TMU_STAT.FLTHI if the TMU_TEMP value is greater than or equal to TMU_FLT_LIM_HI. The TMU_FLT_LIM_HI value should be programmed for value greater than 8'h3C (60 degC).

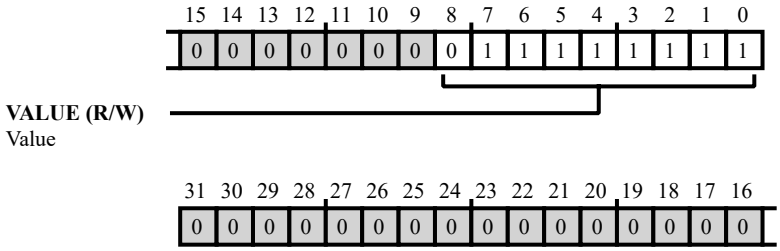

Figure 14-7: TMU_FLT_LIM_HI Register Diagram

Table 14-12: TMU_FLT_LIM_HI Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
8:0 (R/W)	VALUE	Value. The TMU_FLT_LIM_HI.VALUE bit field sets the temperature high limit as an integer in two's complement format. If the limit value is greater than or equal to the high limit the TMU_STAT.FLTHI bit is set.

Fault Low Limit Register

The TMU_FLT_LIM_LO register configures the fault temperature low limit.

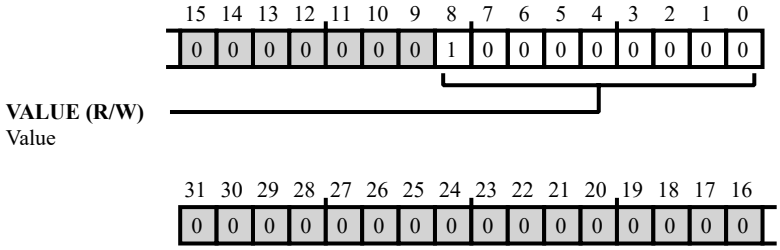

Figure 14-8: TMU_FLT_LIM_LO Register Diagram

Table 14-13: TMU_FLT_LIM_LO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
8:0 (R/W)	VALUE	Value. The TMU_FLT_LIM_LO.VALUE bit field configures the fault temperature low limit as an integer which is stored in two's complement format. If the temperature value is less than or equal to the low limit, the TMU_STAT.FLTLO bit is set.

Gain Value Register

The TMU_GAIN register is used to configure the gain value in two's complement format. This value is used to correct the gain error in the TMU_TEMP register.

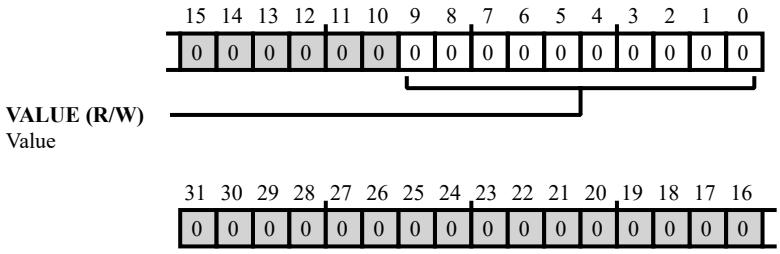

Figure 14-9: TMU_GAIN Register Diagram

Table 14-14: TMU_GAIN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
9:0 (R/W)	VALUE	Value. The TMU_GAIN.VALUE bit field configures the gain value in two's complement format. This value is used to correct the gain error in the TMU_TEMP register.

Interrupt Mask Register

The TMU_IMSK register provides bits that are used to mask and unmask the interrupts associated with the TMU module.

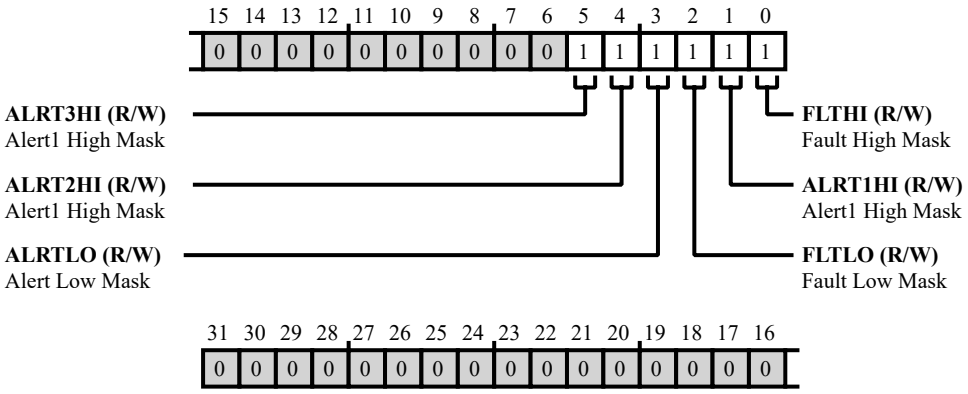

Figure 14-10: TMU_IMSK Register Diagram

Table 14-15: TMU_IMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
5 (R/W)	ALRT3HI	Alert1 High Mask.
4 (R/W)	ALRT2HI	Alert1 High Mask.
3 (R/W)	ALRTLO	Alert Low Mask. The TMU_IMSK.ALRTLO bit masks or unmasks the alert low status change (TMU_STAT.ALRTLO).
2 (R/W)	FLTLO	Fault Low Mask. The TMU_IMSK.FLTLO bit masks or unmasks the fault low status change (TMU_STAT.FLTLO).
1 (R/W)	ALRT1HI	Alert1 High Mask.
0 (R/W)	FLTHI	Fault High Mask. The TMU_IMSK.FLTHI bit masks or unmasks the fault high interrupt (TMU_STAT.FLTHI).

Offset Register

The value programmed in the TMU_OFFSET register is used to correct the offset error in TMU_TEMP register.

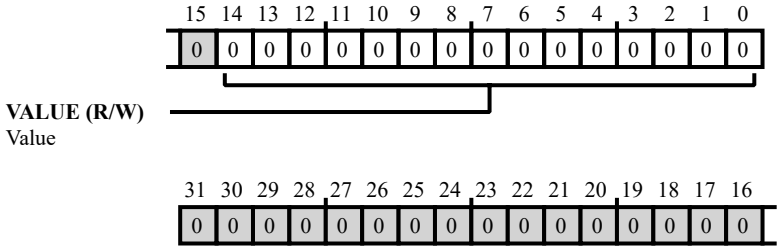

Figure 14-11: TMU_OFFSET Register Diagram

Table 14-16: TMU_OFFSET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
14:0 (R/W)	VALUE	Value. The TMU_OFFSET.VALUE bit field provides the offset value which is used to correct the offset error in the TMU_TEMP register. This value is in a two's complement fixed point Q7.7 format i.e 8 MSB's represent integer part in 2's complement format. and remaining 7 LSB's represent decimal part. Offset will be applied after multiplying gain.

Temperature Refresh Counter

The TMU_REFR_CNTR register defines the refresh-period to refresh temperature value.

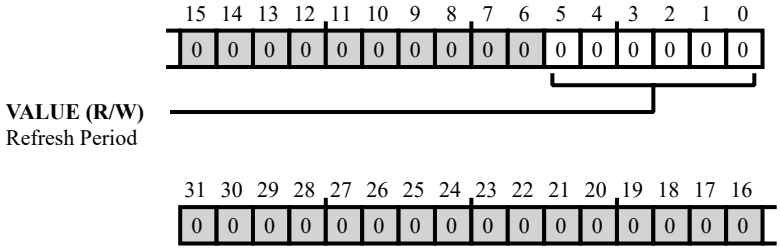

Figure 14-12: TMU_REFR_CNTR Register Diagram

Table 14-17: TMU_REFR_CNTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
5:0 (R/W)	VALUE	Refresh Period. The TMU_REFR_CNTR.VALUE bit field defines the period to refresh the temperature value. Temperature is refreshed for every (VALUE+1)*(21+4*SCLKDIV)*1M system-clock cycles. SCLKDIV is defined in TMU_CTL register. So, by default, the period is 21 million system-clock cycles.

Status Register

The TMU_STAT register bits indicate when an error or fault is detected.

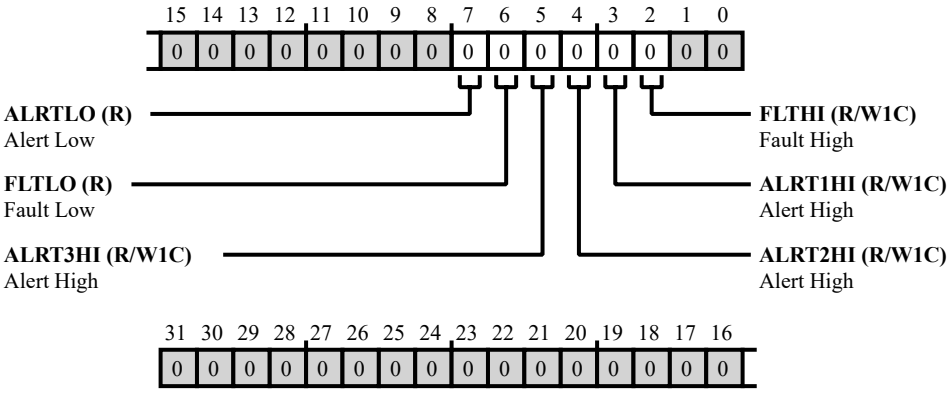

Figure 14-13: TMU_STAT Register Diagram

Table 14-18: TMU_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7 (R/NW)	ALRTLO	Alert Low. The TMU_STAT.ALRTLO bit is set when the temperature value is less than or equal to the setting in the TMU_ALRT_LIM_LO register. The bit assertion is masked if TMU_IMSK.ALRTLO is HIGH.
6 (R/NW)	FLTLO	Fault Low. The TMU_STAT.FLTLO bit is set when the temperature value is less than or equal to the setting in the TMU_FLT_LIM_LO register. The bit assertion is masked if TMU_IMSK.FLTLO is HIGH.
5 (R/W1C)	ALRT3HI	Alert High. The TMU_STAT.ALRT3HI bit is set when the temperature value is greater than or equal to the setting in the TMU_ALRT_LIM_HI register. A Write1toClear is needed to reset the bit if it is asserted. The bit assertion is masked when TMU_IMSK.ALRT3HI =1.
4 (R/W1C)	ALRT2HI	Alert High. The TMU_STAT.ALRT2HI bit is set when the temperature value is greater than or equal to the setting in the TMU_ALRT_LIM_HI register. A Write1toClear is needed to reset the bit if it is asserted. The bit assertion is masked when TMU_IMSK.ALRT2HI =1.

Table 14-18: TMU_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
3 (R/W1C)	ALRT1HI	Alert High. The TMU_STAT.ALRT1HI bit is set when the temperature value is greater than or equal to the setting in the TMU_ALRT_LIM_HI register. A Write1toClear is needed to reset the bit if it is asserted. The bit assertion is masked when TMU_IMSK.ALRT1HI =1.
2 (R/W1C)	FLTHI	Fault High. The TMU_STAT.FLTHI bit is set when the temperature value is greater than or equal to the setting in the TMU_FLT_LIM_HI register. The temperature value register is set to 16'h0D80 (effective temperature value of 27 degrees C) when a W1C is done on this bit. The bit assertion is masked if TMU_IMSK.FLTHI is HIGH.

Temperature Value Register

The TMU_TEMP register provides the temperature value from the A/D converter and the status.

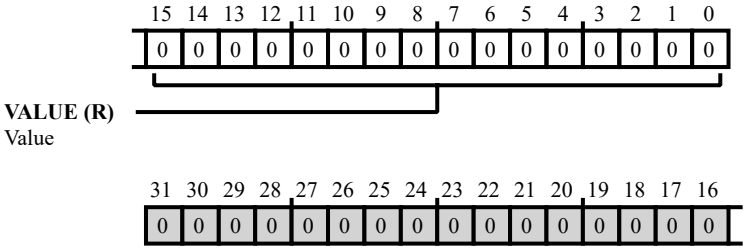

Figure 14-14: TMU_TEMP Register Diagram

Table 14-19: TMU_TEMP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	VALUE	Value. The TMU_TEMP.VALUE bit field is the temperature value from A/D converter. This value is stored in two's complement fixed point Q8.7 format where the 9 MSB's represent the integer part in 2's complement, and the remaining 7 LSB's represent the decimal part.

15 Housekeeping ADC (HADC)

The Housekeeping ADC is a 12-bit (with 10-bit accuracy), successive approximation ADC. It operates from single supply and features throughput rates up to 1 MSPS. The HADC can be used for the collection of housekeeping parameters like voltages, temperatures in the system or for any general-purpose use as well.

NOTE: HADC is used by the TMU for temperature monitor, so it may be unavailable during temperature conversion. For details, refer to the TMU and HADC section.

HADC Features

The HADC supports following features:

- 12-bit ADC core with built-in sample and hold
- ENOB = 10 bit
- 8 input channels which can be extended to 15 channels by putting an external channel multiplexer
- Throughput rates up to 1 MSPS
- Single ended operation
- External reference nominal at 1.8 V
- Analog input 0 V to 1.8 V.
- Selectable ADC clock frequency through a pre-scaler
- Conversion type adaptable to each application–allows single or continuous conversion with option of auto-scan
- Auto sequencing capability provides up to 15 *auto-conversions* in a single session. Each conversion can be programmed to select any of the available input channels.

HADC Functional Description

The HADC provides the analog to digital conversion capability for general-purpose housekeeping tasks, such as voltage and temperature monitoring. The core of HADC is a 12-bit SAR ADC, providing multiple analog input channels.

The HADC has the following functionality:

Fixed and continuous conversion modes

ADC converts the input channel sequence for a fixed number of times or continuously converts an input channel sequence.

Auto scanning

All the input channels can be sampled in a sequential manner.

Channel sequence programming

The sequence of a channel can be selected by programming the channel mask register. If the bit corresponding to the channel is programmed to zero, that channel is included in the auto-scan chain.

ADSP-2184x HADC Register List

The Housekeeping ADC (HADC) provides a general purpose, multi-channel successive approximation A-to-D converter. A set of registers governs HADC operations. For more information on HADC functionality, see the HADC register descriptions.

Table 15-1: ADSP-2184x HADC Register List

Name	Description

HADC Definitions

The following definitions are helpful when using the HADC module.

Auto-scan

Auto-scan is a feature which allows the multiple channels to be scanned and converted in sequence one after the other.

HADC Wakeup Time

It is the time required by the module after coming out of power down before it can start converting.

Signal-to-Noise and Distortion Ratio (SINAD)

The measured ratio of signal-to-noise and distortion at the output of the ADC. The signal is the rms amplitude of the fundamental. Noise is the sum of all non-fundamental signals up to half the sampling frequency ($f_S/2$), excluding dc. The ratio depends on the number of quantization levels in the digitization process; the more levels, the smaller the quantization noise. The theoretical signal-to-noise and distortion ratio for an ideal N-bit converter with a sine wave input is given by:

Signal-to-(Noise + Distortion) = (6.02 N + 1.76) dB

Total Harmonic Distortion (THD)

The ratio of the rms sum to the harmonics to the fundamental.

Peak Harmonic or Spurious Noise

The ratio of the rms value of the next largest component in the ADC output spectrum (up to $f_S/2$ and excluding dc) to the rms value of the fundamental. Typically, the value of this specification is determined by the largest harmonic in the spectrum, but for ADCs where the harmonics are buried in the noise floor, it is a noise peak.

Integral Nonlinearity

The maximum deviation from a straight line passing through the endpoints of the ADC transfer function. The endpoints are zero scale, a point 1 LSB below the first code transition, and full scale, a point 1 LSB above the last code transition.

Differential Nonlinearity

The difference between the measured and the ideal 1 LSB change between any two adjacent codes in the ADC.

Offset Error

The deviation of the first code transition (00...000) to (00...001) from the ideal—that is, GND1 + 1 LSB.

Offset Error Match

The difference in offset error between any two channels.

Gain Error

The deviation of the last code transition (111...110) to (111...111) from the ideal (that is, REFIN – 1 LSB) after the offset error has been adjusted out.

Gain Error Matching

The difference in gain error between any two channels.

Power Supply Rejection Ratio (PSRR)

PSRR is defined as the ratio of the power in the ADC output at full-scale frequency, f, to the power of a 100 mV p-p sine wave applied to the ADC VDD supply of frequency, f_S. The frequency of the input varies from 5 kHz to 25 MHz. PSRR (dB) = 10 log(Pf/Pf_S) where: Pf is the power at frequency, f, in the ADC output. Pf_S is the power at frequency, f_S, in the ADC output.

HADC Block Diagram

The ***HADC Block Diagram*** figure shows the functional blocks within the HADC and the interface to the processor core and the peripherals. The HADC has an internal channel multiplexer that is controlled by a programmable sequencer which selects the desired channel or sequence of channels.

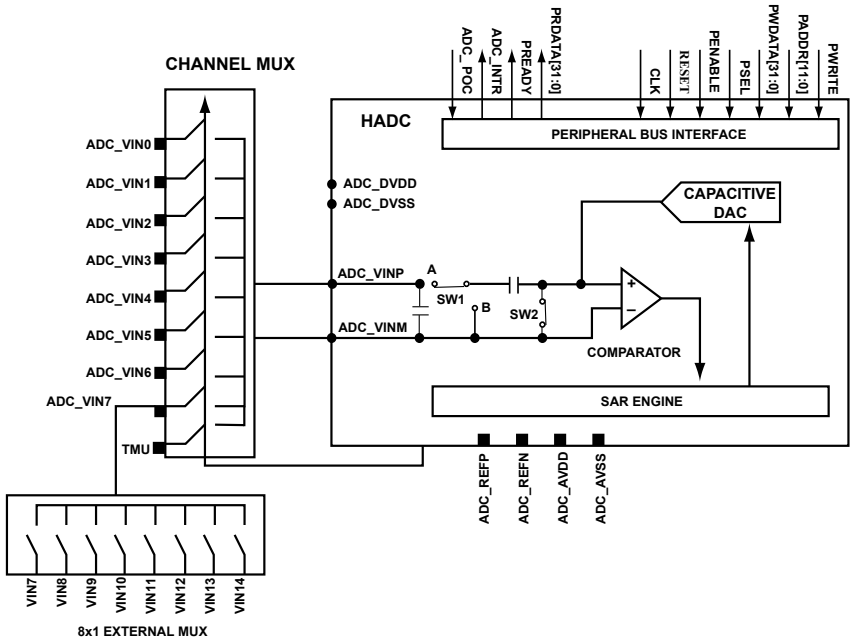

Figure 15-1: HADC Block Diagram

HADC Signal Descriptions

The ***HADC Signal Descriptions*** table provides descriptions of the signals used by the HADC.

Table 15-5: HADC Signal Descriptions

Signal Name	Signal Description
AVDD	ADC I/O supply
G	I/O ground for analog blocks - shorted with other ground pins within the package
VREFP	External reference for ADC
VREFN	Ground reference for ADC
VINn	Analog input at channel n

HADC Architectural Concepts

The HADC is based on a 12-bit SAR ADC that provides a simple register-based access model to obtain the results of conversion. The digital front end of the HADC provides a set of registers to configure the mode of operation, sampling frequency, and input channel selection control. The ADC supports multiple input analog channels which can be individually selected or deselected for conversion. The results of each analog channel are stored in a register. The core can access the register to read the conversion results once the conversion is complete. The HADC also provides the interrupts on completion of each channel conversion to avoid polling by the core. The following sections provide more details about the architecture of the HADC.

Converter Operation

The housekeeping ADC is a 12-bit successive approximation ADC based around a capacitive DAC. The ***ADC Acquisition Phase*** figure and the ***ADC Conversion Phase*** figure show simplified schematics of the ADC. The ADC is comprised of control logic, SAR, and a capacitive DAC. The components are used to add and subtract fixed amounts of charge from the sampling capacitor to bring the comparator back into a balanced condition. The ***ADC Conversion Phase*** figure shows the ADC during its acquisition phase. SW2 is closed and SW1 is in Position A. The comparator is held in a balanced condition and the sampling capacitor acquires the signal on the selected V_{IN} channel.

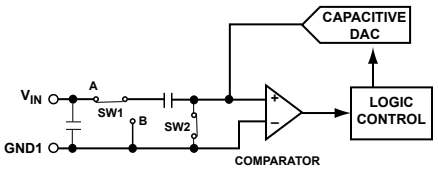

Figure 15-2: ADC Acquisition Phase

When the ADC starts a conversion (see the ***ADC Conversion Phase*** figure), SW2 opens and SW1 moves to Position B, causing the comparator to become unbalanced. The control logic and the capacitive DAC are used to add and subtract fixed amounts of charge to bring the comparator back into a balanced condition. When the comparator is rebalanced, the conversion is complete. The control logic generates the ADC output code.

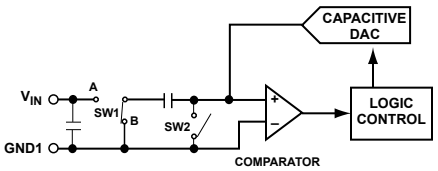

Figure 15-3: ADC Conversion Phase

Auto-Scan

The HADC features auto-scan mode where all the input channels can be sampled in a sequential manner. The number of channels enabled in auto-scan mode can be selected by programming the HADC_CHAN_MSK register. If the bit corresponding to the channel is set high, that particular channel is masked, and is not included in the auto-scan chain. In this way programs can sample all, none, or a selected set of channels by writing a high or a low for the individual channel. Auto sequencing allows the system to convert the same channel multiple times, allowing programs to perform oversampling algorithms.

For example, if the HADC_CHAN_MSK register bits [3:0] are set to 1101, then channel 0, channel 2 and channel 3 are not included in the auto-scan chain. Whether the conversion is a single or fixed number or continuous depends on the status of HADC_CTL.CONT bit. If this bit is low, the HADC_CTL.FIXEDCNV bits determine the number of sequence conversions.

The maximum number of fixed sequence conversions is 15. By default, the first eight channels of the HADC are enabled and extended channels are masked. An extended channel is the increased number of channels when a single channel of ADC is externally multiplexed, effectively increasing the total number of available channels. The total

number of channels supported is 15. The program must configure the HADC_CHAN_MSK register to enable any desired channel.

Channel Sequence Programming

The sequence of a channel can be selected by programming the HADC_CHAN_MSK register. If the bit corresponding to the channel is programmed to zero, that channel is included in the auto-scan chain. If the program must get the conversion results from a particular channel, then the bit corresponding to that channel should be zero. Channels 8-15 are virtual channels; in that they can connect an external multiplexer and increase the effective number of channels. As the output of the external multiplexer is routed to channel 7, this channel is not available (or converted) separately when the virtual channels are not masked in the HADC_CHAN_MSK register. The auto-scan section has more details.

ADC Transfer Function

The output coding is straight binary for the analog input channel conversion. The designed code transitions occur at successive LSB values (that is, 1 LSB, 2 LSBs, and so forth). The LSB size is $V_{REF}/4096$ for the HADC. The *ADC Transfer Function* figure shows the ideal transfer characteristic for straight binary coding.

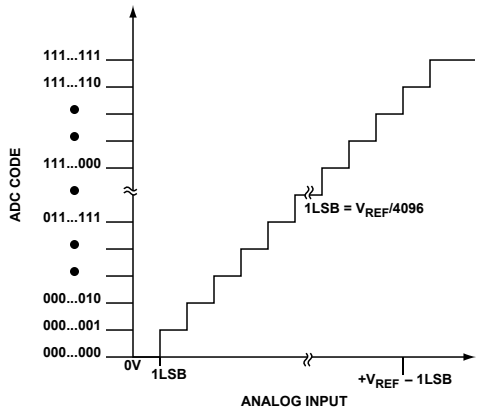

Figure 15-4: ADC Transfer Function

Results

The HADC takes 20 cycles of f_{SAMPLE} for one channel conversion. (The value of the HADC_CTL.FDIV bit field determines f_{SAMPLE}). The time taken to complete one sequence depends on the number of channels in the auto-scan chain. There is a latency of 1 cycle from the time the channel is selected internally to sample to the time the data is ready. After the end of each channel conversion, the data is written into the corresponding data register. An interrupt is generated (if the interrupt mask is not enabled) to signal that the data is ready for that particular channel.

HADC Operating Modes

The HADC has two modes of operation described in the following sections.

Fixed Conversion Mode

In this mode, the ADC converts the input channel sequence for a fixed number of times. The frequency is configured in the HADC_CTL.FIXEDCNV bit field. To use this mode, clear the HADC_CTL.CONT bit.

Continuous Conversion Mode

In this mode ADC continuously converts an input channel sequence, when the HADC_CTL.STARTCNV bit is held high. To use this mode, set the HADC_CTL.CONT bit.

HADC Event Control

The HADC generates different events depending on the state of the ADC and the status of channel conversions. It can generate an event for each of the following conditions:

- When ADC is ready for conversion
- At the end of sequence conversion
- At the end of each individual channel conversion

Each of these events can generate an interrupt. To generate an interrupt on any desired event, clear the respective bit in the HADC_IMSK register.

HADC Programming Model

Following sections provide some guidelines for HADC programming.

Powering Up the HADC

To power-up the HADC, program the following bits in the HADC_CTL register.

- Deassert the HADC_CTL.PD bit (HADC power down)
- Set the HADC_CTL.NRST bit (Reset)
- Set the HADC_CTL.ENLS bit (Enable level shifters)

After deasserting HADC_CTL.PD, the HADC requires a finite wake-up time (t_{WAKEUP}) before it can start converting. The HADC requires only two f_{SAMPLE} clocks from the assertion of the HADC_CTL.NRST bit before the module is ready to convert. (HADC_CTL.PD is low). Poll the HADC_STAT.RDY bit. A 1 on this bit indicates that the HADC is ready to convert data.

Enabling the HADC

Setting the HADC_CTL.STARTCNV bit enables the HADC. When this bit is kept high, the HADC can work in either continuous or fixed conversion mode. After the HADC_CTL.STARTCNV bit is set =1, the HADC_CHAN_MSK can still be re-programmed, but the new sequence only comes into effect after the current sequence conversion is complete.

ADSP-2184x HADC Register Descriptions

Housekeeping ADC (HADC) contains the following registers.

Table 15-6: ADSP-2184x HADC Register List

Name	Description
HADC_CHAN_MSK	Channel Mask Register
HADC_CTL	Control Register
HADC_DATA[nn]	Channel Data Registers
HADC_IMSK	Interrupt Mask Register
HADC_STAT	Status Register

Channel Mask Register

The HADC_CHAN_MSK register provides bits that mask each channel. The LSB corresponds to channel 0 , the second LSB to channel 1 and so on. If a mask bit is set, the corresponding channel is not converted. By default, channels 0-7 are not masked and the extended channels 8-15 are masked.

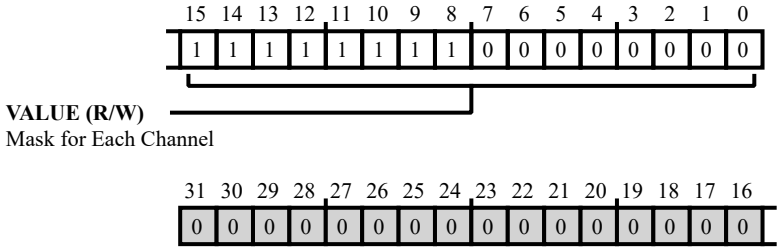

Figure 15-5: HADC_CHAN_MSK Register Diagram

Table 15-7: HADC_CHAN_MSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Mask for Each Channel. The HADC_CHAN_MSK.VALUE bit field is the mask bit for each channel. The first MSB corresponds to channel 15, the second MSB to channel 14 and so on. If the mask is set for a particular channel, that channel is not converted. By default, channels 0-7 are not masked and the extended channels 8-15 are masked. The first MSB corresponds to channel 7, the second MSB to channel 6 and so on. If the mask is set for a particular channel, that channel is not converted. By default, channels 0-7 are not masked.

Control Register

The HADC_CTL register contains control bits that configure various module settings start or reset the module.

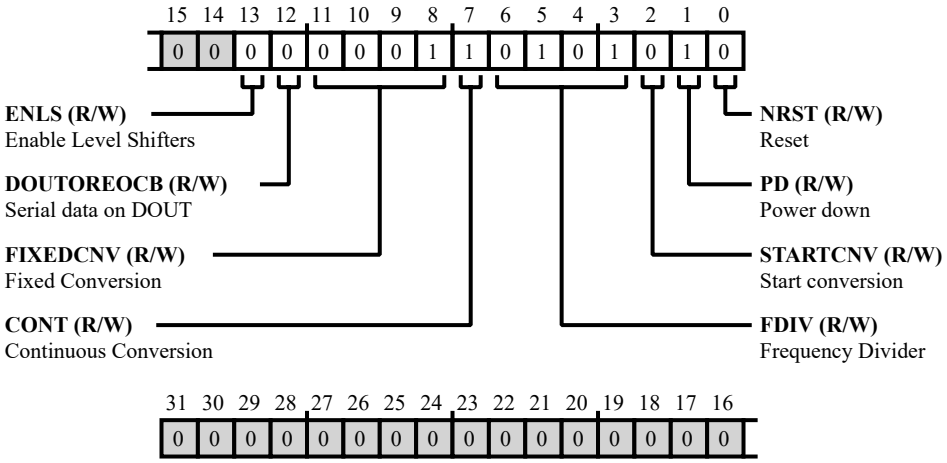

Figure 15-6: HADC_CTL Register Diagram

Table 15-8: HADC_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W)	ENLS	Enable Level Shifters. Setting the HADC_CTL.ENLS bit enables the level shifters, allowing the HADC analog side (which works in the VDD_EXT domain) to work with the digital core and interface is (in the VDD_INT domain).	
		0	Disable down level shifters
		1	Enable down level shifters
12 (R/W)	DOUTOREOCB	Serial data on DOUT. If the HADC_CTL.DOUTOREOCB bit =1, serial data arrives on the EOC_DOUT pin. If this bit =0 (default) it acts as an EOC only if the external multiplexer is connected.	
		0	Reserved
		1	Reserved
11:8 (R/W)	FIXEDCNV	Fixed Conversion. The HADC_CTL.FIXEDCNV bit configures the number of conversions = FIX-EDCNV. This value determines how many times a sequence is converted when the HADC is in fixed conversion mode. This only applies when the HADC_CTL.CONT bit =0. Before changing the HADC_CTL.FIXEDCNV bit, clear the HADC_CTL.NRST bit (=0).	

Table 15-8: HADC_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	CONT	Continuous Conversion. When the HADC_CTL.CONT bit =0, the ADC converts a sequence for a fixed number of times. This number is configured using the HADC_CTL.FIXEDCNV bit field. When the HADC_CTL.CONT bit =1, the ADC continuously converts a given sequence, provided the HADC_CTL.STARTCNV is held high.	
		0	ADC converts sequence for fixed number of times
		1	ADC continuously converts given sequence
6:3 (R/W)	FDIV	Frequency Divider. The HADC_CTL.FDIV bit field configures the f_SAMPLE=f_CLK/(FDIV+1). Select f_CLK and HADC_CTL.FDIV values so that f_SAMPLE is in range of 50 kHz to 22.5 MHz. The minimum value for HADC_CTL.FDIV is 1. Before changing the HADC_CTL.FDIV bits, clear the HADC_CTL.NRST bit.	
2 (R/W)	STARTCNV	Start conversion. The HADC_CTL.STARTCNV bit needs to be set for the ADC to start converting data. If the ADC is running in non continuous mode, it is reset by hardware after the desired number of conversions is completed.	
		0	No action
		1	Start converting
1 (R/W)	PD	Power down. The HADC_CTL.PD bit powers down the analog circuitry of the ADC. After this bit returns to 0 a finite power-up time is required before the ADC can start converting data.	
		0	No action
		1	Power down the analog circuitry of the ADC
0 (R/W)	NRST	Reset. The HADC_CTL.NRST bit resets the ADC.	
		0	Reset the ADC
		1	No action

Channel Data Registers

The HADC_DATA[nn] registers NN ranges from 0-14. Each corresponding to an ADC channel. ADC_DATA_0 corresponds to channel 0, ADC_DATA_1 to channel 1 and so on.

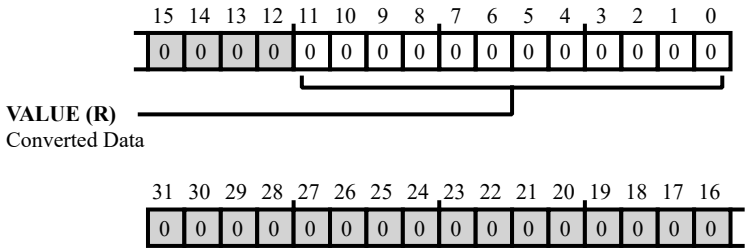

Figure 15-7: HADC_DATA[nn] Register Diagram

Table 15-9: HADC_DATA[nn] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
11:0 (R/NW)	VALUE	Converted Data. The HADC_DATA[nn].VALUE bit field contains the digital code for the sampled analog value. Each channel has its own data register.

Interrupt Mask Register

The HADC_IMSK register masks (disables) or unmasks (enables) the interrupts as programmed.

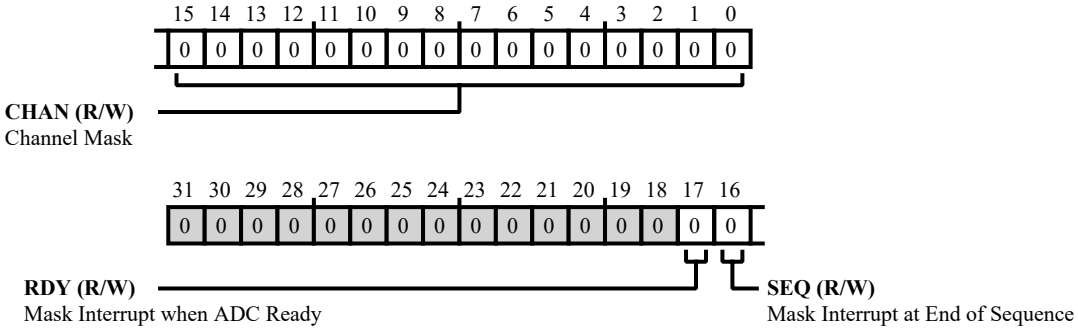

Figure 15-8: HADC_IMSK Register Diagram

Table 15-10: HADC_IMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W)	RDY	Mask Interrupt when ADC Ready. The HADC_IMSK.RDY bit masks the interrupt generated when ADC is ready to convert.	
16 (R/W)	SEQ	Mask Interrupt at End of Sequence. The HADC_IMSK.SEQ bit masks the interrupt which is generated at the end of sequence completion.	
		0	Interrupt is unmasked
		1	Interrupt is masked
15:0 (R/W)	CHAN	Channel Mask. The HADC_IMSK.CHAN bit field provides the interrupt mask bit for each channel. N ranges from 0-15. The MSB corresponds to channel 15, the second MSB to channel 14 and so on. If the bit is SET, interrupt is masked for corresponding channel.	

Status Register

The HADC_STAT register contains bits that provide status information on the HADC module.

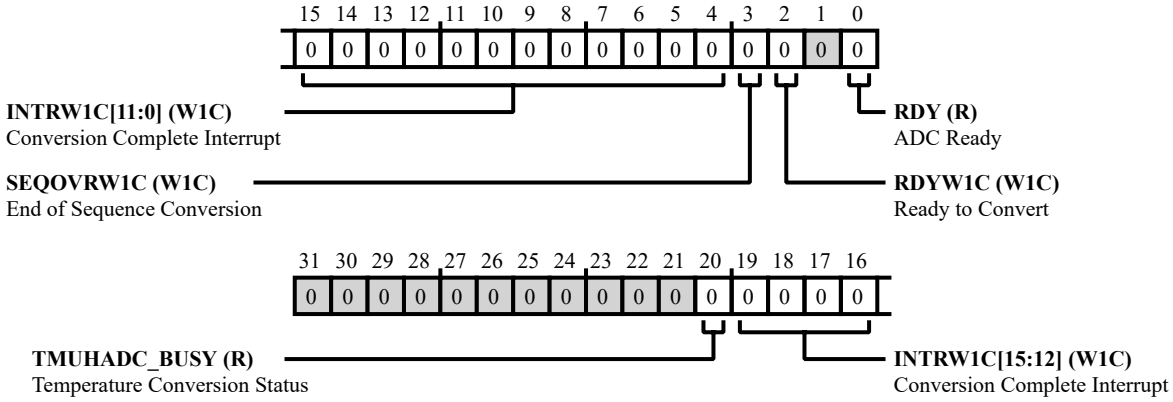

Figure 15-9: HADC_STAT Register Diagram

Table 15-11: HADC_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
20 (R/NW)	TMUHADC_BUSY	Temperature Conversion Status. The HADC_STAT.TMUHADC_BUSY bit, if high, indicates to the system that temperature conversion is ongoing. All ADC conversion requests are ignored.
19:4 (RX/W1C)	INTRW1C	Conversion Complete Interrupt. The HADC_STAT.INTRW1C bit field indicates when the corresponding ADC channel completes conversion. N ranges from 0-15 and the MSB corresponds to channel 15, the second MSB to channel 14 and so on. N ranges from 0-7 and the MSB corresponds to channel 7, the second MSB to channel 6 and so on. These bits are sticky and are W1C.
3 (RX/W1C)	SEQOVRW1C	End of Sequence Conversion. The HADC_STAT.SEQOVRW1C bit indicates the end of a sequence conversion and is a sticky status bit which is W1C.
2 (RX/W1C)	RDYW1C	Ready to Convert. The HADC_STAT.RDYW1C bit is the stick version of the HADC_STAT.RDY bit.
0 (R/NW)	RDY	ADC Ready. The HADC_STAT.RDY bit is set (=1) when the ADC is ready to convert data.

16 Controller Area Network Flexible Data Rate (CANFD)

The controller area network (CAN) protocol is primarily for use as a vehicle serial data bus. It meets the specific requirements of this field, including real-time processing, reliable operation in the EMI environment of a vehicle, cost-effectiveness, and required bandwidth.

The CANFD module is a full implementation of the CAN protocol specification, the CAN with flexible data rate (CAN FD) protocol, and the CAN 2.0 Part B protocol. It supports both standard and extended message frames and long payloads up to 64 bytes, transferred at rates up to 8 Mbps. The message buffers are stored in an embedded RAM dedicated to the CANFD module.

NOTE: This document assumes familiarity with the CAN standard. For more information, refer to Version 2.0 of the CAN specification from Robert Bosch GmbH.

CANFD Features

Key features of the CANFD module include:

- Full implementation of the CAN FD protocol and the CAN specification 2.0 (Part B) including:
  - Standard data frames
  - Extended data frames
  - Zero to sixty-four bytes data length
  - Programmable bit rate
  - Content-related addressing
- ISO 11898-1 standard compliance
- Flexible mailboxes
  - Configurable data lengths from 0 to 64 bytes
  - Configurable as receive or transmit, supporting standard and extended messages
  - Individual Rx mask registers per mailbox

- Full-featured Rx FIFO
    - Storage capacity for up to six frames
    - Automatic internal pointer handling with DMA support
- Transmission abort capability
- 28 message buffers of 8 bytes data length each, configurable as Rx or Tx
- Listen-Only mode capability
- Programmable Loop-Back mode supporting self-test operation
- Programmable transmission priority scheme: lowest ID, lowest buffer number, or highest priority
- Time stamp based on 16-bit free-running timer
- Global network time, synchronized by a specific message
- Independence from the transmission medium (an external transceiver is required)
- Low-power modes, with programmable wakeup on bus activity or matching with received frames (Pretended Networking)
- Transceiver Delay Compensation feature when transmitting CAN FD messages at faster data rates
- Remote request frames may be handled automatically or by software
- Identifier Acceptance Filter Hit Indicator (IDHIT) register for received frames
- Status of synchronization with CAN bus
- CRC status for transmitted message
- Rx FIFO Global Mask register
- Selectable priority between mailboxes and Rx FIFO during matching process
- Rx FIFO ID filtering, matching incoming IDs against 128 extended, 256 standard, or 512 partial (8 bit) IDs
    - Up to 32 ID filter table elements
- Detection and correction of memory read access errors, with five parity bits for each byte of CANFD memory
- Pretended networking functionality in low-power doze mode

CANFD Functional Description

The CANFD module is a CAN protocol engine with a very flexible mailbox system for transmitting and receiving CAN frames. The mailbox system consists of a set of message buffers (MBs) that store configuration and control data, time stamp, message ID, and data. The memory corresponding to the first 38 MBs is configurable to support a FIFO reception scheme with a powerful ID filtering mechanism. The ID filtering mechanism is capable of checking

incoming frames against a table of IDs (up to 128 extended IDs, 256 standard IDs, or 512 8-bit ID slices), with an individual mask register for up to 32 ID filter table elements.

Classical CAN frames support simultaneous reception through a FIFO and mailboxes. CAN FD frames support reception only through mailboxes. For mailbox reception, there is a matching algorithm to store received frames into the MBs that have the same ID programmed in the ID field. There is a masking scheme to match the ID programmed on the MB with a range of IDs on received CAN frames. For transmission, an arbitration algorithm decides the prioritization of MBs to be transmitted based on the message ID (optionally augmented by 3 local priority bits) or the MB ordering.

The CANFD module can also receive and transmit messages in CAN FD format. The MBs are sized to store the quantity of data bytes selected in the MBDSRn fields of the CANFD_FD_CTL register.

The following sections provides listings of the CANFD registers, interrupts, and triggers. It section also provides information on the architectural concepts and functional operation of the CANFD module.

ADSP-2184x CANFD Register List

CANFD module is a communication controller implementing the CAN protocol according to the CAN 2.0B protocol specification. Features : Flexible DataRate, PretendedNetwork, DMA support, ECC for RAM.

CANFD Architectural Concepts

The following sections provide information about the CANFD architecture.

Block Diagram

The *CANFD Block Diagram* figure shows a block diagram of the CANFD module.

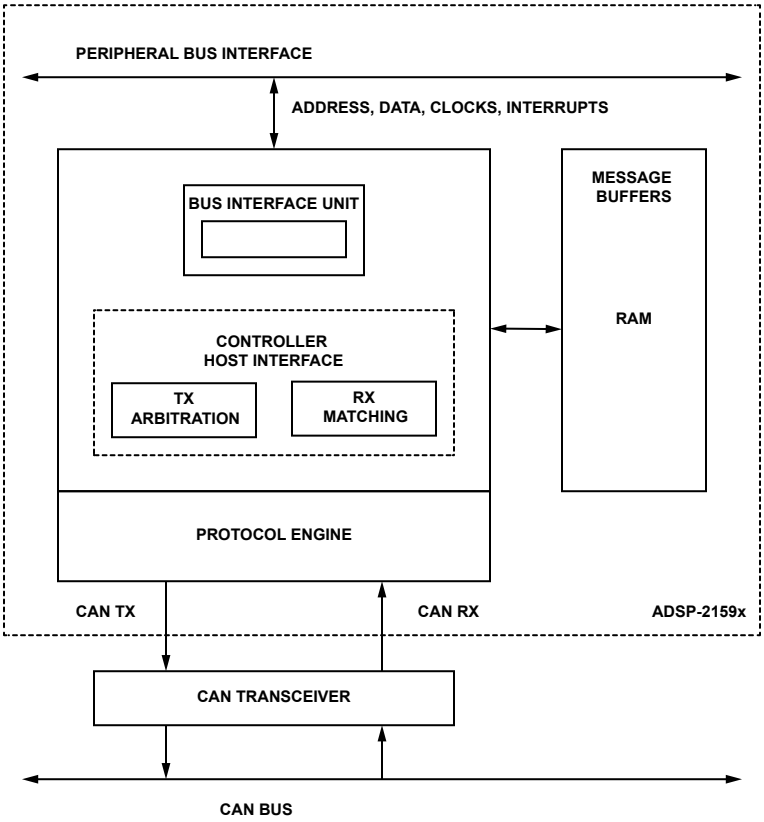

Figure 16-1: CANFD Controller Block Diagram

The CANFD module has the following three submodules and message buffers in an embedded RAM:

Protocol Engine (PE)

The PE submodule manages the serial communication on the CAN bus. It requests RAM access for receiving and transmitting message frames, validates received messages, preforms error handling, and detects CAN FD messages.

Controller Host Interface (CHI)

The CHI submodule handles message buffer selection for reception and transmission, including arbitration, and ID matching algorithms for both flexible data rate (FD) and non-FD message formats.

Bus Interface Unit (BIU)

The BIU submodule controls the access to and from the internal interface bus to establish connection to the CPU and to other blocks. Clocks, address and data buses, interrupt outputs, DMA, and test signals are accessed through the BIU.

Message Buffer (MB)

The CANFD module uses a message buffer structure that represents both extended (29-bit identifier) and standard (11-bit identifier) frames from the CAN specification (Version 2.0, Part B).

Each individual message buffer is 16, 24, 40, or 72 bytes, depending on the quantity of data bytes allocated for the message payload: 8, 16, 32, or 64 data bytes, respectively.

The memory area for mailboxes is from address offset 0x80 to 0x47F. When CAN FD is enabled, the exact address for each memory byte depends on the size of the payload.

The *Message Buffer Structure 64-Byte Payload* figure shows an example of the message buffer structure with a 64-byte payload.

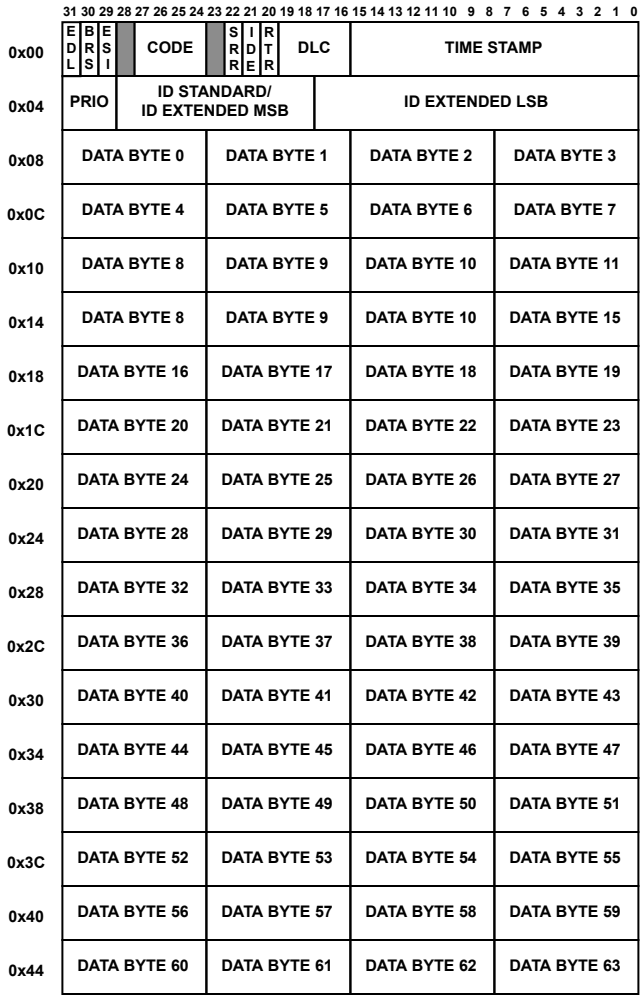

Figure 16-2: Message Buffer Structure 64-Byte Payload

In the example, the first eight bytes of the message buffer is control information associated with the data, followed by the bytes of data in the payload. The control information is defined in the following sections:

Extended Data Length (EDL)

The EDL bit distinguishes between CAN and CAN FD format frames. Do not set EDL when message buffers are configured to RANSWER with code field 0b1010.

Bit Rate Switch (BRS)

The BRS bit defines whether the bit rate is switched inside a CAN FD format frame.

Error State Indicator (ESI)

The ESI bit indicates if the transmitting node is error active or error passive.

Message Buffer Code (CODE)

The CODE field is accessible (read or write) to the processor and the CANFD module, as part of the message buffer matching and arbitration process. The *Message Buffer Code – Rx Buffer* and *Message Buffer Code – Tx Buffer* tables show the encoding.

Table 16-5: Message Buffer Code – Rx Buffer

CODE Description	Rx Code Before New Frame	SRV[*1]	Rx Code After Successful Reception [*2]	RRS [*3]	Comment
0000: INACTIVE – MB is not active.	INACTIVE	N/A	N/A	N/A	MB does not participate in the matching process.
0100: EMPTY – MB is active and empty	EMPTY	N/A	FULL	N/A	When a frame is received successfully, the CODE field is automatically updated to FULL.
0010: FULL – MB is full.	FULL	Yes	FULL	N/A	The act of reading the C/S word followed by unlocking the MB (SRV) does not make the code return to EMPTY. It remains FULL. If a new frame is moved to the MB after the MB was serviced, the code still remains FULL. See Matching Process.
		No	OVERRUN	N/A	If the MB is FULL and a new frame is moved to this MB before the CPU services it, the CODE field is automatically updated to OVERRUN. See Matching Process.
0110: OVERRUN – MB is being overwritten into a full buffer.	OVERRUN	Yes	FULL	N/A	If the CODE field indicates OVERRUN and CPU has serviced the MB, when a new frame is moved to the MB, the code returns to FULL.
		No	OVERRUN	N/A	If the CODE field already indicates OVERRUN, and another new frame must be moved, the MB will be overwritten again, and the code will remain OVERRUN. See Matching Process.
1010: RANSWER[*4] – A frame was configured to recognize a remote request frame and transmit a response frame in return.	RANSWER	N/A	TANSWER(1110)	0	A Remote Answer was configured to recognize a remote request frame received. After that, an MB is set to transmit a response frame. The code is automatically changed to TANSWER (1110). See Matching Process. If the `CANFD_CTL2.RRS` bit is negated, transmit a response frame whenever a remote request frame with the same ID is received.
		N/A	N/A	1	This code is ignored during matching and arbitration process.

Table 16-5: Message Buffer Code – Rx Buffer (Continued)

CODE Description	Rx Code Before New Frame	SRV*1	Rx Code After Successful Reception *2	RRS *3	Comment
CODE[0]=1; BUSY – CANFD is updating the contents of the MB. The CPU must not access the MB.	BUSY*5	N/A	FULL	N/A	Indicates that the MB is being updated. It will be negated automatically and does not interfere with the next CODE.
		N/A	OVERRUN	N/A	

*1 Serviced MB. The MB has been read and unlocked by reading the CANFD_TMR register or other MB.

*2 A frame has a successful reception after it is moved to an MB. See Move Process.

*3 Remote Request Stored bit, see the CANFD_CTL2 register.

*4 Code 1010 is not considered Tx and an MB with this code should not be aborted.

*5 6. For Tx MBs, the BUSY bit is ignored upon read, except when the CANFD_CFG.ABORTEN bit is set. If this bit is asserted, the corresponding MB does not participate in the matching process.

Table 16-6: Buffer Message Code – Tx Buffer

CODE Description	Tx Code Before Tx Frame	MB RTR	Tx Code After Successful Transmission	Comment
1000: INACTIVE – MB is not active.	INACTIVE	N/A	N/A	MB does not participate in arbitration process.
1001: ABORT – MB is aborted.	ABORT	N/A	N/A	MB does not participate in arbitration process.
1100: DATA – MB is a Tx Data Frame (MB RTR must be 0).	DATA	0	INACTIVE	Transmit data frame unconditionally once. After transmission, the MB automatically returns to the INACTIVE state.
1100: REMOTE – MB is a Tx Remote Request Frame (MB RTR must be 1).	REMOTE	1	EMPTY	Transmit remote request frame unconditionally once. After transmission, the MB automatically becomes an Rx Empty MB with the same ID.

Table 16-6: Buffer Message Code – Tx Buffer (Continued)

CODE Description	Tx Code Before Tx Frame	MB RTR	Tx Code After Successful Transmission	Comment
1110: TANSWER – MB is a Tx Response Frame from an incoming Remote Request Frame.	TANSWER	N/A	RANSWER	This is an intermediate code that is automatically written to the MB by the CHI as a result of a match to a remote request frame. The remote response frame will be transmitted unconditionally once, and then the code will automatically return to RANSWER (1010). The CPU can also write this code with the same effect. The remote response frame can be either a data frame or another remote request frame depending on the RTR bit value. See Matching Process and Arbitration Process.

Substitute Remote Request (SRR)

SRR is a fixed recessive bit, only for the extended format. The SRR bit is set to one for transmission (Tx buffers) and is stored with the value received on the CAN bus for Rx receiving buffers. It is received as either recessive or dominant. If the CANFD module receives this bit as dominant, then it is interpreted as an arbitration loss.

When the bit is set, the recessive value is compulsory for transmission in extended format frames. When it is clear, dominant is not a valid value for transmission in extended format frames.

ID Extended Bit (IDE)

IDE identifies whether the frame format is standard or extended.

When the bit is set, the frame format is extended. When the bit is clear, the frame format is standard.

Remote Transmission Request (RTR)

The RTR bit affects the behavior of remote frames and is part of the reception filter:

When the bit is set, the current MB may have a remote request frame to be transmitted if MB is Tx. If the MB is Rx, then incoming remote request frames may be stored. When the RTR bit is clear, the current MB has a data frame to be transmitted. In an Rx MB, it may be considered in matching processes.

See the *Message Buffer Code – Rx Buffer* table, the *Message Buffer Code – Tx Buffer* table, and the description of the `CANFD_CTL2.RRS` bit for additional details.

If the CANFD module transmits RTR as 1 (recessive) and receives it as 0 (dominant), it is interpreted as an arbitration loss. If RTR is transmitted as 0 (dominant) and received as 1 (recessive), the CANFD treats it as a bit error. If the value received matches the value transmitted, it is considered a successful bit transmission.

NOTE: When configuring CAN FD frames, the RTR bit must be negated.

Length of Data in Bytes (DLC)

The 4-bit DLC field is the length (in bytes) of the Rx or Tx data, which is located in offset 0x8 through 0xF of the MB space. In reception, DLC is written by the CANFD module, copied from the DLC (Data Length Code) field of the received frame. In transmission, DLC is written by the processor and corresponds to the DLC field value of the frame to be transmitted. When RTR = 1, the frame to be transmitted is a remote frame and does not include the data field, regardless of the DLC field. See the *Data Byte Validity* table.

Free-Running Counter Time Stamp (TIME STAMP)

The 16-bit TIME STAMP field is a copy of the free-running timer, captured for Tx and Rx frames when the beginning of the identifier field appears on the CAN bus.

Local Priority (PRIO)

The 3-bit PRIO field is used only when the CANFD_CFG.LPRIO_EN bit is set and only makes sense for Tx mailboxes. The PRIO field is not transmitted. It is appended to the regular ID to define the transmission priority. See the Arbitration Process section.

Frame Identifier (ID)

In standard frame format, only the 11 most significant bits (28 to 18) are used for frame identification for both receive and transmit, and the 18 least significant bits are ignored. In extended frame format, all bits are used for frame identification for both receive and transmit.

Data Field (DATA BYTE 0 to 63)

Up to 64 bytes can be used for a data frame, depending on the size of payload selected for the Message Buffers.

For Rx frames, the data is stored as it is received from the CAN bus. DATA BYTE(n) is valid only if n is less than DLC as shown in the *Data Byte Validity* table.

Table 16-7: Data Byte Validity

DLC	Valid Data Bytes
0	None
1	Data Byte 0
2	Data Byte 0 to 1
3	Data Byte 0 to 2

Memory Partition

When CAN FD is enabled, the CANFD RAM can be partitioned in two blocks of 512 bytes. Each block can accommodate a number of message buffers. This depends on the configuration of the size control bit fields in the `CANFD_FD_CTL` register as shown in the *RAM Partition* table.

Table 16-12: RAM Partition

RAM Block	Number of MBs with 8 Bytes[*1]	Size Control Bit Field	Number of MBs of Different Sizes, per Block
0	0 to 31	`CANFD_FD_CTL.MBDSIZR0`	MBDSIZR0=00, 32 MBs with 8 bytes payload MBDSIZR0=01, 21 MBs with 16 bytes payload MBDSIZR0=10, 12 MBs with 32 bytes payload, MBDSIZR0=11, 7 MBs with 64 bytes payload
1	32 to 63	`CANFD_FD_CTL.MBDSIZR1`	MBDSIZR1=00, 32 MBs with 8 bytes payload MBDSIZR1=01, 21 MBs with 16 bytes payload MBDSIZR1=10, 12 MBs with 32 bytes payload MBDSIZR1=11, 7 MBs with 64 bytes payload

*1 default range

When payload sizes of 16, 32, or 64 bytes are configured in some or all RAM blocks, the total number of MBs, and the respective number order may differ from the default configuration of 8 bytes. For example, if block 0 is configured to 8 bytes payload, block 1 to 16 bytes, the following table indicates how the message buffers are arranged into RAM.

Table 16-13: RAM Partition Example

RAM Block	Payload Size	Number of MBs in the RAM Block	MB Range
0	CANFD_FD_CTL.MBDSIZR0 =00, 8 bytes payload	32	0 to 31
1	CANFD_FD_CTL.MBDSIZR1 =01, 16 bytes payload	21	32 to 52

Rx FIFO Structure

When the CANFD_CFG.RFEN bit is set, the memory area from 0x80 to 0xDC (which is normally occupied by MBs 0-5) is used by the Rx FIFO engine.

The region 0x80 to 0x8C contains the output of the FIFO, which must be read by the processor as a message buffer. The FIFO output contains the oldest message that has been received but not yet read. The region 0x90–0xDC is reserved for internal use of the FIFO engine.

An additional memory area, which starts at 0xE0 and may extend up to 0x2DC (normally occupied by MBs 6 to 37) depending on the CANFD_CTL2.RFFNUM bit field setting, contains the ID filter table (configurable from 8 to 128 table elements), which specifies filtering criteria for accepting frames into the FIFO. Out of reset, the ID filter table flexible memory area defaults to 0xE0 and extends only to 0xFC, which corresponds to MBs 6 to 7 for the CANFD_CTL2.RFFNUM bit field setting equal to zero.

The *Rx FIFO Structure* figure shows the Rx FIFO data structure.

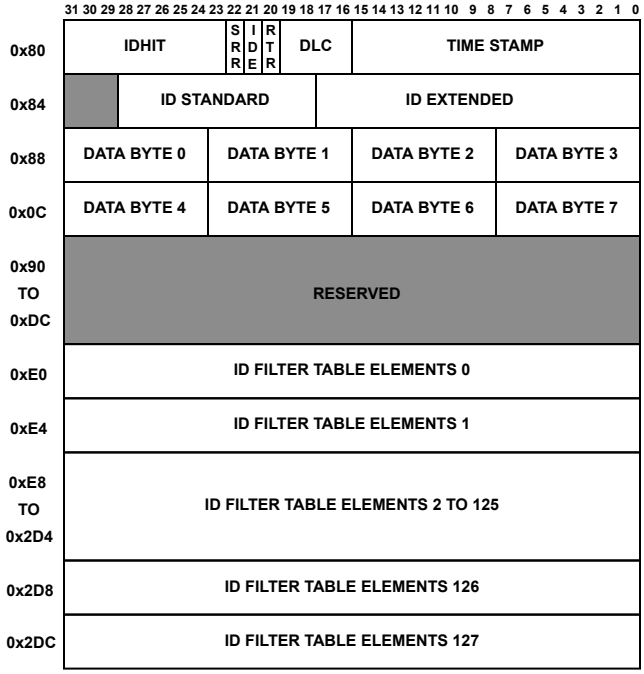

Figure 16-3: Rx FIFO Structure

Each ID filter table element occupies an entire 32-bit word and can be compounded by one, two, or four Identifier Acceptance Filters (IDAF) depending on the `CANFD_CFG.IDAM` bit field setting.

The *ID Filter Table Structure* figure shows the three different formats of the ID table elements. All elements of the table must have the same format, as selected by the `CANFD_CFG.IDAM` bit field.

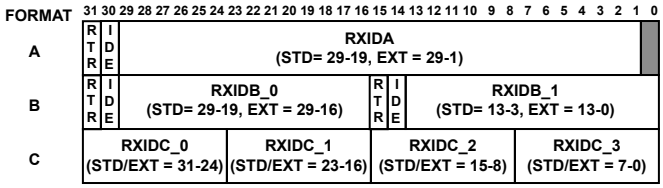

Figure 16-4: ID Filter Table Structure

The *Rx FIFO Filters* table shows the number of Rx FIFO filters configured with the `CANFD_CTL2.RFFNUM` bit field setting.

Table 16-14: Rx FIFO Filters

`CANFD_CTL2.RFFNUM`	**Number of Rx FIFO Filter Elements**	**Message Buffers Occupied by Rx FIFO and ID filter table**	**Remaining Mailboxes**	**Rx FIFO ID Filter Table Elements Affected by Rx Individual Masks**	**Rx FIFO ID filter table elements affected by Rx FIFO global mask**
0x0	8	MB 0 to 7	MB 8 to 63	Elements 0 to 7	None
0x1	16	MB 0 to 9	MB 10 to 63	Elements 0 to 9	Elements 10 to 15
0x2	24	MB 0 to 11	MB 12 to 63	Elements 0 to 11	Elements 12 to 23

Table 16-14: Rx FIFO Filters (Continued)

CANFD_CTL2.RFFNUM	Number of Rx FIFO Filter Elements	Message Buffers Occupied by Rx FIFO and ID filter table	Remaining Mailboxes	Rx FIFO ID Filter Table Elements Affected by Rx Individual Masks	Rx FIFO ID filter table elements affected by Rx FIFO global mask
0x3	32	MB 0 to 13	MB 14 to 63	Elements 0 to 13	Elements 14 to 31
0x4	40	MB 0 to 15	MB 16 to 63	Elements 0 to 15	Elements 16 to 39

0xB	96	MB 0 to 29	MB 30 to 63	Elements 0 to 29	Elements 30 to 95
0xC	104	MB 0 to 31	MB 32 to 63	Elements 0 to 31	Elements 32 to 103
0xD	112	MB 0 to 33	MB 34 to 63	Elements 0 to 31	Elements 32 to 111
0xE	120	MB 0 to 35	MB 36 to 63	Elements 0 to 31	Elements 32 to 119
0xF	128	MB 0 to 37	MB 38 to 63	Elements 0 to 31	Elements 32 to 127

Remote Frame (RTR)

The RTR bit specifies if remote frames are accepted into the FIFO if they match the target ID. If the bit is set, remote frames are accepted and data frames are rejected. If the bit is clear, remote frames are rejected and data frames are accepted.

Extended Frame (IDE)

The IDE bit specifies whether extended or standard frames are accepted into the FIFO if they match the target ID. If the bit is set, extended frames are accepted and standard frames are rejected. If the bit is clear, extended frames are rejected and standard frames are accepted.

Rx Frame Identifier Format A (RXIDA)

Specifies the ID for as acceptance criteria for the FIFO. In the standard frame format, only the 11 most significant bits (29 to 19) are used for frame identification. In the extended frame format, all bits are used.

Rx Frame Identifier Format B (RXIDB_0, RXIDB_1)

Specifies an ID to be used as acceptance criteria for the FIFO. In the standard frame format, the 11 most significant bits (a full standard ID) (29 to 19 and 13 to 3) are used for frame identification. In the extended frame format, all 14 bits of the field are compared to the 14 most significant bits of the received ID.

Rx Frame Identifier Format C (RXIDC_1, RXIDC_2, RXIDC_3)

Specifies an ID to be used as acceptance criteria for the FIFO. In both standard and extended frame formats, all 8 bits of the field are compared to the 8 most significant bits of the received ID.

Identifier Acceptance Filter Hit Indicator (IDHIT)

The 9-bit IDHIT field indicates which identifier acceptance filter is hit by the received message that is in the output of the Rx FIFO. See the Rx FIFO section for more information.

CANFD Processes

The following sections describe the how to transmit and receive CAN and CAN FD frames using the mailbox system.

Transmit Process

To transmit a CAN frame, the processor must prepare a message buffer for transmission by executing the following procedure:

1. Check if the respective interrupt bit is set and clear it.
2. If the MB is active (transmission pending), write the ABORT code (1001) to the CODE field of the control and status (C/S) word to request an abortion of the transmission. Wait for the corresponding IFLAG bit to be asserted by polling the `CANFD_IFLG1` or `CANFD_IFLG2` register or by the interrupt request if enabled in the respective IMASK bit in the `CANFD_IMSK1` or `CANFD_IMSK2` register. Then, read back the CODE field to check if the transmission was aborted or transmitted (see the Transmission Abort Mechanism section).
3. Write the ID word.
4. Write the data bytes.
5. Write the DLC, Control, and CODE fields of the C/S word to activate the MB. When `CANFD_CFG.FDEN` is set, also write the EDL, BRS and ESI bits.

When the MB is activated, it participates in the arbitration process and is eventually transmitted according to its priority. When the DLC value stored in the MB selected for transmission is larger than the respective MB payload size, the CANFD adds the necessary number of bytes with constant 0xCC pattern to complete the expected DLC.

At the end of the successful transmission, the value of the `CANFD_TMR` register is written into the TIME STAMP field, the CODE field in the C/S word is updated, both `CANFD_CRC` and `CANFD_FD_CRC` registers are updated, a status flag is set in the `CANFD_IFLG1` or `CANFD_IFLG2` register, and an interrupt is generated if allowed by the corresponding CANFD_IFLAGn bit. The new CODE field after transmission depends on the code that was used to activate the MB. See the *Message Buffer Code – Rx Buffer* table.

When the Abort feature is enabled (`CANFD_CFG.ABORTEN` is asserted), after the interrupt flag is asserted for a mailbox configured as transmit buffer, the mailbox is blocked. Therefore, the processor is not able to update it until the interrupt flag is disabled by the processor. This means that the processor must clear the corresponding CANFD_IFLAGn bit before starting to prepare this MB for a new transmission or reception.

Arbitration Process

The arbitration process scans the mailboxes, searching for the Tx mailbox that holds the message to be sent in the next opportunity. This mailbox is called the arbitration winner.

The scan starts from the lowest number mailbox and runs toward the higher ones. The arbitration process is triggered in the following events:

- From the CRC field of the CAN frame. The start point depends on the `CANFD_CTL2.TXASDLY` field value.
- During the error delimiter field of a CAN frame.
- During the overload delimiter field of a CAN frame.
- When the winner is inactivated, and the CAN bus has still not reached the first bit of the intermission field.
- When there is a processor write to the C/S word of a winner MB and the CAN bus has still not reached the first bit of the intermission field.
- When CHI is in idle state and the processor writes to the C/S word of any MB.
- When CANFD module exits the bus off state.
- Upon leaving freeze mode or low power mode.

If the arbitration process does not manage to evaluate all mailboxes before the CAN bus has reached the first bit of the intermission field, the temporary arbitration winner is invalidated and the CANFD module does not compete for the CAN bus in the next opportunity.

The arbitration process selects the winner among the active Tx mailboxes at the end of the scan according to the `CANFD_CTL1.LBUF` and `CANFD_CFG.LPRIOEN` bit settings.

Lowest Number Mailbox First

If the `CANFD_CTL1.LBUF` bit is enabled, the first (lowest number) active Tx mailbox found is the arbitration winner. The `CANFD_CFG.LPRIOEN` bit has no effect when the `CANFD_CTL1.LBUF` bit is enabled.

Highest-Priority Mailbox First

If the `CANFD_CTL1.LBUF` bit is disabled, then the arbitration process searches the active Tx mailbox with the highest priority. This mailbox frame with the highest priority has a higher probability to win the arbitration on CAN bus when multiple external nodes compete for the bus at the same time.

The sequence of bits considered for this arbitration is called the arbitration value of the mailbox. The highest-priority Tx mailbox is the one that has the lowest arbitration value among all Tx mailboxes.

If two or more mailboxes have equivalent arbitration values, the mailbox with the lowest number is the arbitration winner.

The composition of the arbitration value depends on the `CANFD_CFG.LPRIOEN` bit.

Local Priority Disabled

When the CANFD_CFG.LPRIOEN is disabled, local priority is disabled, and the arbitration value is built in the exact sequence of bits transmitted in a CAN frame as shown in the *Arbitration Value Priority Disabled* table.

Table 16-15: Arbitration Value Priority Disabled

Format	Mailbox Arbitration Value (32 bits)				
Standard (IDE = 0)	Standard ID (11 bits)	RTR (1bit)	IDE (1 bit)	- (18 bits)	- (1 bit)
Extended (IDE = 1)	Extended ID[28:18] (11 bits)	SRR (1bit)	IDE (1 bit)	Extended ID[17:0] (11 bits)	RTR (1bit)

Local Priority Enabled

If the CANFD_CFG.LPRIOEN is enabled, local priority is enabled. In this case, the mailbox PRIO field is included at the very left of the arbitration value as shown in the *Arbitration Value Priority Enabled table.*

Table 16-16: Arbitration Value Priority Enabled

Format	Mailbox Arbitration Value (35 bits)					
Standard (IDE = 0)	PRIO (3 bits)	Standard ID (11 bits)	RTR (1bit)	IDE (1 bit)	- (18 bits)	- (1 bit)
Extended (IDE = 1)	PRIO (3 bits)	Extended ID[28:18] (11 bits)	SRR (1bit)	IDE (1 bit)	Extended ID[17:0] (11 bits)	RTR (1bit)

As the PRIO field is the most significant part of the arbitration value, mailboxes with low PRIO values have higher priority than mailboxes with high PRIO values, regardless of the rest of their arbitration values.

NOTE: The PRIO field is not part of the frame on the CAN bus and only affects the internal arbitration process.

Arbitration Completion

After the arbitration winner is found, its content is copied to a hidden auxiliary MB called Tx Serial Message Buffer (Tx SMB), which has the same structure as a normal MB but is not user accessible. This operation is called move-out and, after it is done, write access to the C/S word of the corresponding MB is blocked (if CANFD_CFG.ABORTEN is asserted). Write access is restored in the following events:

- After the MB is transmitted and the corresponding IFLAG bit is cleared by the processor.
- The CANFD module enters freeze mode or bus off.
- The CANFD module loses the bus arbitration or there is an error during the transmission.

At the first opportunity window on the CAN bus, the message on the Tx SMB is transmitted according to the CAN protocol rules.

Arbitration Start and Stop Conditions

The arbitration process is triggered in the following situations:

- During Rx and Tx frames from CAN CRC field to end of frame. The `CANFD_CTL2.TXASDLY` value may be changed to optimize the arbitration start point.
- During CAN bus off state from TX_ERR_CNT = 124 to 128. The `CANFD_CTL2.TXASDLY` value may be changed to optimize the arbitration start point.
- During C/S write by the processor in bus idle mode. The first C/S write starts the arbitration process and a second C/S write during this same arbitration restarts the process. If other C/S writes are performed, the Tx arbitration process is pending. If there is no arbitration winner after the arbitration process has finished, the Tx arbitration machine begins a new arbitration process. If there is a pending arbitration and the bus idle state starts, an arbitration process is triggered. In this case, the first and second C/S write in the bus idle state do not restart the arbitration process. It is possible that there is not enough time to finish arbitration in the wait for bus idle state and the next state is idle. In this case, the scan is not interrupted, and it is completed during the bus idle state. During this arbitration, a C/S write does not cause an arbitration restart.
- Arbitration winner deactivation during a valid arbitration window.
- Upon exiting freeze mode (first bit of the wait for bus idle state). If there is a re- synchronization during wait for bus idle state, the arbitration process restarts.

Arbitration process stops in the following situations:

- All mailboxes were scanned.
- A Tx active mailbox is found when the lowest buffer feature is enabled.
- Arbitration winner inactivation or abort during any arbitration process.
- There was not enough time to finish the Tx arbitration process (for example, when a deactivation was performed near the end of frame). In this case, the arbitration process is pending.
- There is an error or overload flag in the bus.
- There is a low power or freeze mode request in the idle state.

Arbitration is considered pending as described below:

- It was not possible to finish the arbitration process in time.
- C/S write during arbitration if write is performed in a MB whose number is lower than the Tx arbitration pointer.
- Any C/S write if there is no Tx arbitration process in progress.
- Rx Match has just updated an Rx code to Tx code
- Entering the bus off state.

C/S write during arbitration has the following effect:

- If the C/S write is performed in the arbitration winner, a new process is restarted immediately.
- If the C/S write is performed in an MB whose number is higher than the Tx arbitration pointer, the ongoing arbitration process will scan this MB as normal.

Receive Process

To receive CAN frames into a mailbox, the processor must prepare the mailbox for reception by executing the following steps:

1. If the mailbox is active (either Tx or Rx), inactivate the mailbox (See Mailbox Inactivation), preferably with a safe inactivation (See Transmission Abort Mechanism).
2. Write the ID word.
3. Write the EMPTY code (0b0100) to the CODE field of the C/S word to activate the mailbox. No setup is required for the EDL, BRS, and ESI bits; they are overwritten by the respective bit fields in the received message.

After the MB is activated, it will be able to receive frames that match the programmed filter. At the end of a successful reception, the mailbox is updated by the move-in process (See Move-In) as follows:

1. The received data field (8 bytes at most for classical CAN message format and up to 64 bytes for the CAN FD message format) is stored.
2. The received ID field is stored.
3. The value of the `CANFD_TMR` register at the time of the second bit of the frame identifier field is written into the mailbox TIME STAMP field.
4. The received SRR, IDE, RTR, EDL, BRS, ESI, and DLC fields are stored.
5. The CODE field in the C/S word is updated according to the *Message Buffer Code – Rx Buffer* and *Message Buffer Code – Tx Buffer* tables.
6. A status flag is set in the `CANFD_IFLG1` or `CANFD_IFLG2` register and an interrupt is generated if allowed by the corresponding `CANFD_IMSK1` or `CANFD_IMSK2` register bit.

The recommended procedure for the processor to service (read) the frame received in a mailbox is:

The processor polls for frame reception by checking the status flag bit for the specific mailbox in the respective CANFD_IFLAGn register and not by polling the CODE field of that mailbox. Polling the CODE field does not work because, once a frame is received and the processor services the mailbox (by reading the C/S word followed by unlocking the mailbox), the CODE field does not return to EMPTY. It remains FULL, as explained in the *Message Buffer Code – Rx Buffer* table. If the processor tries to work around this behavior by writing to the C/S word to force an EMPTY code after reading the mailbox without a prior safe inactivation, a newly received frame matching the filter of that mailbox may be lost.

NOTE: Never poll by reading the C/S word directly from the mailboxes. Always read the `CANFD_IFLG1` or `CANFD_IFLG2` register.

The identifier field of the receive frame is always stored in the matching mailbox. Therefore, the contents of the ID field in a mailbox may change if the match was due to masking.

When the CANFD_CFG.SRXDIS bit is enabled, the CANFD module does not store frames transmitted by itself in any MB, even if it contains a matching Rx mailbox, and no interrupt flag or interrupt signal is generated. Otherwise, when the CANFD_CFG.SRXDIS bit is disabled, the CANFD module can receive frames transmitted by itself if there is a matching Rx mailbox.

To be able to receive CAN frames through the Rx FIFO, the processor must enable and configure the Rx FIFO during freeze mode (See Rx FIFO). Upon receiving the frames available in Rx FIFO interrupt (see the CANFD_IFLG1.MB05 bit description), the processor services the received frame using the following procedure:

1. Read the C/S word (optional: needed only if a mask was used for the IDE and RTR bits).
2. Read the ID field (optional: needed only if a mask was used).
3. Read the Data field.
4. Read the CANFD_RX_FIFO register (optional).
5. Clear the frames available in Rx FIFO interrupt by writing a one to the CANFD_IFLG1.MB05 bit to release the MB and allow the processor to read the next Rx FIFO entry.

When the CANFD_CFG.DMAEN bit is enabled, upon receiving a frame in the Rx FIFO, the CANFD_IFLG1.MB05 bit generates a DMA request and does not generate a processor interrupt (See Rx FIFO Under DMA Operation). The CANFD_IMSK1 bits in the Rx FIFO region are not used.

The DMA controller must service the received frame using the following procedure:

1. Read the C/S word (read 0x80 address, optional).
2. Read the ID field (read 0x84 address, optional).
3. Read all data bytes (start read at 0x88 address, optional).
4. Read the last data bytes (read 0x8C address is mandatory).

Matching Process

The matching process scans the MB memory looking for Rx MBs programmed with the same ID as the one received from the CAN bus. If the FIFO is enabled, the priority of scanning can be selected between mailboxes and FIFO filters. The matching starts from the lowest number MB toward the higher ones. When no match is found within the first structure, then the other is scanned subsequently. When the FIFO is full, the matching algorithm always looks for a matching MB outside the FIFO region.

As the frame is being received, it is stored in a hidden auxiliary MB called Rx Serial Message Buffer (Rx SMB).

The matching process start point depends on the following conditions:

- When the received frame is a remote frame, the start point is the CRC field of the frame.

- When the received frame is a data frame with DLC field equal to zero, the start point is the CRC field of the frame.
- When the received frame is a data frame with DLC field different than zero, the start point is the DATA field of the frame.

When a matching ID is found in the FIFO table or in one of the mailboxes, the contents of the Rx SMB are transferred to the FIFO or to the matched mailbox by the move-in process. When any CAN protocol error is detected, then no match results are transferred to the FIFO or to the matched mailbox at the end of reception.

The matching process scans all matching elements of both Rx FIFO (if enabled) and the active Rx mailboxes (CODE is EMPTY, FULL, OVERRUN, or RANSWER) in search of a successful comparison with the matching elements of the Rx SMB that is receiving the frame on the CAN bus. The Rx SMB has the same structure as a mailbox. The reception structures (Rx FIFO or mailboxes) associated with the matching elements that had a successful comparison are the matched structures. The matching winner is selected at the end of the scan among those matched structures and depends on conditions described below.

Table 16-17: Matching Architecture

Structure	SMB.RTR	CTRL2.RSS	CTRL2.EA-CEN	MB.IDE	MB.RTR	MB.ID*1	MB.CODE
Mailbox	0	N/A	0	cmp*2	no_cmp*3	cmp_msk*4	
Mailbox	0	N/A	1	cmp_msk	cmp_msk	cmp_msk	
Mailbox	1	0	N/A	cmp	no_cmp	cmp	
Mailbox	1	1	0	cmp	no_cmp	cmp_msk	
Mailbox	1	1	1	cmp_msk	cmp_msk	cmp_msk	
FIFO*5	N/A	N/A	N/A	cmp_msk	cmp_msk	cmp_msk	

*1 1. For mailbox structure, If SMB.IDE is asserted, the ID is 29 bits (ID Standard + ID Extended). If SMB.IDE is negated, the ID is only 11 bits (ID Standard). For FIFO structure, the ID depends on CANFD_CFG.IDAM.

*2 cmp: Compares the Rx SMB contents with the MB contents regardless the masks.

*3 no_cmp: The Rx SMB contents are not compared with the MB contents.

*4 cmp_msk: Compares the Rx SMB contents with MB contents taking into account the masks.

*5 SMB.IDE and SMB.RTR. are not considered when CANFD_CFG.IDAM is format C.

A reception structure is free-to-receive when any of the following conditions is satisfied:

- The CODE field of the mailbox is EMPTY.
- The CODE field of the mailbox is either FULL or OVERRUN and it has already been serviced (the C/S word was read by the processor and unlocked as described in the Mailbox Lock Mechanism section).
- The CODE field of the mailbox is either FULL or OVERRUN and an inactivation is performed. See the Mailbox Inactivation section.
- The Rx FIFO is not full.

The scan order for mailboxes and the Rx FIFO is from the matching element with lowest number to the higher ones.

The matching winner search for mailboxes is affected by the CANFD_CFG.IRMQEN bit. If the CANFD_CFG.IRMQEN bit is disabled, the matching winner is the first matched mailbox regardless if it is free-to-receive or not. If the CANFD_CFG.IRMQEN bit is enabled, the matching winner is selected according to the priority below:

1. The first free-to-receive matched mailbox.
2. The last non free-to-receive matched mailbox.

It is possible to select the priority of scan between mailboxes and the Rx FIFO by using the-CANFD_CTL2.MRPRIO bit.

If the selected priority is Rx FIFO first:

- If the Rx FIFO is a matched structure and is free-to-receive, then the Rx FIFO is the matching winner regardless of the scan for mailboxes.
- Otherwise (the Rx FIFO is not a matched structure or is not free-to-receive), then the matching winner is searched for among mailboxes as described above.

If the selected priority is mailboxes first:

- If a free-to-receive matched mailbox is found, it is the matching winner regardless of the scan for the Rx FIFO.
- If no matched mailbox is found, then the matching winner is searched for in the scan for the Rx FIFO.

If both conditions above are not satisfied and a non free-to-receive matched mailbox is found, then the matching winner determination is conditioned by the CANFD_CFG.IRMQEN bit:

- If the CANFD_CFG.IRMQEN bit is disabled, the matching winner is the first matched mailbox.
- If the CANFD_CFG.IRMQEN bit is enabled, the matching winner is the Rx FIFO if it is a free-to- receive matched structure; otherwise, the matching winner is the last non free-to- receive matched mailbox.

See the *Matching Possibilities and Resulting Reception Structures* table for a summary of matching possibilities.

Table 16-18: Matching Possibilities and Resulting Reception Structures

RFEN	IRMQEN	MRPRIO	Matched in MB[*1]	Matched in FIFO[*2]	Reception Structure	Description
No FIFO, only MB, match is always MB first:						
0	0	X[*3]	None	_[*4]	None	Frame lost by no match
0	0	X	Free	–	FirstMB	
0	1	X	None	–	None	Frame lost by no match

Table 16-18: Matching Possibilities and Resulting Reception Structures (Continued)

RFEN	IRMQEN	MRPRIO	Matched in MB*1	Matched in FIFO*2	Reception Structure	Description
0	1	X	Free	–	FirstMB	
0	1	X	Not Free	–	LastMB	Overrun
FIFO enabled, no match in FIFO (as if FIFO does not exist):						
1	0	X	None	None	None	Frame lost by no match
1	0	X	Free	None	FirstMB	
1	1	X	None	None	None	Frame lost by no match
1	1	X	Free	None	FirstMB	
1	1	X	Not Free	None	LastMB	Overrun
FIFO enabled, queue disabled:						
1	0	0	X	NotFull	FIFO	
1	0	0	None	Full	None	Frame lost by FIFO full (FIFO overflow)
1	0	0	Free	Full	FirstMB	
1	0	0	Not Free	Full	FirstMB	
1	0	1	None	NotFull	FIFO	
1	0	1	None	Full	None	Frame lost by FIFO full (FIFO overflow)
1	0	1	Free	X	FirstMB	
1	0	1	Not Free	X	FirstMB	Overrun
FIFO enabled, queue enabled:						
1	1	0	X	NotFull	FIFO	
1	1	0	None	Full	None	Frame lost by FIFO full (FIFO overflow)
1	1	0	Free	Full	FirstMB	
1	1	0	Not Free	Full	LastMB	Overrun
1	1	1	None	NotFull	FIFO	
1	1	1	Free	X	FirstMB	
1	1	1	Not Free	NotFull	FIFO	

Table 16-18: Matching Possibilities and Resulting Reception Structures (Continued)

RFEN	IRMQEN	MRPRIO	Matched in MB*1	Matched in FIFO*2	Reception Structure	Description
1	1	1	Not Free	Full	LastMB	Overrun

*1 In the Matched in MB column, the term "None" means the frame has not matched an MB (free-to-receive or non-free-to receive). The term "Free" means the frame matched at least one MB free-to-receive regardless of whether it has matched MBs non-free-to-receive.

*2 In the Matched in FIFO column, the term "None" means the frame has not matched any filter for the Rx FIFO. It is as if the Rx FIFO does not exist (CANFD_CTL2.RFEN = 0). The term "NotFull" means that the frame has matched a FIFO filter and has empty slots to receive it. The term "Full" means that the frame has matched a FIFO filter, but the FIFO couldn't store it because the FIFO has no empty slots to receive it.

*3 The X denotes a don't-care condition.

*4 The – denotes a forbidden condition.

When a non-safe mailbox inactivation (See Mailbox Inactivation) occurs during the matching process and the mailbox inactivated is the temporary matching winner, then the temporary matching winner is invalidated. The matching elements scan is not stopped nor restarted; it continues normally. The consequence is that the current matching process works as if the matching elements compared before the inactivation did not exist, therefore a message may be lost.

Suppose, for example, that the Rx FIFO is disabled, the `CANFD_CFG.IRMQEN` is enabled, there are two MBs with the same ID, and the CANFD starts receiving messages with that ID. If the two MBs are the second and the fifth in the array, then when the first message arrives, the matching algorithm finds the first match in MB number 2. The code of this MB is EMPTY, so the message is stored there. When the second message arrives, the matching algorithm finds MB number 2 again, but it is not "free-to-receive," so it keeps looking, finds MB number 5 and stores the message there. If yet another message with the same ID arrives, the matching algorithm finds out that there are no matching MBs that are "free-to-receive," so it decides to overwrite the last matched MB, which is number 5. In doing so, it sets the CODE field of the MB to indicate OVERRUN.

The ability to match the same ID in more than one MB can be exploited to implement a reception queue (in addition to the full-featured FIFO) to allow more time for the processor to service the MBs. By programming more than one MB with the same ID, received messages are queued into the MBs. The CPU can examine the TIME STAMP field of the MBs to determine the order in which the messages arrived.

Matching to a range of IDs is possible by using ID acceptance masks. The CANFD module supports individual masking per MB. During the matching algorithm, if a mask bit is asserted, then the corresponding ID bit is compared. If the mask bit is negated, the corresponding ID bit is a "don't care." The `CANFD_IMSK1` and `CANFD_IMSK2` registers are implemented in RAM, so they are not initialized out of reset. Also, they can only be programmed while the CANFD module is in freeze mode; otherwise, they are blocked by hardware.

The CANFD also supports an alternate masking scheme with only four mask registers (`CANFD_RX_FIFO_GMSK`, `CANFD_RX_MB_GMSK`, `CANFD_RX_14_MSK`, and `CANFD_RX_15_MSK`) for backward compatibility with legacy applications. This alternate masking scheme is enabled when `CANFD_CFG.IRMQEN` is enabled.

Receive Process Pretending Network Mode

Pretended networking mode adds specific wake up functionality in low power modes (doze mode). When pretended network (PN) mode is enabled by asserting the CANFD_CFG.PNETEN bit, the CANFD module continues processing Rx CAN messages under low power mode, able to detect specific wake up messages by filtering them against ID and payload target values using preselected matching criteria. Wake up functionality is not available for messages in CAN FD format. While in pretended networking mode, CAN FD format messages are ignored.

PN registers are in the 0x0B00–0x0B7C address range and can only be written only in freeze mode. These registers are used for writing PN configuration (both control and target values) prior entering into pretended networking mode, and for reading wake up flags and the received message ID and data when returning to normal mode after waking. The processor waits for the CANFD_CFG.LPMACK bit to be disabled before performing any access to CANFD PN registers.

PN control registers are CANFD_PN_CTL1 and CANFD_PN_CTL2. The control bit fields that configure the filtering criteria are:

- CANFD_PN_CTL1.PLFSEL: Payload filtering selection.
- CANFD_PN_CTL1.IDFSEL: ID filtering selection.
- CANFD_PN_CTL1.FCSEL: Filtering combination selection.

PN target values are:

- CANFD_FLTR_ID1.IDE: IDE target value used to filter the incoming message by its format (standard or extended).
- CANFD_FLTR_ID1.RTR: RTR target value used to filter the incoming message by its type (data or remote frame).
- CANFD_FLTR_DLC.HI and CANFD_FLTR_DLC.LO: Target DLC range used to filter the size of payload part of an incoming message.
- CANFD_FLTR_ID1.VALUE: ID target value used to filter the incoming message ID (equal to, smaller than or equal, greater than or equal, or the lower limit value in an ID range).
- CANFD_FLTR_ID2_IDMSK: ID target value used as the upper limit in an ID range.
- PL1: Payload target value used to filter the incoming message payload (equal to, smaller than or equal, greater than or equal, or the lower limit value in a payload range).
- PL2: Payload target value used as the upper limit in a payload range.

The IDE, RTR, ID, and payload filters have their respective masks. These masks determine which bits are considered in equality comparisons (1 in certain mask positions) and which ones are don't care (0 in other mask positions). ID and payload masks are used only for exact ID and/or exact payload comparisons.

The ID of Rx incoming messages can be filtered based on the following criteria:

- A match with the exact ID value by detecting the equality between the ID field of the incoming message and the content of target CANFD_FLTR_ID1 register. The ID mask is used.
- A match with the maximum range of ID; in other words, any message with ID value smaller than or equal to the content of target CANFD_FLTR_ID11 register is accepted. The ID mask is not used.
- A match with the minimum range of ID; in other words, any message with ID value greater than or equal to the content of target CANFD_FLTR_ID1 register is accepted. The ID mask is not used.
- A match inside a range of IDs; in other words, any message with an ID value that is greater than or equal to the content of target CANFD_FLTR_ID1 register and smaller than or equal to the content of target CANFD_FLTR_ID2_IDMSK register is accepted. The ID mask is not used.

The above criteria for ID filtering must be coherent with CANFD_FLTR_ID1.IDE and CANFD_FLTR_ID1.RTR target values. Only Rx frames that match the respective IDE and RTR bits to the contents of FLT_IDE and FLT_RTR bit fields are compared. When range of IDs is selected (CANFD_PN_CTL1.IDFSEL = 11), both the CANFD_FLTR_ID1.VALUE field and the CANFD_FLTR_ID2_IDMSK register are referred to the same CANFD_FLTR_ID1.IDE and CANFD_FLTR_ID1.RTR bits.

The ID mask is applied only to the exact ID comparison filtering option (CANFD_PN_CTL1.IDFSEL = 00) to determine which bits are considered in the comparison. For the exact match option, the mask can select any bit within the ID field. For maximum range, minimum range and inside range comparisons, the ID mask is not considered.

The IDE and RTR masks are applied in both exact and range ID comparison filtering options to determine which bits are considered in comparison.

Similarly to the ID criteria, 64-bit data or payloads (PL) of Rx incoming messages can be filtered based on the following criteria:

- A match with the exact payload value by detecting the equality between the payload field of the incoming message and the content of PL1 register. The payload mask is used.
- A match with the maximum range of payload–in other words, any message with payload value smaller than or equal to the content of PL1 register is accepted. The payload mask is not used.
- A match with the minimum range of payload–in other words, any message with payload value greater than or equal to the content of PL1 register is accepted. The payload mask is not used.
- A match inside a range of payloads–in other words, any message with a payload value that is greater than or equal to the content of PL1 register and smaller than or equal to the content of PL2 register is accepted. The payload mask is not used.

The above criteria for payload filtering must be coherent with CANFD_FLTR_DLC.HI and CANFD_FLTR_DLC.LO limit values. The payload of a Rx incoming message is filtered in accordance with the selected criteria only when the DLC value of the Rx incoming message is inside a DLC range:

- Greater than or equal to the CANFD_FLTR_DLC.LO (lower limit) and

- Lower than or equal to the CANFD_FLTR_DLC.HI (upper limit)

Conversely, a DLC value out of the specified range results in mismatch. By making CANFD_FLTR_DLC.LO = CANFD_FLTR_DLC.HI, only payloads of specified quantity of bytes will be filtered. DLC is not maskable.

When the inside range of payloads option is selected (CANFD_PN_CTL1.PLFSEL = 11), both PL1 and PL2 are considered with the 8-byte data length. All the data bytes excluded by the DLC of the received message are considered with value zero.

Payload mask is only used in the exact match option (CANFD_PN_CTL1.PLFSEL = 00) to select which bits or bytes in the 8-byte data field of both Rx incoming message and the contents of PL1 register are selected for matching. Mask length must be in accordance with the expected range of DLC values. For maximum range, minimum range, and inside range comparisons, the payload mask is not considered.

When a remote frame is received by the CANFD module and the CANFD_PN_CTL1.FCSEL bit is configured to select the payload comparison, the payload filtering is not considered and the comparison results in a mismatch.

Rx incoming messages can also be filtered based upon the quantity and rate of message reception, specifically:

- Several messages that match the filtering criteria for ID or payload a predefined quantity of times. This quantity can be configured in the 1 to 255 range. See the CANFD_CTL1 register.
- No message matching the filtering criteria for ID or payload up to a timeout trigger.

  That is, non-reception of a matching message for a defined quantity of time. See the CANFD_CTL2 register.

The CANFD module can generate a wakeup timeout event from an internal timer with associated comparator circuitry capable of generating a timeout flag when the counting reaches the predefined timeout value, as specified in the CANFD_PN_CTL2.MATCHTO bit field.

The above filtering criteria can be used together as follows:

- Message ID filtering only.
- Message ID filtering and payload filtering.
- Message ID filtering only occurring N times.
- Message ID filtering and payload filtering occurring N times.

The timeout counter runs concurrently with the reception filtering process. Both engines, timeout counter and message filtering, are independent. If an incoming message matches the selected filter criteria, the timeout counter keeps counting until the processor wakes up.

Conversely, if the timeout counter reaches the target value, then the message filtering process continue to filter incoming messages until the processor wakes up. The CANFD_WUM.MCNT field reports the number of matched messages that occurred under pretended networking mode up to the moment the processor wakes up.

Under pretended networking mode, a wakeup event that occurs sets the respective wake up flag (see the CANFD_WUM register.

- In case of a successful match with the selected filtering criteria, the CANFD_WUM.WUMF bit field.

- In case of a timeout trigger, the CANFD_WUM.WTOF bit field.

Either of these flags generates an interrupt to the processor if the respective mask bit is asserted (CANFD_PN_CTL1.WUMFMSK or CANFD_PN_CTL1.WTOFMSK).

There are four wake up message buffers (WMBs) for storing incoming messages in pretended networking mode. They stored in the following registers: CANFD_WMB0_ID, CANFD_WMB1_ID, CANFD_WMB2_ID, and CANFD_WMB3_ID When the CANFD_PN_CTL1.MATCHCNT value is one, just one message is received if matching the filtering criteria, and this message is stored in the CANFD_WMB0 register. If the CANFD_PN_CTL1.MATCHCNT value is between two and four, CANFD_WMB1, CANFD_WMB2, and CANFD_WMB3 are used to store the second, third, and fourth matching messages, respectively. If CANFD_PN_CTL1.MATCHCNT is greater than four, the last four matching messages are stored in the WMBs; respecting the WMB index to indicate the arrival order, the latest is stored in CANFD_WMB3. Only the valid data bytes of the incoming match message is stored in data field of WMBs. The non-valid data bytes are read as zero. In case the of DLC = 0 and RTR = 1, the data field is filled with zero. In any of the above cases, the wake up interrupt is generated just when the filtering criteria is completed and the CANFD_PN_CTL1.WUMFMSK bit is set.

When a non-match wakeup event occurs (timeout or external) and the CANFD_WUM.MCNT value is equal or greater than four, the message stored in WMB0 does not have a valid content. The CANFD_WMB0 is used as the buffer for the current message on the CAN bus. Messages received during pretended networking mode do not have timestamps and respective field in the WMB structure must be ignored.

Under low-power mode (doze or stop), all processes are shut down except for the PN functionality in the PE submodule, which is kept clocked by the oscillator clock. The CANFD continues to receive Rx incoming messages and just compares them against the predefined target values and according to the selected filtering criteria. The matching, arbitration, move-in, and move-out processes, normally available in normal mode, are not performed under pretended networking mode.

Under pretended networking, the CANFD reacts to messages on the CAN bus in the same manner as in normal mode (generates acknowledge bits, detects and counts errors, etc.).

Move Process

There are two types of move process: move-in and move-out.

Move-In

The move-in process is the copy of a message received by an Rx SMB to an Rx mailbox or FIFO that has matched it. If the move destination is the Rx FIFO, attributes of the message are also copied to the CANFD_RX_FIFO register. Each Rx SMB has its own move-in process, but only one is performed at a given time as described below. The move-in starts only when the message held by the Rx SMB has a corresponding matching winner (See Matching Process) and all of the following conditions are true:

- The CAN bus has reached or let past either of the following:
  - The second bit of the Intermission field next to the frame that carried the message that is in the Rx SMB
  - The first bit of an overload frame next to the frame that carried the message that is in the Rx SMB

- There is no ongoing matching process.
- The destination mailbox is not locked by the processor.
- There is no ongoing move-in process from another Rx SMB. If more than one move-in processes are to be started at the same time, both are performed and the newest substitutes the oldest.

The term pending *move-in* is used throughout the documentation and stands for a *move-to- be* that still does not satisfy all the previously mentioned conditions.

The move-in is canceled and the Rx SMB can receive another message when any of the following conditions is satisfied:

- The destination mailbox is inactivated after the CAN bus has reached the first bit of intermission field next to the frame that carried the message and its matching process has finished.
- There is a previous pending move-in to the same destination mailbox.
- The Rx SMB is receiving a frame transmitted by the CANFD itself and the self-reception is disabled (`CANFD_CFG.SRXDIS` bit is enabled)
- Any CAN protocol error is detected.

Note that the pending move-in is not canceled if the CANFD module enters freeze or low-power mode. The pending move-in stays on hold waiting for exit from freeze or low-power mode and to be unlocked. If an MB is unlocked during freeze mode, the move-in happens immediately.

The move-in process is the execution by the CANFD module of the following steps:

1. Push `CANFD_RX_FIFO.IDHIT` into the `CANFD_RX_FIFO` FIFO if the message is destined to the Rx FIFO.
2. Read all data words from the Rx SMB according to the selected payload size for the Rx storage element.
3. Write all data words to the Rx mailbox according to the selected payload size for the Rx storage element. If the data size of the storage element is smaller than the original payload size described in the message DLC field, the payload is truncated and the high order bytes that do not fit the destination size are lost.
4. Read the C/S and ID words from the Rx SMB.
5. Write C/S and ID words to the Rx mailbox and update the CODE field.

The move-in process is not atomic, in such a way that it is immediately canceled by the inactivation of the destination mailbox (See Mailbox Inactivation). In this case, the mailbox may be left partially updated, thus incoherent. The exception is if the move-in destination is an Rx FIFO message buffer, in which case the process cannot be canceled.

The BUSY bit (least significant bit of the CODE field) of the destination message buffer is asserted while the move-in is being performed to alert the processor that the message buffer content is temporarily incoherent.

Move-Out

The move-out process is the copy of the content from a Tx mailbox to the Tx SMB when a message for transmission is available (See Arbitration Process). The move-out occurs in the following conditions:

- The first bit of intermission field.
- During the bus off state when Tx error counter is in the 124 to 128 range.
- During bus idle state.
- During the wait for bus idle state.

The move-out process is not atomic. Only the processor has priority to access the memory concurrently out of bus idle state. In bus idle, the move-out has the lowest priority to the concurrent memory accesses.

Data Coherence

In order to maintain data coherency and proper operation of the CANFD module, the processor must obey the rules described in the Transmit Process and Receive Process sections.

Transmission Abort Mechanism

The abort mechanism provides a safe way to request the abortion of a pending transmission. A feedback mechanism is provided to inform the processor if the transmission was aborted or if the frame could not be aborted and was transmitted instead.

Two primary conditions must be fulfilled in order to abort a transmission:

- The `CANFD_CFG.ABORTEN` bit is enabled.
- The first processor action must be the writing of abort code (1001) into the CODE field of the C/S word.

Active MBs configured for transmission must be aborted first before they can be updated. If the abort code is written to a mailbox that is currently being transmitted or to a mailbox that was already loaded into the Tx SMB for transmission, the write operation is blocked, and the transmission is not disturbed. However, the abort request is captured and kept pending until one of the following conditions is satisfied:

- The CANFD module loses the bus arbitration.
- There is an error during the transmission.
- The CANFD module is put into freeze mode.
- The CANFD enters the bus off state.
- There is an overload frame.

When none of the conditions above are reached, the MB is transmitted correctly, the interrupt flag is set in the respective `CANFD_IFLG1` or `CANFD_IFLG2` register, and an interrupt to the processor is generated (if enabled). The abort request is automatically cleared when the interrupt flag is set. On the other hand, when one of the above conditions is reached, the frame is not transmitted; therefore, the abort code is written into the CODE field, the

interrupt flag is set in the respective CANFD_IFLG1 or CANFD_IFLG2 register, and an interrupt is (optionally) generated.

When the processor writes the abort code before the transmission begins internally, then the write operation is not blocked; therefore, the MB is updated, and the interrupt flag is set. The processor just needs to read the abort code to make sure the active MB was safely inactivated. Although the CANFD_CFG.ABORTEN bit is asserted and the processor wrote the abort code, in this case the MB is inactivated and not aborted, because the transmission did not start yet. One mailbox is only aborted when the abort request is captured and kept pending until one of the previous conditions are satisfied.

The abort procedure can be summarized as follows:

- The processor checks the corresponding IFLAG and clears it, if asserted.
- The processor writes 1001 into the CODE field of the C/S word.
- The processor waits for the corresponding IFLAG indicating that the frame was either transmitted or aborted.
- The processor reads the CODE field to check if the frame was either transmitted (CODE = 1000) or aborted (CODE = 1001).
- It is necessary to clear the corresponding IFLAG to allow the MB to be reconfigured.
- It is necessary to reconfigure the EDL, BRS, and ESI fields of the aborted MB before transmitting it again.

Mailbox Inactivation

Inactivation is a mechanism provided to protect the mailbox against updates by the CANFD internal processes, thus allowing the processor to rely on mailbox data coherence after having updated it, even in normal mode.

Inactivation of transmission mailboxes must be performed only when the CANFD_CFG.ABORTEN bit is deasserted.

If a mailbox is inactivated, it participates in neither the arbitration process nor the matching process until it is reactivated.

To inactivate a mailbox, the processor must update its CODE field to INACTIVE (either 0000 or 1000).

Because the processor is not able to synchronize the CODE field update with the CANFD internal processes, an inactivation has the following consequences:

- A frame on the bus that matches the filtering of the inactivated Rx mailbox may be lost without notice, even if there are other mailboxes with the same filter.
- A frame containing the message within the inactivated Tx mailbox may be transmitted without setting the respective IFLAG.

To perform a safe inactivation and avoid the above consequences for Tx mailboxes, the processor must use the transmission abort mechanism .

The inactivation automatically unlocks the mailbox (See Mailbox Lock Mechanism).

NOTE: Message buffers that are part of the Rx FIFO cannot be inactivated. There is no write protection on the FIFO region. The processor must maintain data coherency in the FIFO region when the CANFD_CFG.RFEN bit is enabled.

Mailbox Lock Mechanism

Other than mailbox inactivation, the CANFD module has another data coherence mechanism for the receive process. When the processor reads the C/S word of an Rx MB with codes FULL or OVERRUN, the CANFD assumes that the processor wants to read the whole MB in an atomic operation and therefore it sets an internal lock flag for that MB. The lock is released when the processor reads the CANFD_TIMING register (global unlock operation), or when it reads the C/S word of another MB regardless of its code. A processor write into the C/S word also unlocks the MB, but this procedure is not recommended for normal unlock use because it cancels a pending move and potentially may lose a received message. The MB locking prevents a new frame from being written into the MB while the processor is reading it.

NOTE: The locking mechanism applies only to Rx MBs that are not part of the FIFO and have a code other than INACTIVE (0000) or EMPTY (0100). Tx MBs can not be locked. When the CANFD_CFG.IRMQEN bit is disabled, reading the C/S word locked the MB even if it was EMPTY.

When the FIFO is disabled and the second and the fifth MBs of the array are programmed with the same ID, and the CANFD module has already received and stored messages into these two MBs. If the processor then attempts to read MB number five and at the same time another message with the same ID is arriving, then when the processor reads the C/S word of MB number five, this MB is locked. The new message arrives, and the matching algorithm finds out that there are no “free-to-receive” MBs, it decides to override MB number five. However, this MB is locked, so the new message cannot be written there. It remains in the Rx SMB waiting for the MB to be unlocked, and only then will be written to the MB.

When the MB is not unlocked in time and yet another new message with the same ID arrives, the new message overwrites the message in the Rx SMB and there is no indication of lost messages either in the CODE field of the MB or in the Error and Status Register.

While the message is being moved-in from the Rx SMB to the MB, the BUSY bit on the CODE field is enabled. If the processor reads the C/S word and finds out that the BUSY bit is set, it should defer accessing the MB until the BUSY bit is cleared.

NOTE: If the BUSY bit is enabled or if the MB is empty, then reading the C/S word does not lock the MB.

Inactivation takes precedence over locking. If the processor inactivates a locked Rx MB, then the lock status is negated and the MB is marked as invalid for the current matching round. Any pending message on the Rx SMB is transferred to the MB. An MB is unlocked when the processor reads the CANFD_TMR register, or the C/S word of another MB.

Lock and unlock mechanisms have the same functionality in both normal and freeze modes.

An unlock during normal or freeze mode results in the move-in of the pending message. However, the move-in is postponed if an unlock occurs during a low power mode, and it takes place only when the module resumes to normal or freeze mode.

Rx FIFO

The Rx FIFO is receive-only and is enabled by asserting the CANFD_CFG.RFEN bit. The reset value of this bit is zero to maintain software backward compatibility with previous versions of the CANFD module that did not have the FIFO feature.

NOTE: The Rx FIFO must not be enabled when the CAN FD feature is enabled.

The Rx FIFO is 6 messages deep. The memory region occupied by the FIFO structure (both message buffers and FIFO engine) is described in the Rx FIFO Structure section. The processor can read the received messages sequentially, in the order they were received, by repeatedly reading a message buffer structure at the output of the FIFO.

The frames available bit (CANFD_IFLG1.MB05)is enabled when there is at least one frame available to be read from the Rx FIFO. An interrupt is generated if it is enabled by the corresponding mask bit. Upon receiving the interrupt, the processor reads the message (accessing the output of the FIFO as a message buffer) and the CANFD_RX_FIFO register, then clears the interrupt. If there are more messages in the Rx FIFO, the act of clearing the interrupt updates the output of the FIFO with the next message and updates the CANFD_RX_FIFO register with the attributes of that message, reissuing the interrupt to the processor. Otherwise, the flag remains negated. The output of the Rx FIFO is only valid while the CANFD_IFLG1.MB05 bit enabled.

The Rx FIFO warning bit (CANFD_IFLG1.MB06) is enabled when the number of unread messages in the Rx FIFO is increased to five from four due to the reception of a new message, meaning that the Rx FIFO is almost full. The flag remains enabled until the processor clears it.

The Rx FIFO overflow bit (CANFD_IFLG1.MB07) is enabled when an incoming message is lost because the Rx FIFO is full. The CANFD_IFLG1.MB07 bit is not set when the Rx FIFO is full, and the message is captured by a mailbox. The CANFD_IFLG1.MB07 remains set until the processor clears it.

Clearing one of those three flags does not affect the state of the other two.

An interrupt is generated when an IFLAG bit asserts and the corresponding mask bit is enabled.

A powerful filtering scheme is provided to accept only frames intended for the target application, reducing the interrupt servicing workload. The filtering criteria is specified by programming a table of up to 128 32-bit registers, according to the CANFD_CTL2.RFFNUM bit setting, which is configurable to one of the following formats:

- Format A: 128 IDAFs (extended or standard IDs including IDE and RTR)
- Format B: 256 IDAFs (standard IDs or extended 14-bit ID slices including IDE and RTR)
- Format C: 512 IDAFs (standard or extended 8-bit ID slices)

NOTE: A chosen format is applied to all entries of the filter table. It is not possible to mix formats within the table.

Every frame available in the FIFO has a corresponding identifier acceptance filter hit indicator (IDHIT) that can read in the IDHIT field from C/S word. Another way the processor can obtain this information is by accessing the CANFD_RX_FIFO register. The CANFD_RX_FIFO.IDHIT field refers to the message at the output of the FIFO

and is valid while the CANFD_IFLG1.MB05 flag is enabled. The CANFD_RX_FIFO register must be read only before clearing the flag, to guarantee that the information refers to the correct frame within the FIFO.

Up to 32 elements of the filter table are individually affected by the individual mask registers (CANFD_IMSK1 and CANFD_IMSK2), according to the setting of the CANFD_CTL2.RFFNUM bit, allowing very powerful filtering criteria to be defined. If the CANFD_CFG.IRMQEN bit is disabled, then the FIFO filter table is affected by the CANFD_RX_FIFO_GMSK register value.

Rx FIFO Under DMA Operation

The Rx FIFO can support DMA. Using the Rx FIFO with the DMA feature is enabled by enabling both CANFD_CFG.RFEN and CANFD_CFG.DMAEN bits. The DMA controller reads the received message by reading a message buffer structure at the FIFO output port at the 0x80–0x8C address range.

The reset value of the CANFD_CFG.DMAEN bit is zero. When the CANFD_CFG.DMAEN is enabled, the processor must not access the FIFO output port address range. Before enabling the CANFD_CFG.DMAEN bit, the processor must service the IFLAGs asserted in the Rx FIFO region. Otherwise, these IFLAGs may show that the FIFO has data to be serviced, and mistakenly generate a DMA request. Before disabling the CANFD_CFG.DMAEN, the processor must perform a clear FIFO operation.

The Frames available in Rx FIFO bit (CANFD_IFLG1.MB05) is asserted when there is at least one frame available to be read from the FIFO; consequently, a DMA request is generated simultaneously. Upon receiving the request, the DMA controller reads the message (accessing the output of the FIFO as a message buffer). The DMA reading process must end by reading address 0x8C, which clears the CANFD_IFLG1.MB05 bit and updates both the FIFO output with the next message (if FIFO is not empty) and the CANFD_RX_FIFO register with the attributes of the new message. If there are more messages stored in the FIFO, the CANFD_IFLG1.MB05 bit is re-enabled, and another DMA request is issued.

NOTE: The CANFD_RX_FIFO register contents cannot be read after the DMA completes the FIFO read. The IDHIT information is also available in the C/S word at address 0x080.

The CANFD_IFLG1.MB06 and CANFD_IFLG1.MB07 flags are not used when the DMA feature is enabled.

When the CANFD module is working with DMA, the processor does not receive any Rx FIFO interrupts and must not clear the related IFLAGs. In addition, the related IMASKs are not used to mask the generation of DMA requests.

There is no dedicated DMA channel for reading the CANFD FIFO, however, the MDMA along with the TRU can read from the FIFO RAM. This works by configuring the CANFD module to generate a trigger whenever the CANFD_IFLG1.MB05 bit is set. The MDMA is configured to wait for the trigger from the CANFD module and on receiving the trigger, read from the CANFD FIFO start address at 0x80 offset. Once 16 bytes of FIFO data are read, the CANFD_IFLG1.MB05 bit is cleared.

Only MDMA2 and MDMA6 streams can access the CANFD FIFO.

Clear FIFO Operation

When the CANFD_CFG.RFEN is enabled, the clear FIFO operation empties the FIFO contents. With the CANFD_CFG.RFEN bit enabled, the clear FIFO occurs when the processor writes a one to the

CANFD_IFLG1.MB00 bit. This operation only can only occur in freeze mode and is blocked by hardware in other modes. This operation does not clear the FIFO IFLAGs; consequently, the processor must service all FIFO IFLAGs before executing the clear FIFO task.

When the Rx FIFO is working with DMA, the clear FIFO operation clears the CANFD_IFLG1.MB05 flag and the DMA request is canceled.

NOTE: The clear FIFO operation does not clear IFLAGs, except when the CANFD_CFG.DMAEN bit is enabled. When the CANFD_CFG.DMAEN bit is enabled, only the CANFD_IFLG1.MB05 flag is cleared.

CAN Protocol Features

This section describes the CAN protocol related features.

CAN FD Frames

The ISO 11898-1 standard specifies the classical Frame format compliant to ISO 11898-1 (2003) and introduces the CAN flexible data rate frame format. The classical frame format allows bit rates up to 1 Mbit/s and payloads up to 8 bytes per frame. The flexible data rate frame format allows bit rates higher than 1 Mbit/s and payloads longer than 8 bytes per frame. The CANFD module can receive and transmit CAN FD messages interleaved with classical CAN messages.

There are three additional control bits in the CAN FD frame:

- The extended data length (EDL) bit enables a longer data payload with different data length coding.
- The bit rate switch (BRS) bit decides whether the bit rate is switched inside a CAN FD format frame.
- The error state indicator (ESI) flag is transmitted dominant by error active nodes, and recessive by error passive nodes.

There are no remote frames in the CAN FD format. A message configured to transmit a remote frame is always sent out in the classical CAN format. When a FD frame is received and matches a mailbox, the RTR bit in the receiving message buffer is cleared. The RTR bit is considered in only in classical CAN frames.

CAN FD messages can be formatted as long frames, in which the data field exceeds 8 bytes and may range from 12 up to 64 bytes. CAN FD messages can also be configured to support bit rate switching, where the control field, the data field, and the CRC field of a CAN frame are transmitted with a higher bit rate than the beginning and the end of the frame.

Messages in the classical CAN format are limited to transport a maximum payload of 8 bytes at nominal rate. The *CAN Message Format* figure illustrates the message formats for classical and FD frames with either a standard or extended ID.

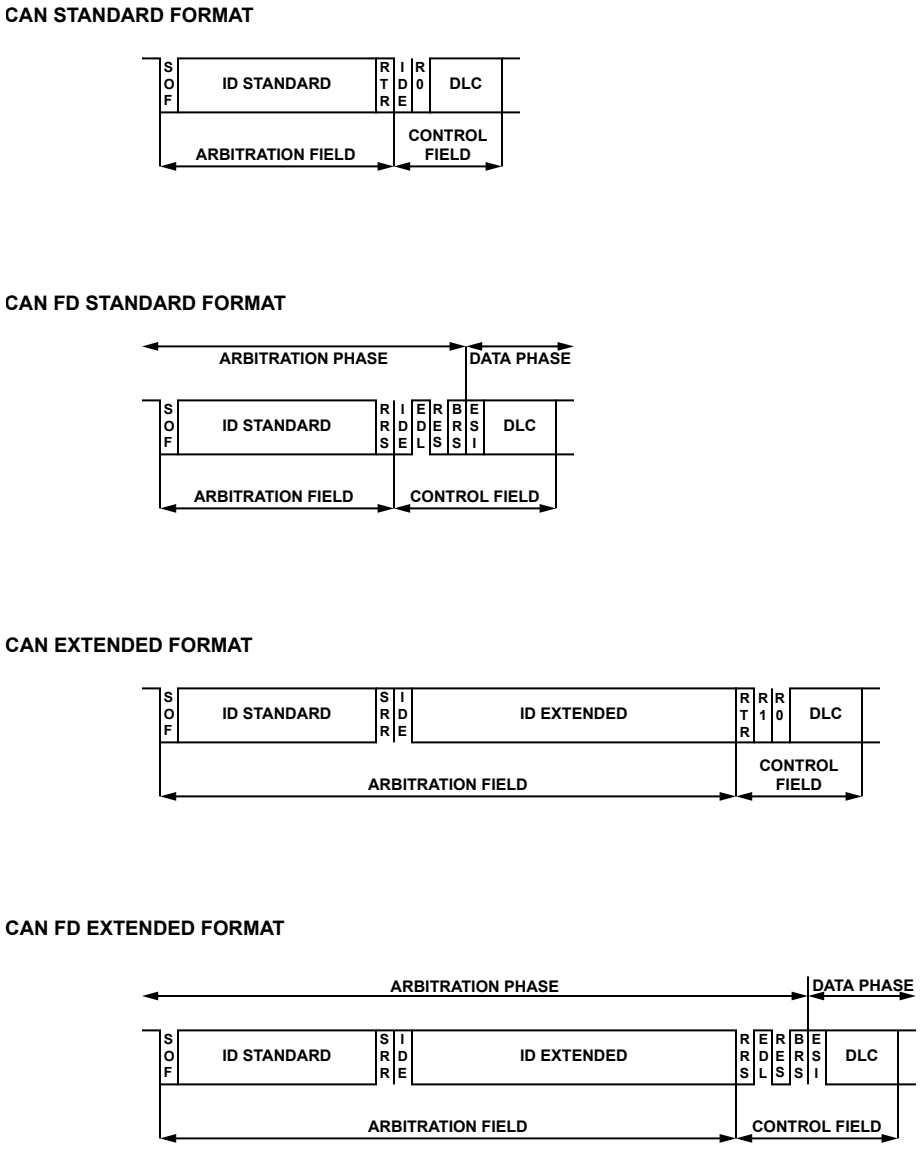

Figure 16-5: CAN Message Format

The ability to receive and transmit CAN FD messages is enabled by the `CANFD_CFG.FDEN` bit. Either a recessive R0 bit in CAN frames with 11-bit identifiers or a recessive R1 bit in CAN frames with 29-bit identifiers are decoded as an EDL bit (not a reserved one). A CAN FD frame is recognized by a recessive EDL bit, while a classical CAN frame is recognized by a dominant EDL bit. The BRS bit specifies whether this frame switches the bit rate in its data phase. A long frame is decoded according to the DLC field value.

CANFD messages can be transmitted with two different bit rates. The first part of a CAN FD frame, from the start of frame (SOF) bit until the bit rate switch (BRS) bit, also called the arbitration phase, is transmitted with the nominal bit rate based on a set of nominal CAN bit timing configuration values. The second part, from the BRS bit until the CRC delimiter bit, also named the data phase, is transmitted with the data bit rate defined by a second set of CAN data bit timing configuration values. Finally, from the CRC delimiter until the intermission bits, the transmission resumes to nominal bit rate. In CAN FD frames with bit rate switching, the bit timing is changed inside the frame at the sample point of the BRS bit if this bit is recessive. Before the BRS bit, in the

CAN FD arbitration phase, the nominal CAN bit timing defined by the CANFD_TIMING register and by the CANFD_CTL1 register for backward compatibility. Upon detecting a recessive BRS bit, the CAN data bit timing is used as defined by the CANFD_FD_TIMING register.

NOTE: If the length of the time quantum in the nominal bit timing and the length of the time quantum in the data bit timing are not identical, a quantization error of up to one time quantum of the arbitration phase may be present as a phase error. This situation can occur after the switch from arbitration to data phase and lasts until the next synchronization event. Thus, the length of the time quantum should be the same in nominal and data bit timing to minimize the chance of error frames on the CAN bus, and to optimize the clock tolerance in networks that use CAN FD frames.

The CANFD_FD_CTL.BRSEN bit enables the transmission of all frames with bit rate switching if the BRS bit in the selected Tx MB is set. When the bit is cleared, the transmission is performed at nominal rate regardless of the BRS bit value. The CANFD_FD_CTL.BRSEN bit can be written any time but takes effect only for the next message transmitted or received.

The nominal bit timing is resumed at either the sample point of the CRC delimiter bit or when an error is detected, whichever occurs first. The *CAN FD Message Bit Rate Switching* figure describes the mechanism for entering and leaving the data phase when the BRS bit is recessive.

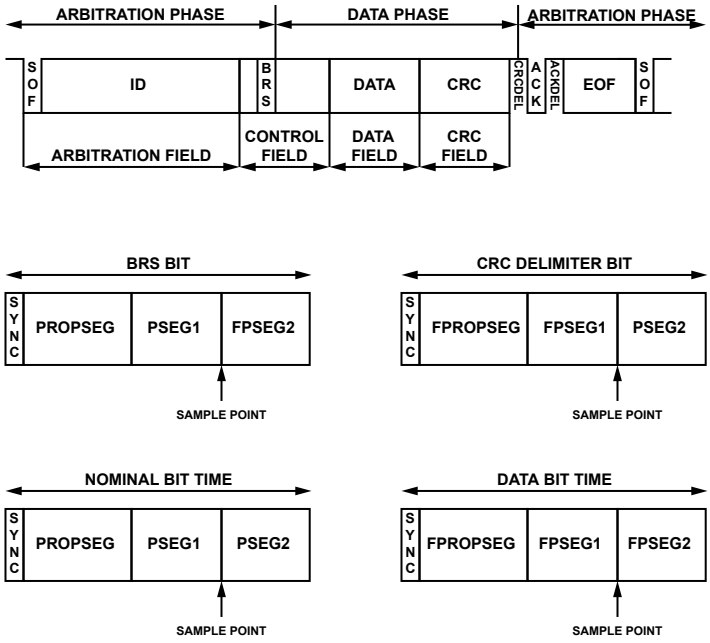

Figure 16-6: CAN FD Message Bit Rate Switching

NOTE: In classical CAN frames, the CRC delimiter is one single recessive bit. In CAN FD frames, the CRC delimiter may consist of one or two recessive bits. The CANFD module sends only one recessive bit as the CRC delimiter, but it accepts two recessive bits before the edge from recessive to dominant that starts the acknowledge slot. As a receiver, the CANFD module sends its acknowledge bit after the first CRC delimiter bit. In CAN FD frames, the CANFD module accepts a two-bit dominant ACK slot as a valid ACK to compensate for phase shifts between the receivers.

The value of the ESI bit is determined either by the error state of the transmitter at the start of the transmission, if the frame is originated in the CANFD node, or by the original transmitting node if the CANFD module is acting as a gateway for the message. If the transmitter is error passive, the ESI is transmitted recessive; otherwise, it is transmitted dominant.

There are different CRC polynomials for different CAN frame formats:

- The first polynomial, CRC_15, is for all frames in classical CAN format.
- The second, CRC_17, is for frames in CAN FD format with a data field up to 16 bytes long.
- The third, CRC_21, is for frames in CAN FD format with a data field longer than 16 bytes.

Each polynomial results in a hamming distance of 6. At the start of the frame, all three CRC polynomials are calculated concurrently. The CRC sequence to be transmitted is selected by the values of the EDL bit and the DLC bit field. When receiving a message, the CANFD module decodes the EDL and DLC bits to select the proper CRC polynomial to check for a CRC error.

In CAN FD format frames, stuff bits are included in the bit stream for CRC calculation. In classical CAN format frames, stuff bits are not included. After the transmission of the last bit relevant to the CRC calculation, the CANFD_FD_CRC register stores the calculated CRC for the transmitted message, with the adequate length for the type of message, for both CAN FD and non-FD messages. The CANFD_CRC register reports a valid CRC for classical CAN messages only.

In CAN FD format frames, the CAN bit stuffing method is changed for the CRC sequence so that the stuff bits are inserted at fixed positions. When the CANFD module is transmitting a CAN FD frame, a fixed stuff bit is inserted just before the first bit of the CRC sequence, even if the last bits of the preceding field do not fulfill the CAN stuff condition. Additional stuff bits are inserted after each fourth bit of the CRC sequence. The value of any fixed stuff bit is the inverse value of its preceding bit. When the CANFD module is receiving a CAN FD frame, it discards the fixed stuff bits from the bit stream for the CRC check. A stuff error is detected if the fixed stuff bit has the same value as its preceding bit.

The CANFD module detects errors in CAN FD frames the same way as in Classical CAN frames. The error counters CANFD_ECR.RXERRCNT and CANFD_ECR.TXERRCNT in the CANFD_ECR register accumulate the counts of Rx and Tx errors, respectively, for both FD and non-FD frames indistinctly. There are two extra error counters (CANFD_ECR.RXERRCNTF and CANFD_ECR.TXERRCNTF) that accumulate Rx and Tx errors occurring in the data phase of CAN FD frames with the BRS bit set. The rules for updating the error counters are the same for both CAN FD and non-FD frames.

The error flags CANFD_ESR1.B1ERR, CANFD_ESR1.B0ERR, CANFD_ESR1.ACKERR, CANFD_ESR1.CRCERR, CANFD_ESR1.FRMERR, and CANFD_ESR1.STFERR report errors in both CAN FD and non-FD frames. They also generate the ERRINT interrupt if the CANFD_CTL1.ERRMSK bit is enabled. The CANFD_ESR1 register has additional error flags (CANFD_ESR1.B1ERRF, CANFD_ESR1.B0ERRF, CANFD_ESR1.CRCERRF, CANFD_ESR1.FRMERRF, and CANFD_ESR1.STFERRF) to individually indicate the occurrence of errors in the data phase of CAN FD frames with the BRS bit set. There is no ACKERR detected in the data phase of a CAN FD frame. Fault confinement status reported with the CANFD_ESR1.FLTCONF bit is the same for both CAN FD and classical CAN frames, and is based on CANFD_ECR.RXERRCNT

and CANFD_ECR.TXERRCNT error counters only. Information contained in CANFD_ECR.RXERRCNTF and CANFD_ECR.TXERRCNTF counters may be considered as status to help detect the error nature related to the bit rate value. The *CANFD State Related Bit Encoding* table shows how the CANFD state is related to the CANFD_ESR1.SYNC, CANFD_ESR1.IDLE, CANFD_ESR1.TXINPROG, and CANFD_ESR1.RXINPROG bits.

Table 16-19: CANFD State Related Bit Encoding

SYNC	IDLE1	TXINPROG	RXINPROG	CANFD State
0	0	0	0	Not synchronized to CAN bus
1	1	x	x	Idle
1	0	1	0	Transmitting
1	0	0	1	Receiving

When the CANFD is in the data phase, either transmitting or receiving a CAN FD message, and detects an error, it immediately switches back to the arbitration phase and to the nominal rate to start an error flag

Resynchronization and hard synchronization occur in CAN FD frames in the same way as in classical CAN frames. A hard synchronization is also performed at the recessive-to-dominant edge from EDL to R0 in CAN FD format frames. The CANFD does not resynchronize while transmitting in the CAN FD data phase.

Transceiver Delay Compensation

The CAN FD protocol allows the transmission and reception of data at a higher bit rate than the nominal rate used in the arbitration phase when the BRS bit of the message is set. This feature enables the use of rates up to 8 Mbps.

During the data phase of a CAN FD frame, the transmitter detects a bit error if it cannot receive its own latest transmitted bit at the sample point of that bit. When bit rate switching is enabled, the length of the CAN bit time in the data phase can become shorter than the transceiver's loop delay, thus impeding the correct comparison between the transmitted bit and the received bit within the current CAN bit time interval.

The CANFD module supports an optional transceiver delay compensation (TDC) mechanism that defines a secondary sample point where the transmitted bit is correctly compared with the received bit to check for bit errors.

The TDC mechanism is enabled by the CANFD_FD_CTL.TDCOMPEN bit and is effective only during the data phase of CAN FD frames having the BRS bit set. It has no effect either on non-FD frames, or on FD frames transmitted at normal bit rate. The TDC mode is active from the sample point of the BRS bit until the sample point of the CRC delimiter bit, provided the respective message under transmission has the BRS bit set. When it is active, a comparison is done between the real received bit and the delayed transmitted bit, where the delay is calculated based on the measured transceiver loop delay.

NOTE: The actual value of the CRC delimiter bit is disregarded by transmitters using the TDC mechanism. A global error at the end of the CRC field will cause the receivers to send error frames that the transmitter will detect during an acknowledge or end of frame.

For every transmitted FD frame having the BRS bit set, the delay measurement is triggered by the transition from the recessive EDL bit to the dominant R0 bit, as shown in the *Transceiver Loop Delay Measurement* figure.

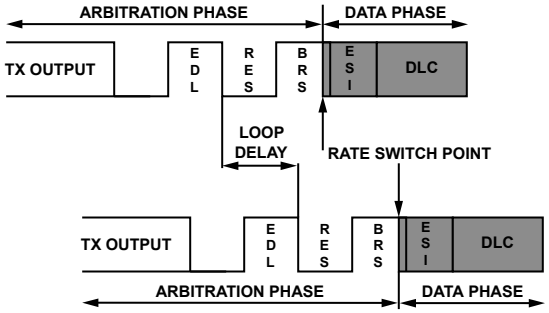

Figure 16-7: Transceiver Loop Delay Measurement

The loop delay is measured in PE clock periods (CANCLK) , from the transmitted EDL-R0 edge to the received EDL-R0 edge. The position of the secondary sample point is defined by the measured loop delay time added to an offset value specified with the `CANFD_FD_CTL.TDCOMPOFF` bit. The `CANFD_FD_CTL.TDCOMPVAL` bit field stores the result of this calculation. The `CANFD_FD_CTL.TDCOMPVAL` value saturates at the maximum value of 15 CANCLK when the delay measurement is too long.

The measured loop delay is not enough to be used to define the secondary sample point because it relates to the CAN bit edges. The transceiver delay compensation offset (`CANFD_FD_CTL.TDCOMPOFF`) shifts the secondary sample point from the edge to an intermediate point inside the bit time (for example, half of the bit time in the data phase), far away from its edges. Therefore, the `CANFD_FD_CTL.TDCOMPOFF` value cannot be larger than the CAN bit duration in the data phase.

During the data phase of CAN FD frames with bit rate switching enabled, at the onset of every Tx CAN bit, the transmitted Tx bit value is temporarily stored in a buffer and a time countdown based on the `CANFD_FD_CTL.TDCOMPVAL` value is started which ends with the comparison of the received Rx bit (delayed by the external loop delay plus the specified offset) with the stored Tx bit. If a bit error is detected at the secondary sample point, the CANFD module issues an error flag to the CAN bus at the next sample point.

During the arbitration phase, the delay compensation is always disabled. The maximum delay that can be compensated by the transceiver delay compensation during the data phase is 3 CAN bit times - 2 Tq. Beyond this limit, the `CANFD_FD_CTL.TDCOMPFAIL` flag is set to indicate when the TDC mechanism is out of range and unable to compensate the transceiver loop delay.

Remote Frames

A remote frame is a special kind of frame. The processor can program a mailbox to be a remote request frame by configuring the mailbox to transmit with the RTR bit set to one. After the remote request frame is transmitted successfully, the mailbox becomes a receive message buffer, with the same ID as before.

When a remote request frame is received by the CANFD module, it is treated in one of the following ways, depending on the `CANFD_CTL2.RRS` and `CANFD_CFG.RFEN` bits:

- When RRS is disabled, the frame ID is compared to the IDs of the transmit message buffers with the CODE field 1010. If there is a matching ID, then this mailbox frame is transmitted. Note that if the matching mailbox has the RTR bit set, then the CANFD module transmits a remote frame as a response. The received remote request frame is not stored in a receive buffer. It is only used to trigger a transmission of a frame in response. The mask registers are not used in remote frame matching, and all ID bits (except RTR) of the incoming received frame match. In the case that a remote request frame is received and matches a mailbox, this message buffer immediately enters the internal arbitration process, but is considered a normal Tx mailbox, with no higher priority. The data length of this frame is independent of the DLC field in the remote frame that initiated its transmission.
- When RRS is enabled, the frame ID is compared to the IDs of the receive mailboxes with the CODE field 0100, 0010, or 0110. If there is a matching ID, then this mailbox stores the remote frame in the same fashion of a data frame. No automatic remote response frame is generated. The mask registers are used in the matching process.
- When RFEN is asserted, the CANFD does not generate an automatic response for remote request frames that match the FIFO filtering criteria. If the remote frame matches one of the target IDs, it is stored in the FIFO and presented to the processor. Note that for filtering formats A and B, it is possible to select whether remote frames are accepted or not. For format C, remote frames are always accepted (if they match the ID). Remote request frames are considered normal frames,and generate a FIFO overflow when a successful reception occurs, and the FIFO is already full.

NOTE: There is no remote frame in the CAN FD format. The RTR bit is replaced by a fixed dominant RRS bit. The CANFD receives and transmits remote frames in the classical CAN format.

Overload Frames

The CANFD module transmits overload frames due to the detection of the following CAN bus conditions:

- Detection of a dominant bit in the first/second bit of intermission.
- Detection of a dominant bit at the 7th bit (last) of end of frame field (Rx frames).
- Detection of a dominant bit at the 8th bit (last) of error frame delimiter or overload frame delimiter.

Time Stamp

The value of the CANFD_TMR register is sampled at the beginning of the identifier field on the CAN bus and stored at the end of the move-in process in the TIME STAMP field, providing network behavior with respect to time. The free running timer is clocked by the CANFD bit-clock, which defines the baud rate on the CAN bus. During a message transmission or reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate.

The CANFD_TMR register is not incremented during module disable, doze, stop, and freeze modes. It can be reset upon a specific frame reception, enabling network time synchronization.

Protocol Timing

The *CAN Engine Clocking Scheme* figure shows the structure of the clock generation circuitry that prescales the CAND module clock to generate the Sclock.

Figure 16-8: CAN Engine Clocking Scheme

The CANFD module supports a variety of means to set up bit timing parameters that are required by the CAN protocol. The CANFD_CTL1 register has fields to control bit timing parameters: CANFD_CTL1.PRESDIV, CANFD_CTL1.PROPSEG, CANFD_CTL1.PSEG1, CANFD_CTL1.PSEG2, and CANFD_CTL1.RJW.

The CANFD_TIMING register extends the range of the CAN bit timing variables in the CANFD_CTL1 register. The CANFD_TIMING register provides a second set of CAN bit timing variables to be applied at the data phase of CAN FD frames with the BRS bit set.

NOTE: When the CAN FD feature is enabled, always set the CANFD_TIMING.BTF bit and configure the CAN bit timing variables in the CANFD_TIMING register.

The CANFD_CTL1.PRESDIV bit field (as well as the extended range CANFD_TIMING.EPRESDIV and CANFD_FD_TIMING.FPRESDIV for the data phase bits of CAN FD messages) defines the prescaler value that generates Sclock. The Sclock period defines the time quantum used to compose the CAN waveform. A time quantum (Tq) is the atomic unit of time handled by the CAN engine.

$Tq = (PRESDIV + 1) / f_{CANCLK}$

The bit rate, which defines the rate at which the CAN message is either received or transmitted, is given by the formula:

CAN Bit Time = (Number of Time Quanta in 1 bit time) * Tq

Bit Rate = 1/CAN Bit Time

A bit time is subdivided into three segments:

- SYNC_SEG – Has a fixed length of one time quantum. Signal edges are expected to occur within this segment.
- Time segment 1 – Includes the propagation segment and the phase segment 1 of the CAN standard. Time segment 1 is programmed by setting the CANFD_CTL1.PROPSEG and the CANFD_CTL1.PSEG1 fields so that their sum (plus 2) is in the range of 2 to 16 time quanta. When the CANFD_TIMING.BTF bit is enabled, the CANFD module uses the CANFD_TIMING.EPROPSEG and CANFD_TIMING.EPSEG1 bit fields so that their sum (plus 2) is in the range of 2 to 96 time quanta. For messages in CAN FD format with the BRS bit set, the CANFD uses CANFD_FD_TIMING.FPROPSEG and CANFD_FD_TIMING.FPSEG1 bit fields, so that their sum (plus 1) is in the range of 2 to 39 time quanta.
- Time Segment 2 – Represents the phase segment 2 of the CAN standard. It can be programmed by setting the CANFD_CTL1.PSEG2 bit field (plus 1) to be 2 to 8 time quanta long. When the CANFD_TIMING.BTF

bit is enabled, the CANFD module configures the CANFD_TIMING.EPSEG2 bit field with a value (plus 1) is in the range of 2 to 32 time quanta. For messages in CAN FD format with the BRS bit set, the CANFD uses the CANFD_FD_TIMING.FPSEG2 bit field instead, so that the value (plus 1) is in the range of 2 to 8 time quanta. The time segment 2 cannot be smaller than the information processing time (IPT), which is 2 time quanta.

See the *Bit Time Segment Example One* figure for an example using CANFD_CTL1 register bit timing variables for classical can format. See the *Bit Time Segment Example Two* figure for an example using CANFD_TIMING and CANFD_FD_TIMING register bit timing variables for CAN FD format. See the *Time Segment Syntax* table for syntax descriptions.

NOTE: For further explanation of the underlying concepts, see the ISO 11898-1 standard and the CAN 2.0A/B protocol specification for bit timing.

The bit time defined by the above time segments must not be smaller than 5 time quanta. For bit time calculations, use an IPT of 2, which is the value implemented in the CANFD module.

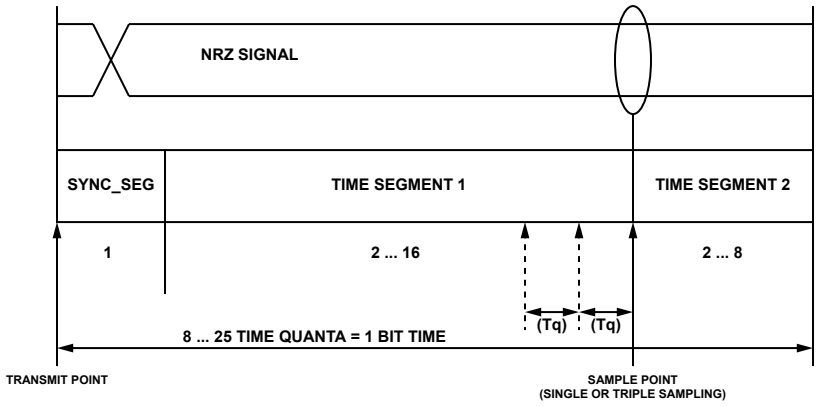

Figure 16-9: Bit Time Segment Example One

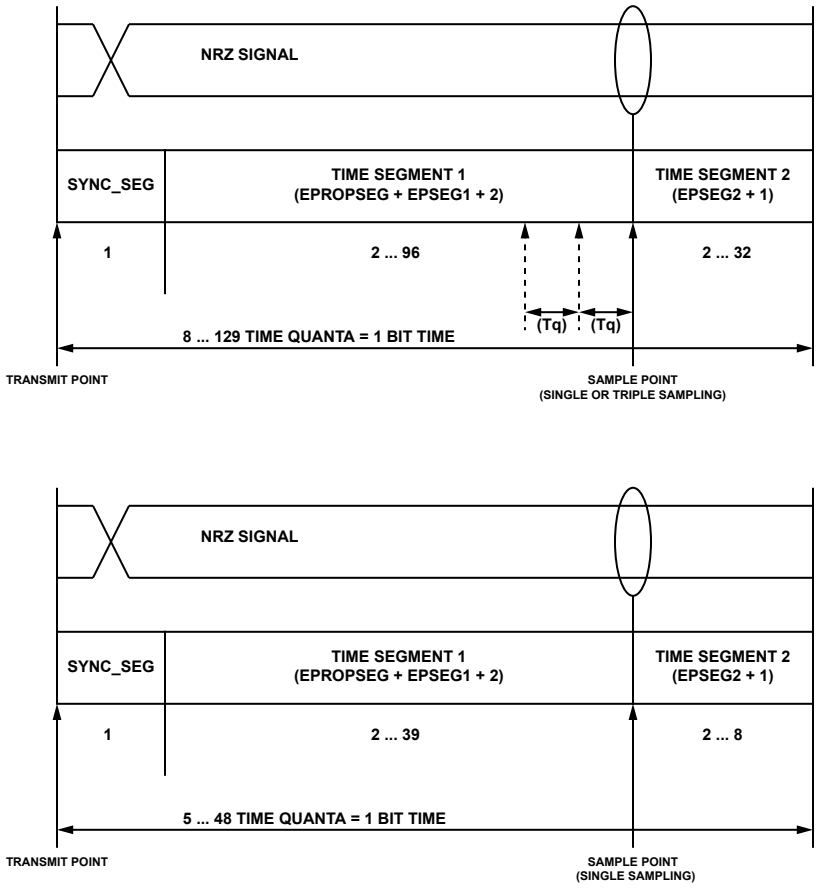

Figure 16-10: Bit Time Segment Example Two

Table 16-20: Time Segment Syntax

Syntax	Description
SYNC_SEG	System expects transitions to occur on the bus during this period.
TSEG1	Corresponds to the sum of PROPSEG and PSEG1.
TSEG2	Corresponds to the PSEG2 value.
Transmit Point	A node in transmit mode transfers a new value to the CAN bus at this point.
Sample Point	A node samples the bus at this point. If the three samples per bit option is selected, then this point marks the position of the third sample.

The *BOSCH CAN 2.0B Standard Compliant Bit Time Segment Settings* table gives some examples of the CAN compliant segment settings for classical CAN format (Bosch CAN 2.0B) (non-FD) messages.

Table 16-21: BOSCH CAN 2.0B Standard Compliant Bit Time Segment Settings

Time Segment 1	Time Segment 2	Resynchronization Jump Width
	2	1 .. 2

Table 16-21: BOSCH CAN 2.0B Standard Compliant Bit Time Segment Settings (Continued)

Time Segment 1	Time Segment 2	Resynchronization Jump Width
5 .. 10		
4 .. 11	3	1 .. 3
5 .. 12	4	1 .. 4
6 .. 13	5	1 .. 4
7 .. 14	6	1 .. 4
8 .. 15	7	1 .. 4
9 .. 16	8	1 .. 4

NOTE: Ensure the bit time settings comply with the CAN Protocol standard (ISO 11898-1).

Whenever a CAN bit is used as a measure of time duration (for example, estimating the occurrence of a CAN bit event in a message), the number of peripheral clocks in one CAN bit (NumClkBit) is calculated as NumClkBit = (f_{SYS}/f_{CANCLK}) x (PRESDIV + 1) x (PROPSEG + PSEG1 + PSEG2 + 4), where:

- NumClkBit is the number of peripheral clocks in one CAN bit.
- f_{CANCLK} is the PE clock in Hz
- f_{SYS} is the frequency of operation of the system CHI clock in Hz.
- PSEG1 is the `CANFD_CTL1.PSEG1` value.
- PSEG2 is the `CANFD_CTL1.PSEG2` value.
- PROPSEG is the `CANFD_CTL1.PROPSEG` value.
- PRESDIV is the `CANFD_CTL1.PRESDIV` value.

The formula above is also applicable to the alternative CAN bit timing variables described in the `CANFD_TIMING` register and the `CANFD_FD_TIMING` register. For example, 180 CAN bits = (180 x NumClkBit) peripheral clock periods.

Arbitration and Matching Timing

During normal reception and transmission, the matching, arbitration, move-in and move-out processes are executed during certain time windows inside the CAN frame, as shown in the following figures.

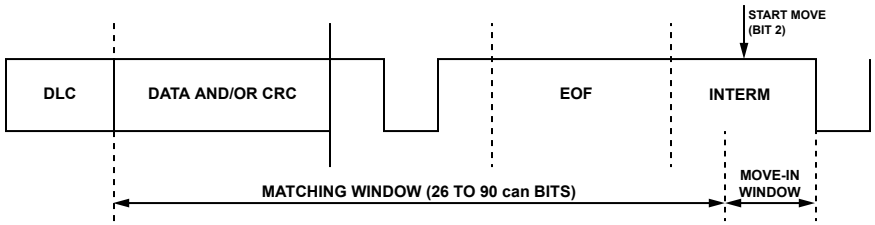

Figure 16-11: Matching and Move-In Time Windows

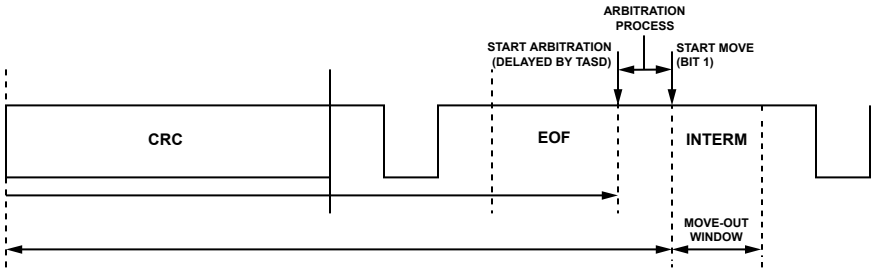

Figure 16-12: Arbitration And Move-out Time Windows

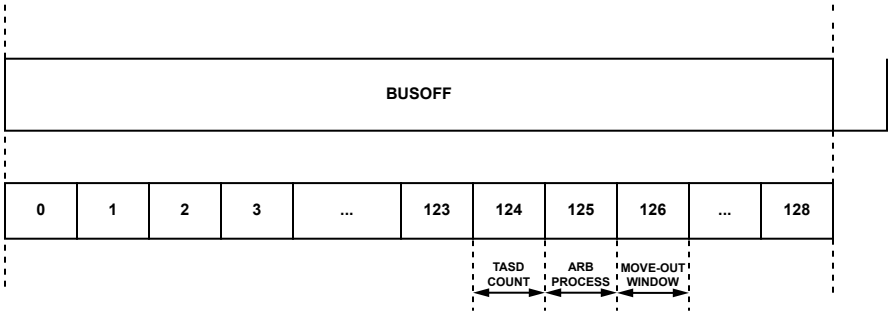

Figure 16-13: Arbitration At The End Of Bus Off And Move-out Time Windows

NOTE: In the previous figures, the matching and arbitration timing does not consider the delay caused by the concurrent memory access due to the processor or other internal CANFD submodules.

Tx Arbitration Start Delay

The Tx arbitration start delay (`CANFD_CTL2.TXASDLY` bit field) is a variable that indicates the number of CAN bits used by the CANFD to delay the Tx arbitration process start point from the first bit of the CRC field of the current frame.

The `CANFD_CTL2.TXASDLY` bit field can only be written only in freeze mode and is blocked by hardware in other modes.

The transmission performance is impacted by the ability of the processor to reconfigure MBs for transmission after the end of the internal arbitration process, in which the CANFD module finds the winner MB for transmission according to the standard arbitration process. If the arbitration ends before the first bit of the intermission field, then there is a chance the processor reconfigures some Tx MBs and the winner MB is no longer the best candidate to be transmitted.

The `CANFD_CTL2.TXASDLY` bit field is useful to optimize the transmission performance by defining the arbitration start point, as shown in the next figure, based on factors such as the CAN bit timing variables that determine the CAN bit rate and the number of MBs in use by the matching and arbitration processes.

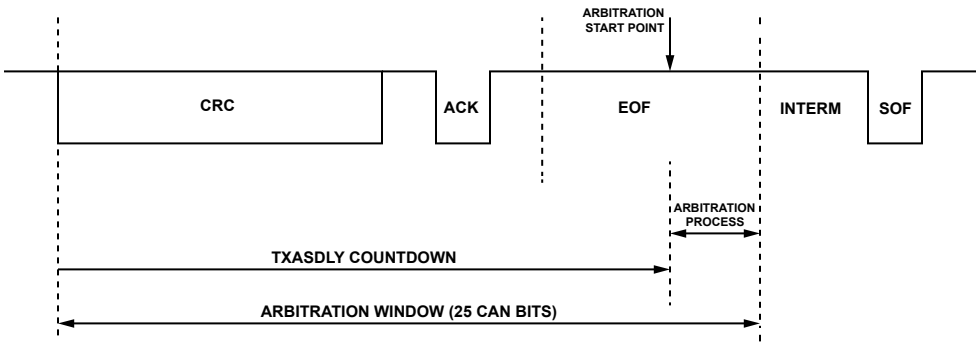

Figure 16-14: Optimal Tx Arbitration Start Point

The duration of an arbitration process, in terms of CAN bits, is directly proportional to the number of available MBs and to the CAN bit rate, and inversely proportional to the peripheral clock frequency.

The optimal arbitration timing is that in which the last MB is scanned right before the first bit of the intermission field of a CAN frame. For instance, if there are few MBs and the peripheral/oscillator clock ratio is high and the CAN baud rate is low, then the arbitration is placed closer to the frame's end, adding more delay to its start point, and vice-versa.

When the `CANFD_CTL2.TXASDLY` field is set to zero, the arbitration start is not delayed, and more time is reserved for arbitration. On the other hand, when the `CANFD_CTL2.TXASDLY` value is close to 24, then the processor can configure a Tx MB later and less time is reserved for arbitration. When too little time is reserved for arbitration, the CANFD module may not be able to find a winner MB in time to be transmitted with the best chance to win the bus arbitration against external nodes on the CAN bus.

The optimal `CANFD_CTL2.TXASDLY` value is calculated as follows:

For CAN FD frames and (MAXMB + 1) $\leq NMB_{END}$, TXASDLY = 31 – ((2*(MAXMB + 1) + 4)/$CPCB_N$)

For CAN FD frames and (MAXMB + 1) > NMB_{END}, TXASDLY = 22 – ((2*(MAXMB + 1) - NMB_{END})/ $CPCB_F$)

For non-FD frames, TXASDLY = 25 – (((2*(MAXMB + 1) + 4)) / CPCB) where:

NMB_{END} = ((9 * CPCBN) - 4) / 2

$BITRATE_N$= f_{CANCLK} / ([1 + (EPSEG1 + 1) + (EPSEG2 + 1) + (EPROPSEG + 1)] x (EPRESDIV + 1))

$BITRATE_F$= f_{CANCLK} / ([1 + (FPSEG1 + 1) + (FPSEG2 + 1) + FPROPSEG] x (FPRESDIV + 1))

$CPCB_N$ = f_{SYS} / $BITRATE_N$

$CPCB_F$ = f_{SYS} / $BITRATE_F$

CPCB = $CPCB_N$

- MAXMB is the `CANFD_CFG.MAXMB` value.

- NMBEND is the number of MBs that can be scanned by the arbitration process during the 9 last CAN bits at the end of a frame.
- BITRATEN is the CAN bit rate in bits per second calculated by the nominal CAN bit time variables.
- BITRATEF is the CAN bit rate in bits per second calculated by the data CAN bit time variables.
- CPCBN is the number of peripheral clocks per CAN bit in nominal bit rate for CAN FD frames.
- CPCBF is the number of peripheral clocks per CAN bit in data bit rate for CAN FD frames.
- CPCB is the number of peripheral clocks per CAN bit for non-FD frames.
- f_{CANCLK} is the oscillator clock, in Hz.
- f_{SYS} is the peripheral clock, in Hz.
- EPSEG1 is the `CANFD_TIMING.EPSEG1` or `CANFD_CTL1.PSEG1` value.
- EPSEG2 is the `CANFD_TIMING.EPSEG2` or `CANFD_CTL1.PSEG2` value.
- EPROPSEG is the `CANFD_TIMING.EPROPSEG` or `CANFD_CTL1.PROPSEG` value.
- EPRESDIV is the `CANFD_TIMING.EPRESDIV` or `CANFD_CTL1.PRESDIV` value.
- FPSEG1 is the `CANFD_FD_TIMING.FPSEG1` value.
- FPSEG2 is the `CANFD_FD_TIMING.FPSEG2` value.
- FPROPSEG is the `CANFD_FD_TIMING.FPROPSEG` value.
- FPRESDIV is the `CANFD_FD_TIMING.FPRESDIV` value.

NOTE: The f_{SYS} and f_{CANCLK} is same clocked from CDU CLKO4.

The following table give the TXASDLY value calculated for some configuration cases.

- f_{CANCLK} = 40 MHz
- Bit rate in arbitration phase = 1 Mbaud

Table 16-22: TXASDLY Values For Case Example

Number of MBs	TXASDLY Value	Maximum Bit Rate in Data Phase (Mbaud)
16	24	Invalid
32	23	6.67
54	22	5.0
64	21	3.33
96	20	1.6

CANFD Clock Domains and Restrictions

When doing matching and arbitration, the CANFD module needs to scan the entire MB memory during the time slot of one CAN frame, comprising a number of CAN bits. To have sufficient time to do that, there must be a minimum number of peripheral clocks per CAN bit, as specified in the *CAN Bit Minimum Peripheral Clock* table.

Table 16-23: CAN Bit Minimum Peripheral Clock

Number of Mailboxes	**CANFD_CFG.RFEN** Bit Value	Minimum Peripheral Clocks per CAN Bit
16	0	16
32	0	16
64	0	25
96	0	37
128	0	49
16	1	16
32	1	17
64	1	30

For the classical CAN frame format, the minimum number of peripheral clocks per CAN bit specified in the *TXASDLY Values For Case Example* table determines the minimum peripheral clock frequency for a given number of mailboxes and for an expected CAN bit rate. The CAN bit rate depends on the number of time quanta in a CAN bit, that can be defined by adjusting one or more of the bit timing values contained in either the CANFD_CTL1 register or the CANFD_TIMING register. The time quantum (Tq) is defined in the Protocol Timing section. The minimum number of time quanta per CAN bit must be 8, so the CAN clock frequency is at least 8 times the CAN bit rate.

For the CAN FD frame format, the number of peripheral clocks per CAN bit in nominal bit rate (NumClkNom-Bit) is calculated with the following equation:

NumClkNomBit =(fSYS/fCANCLK) X (PRESDIV + 1) X (PROPSEG + PSEG1 + PSEG2 + 4)

= fSYS/NomBitRate

where PRESDIV, PSEG1 and PSEG2 are CAN bit time values in the CANFD_CTL1 register. Alternatively, the EPRESDIV, EPSEG1 and EPSEG2 values in the CANFD_TIMING register can be used instead. NumClkNomBit is also calculated as a function of the expected nominal bit rate used in the arbitration phase (NomBitRate).

The number of CAN bits in the data phase of a FD frame with the BRS bit set depends on the number of data bytes in the payload. The number of fast CAN bits (NumOfFastBits) is determined as shown in the *CAN FD Frame Fast CAN Bits* table. The less the number of data bytes, the less the number of fast CAN bits, and less time is available for the CANFD module to scan the whole MB memory during the internal matching and arbitration processes.

Table 16-24: CAN FD Frame Fast CAN Bits

Minimum Data Bytes	DLC Field	Number of Fast Bits
0	0x0	21
1	0x1	29
2	0x2	37
3	0x3	45
4	0x4	53
5	0x5	61
6	0x6	69
7	0x7	77
8	0x8	85
12	0x9	117
16	0xA	149
20	0xB	186
24	0xC	218
32	0xD	282
48	0xE	410
64	0xF	538

The critical part of a CAN FD frame is during the data phase, where the CAN bit rate is faster than in the arbitration phase. The minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) is calculated so that enough time is available for the CANFD module to scan the MB memory during reception and transmission. The equation below calculates this constraint:

MinNumClkFastBit = ((8.5 x MaxNumOfMb) + 64 - (9 x NumClkNomBit)) / NumOfFastBits

where MaxNumOfMb is the maximum number of available mailboxes defined in the `CANFD_CFG.MAXMB` bit field.

The clock domain crossing circuit between the CHI and PE submodules also imposes a minimum number of peripheral clocks per fast CAN bit for the handshake mechanism to work properly without losing status information through the interface, as shown in the following equation:

$$MinNumClkFastBit = 3 \times (1 + (f_{SYS}/f_{CANCLK}))$$

Therefore, the minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) is determined by the larger of the two values calculated above:

MinNumClkFastBit = Maximum (MinNumClkFastBit , MinNumClkFastBit)

Then, the maximum CAN bit rate in the data phase of CAN FD frames (DataBitRateMAX) is calculated as follows:

DataBitRate = f_{CANCLK} / (ROUNDUP ((MinNumClkFastBit x f_{CANCLK}) / f_{SYS}

The peripheral and oscillator clock frequencies, the maximum number of mailboxes, and the expected nominal bit rate affect the maximum data bit rate attainable by the CANFD module in CAN FD mode. In addition, the data bit rate depends on the minimum payload size of FD frames used in each application.

To illustrate how the CAN FD bit rate is affected by the configuration of CANFD variables, an consider an application example with the peripheral and oscillator clock frequencies set to 50 MHz.

1. Considering the nominal bit rate as 1 Mbps, the number of peripheral clocks per CAN bit in nominal bit rate is calculated as follows: NumClkNomBit = (50 x 10^6)/(1 x 10^6) = 50
2. The number of fast CAN bits (NumOfFastBits) is determined as shown in the *CAN FD Frames Maximum CAN Bit Rate In Data Phase* table. For example, if the minimum payload in FD frames is 8 bytes, then there are 85 CAN bits in the data phase.
3. Assuming the maximum number of mailboxes is 96, the minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) can be calculated as follows:

   MinNumClkFastBit = ((8.5 X 96) + 64 - (9 X 50)) / 85 = 5.06

   MinNumClkFastBit = 3 x (1 + 50/50) = 6.0

   MinNumClkFastBit = Maximum (5.06 , 6.0) = 6.0

As demonstrated in this example, even though the oscillator clock frequency (50 MHz) is adequate to generate a data rate of 8 Mbps in CAN FD mode, the specific CANFD configuration limits this rate to 6.667 Mbps. This limitation is due to the low peripheral clock frequency that imposes the $MinNumClkFastBit_B$ limit.

The *CAN FD Frames Maximum CAN Bit Rate In Data Phase* table shows the maximum data rate for CAN FD according to the clock frequencies, payload size, and number of available mailboxes. As shown in the *CAN FD Frames Maximum CAN Bit Rate In Data Phase* table, for some cases, if the number of available mailboxes is reduced, the CANFD module achieves a data rate up to 8 Mbps.

Table 16-25: CAN FD Frames Maximum CAN Bit Rate In Data Phase

Peripheral Clock Frequency (MHz)	Payload Size	Number of Available Mailboxes	Maximum Data Rate (Mbps)
40	8	94	6.667
40	8	114	5.0
40	12	117	6.667
40	12	128	5.714
50	12 to 64	128	6.667
60	8	128	8.0
60	12	128	8.0

Table 16-25: CAN FD Frames Maximum CAN Bit Rate In Data Phase (Continued)

Peripheral Clock Frequency (MHz)	Payload Size	Number of Available Mailboxes	Maximum Data Rate (Mbps)
67	6	128	8.0
80	3	128	8.0
100	0	128	8.0

CANFD Operating Modes

The CANFD module has functional modes and low-power modes.

CAUTION: The CANFD does not support the permanent dominant failure on the CAN bus line. If a low-power request or freeze mode request is done during a permanent dominant, the corresponding acknowledge can never be asserted.

The CANDFD module has the following main functional modes:

- Normal Mode
- Freeze Mode
- Loop-Back Mode
- Listen-Only Mode
- CAN FD Active Mode

For low-power operation, the CANDFD module has the following modes:

- Module Disable Mode
- Doze Mode
- Stop Mode
- Pretended Network Mode

NOTE: The CANFD does not support the permanent dominant failure on the CAN bus line. If there is a low-power request or freeze mode request during a permanent dominant, the corresponding acknowledge will not be asserted.

Normal Mode

In normal mode, the CANFD module operates by receiving and transmitting message frames. In this mode, errors are handled normally, and all CAN protocol functions are enabled.

Freeze Mode

In freeze mode, there is no transmission or reception of frames and synchronicity to the CAN bus is lost. Freeze mode is enabled by setting the CANFD_CFG.FRZ bit.

Freeze mode is requested either by the processor by enabling the CANFD_CFG.HALT bit or when it is put into debug mode. In both cases, when the CANFD_CFG.FRZ bit is enabled, the CANFD module must not be in a low-power mode. Freeze mode is also requested through the automatic assertion of both the CANFD_CFG.HALT and CANFD_CFG.FRZACK bits when the CANFD_MEC.NCERRFRZEN bit is set and a non-correctable error is detected in a memory read access performed by CANFD internal processes. The acknowledgement is obtained through the assertion by the CANFD_CFG.FRZACK bit. The CANFD module is only in freeze mode when both the request and acknowledge conditions are satisfied.

In response to a freeze mode request, the CANFD module performs the following operations:

- Waits to be in either the intermission, passive error, bus off, or idle state.
- Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. A pending move-in does not prevent going to freeze mode.
- Ignores the Rx input pin and drives the Tx pin as recessive.
- Stops the prescaler, thus halting all CAN protocol activities.
- Grants write access to the CANFD_ECR register, which is read-only in other modes.
- Sets the CANFD_CFG.NOTRDY and CANFD_CFG.FRZACK bits.

After requesting freeze mode, wait for the CANFD_CFG.FRZACK bit to be set before executing any other action, or the CANFD module will not operate properly.

To exit freeze mode, disable the CANFD_CFG.FRZ bit, remove the processor from debug mode, or disable the CANFD_CFG.HALT bit.

The CANFD_CFG.FRZACK bit is disabled after the PE recognizes the negation of the freeze request. Once out of freeze mode, the CANFD module tries to re-synchronize to the CAN bus by waiting for 11 consecutive recessive bits.

Loop-Back Mode

The CANFD module enters loop-back mode when the CANFD_CTL1.LBEN is set. In loop-back mode, the CANFD module performs an internal loop back for self-test operation. The bit stream output of the transmitter is internally fed back to the receiver input. The Rx CAN input pin is ignored and the Tx CAN output goes to the recessive state (logic ‘1’). The CANFD module behaves as it normally does when transmitting and treats its own transmitted message as a message received from a remote node. In loop-back mode, the CANFD ignores the bit sent during the ACK slot in the CAN frame acknowledge field to ensure proper reception of its own message. Both transmit and receive interrupts are generated.

Listen-Only Mode

The CANFD module enters listen-only mode when the CANFD_CTL1.LOMEN bit is enabled. In listen-only mode, transmission is disabled, all error counters are frozen, and the CANFD module operates in a CAN error passive mode. The module only receives messages acknowledged by another CAN station. If the CANFD detects a message that has not been acknowledged, it flags a BIT0 error (without changing the receive error counter), as if it were trying to acknowledge the message.

CAN FD Active Mode

In CAN FD active mode, the CANFD module can transmit and receive all messages formatted according to the CAN FD protocol and CAN 2.0 (protocol 2.0) in an interleaved fashion. The CANFD module is put into CAN FD active mode by setting the CANFD_CFG.FDEN bit when in freeze mode.

Module Disable Mode

The module disable mode is a low-power mode normally used to temporarily disable a complete CANFD block, with no power consumption. To enter module disable mode, enable the CANFD_CFG.DIS bit. Once the processor is in module disable mode, the CANFD_CFG.LPMACK bit is set.

Do not use module disable mode under pretended networking mode. Disable the CANFD_CFG.DIS bit and wait for CANFD_CFG.LPMACK bit to clear before enabling the CANFD_CFG.PNETEN bit.

If the CNAFD module is disabled during transmission or reception, it will perform the following operations:

- Waits to be in either the idle or bus off state, or else waits for the third bit of intermission and then checks it to be recessive.
- Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. A pending move-in is not considered.
- Ignores its Rx input pin and drives its Tx pin as recessive.
- Shuts down the clocks to the PE and CHI submodules.
- Sets the CANFD_CFG.NOTRDY and CANFD_CFG.LPMACK bits.

The bus interface unit continues to operate, enabling the processor to access memory mapped registers, except the CANFD_RX_FIFO_GMSK, CANFD_RX_14_MSK, CANFD_RX_15_MSK, and CANFD_RX_FIFO_GMSK registers. The CANFD_RX_FIFO, the message buffers, the Rx individual mask registers, and the reserved words within RAM are not accessible when the CANFD module is in the module disable mode.

To exit module disable mode, disable the CANFD_CFG.DIS bit. If the CANFD module is disabled during freeze mode, it sends a requests to disable the clocks to the PE and CHI submodules, sets the CANFD_CFG.LPMACK bit, and clears the CANFD_CFG.FRZACK bit.

Doze Mode

The doze mode is a system low-power mode in which the processor bus is kept alive, and a global doze mode request is sent to all peripherals asking them to enter low-power mode. Before sending a global doze mode request, set the CANFD_CFG.DOZEN bit. The global doze request is set with the MISCREG_CAN_SYSCTL.CAN1_IPG_DOZE or MISCREG_CAN_SYSCTL.CAN0_IPG_DOZE bit. Once the processor requests the doze mode, the CANFD_CFG.LPMACK bit is set.

To exit doze mode, disable the CANFD_CFG.DOZEN bit or clear the IPG_DOZE bits in the MISCREG_CAN_SYSCTL register. The CANFD module also exits doze mode when activity is detected on the CAN bus and the self-wake up mechanism is enabled using the CANFD_CFG.SLFWAKEN bit.

If the doze mode is triggered during freeze mode, the CANFD module requests to disable the clocks to the PE and CHI submodules, sets the CANFD_CFG.LPMACK bit, and clears the CANFD_CFG.FRZACK bit.

If doze mode is triggered during transmission or reception, the CANFD module performs the following operations:

- Waits to be in either idle or bus off state, or else waits for the third bit of intermission and checks it to be recessive.
- Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. A pending move-in is not considered.
- Ignores its Rx input pin and drives its Tx pin as recessive.
- Shuts down the clocks to the PE and CHI submodules.
- Sets the CANFD_CFG.NOTRDY and CANFD_CFG.LPMACK bits.

The bus interface unit continues to operate, enabling the processor to access memory mapped registers, except the CANFD_RX_FIFO_GMSK, CANFD_RX_14_MSK, CANFD_RX_15_MSK, and CANFD_RX_FIFO_GMSK registers. The CANFD_RX_FIFO, the message buffers, the Rx individual mask registers, and the reserved words within RAM are not accessible when the CANFD module is in the doze mode.

Exiting Doze mode is done in one of the following ways:

- Disabling the doze mode request in the MISCREG_CAN_SYSCTL register.
- Disabling the CANFD_CFG.DOZEN bit.
- When the CANFD module detects activity on the CAN bus and the self-wake up mechanism is enabled using the CANFD_CFG.SLFWAKEN bit.

When the self-wake up mechanism is enabled at the time that the CANFD module entered doze mode, then upon detection of a recessive-to-dominant transition on the CAN bus, the CANFD module clears the CANFD_CFG.DOZEN bit, requests to resume clocks, and disables the CANFD_CFG.LPMACK bit after the CAN PE recognizes the doze mode is disabled.

The CANFD module also sets the CANFD_ESR1.WAKINT bit, so if the CANFD_CFG.WAKMSK bit is enabled, it generates a wake up interrupt to the processor. The CANFD module then waits for 11 consecutive recessive

bits to synchronize to the CAN bus. Consequently, the CANFD module does not receive the frame that woke it up. The *Wake Up From Doze Mode* table details the effect of the CANFD_CFG.SLFWAKEN and the CANFD_CFG.WAKMSK bits upon waking from the doze mode.

Table 16-26: Wake Up From Doze Mode

SLFWAKEN	WAKINT	WAKMSK	CANFD Clocks Enabled	Wakeup Interrupt Generated
0	N/A	N/A	No	No
0	N/A	N/A	No	No
1	0	0	No	No
1	0	1	No	No
1	1	0	Yes	No
1	1	1	Yes	Yes

Applying a low-pass filter function to the Rx CAN input line while in doze mode will modify sensitivity to CAN bus activity as described in the CANFD_CFG.WSFLTREN bit description. This feature also protects the CANFD module from waking up due to short glitches on the CAN bus lines that can result from electromagnetic interference in noisy environments.

Stop Mode

The stop mode is a system low-power mode in which all clocks are stopped for maximum power savings. A global stop request is set with the MISCREG_CAN_SYSCTL.CAN0_IPG_STOP or MISCREG_CAN_SYSCTL.CAN1_IPG_STOP bit. Once the processor is in the stop mode, the CANFD_CFG.LPMACK bit is set.

If the CANFD module receives a global stop mode request during freeze mode, it sets the CANFD_CFG.LPMACK bit, clears the CANFD_CFG.FRZACK bit, and then sends the stop acknowledge signal to the processor to shut down the clocks globally.

If stop mode is requested during transmission or reception, the CANFD module performs the following operations:

- Waits to be in either the idle or bus off state, or else waits for the third bit of intermission and checks it to be recessive.
- Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. A pending move-in is not considered.
- Ignores its Rx input pin and drives its Tx pin as recessive.
- Sets the CANFD_CFG.NOTRDY and CANFD_CFG.LPMACK bits.
- Sends a stop acknowledge signal to the processor to shut down the clocks globally.

Stop mode is exited when the processor resumes the clocks and removes the stop mode request, or when activity is detected on the CAN bus and the self-wake up mechanism is enabled using the CANFD_CFG.SLFWAKEN bit.

When the self-wake up mechanism is enabled at the time that the CANFD module entered stop mode, then upon detection of a recessive-to-dominant transition on the CAN bus, the CANFD module sets the CANFD_ESR1.WAKINT bit, so if the CANFD_CFG.WAKMSK bit is enabled, it generates a wake up interrupt to the processor. Upon receiving the interrupt, the processor resumes the clocks and removes the stop mode request. The CANFD module then waits for 11 consecutive recessive bits to synchronize to the CAN bus. Consequently, the CANFD module does not receive the frame that woke it up. The *Wakeup From Stop Mode* table details the effect of the CANFD_CFG.SLFWAKEN and the CANFD_CFG.WAKMSK bits upon wakeup from the stop mode. Note that wakeup from the stop mode only works when both bits are asserted.

Table 16-27: Wakeup From Stop Mode

SLFWAKEN	WAKINT	WAKMSK	Chip Clocks Enabled	Wakeup Interrupt Generated
0	N/A	N/A	No	No
0	N/A	N/A	No	No
1	0	0	No	No
1	0	1	No	No
1	1	0	No	No
1	1	1	Yes	Yes

Applying a low-pass filter function to the Rx CAN input line while in stop mode will modify sensitivity to CAN bus activity as described in the CANFD_CFG.WSFLTREN bit description. This feature also protects the CANFD module from waking up due to short glitches on the CAN bus lines that can result from electromagnetic interference in noisy environments.

Pretended Network Mode

Pretended networking is a special low-power mode used to receive wake up messages with low power consumption. Pretended networking mode can be selected to operate together with doze mode. Before entering low-power mode, the CANFD_CFG.PNETEN bit must be asserted. Once in low-power mode, the CHI submodule clocks are shut down and the PE submodule is kept clocked, so that the receive process is still active to filter incoming messages as defined by the configuration.

Upon detecting a wakeup event, a wake up interrupt is issued to the system. When the CANFD_CFG.PNETEN bit is enabled, the processor disables the self-wake up feature by disabling the CANFD_CFG.SLFWAKEN bit. Wake up from matched message or time-out in pretended networking modes happens only when pretended networking mode is used along with doze mode. Wakeup is not supported in stop mode.

- Waits to be in the idle state, or else waits for the third bit of intermission, and then checks it to be recessive.
- Sets the CANFD_CFG.LPMACK bit.
- Requests the shutdown of the CHI submodule clock, while keeping the PE submodule clock active.

The CANFD module exits pretended networking mode in the following ways:

- The processor removes the doze mode request.
- The processor disables the CANFD_CFG.DOZEN bit.

The CANFD will wait until bus idle or the third bit of the intermission state to disable the CANFD_CFG.LPMACK bit.

The above exit methods are triggered either by the CANFD module detecting a wake up event and issuing the respective interrupt, or by the processor itself upon being woken up. The CANFD will wait until the bus idle state or until the third bit of the intermission state to disable the CANFD_CFG.LPMACK bit and resume normal mode. This procedure ensures that the CANFD module is synchronized to the CAN bus after exiting pretended networking mode. The processor must wait for the CANFD_CFG.LPMACK bit to be disabled before performing any access to the CANFD.

CANFD Event Control

The following section describe how the CANFD module generates and controls events.

Interrupts

The CANFD module has many interrupt sources: interrupts due to MBs and interrupts due to the OR'd interrupts from MBs, bus off, bus off done, error, error fast (errors detected in the data phase of CAN FD format messages with the CANFD_FD_CTL.BRSEN bit set), wake up, wake up match, wake up timeout, Tx warning, and Rx warning states.

Each one of the MBs can be an interrupt source if the corresponding IMASK bit is set. There is no distinction between Tx and Rx interrupts for a particular buffer, under the assumption that the buffer is initialized for either transmission or reception. Each of the buffers has an assigned flag bit in the CANFD_IFLG1 and CANFD_IFLG2 registers. The bit is set when the corresponding buffer completes a successful transfer and is cleared when the processor writes it to 1 (unless another interrupt is generated at the same time).

NOTE: The processor must only clear the bit causing the current interrupt, so bit manipulation instructions (BSET) must not be used to clear interrupt flags. These instructions may cause the accidental clearing of interrupt flags which are set after entering the current interrupt service routine.

If the Rx FIFO is enabled (CANFD_CFG.RFEN = 1) and DMA is disabled (CANFD_CFG.DMAEN = 0), the interrupts corresponding to MBs 0 to 7 have different meanings:

- Bit 7 of the CANFD_IFLG1 register becomes the "FIFO Overflow" flag.
- Bit 6 of the CANFD_IFLG1 register becomes the "FIFO Warning" flag.
- Bit 5 of the CANFD_IFLG1 register becomes the "Frames Available in FIFO" flag.
- Bit 4-0 of the CANFD_IFLG1 register are unused.

If both Rx FIFO and DMA are enabled (CANFD_CFG.RFEN =1 and CANFD_CFG.DMAEN = 1), the CANFD does not generate any FIFO interrupt. Bit 5 of the CANFD_IFLG1 register still indicates “Frames Available in FIFO” and generates a DMA request. Bits 7, 6, and 4–0 are unused.

NOTE: The Rx FIFO cannot be enabled when the CAN FD feature is enabled.

For a combined interrupt where multiple MB interrupt sources are OR’d together, the interrupt is generated when any of the associated MBs (or FIFO, if applicable) generates an interrupt. In this case, the processor must read the CANFD_IFLG1 and CANFD_IFLG2 registers to determine which MB or FIFO source caused the interrupt.

The interrupt sources for bus off, bus off done, error, error fast, wake up, Tx warning ,and Rx warning generate interrupts like the MB interrupt sources, and are read from the CANFD_ESR1 register. The bus off, error, Tx warning, and Rx warning interrupt mask bits are located in the CANFD_CTL1 register; the wake up interrupt mask bit is located in CANFD_CFG register.

The interrupt sources for pretended networking (wake up by match flag and wake up by timeout flag) are read in the CANFD_WUM register and the respective interrupts masks bits are located in CANFD_PN_CTL1 register.

Bus Interface

The processor accesses to CANFD registers are subject to the following rules:

- Read and write accesses to reserved address space result in access errors.
- Write accesses to positions with bits that are all currently read-only results in access errors.

  If at least one of the bits is not read-only then no access error is issued. Write permission to positions or some of their bits can change depending on the mode of operation or transitory state. Refer to the register and bit descriptions for details.
- Read and write accesses to unimplemented address space results in access errors.
- Read and write accessed to RAM located positions during low-power modes results in access errors.
- If CANFD_CFG.MAXMB is programmed with a value smaller than the available number of MBs, then the unused memory space can be used as general purpose RAM space. Reserved words within RAM cannot be used.

  For example, suppose the CANFD RAM can support up to 16 MBs, the CANFD_CTL2.RFFNUM bit field is 0x0, and the CANFD_CFG.MAXMB bit field is programmed with zero. The maximum number of MBs in this case becomes one. The RAM starts at 0x0080, and the space from 0x0080 to 0x008F is used by the one MB. The memory space from 0x0090 to 0x017F is available. The space between 0x0180 and 0x087F is reserved. The space from 0x0880 to 0x0883 is used by the one individual mask and the available memory in the mask registers space is from 0x0884 to 0x08BF. From 0x08C0 through 0x09DF, there are reserved words for internal use which cannot be used as general purpose RAM. Generally, free memory space for general-purpose usage depends only on the CANFD_CFG.MAXMB bit field.

Detection and Correction of Memory Errors

The CANFD module supports detection and correction of errors in memory read accesses. Each byte of CANFD memory is associated with five parity bits, which ensures a Hamming distance of four. The error correction mechanism ensures that in this 13-bit word, errors in one bit can be corrected (correctable errors), and errors in 2 bits can be detected but not corrected (non-correctable errors). Errors in more than 2 bits may not be detected. In case of non-correctable errors, the corrupted data is not changed by the error correction logic. When a read access is performed, the parity bits are used to calculate a syndrome, which indicates the error in each byte.

The CANFD module detects a non-correctable error in the event either an all-zeros or an all-ones read occurs and updates the CANFD_ERR_RSYN register. The CANFD_ERR_RSYN register holds the syndrome detected in a memory read with an error. It reports the bytes that are read in the 32-bit read transaction.

The *Syndrome Definition* table shows the SYNDn field in the CANFD_ERR_RSYN register, indicates the type of error, and the bit in byte (n) affected by the error. Each BEn field in the CANFD_ERR_RSYN register indicates which byte in the 32-bit word reported was effectively read. The syndrome bits are calculated for all bytes, even for the non-read ones. Errors detected in non-read bytes are indicated and reported as described in the Error Indication and Error Reporting sections.

Table 16-28: Syndrome Definition

SYNDn	Type	Bit Affected
0x00	N/A	None (no error)
0x01	Code	0
0x02	Code	1
0x04	Code	2
0x07	Data	5
0x08	Code	3
0x0E	Data	7
0x10	Code	4
0x13	Data	2
0x15	Data	6
0x16	Data	1
0x19	Data	3
0x1A	Data	4
0x1C	Data	0
0x06	N/A	All-zeros non-correctable error
0x1F	N/A	All-ones non-correctable error
All others	N/A	Non-correctable error

Memory errors are indicated to the host through the CANFD_ERR_STAT register and bus transfer errors, and reported through the CANFD_ERR_RADDR,CANFD_ERR_RDAT, and CANFD_ERR_RSYN registers.

The error detection and correction mechanism is activated by the CANFD_MEC.ECCDIS bit. When error detection and correction is disabled, updates on indications and reporting registers are stopped, but the parity bits are still calculated and written along with data in memory write operations to ensure that memory has consistent parity bits associated to the data.

NOTE: All CANFD memory must be initialized before any operation for the parity bits in memory to properly update. The CANFD_CTL2.WRMFRZEN bit grants write access to all memory positions that require initialization, ranging from 0x080 to 0xADF (and from 0xF28 to 0xFFF when the CAN FD feature is enabled). The CANFD_RX_MB_GMSK, CANFD_RX_14_MSK, CANFD_RX_15_MSK, and CANFD_RX_FIFO_GMSK registers also need to be initialized. The CANFD_CFG.RFEN bit must not be set during memory initialization. The *Identifier Acceptance Filter Fields for Global Bits* table shows the configurations for the CANFD_RX_FIFO_GMSK register.

Table 16-29: Identifier Acceptance Filter Fields for Global Mask Bits

Rx FIFO ID Filter Table Element Format **CANFD_CFG.IDAM**	**Identifier Acceptance Filter Fields**					
RTR	IDE	RXIDA	RXIDB	RXIDC	Reserved	VALUE[0]
A	VALUE[31]	VALUE[30]	VALUE[29:1]	N/A	N/A	
B	VALUE[31], VALUE[15]	VALUE[30], VALUE[14]	N/A	VALUE[29:16], VALUE[13:0]	N/A	N/A
C	N/A	N/A	N/A	N/A	VALUE[31:24], VALUE[23:16], VALUE[15:8], VALUE[7:0]	N/A

To avoid accidentally changing the critical error correction configuration, use the following protocol to enable the CANFD_MEC register update:

1. By default, the CANFD_CTL2.ECRWREN bit is zero and the CANFD_MEC.ECRWRDIS bit is one.
2. Set the CANFD_CTL2.ECRWREN bit.
3. Clear the CANFD_MEC.ECRWRDIS bit.
4. All writes to the CANFD_MEC register must keep the CANFD_MEC.ECRWRDIS bit cleared.
5. After configuration is done, lock the CANFD_MEC register by either setting the CANFD_MEC.ECRWRDIS bit or clearing the CANFD_CTL2.ECRWREN bit.

Sources of Memory Access

The CANFD memory can be accessed by two major sources (or requesters):

- Host (processor): The largest word accessed is 32 bits wide.
- CANFD internals processes (Rx matching, Tx arbitration, move-in on reception, move-out on transmission): The largest word accessed is 64 bits wide.

The way that non-correctable errors are indicated and reported depends on the source of access.

Error Indication

Memory errors are indicated by the CANFD_ERR_STAT.HNCEI, CANFD_ERR_STAT.INCEI, and CANFD_ERR_STAT.CEI flag bits. Non-correctable errors detected in memory reads requested by the host are indicated separately from the errors detected in requests by CANFD internal processes. The CANFD makes no distinction of the source of the access when correctable errors are detected. There are three independent flags for these three cases, and each flag raises an interrupt unless it is masked in the CANFD_MEC register. If both non-correctable and correctable errors are found in different bytes of the same read operation, both flags are set.

A non-correctable error detected in host access is also indicated as a bus transfer error. A bus wait request asserts to extend the memory transaction to the moment the report registers are updated. This indication cannot be masked. If the CANFD_ERR_STAT.HNCEI bit is not masked, the same non-correctable error will raise a bus transfer error and an interrupt request.

Each indication flag has one overrun flag in the CANFD_ERR_STAT register. The overrun flags do not request interrupts. Overrun flags for non-correctable errors indicate that other errors of the same nature were detected after current error being treated, while overrun flags for correctable errors indicate that other errors of the same nature were detected before the current error being treated. The recommended handling sequence for error indication is as follows:

1. Get the error report information from the report registers CANFD_ERR_RADDR, CANFD_ERR_RDAT, and CANFD_ERR_RSYN.
2. Use the error report information to take proper measures in the application.
3. Clear the CANFD_ERR_STAT.HNCEI, CANFD_ERR_STAT.INCEI, CANFD_ERR_STAT.CEI flag bits.
4. If the overrun flag is active:
    a. Alert that application that at least one error could not be handled.
    b. Clear the overrun flag bit.

The CANFD internal processes can access memory in transactions larger than 32 bits. For the indication, this kind of access is considered a consecutive sequence of 32-bit accesses. If errors are found in 2 or more 32-bit words, the interrupt and overrun flags are set simultaneously.

Error Reporting

The report registers CANFD_ERR_RADDR, CANFD_ERR_RDAT, and CANFD_ERR_RSYN provide detailed information about the address read, raw data, and syndrome read with error and indicated by the flags.

The address, data, and syndrome registers are updated simultaneously along with the error flags, according to these rules:

1. If any of the two non-correctable error flags is currently set, the report registers are not updated (the previous non-correctable error reporting is preserved).
2. Otherwise (either no error flag is currently set or only the correctable error flag is currently set), the report registers are updated according to the new error, or according to the most severe of new errors if non-correctable and correctable errors are simultaneously detected.

Reporting of errors detected in accesses larger than 32 bits follows the rules described in the CANFD_ERR_RADDR register.

The address reported in the CANFD_ERR_RADDR register and defined in the CANFD_ERR_IADDR register are not the same as those listed in the module memory map. The relation between the reported addresses and the respective ones in the module memory map is shown in the Error Injection section.

Addresses reported when reading memory portions organized as FIFOs, such as the CANFD_RX_FIFO register, refer to the address of the specific entry accessed in the FIFO, not to the FIFO base address.

To ensure coherence of the error report registers, turn off the report update by setting the CANFD_MEC.RERDIS bit before reading the report registers.

Response to Errors

Correctable errors have no effect on CANFD operation because affected data is corrected before use by the host or CANFD internal processes.

For host-initiated reads, a non-correctable error affects the host, but does not affect CANFD operation.

Non-correctable errors detected on memory reads requested by the CANFD internal processes result in incorrect operation depending on the state of the CANFD_MEC.NCERRFRZEN bit, as follows:

- During reception (either matching or move-in processes), when a non-correctable error occurs, an incorrect destination is selected to store the incoming frame, a corrupted frame is stored in the correct destination, or both. If the CANFD_MEC.NCERRFRZEN is set, the CANFD module stops operation automatically and enters freeze mode to prevent corrupted data from being treated as valid by CANFD internal processes. If the CANFD_MEC.NCERRFRZEN bit is cleared, the CANFD continues working and a corrupted frame is received.
- During the arbitration process, when a non-correctable error occurs, either a non-highest priority Tx message buffer is mistakenly selected for transmission or the data is corrupted. If the CANFD_MEC.NCERRFRZEN bit is set, the CANFD module stops operation automatically and enters freeze mode before starting the move-out. If the CANFD_MEC.NCERRFRZEN bit is cleared, the CANFD proceeds to move-out with a corrupted frame that will transmit on the CAN bus.

- During the move-out process, when a non-correctable error occurs, a corrupted frame is copied from the selected Tx MB that won the arbitration to the Tx SMB for transmission. If the CANFD_MEC.NCERRFRZEN bit is set, the CANFD module stops operation automatically and enters freeze mode before starting the transmission. If the CANFD_MEC.NCERRFRZEN bit is cleared, the corrupted frame is transferred from the Tx SMB to the PE submodule and transmits on the CAN bus.
- A non-correctable error can be detected beyond the move-out process, when Tx data is read from the Tx SMB (buffer located in RAM) to be transferred to the PE submodule for transmission. In this case, a frame with corrupted ID and/or data is transmitted on the CAN bus. To prevent the frame from being successfully received by the external nodes, the CANFD module inverts all bits in the CRC field (CRC sequence plus CRC Delimiter) and transmits an error flag just after CRC delimiter because of a self-detecting bit1 error and a form error due to the CRC field inversion. When the CANFD_MEC.NCERRFRZEN bit is set, the CANFD module stops operation automatically and enters freeze mode just after the error frame. If the CANFD_MEC.NCERRFRZEN bit is negated, the CANFD module attempts to re-transmit the same frame, when no other higher priority Tx MB is subsequently configured for transmission. In the event the non-correctable error persists, the CANFD module eventually reaches the bus off state because of consecutive error detections. The CANFD_ECR.TXERRCNT field is updated every time the CANFD module inverts the CRC field causing errors as described above.

When the CANFD_MEC.NCERRFRZEN bit is set and the CANFD module enters freeze mode, only the host processor can cause then CANFD to exit freeze mode and resume normal mode. Assertion of the CANFD_MEC.NCERRFRZEN bit is the only way to prevent corrupted frames from transmitting on the CAN bus up to the move-out internal process.

The error report registers provide information to the application for customized handling of these situations.

Error Injection

The error injection registers CANFD_ERR_IADDR, CANFD_ERR_IDP, and CANFD_ERR_IPP are used to inject errors in memory reads in order to force errors and consequently update the indication and reporting registers.

The *Error Injection Address Mapping* table shows the relationship between the error injection addresses and the ones in the module memory map. Use this table to convert from the memory map address to the correct location in the physical CANFD RAM.

NOTE: Where pairs of values are provided in the table, the first is the address when the CANFD_CFG.FDEN bit is disabled and the second is when the CANFD_CFG.FDEN bit is enabled.

Table 16-30: Error Injection Address Mapping

RAM Contents	Injection Address	Memory Map
CANFD registers	Not mapped	N/A
MBs	0x0000	0x0080
Reserved	N/A	0x0480
RXIMRs	0x0400	0x0880

Table 16-30: Error Injection Address Mapping (Continued)

RAM Contents	Injection Address	Memory Map
Reserved	N/A	0x0980
RXFIR_0	0x0500	0x0A80
RXFIR_1	0x0504	0x0A84
RXFIR_2	0x0508	0x0A88
RXFIR_3	0x050C	0x0A8C
RXFIR_4	0x0510	0x0A90
RXFIR_5	0x0514	0x0A94
Reserved	N/A	0x0A98
CANFD_RX_MB_GMSK	0x0520	0x0010
CANFD_RX_FIFO_GMSK	0x0524	0x0048
CANFD_RX_14_MSK	0x0528	0x0014
CANFD_RX_15_MSK	0x052C	0x0018
Tx_SMB	0x0530	0x0AB0 / 0x0F28
Rx_SMB0	0x0540 / 0x0578	0x0AC0 / 0x0F70
Rx_SMB1	0x0550 / 0x05C0	0x0AD0 / 0x0FB8
ECC registers	Not mapped	0x0AE0
Pretended networking registers	Not mapped	0x0B00
CAN FD registers	Not mapped	0x0C00
Reserved	N/A	0x0C0C

The injection is done by flipping the data and parity bits corresponding to the bits set to 1 in the CANFD_ERR_IDP and CANFD_ERR_IPP registers. Injection can be selected specifically for memory accesses requested by host or by CANFD internal processes.

In case of accesses larger than 32 bits, the CANFD_MEC.EXTERRIEN bit extends the injection pattern, replicating it in 32-bit words to fill the width of the access.

NOTE: It is very unlikely, but error injection may correct a bit with an error. This will not raise the error flags and reports as expected.

To ensure coherence among error injection registers and avoid spurious error injections, the CANFD_MEC.HAERRIEN and CANFD_MEC.IAERRIEN bits must be cleared while configuring the memory injection.

CANFD Programming Model

Following sections provide some guidelines for CANFD programming.

Initialization

The CANFD module is reset in one of the following ways:

- A chip level hard reset that resets all memory mapped registers asynchronously.
- Setting the CANFD_CFG.SOFTRST bit , which resets some of the memory mapped registers synchronously. The *Register Reset States* table shows the registers affected by a soft reset.
- Chip level soft reset, which has the same effect as setting the CANFD_CFG.SOFTRST bit.

A soft reset is synchronous and must follow an internal request and acknowledge procedure across clock domains and takes time to fully propagate the effects. The CANFD_CFG.SOFTRST bit remains set while soft reset is pending, so software can poll this bit to know when the reset has completed. Also, soft reset cannot be applied while clocks are shut down in a low-power mode. Exit the low-power mode and resume the clocks before applying a soft reset.

Table 16-31: Register Reset States

Register	Affected by Hard Reset	Affected by Soft Reset
CANFD_TIMING	Yes	No
CANFD_CRC	Yes	Yes
CANFD_CTL1	Yes	No
CANFD_PN_CTL1	Yes	Yes
CANFD_CTL2	Yes	No
CANFD_PN_CTL2	Yes	Yes
CANFD_ECR	Yes	Yes
CANFD_ERR_IADDR	Yes	Yes
CANFD_ERR_IDP	Yes	Yes
CANFD_ERR_IPP	Yes	Yes
CANFD_ERR_STAT	Yes	Yes
CANFD_ESR1	Yes	Yes
CANFD_ESR2	Yes	Yes
CANFD_FD_TIMING	Yes	No
CANFD_FD_CRC	Yes	Yes
CANFD_FD_CTL	Yes	No
CANFD_FLTR_DLC	Yes	Yes
CANFD_FLTR_ID1	Yes	Yes
CANFD_FLTR_ID2_IDMSK	Yes	Yes

Table 16-31: Register Reset States (Continued)

Register	Affected by Hard Reset	Affected by Soft Reset
CANFD_IFLG1	Yes	Yes
CANFD_IFLG2	Yes	Yes
CANFD_IMSK1	Yes	Yes
CANFD_IMSK2	Yes	Yes
CANFD_CFG	Yes	Yes
CANFD_MEC	Yes	Yes
CANFD_FLTR_DATA1_HI	Yes	Yes
CANFD_FLTR_DATA1_LO	Yes	Yes
CANFD_FLTR_DATA2_DMSK_HI	Yes	Yes
CANFD_FLTR_DATA2_DMSK_LO	Yes	Yes
CANFD_ERR_RADDR	Yes	Yes
CANFD_ERR_RDAT	Yes	Yes
CANFD_ERR_RSYN	Yes	Yes
CANFD_RX_14_MSK	No	No
CANFD_RX_15_MSK	No	No
CANFD_RX_FIFO_GMSK	No	No
CANFD_RX_FIFO	No	No
CANFD_RX_IMSK[n]	No	No
CANFD_RX_MB_GMSK	No	No
CANFD_TMR	Yes	Yes
CANFD_WUM	Yes	Yes

Note that the MBs and the Rx individual mask registers are not affected by reset, so they are not automatically initialized.

CANFD Initialization Sequence

For any configuration change or initialization, the CANFD must be is put into freeze mode. The following steps are a generic initialization sequence applicable to the CANFD module:

1. Initialize the Module Configuration Register (CANFD_CFG):
    - Enable the individual filtering per MB and reception queue features by setting the CANFD_CFG.IRMQEN bit.
    - Enable the warning interrupts by setting the CANFD_CFG.WRNEN bit.
    - Optionally disable frame self reception by setting the CANFD_CFG.SRXDIS bit.

- Enable the Rx FIFO by setting the CANFD_CFG.RFEN bit.
- If Rx FIFO is enabled and DMA is required, set the CANFD_CFG.DMAEN bit.
- If Pretended Networking mode is required, set the CANFD_CFG.PNETEN bit.
- Enable the abort mechanism by setting the CANFD_CFG.ABORTEN bit.
- Enable the local priority feature by setting the CANFD_CFG.LPRIOEN bit.

2. Initialize the Control 1 Register (CANFD_CTL1) and optionally the CAN Bit Timing Register (CANFD_TIMING). Also, initialize the CAN FD CAN Bit Timing Register (CANFD_FD_TIMING):
   - Determine the bit timing parameters: CANFD_CTL1.PROPSEG, CANFD_CTL1.PSEG1, CANFD_CTL1.PSEG2, CANFD_CTL1.RJW.
   - Optionally determine the extended bit timing parameters: CANFD_TIMING.EPROPSEG, CANFD_TIMING.EPSEG1, CANFD_TIMING.EPSEG2, CANFD_TIMING.ERJW.
   - Determine the CAN FD bit timing parameters: CANFD_FD_TIMING.FPROPSEG, CANFD_FD_TIMING.FPSEG1, CANFD_FD_TIMING.FPSEG2, CANFD_FD_TIMING.FRJW.
   - Determine the bit rate by programming the CANFD_CTL1.PRESDIV field and optionally the CANFD_TIMING.EPRESDIV field.
   - Determine the CAN FD bit rate by programming the CANFD_FD_TIMING.FPRESDIV field. Determine the internal arbitration mode (CANFD_CTL1.LBUF bit).
3. Initialize the Message Buffers:
   - Initialize the C/S word of all MBs.
   - If the Rx FIFO is enabled, initialize the ID filter table.
   - Initialize other entries in each MB.
4. Initialize the individual masks in the CANFD_IMSK1 and CANFD_IMSK2 registers.
5. Set required interrupt mask bits in the CANFD_IMSK1 and CANFD_IMSK2 registers (for all MB interrupts), in the CANFD_CFG register for the wake up interrupt, and in the CANFD_CTL1 and CANFD_CTL2 registers for the bus off and error interrupts.
6. If pretended networking mode is enabled, configure the necessary registers for selective wake up.
7. Disable the CANFD_CFG.HALT bit.

After the last step listed, the CANFD module attempts to synchronize to the CAN bus.

Pretended Network - Doze Mode

Complete the following sequence to enter the pretended networking mode in doze mode:

1. Set the CANFD_CFG.PNETEN bit to enable the controller to enter the pretended networking mode, when one of the low power modes is requested.
2. Clear the CANFD_PN_CTL1.WTOFMSK and CANFD_PN_CTL1.WUMFMSK bits.
3. Request the CANFD to enter Doze mode.
4. Wait for the CANFD to set the CANFD_CFG.LPMACK bit.
5. Clear the CANFD_WUM.WTOF and/or CANFD_WUM.WUMF bits (if either bit is set).
6. Set the CANFD_PN_CTL1.WTOFMSK and CANFD_PN_CTL1.WUMFMSK bits.

Pretended Network - Stop Mode

Complete the following sequence to enter the pretended networking mode in stop mode:

1. Set the CANFD_CFG.PNETEN bit to enable the controller to enter pretended networking mode, when one of the low power modes is requested.
2. Clear the CANFD_PN_CTL1.WTOFMSK and CANFD_PN_CTL1.WUMFMSK bits.
3. Request the CANFD to enter Stop mode. Keep CAN0_IPG_STOP_CLK_EXT/ CAN1_IPG_STOP_CLK_EXT bits set to keep the clock to register block running.
4. Wait for the CANFD to set the CANFD_CFG.LPMACK bit.
5. Clear the CANFD_WUM.WTOF and/or CANFD_WUM.WUMF bits (if either bit is set).
6. Set the CANFD_PN_CTL1.WTOFMSK and CANFD_PN_CTL1.WUMFMSK bits.
7. Disable CANFD register clocks by clearing bits CAN0_IPG_STOP_CLK_EXT/ CAN1_IPG_STOP_CLK_EXT for CANFD0/CANFD1 respectively.

ADSP-2184x CANFD Register Descriptions

Controller Access Network with Flexible Data Rate (CANFD) (CANFD) contains the following registers.

Table 16-32: ADSP-2184x CANFD Register List

Name	Description
CANFD_TIMING	Can Bit Timing Register
CANFD_CRC	CRC Register
CANFD_CTL1	Control 1 Register
CANFD_PN_CTL1	Pretended Networking Control1 Register
CANFD_CTL2	Control 2 Register
CANFD_PN_CTL2	Pretended Networking Control2 Register

Table 16-32: ADSP-2184x CANFD Register List (Continued)

Name	Description
CANFD_ECR	Error Counter Register
CANFD_ERR_IADDR	Error Injection Address Register
CANFD_ERR_IDP	Error Injection Data Pattern Register
CANFD_ERR_IPP	Error Injection Parity Pattern Register
CANFD_ERR_STAT	Error Status Register
CANFD_ESR1	Error and Status 1 Register
CANFD_ESR2	Error and Status 2 Register
CANFD_FD_TIMING	CANFD Bit Timing Register
CANFD_FD_CRC	CANFD CRC Register
CANFD_FD_CTL	CANFD Control Register
CANFD_FLTR_DLC	Pretended Networking DLC Filter Register
CANFD_FLTR_ID1	Pretended Networking ID Filter1 Register
CANFD_FLTR_ID2_IDMSK	Pretended Networking ID Filter2 / IDMask Register
CANFD_IFLG1	Mailbox Interrupt Flag 1 Register
CANFD_IFLG2	Mailbox Interrupt Flag 2 Register
CANFD_IMSK1	Mailbox Interrupt Mask 1 Register
CANFD_IMSK2	Mailbox Interrupt Mask 2 Register
CANFD_CFG	Module Configuration Register
CANFD_MEC	Memory Error Control Register
CANFD_FLTR_DATA1_HI	Pretended Networking Payload Low Filter2 Register
CANFD_FLTR_DATA1_LO	Pretended Networking Payload Low Filter1 Register
CANFD_FLTR_DATA2_DMSK_HI	Pretended Networking Payload High Filter2 High Order Bits / Payload High Mask Register
CANFD_FLTR_DATA2_DMSK_LO	Pretended Networking Payload Low Filter2 / Payload Low Mask Register
CANFD_ERR_RADDR	Error Report Address Register
CANFD_ERR_RDAT	Error Report Data Register
CANFD_ERR_RSYN	Error Report Syndrome Register
CANFD_RX_14_MSK	Receive Mailbox14 Mask Register
CANFD_RX_15_MSK	Receive Mailbox15 Mask Register
CANFD_RX_FIFO_GMSK	Receive FIFO Global Mask Register
CANFD_RX_FIFO	Receive FIFO Information Register
CANFD_RX_IMSK[n]	Receive Individual Mask Register

Table 16-32: ADSP-2184x CANFD Register List (Continued)

Name	Description
CANFD_RX_MB_GMSK	Receive Mailbox Global Mask Register
CANFD_TMR	Free Running Timer Register
CANFD_WMB0_CS	Pretended Networking Wake Up Message Buffer 0 Control Status Register
CANFD_WMB0_D03	Pretended Networking Wake Up Message Buffer 0 Data 0-3 Register
CANFD_WMB0_D47	Wakeup Message Buffer Data 4-7 Register
CANFD_WMB0_ID	Pretended Networking Wake Up Message Buffer ID 0 Register
CANFD_WMB1_CS	Pretended Networking Wake Up Message Buffer 1 Control Status Register
CANFD_WMB1_D03	Pretended Networking Wake Up Message Buffer 1 Data 0-3 Register
CANFD_WMB1_D47	Pretended Networking Wake Up Message Buffer 1 Data 4-7 Register
CANFD_WMB1_ID	Pretended Networking Wake Up Message Buffer ID 1 Register
CANFD_WMB2_CS	Pretended Networking Wake Up Message Buffer 2 Control Status Register
CANFD_WMB2_D03	Pretended Networking Wake Up Message Buffer 2 Data 0-3 Register
CANFD_WMB2_D47	Pretended Networking Wake Up Message Buffer 2 Data 4-7 Register
CANFD_WMB2_ID	Pretended Networking Wake Up Message Buffer ID 2 Register
CANFD_WMB3_CS	Pretended Networking Wake Up Message Buffer 3 Control Status Register
CANFD_WMB3_D03	Pretended Networking Wake Up Message Buffer 3 Data 0-3 Register
CANFD_WMB3_D47	Pretended Networking Wake Up Message Buffer 3 Data 4-7 Register
CANFD_WMB3_ID	Pretended Networking Wake Up Message Buffer ID 3 Register
CANFD_WUM	Pretended Networking Wakeup Match Register

Can Bit Timing Register

The CANFD_TIMING register is an alternative way to store the CAN bit timing variables described in the CANFD_CTL1 register. The CANFD_TIMING.EPRESDIV, CANFD_TIMING.EPROPSEG, CANFD_TIMING.EPSEG1, CANFD_TIMING.EPSEG2, and CANFD_TIMING.ERJW bit fields are extended versions of the CANFD_CTL1 register CANFD_CTL1.PRESDIV, CANFD_CTL1.PROPSEG, CANFD_CTL1.PSEG1, CANFD_CTL1.PSEG2 and CANFD_CTL1.RJW bit fields respectively.

The CANFD_TIMING.BTF bit selects the use of the timing variables defined in the CANFD_TIMING register. The contents of the CANFD_TIMING register are not affected by a soft reset.

NOTE: The CAN bit variables in the CANFD_CTL1 and CANFD_TIMING registers are stored in the same register.

NOTE: When the CAN FD feature is enabled (CANFD_CFG.FDEN is set), always set CANFD_TIMING.BTF.

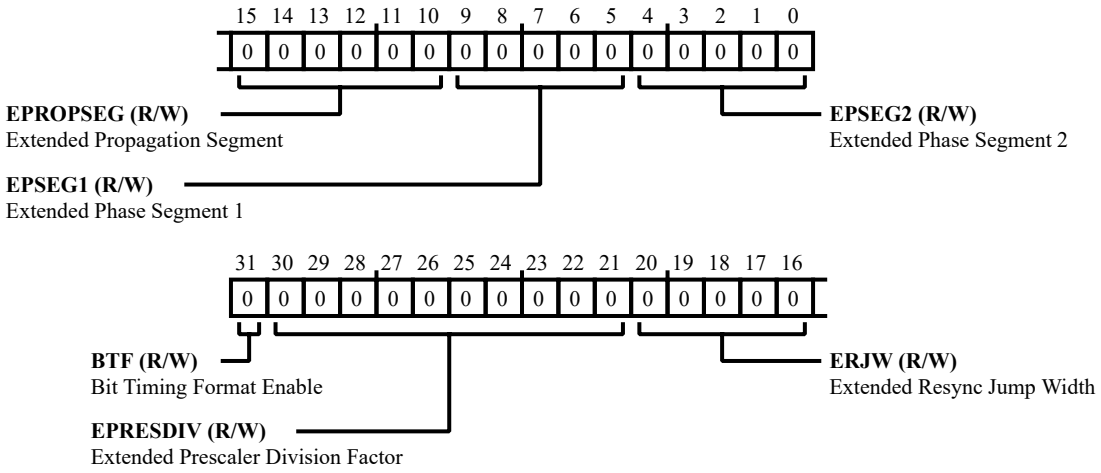

Figure 16-15: CANFD_TIMING Register Diagram

Table 16-33: CANFD_TIMING Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	BTF	Bit Timing Format Enable. The CANFD_TIMING.BTF bit enables the use of the extended CAN bit timing fields in the CANFD_TIMING register to replace the CAN bit time variables defined in the CANFD_CTL1 register. The CANFD_TIMING.BTF bit can only be written in freeze mode.	
		0	Disable
		1	Enable

Table 16-33: CANFD_TIMING Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
30:21 (R/W)	EPRESDIV	Extended Prescaler Division Factor. When the CANFD_TIMING.BTF bit is enabled, the CANFD_TIMING.EPRESDIV bit field defines the ratio between the PE clock frequency and the serial clock (Sclock) frequency. The CANFD_TIMING.EPRESDIV bit field extends the CANFD_CTL1.PRESDIV value range. Sclock frequency = PE clock frequency / (EPRESDIV + 1) The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency. When the CANFD_TIMING.BTF bit is disabled, the CANFD_TIMING.EPRESDIV bit field has no effect. The CANFD_TIMING.EPRESDIV bit field can only be written in freeze mode and is blocked by hardware in other modes.
20:16 (R/W)	ERJW	Extended Resync Jump Width. When the CANFD_TIMING.BTF bit is enabled, the CANFD_TIMING.ERJW bit field defines the maximum number of time quanta that a bit time can be changed by one resynchronization. The CANFD_TIMING.ERJW bit field extends the CANFD_CTL1.RJW value range. Resync Jump Width = ERJW + 1 One time quantum is equal to the Sclock period. When the CANFD_TIMING.BTF bit is disabled, the CANFD_TIMING.ERJW bit field has no effect. The CANFD_TIMING.ERJW bit field can only be written in freeze mode and is blocked by hardware in other modes.
15:10 (R/W)	EPROPSEG	Extended Propagation Segment. When the CANFD_TIMING.BTF bit is enabled, the CANFD_TIMING.EPROPSEG bit field defines the length of the propagation segment in the bit time. The CANFD_TIMING.EPROPSEG bit field extends the CANFD_CTL1.PROPSEG value range. Propagation Segment Time = (EPROPSEG + 1) * Time-Quanta One time quantum is equal to the Sclock period. When the CANFD_TIMING.BTF bit is disabled, the CANFD_TIMING.EPROPSEG bit field has no effect. The CANFD_TIMING.EPROPSEG bit field can only be written in freeze mode and is blocked by hardware in other modes.

Table 16-33: CANFD_TIMING Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
9:5 (R/W)	EPSEG1	Extended Phase Segment 1. When the CANFD_TIMING.BTF bit is enabled, the CANFD_TIMING.EPSEG1 bit field defines the length of phase segment 1 in the bit time. The CANFD_TIMING.EPSEG1 bit field extends the CANFD_CTL1.PSEG1 value range. Phase Buffer Segment 1 = (EPSEG1 + 1) * Time-Quanta One time quantum is equal to the Sclock period. When the CANFD_TIMING.BTF bit is disabled, the CANFD_TIMING.EPSEG1 bit field has no effect. The CANFD_TIMING.EPSEG1 bit field can only be written in freeze mode and is blocked by hardware in other modes.
4:0 (R/W)	EPSEG2	Extended Phase Segment 2. When the CANFD_TIMING.BTF bit is enabled, the CANFD_TIMING.EPSEG2 bit field defines the length of phase segment 2 in the bit time. The CANFD_TIMING.EPSEG2 bit field extends the CANFD_CTL1.PSEG2 value range. Phase Buffer Segment 1 = (EPSEG1 + 1) * Time-Quanta One time quantum is equal to the Sclock period. When the CANFD_TIMING.BTF bit is disabled, the CANFD_TIMING.EPSEG2 bit field has no effect. The CANFD_TIMING.EPSEG2 bit field can only be written in freeze mode and is blocked by hardware in other modes.

CRC Register

The CANFD_CRC register provides information about the CRC of transmitted messages for non-FD messages. For messages in CAN FD format that require either 17 or 21 bits, the CANFD_CRC register only reports the 15 low order bits of CRC calculations. For CAN FD format frames, the CANFD_FD_CRC register must be used. The CANFD_CRC register updates at the same time the Tx Interrupt Flag is set.

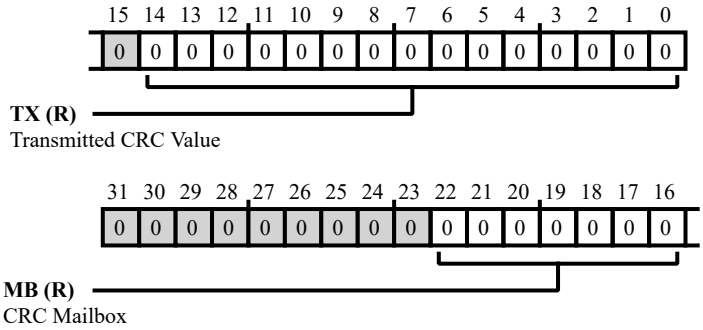

Figure 16-16: CANFD_CRC Register Diagram

Table 16-34: CANFD_CRC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
22:16 (R/NW)	MB	CRC Mailbox. The CANFD_CRC.MB bit field indicates the number of the mailbox corresponding to the value in the CANFD_CRC.TX field.
14:0 (R/NW)	TX	Transmitted CRC Value. The CANFD_CRC.TX bit field indicates the CRC value of the last transmitted message for non-FD frames. For CAN FD frames, the CRC value is reported in the CANFD_FD_CRC register.

Control 1 Register

The CANFD_CTL1 register is defined for specific CANFD control features related to the CAN bus, such as bit-rate, programmable sampling point within an Rx bit, loop-back mode, listen-only mode, bus off recovery behavior, and interrupt enabling (bus off, error, warning). It also determines the division factor for the clock prescaler.

The CAN bit timing variables (PRESDIV, PROPSEG, PSEG1, PSEG2, and RJW) are also configurable in the CANFD_TIMING register, which extends the range of all these variables. If the CANFD_TIMING.BTF bit is set, the PRESDIV, PROPSEG, PSEG1, PSEG2, and RJW fields of the CANFD_CTL1 register become read-only.

NOTE: When the CAN FD feature is enabled, do not use the CANFD_CTL1.PRESDIV, CANFD_CTL1.RJW, CANFD_CTL1.PSEG1, CANFD_CTL1.PSEG2, and CANFD_CTL1.PROPSEG fields of the CANFD_CTL1 register for CAN bit timing. Instead, use the CANFD_TIMING.EPRESDIV, CANFD_TIMING.ERJW, CANFD_TIMING.EPSEG1, CANFD_TIMING.EPSEG2, and CANFD_TIMING.EPROPSEG fields of the CANFD_TIMING register.

The contents of the CANFD_CTL1 register are not affected by a soft reset.

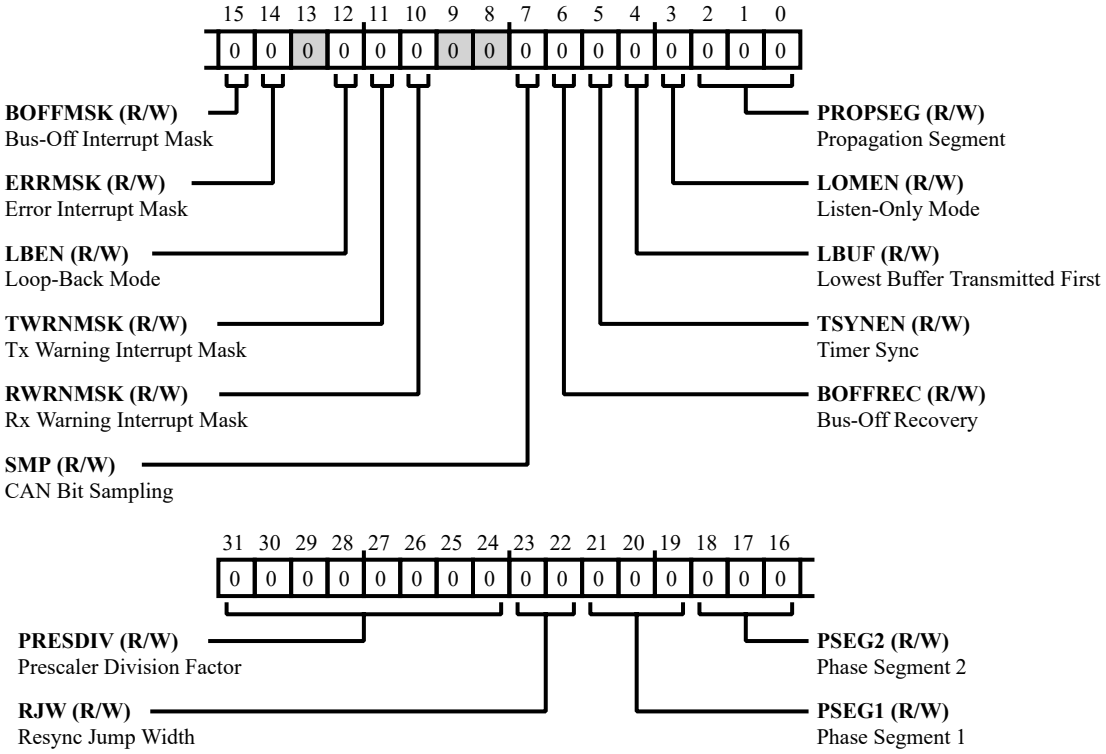

Figure 16-17: CANFD_CTL1 Register Diagram

Table 16-35: CANFD_CTL1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:24 (R/W)	PRESDIV	Prescaler Division Factor. The CANFD_CTL1.PRESDIV bit field defines the ratio between the PE clock frequency and the serial clock (SCLOCK) frequency. The SCLOCK period defines the time quantum of the CAN protocol. For the reset value, the SCLOCK frequency is equal to the PE clock frequency. The maximum value of PRESDIV is 0xFF, which gives a minimum SCLOCK frequency equal to the PE clock frequency divided by 256. The CANFD_CTL1.PRESDIV bit can only be written in freeze mode and is blocked by hardware in other modes. SCLOCK Frequency = PE Clock Frequency / (PRESDIV + 1)	
23:22 (R/W)	RJW	Resync Jump Width. The CANFD_CTL1.RJW bit field defines the maximum number of time quanta that a bit time can change with one re-synchronization. One time quantum is equal to the SCLOCK period. The valid programmable values for the CANFD_CTL1.RJW bits are 0-3. This bit field can only be written in freeze mode and is blocked by hardware in other modes. Resync Jump Width = RJW + 1	
21:19 (R/W)	PSEG1	Phase Segment 1. The CANFD_CTL1.PSEG1 bit field defines the length of the phase segment 1 of the bit time. The valid programmable values are 0-7. This bit field can only be written in freeze mode and is blocked by hardware in other modes. Phase Buffer Segment 1 = (PSEG1 + 1) x Time-Quanta	
18:16 (R/W)	PSEG2	Phase Segment 2. The CANFD_CTL1.PSEG2 bit field defines the length of phase segment 2 of the bit time. The valid programmable values are 1-7. This bit field can only be written in freeze mode and is blocked by hardware in other modes. Phase Buffer Segment 2 = (PSEG2 + 1) x Time-Quanta	
15 (R/W)	BOFFMSK	Bus-Off Interrupt Mask. The CANFD_CTL1.BOFFMSK bit provides a mask for the bus off interrupt (CANFD_ESR1.BOFFINT).	
		0	Disable
		1	Enable

Table 16-35: CANFD_CTL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
14 (R/W)	ERRMSK	Error Interrupt Mask. The CANFD_CTL1.ERRMSK bit provides a mask for the error interrupt (CANFD_ESR1.ERRINT).	
		0	Disable
		1	Enable
12 (R/W)	LBEN	Loop-Back Mode. The CANFD_CTL1.LBEN bit configures the CANFD module to operate in loop-back mode. In loop-back mode, the CANFD modules performs an internal loop back to use for self-test operation. The bit stream output of the transmitter is fed back internally to the receiver input. The Rx CAN input pin is ignored and the Tx CAN output goes to the recessive state (logic 1). The CANFD module behaves as it normally does when transmitting, and treats its own transmitted message as a message received from a remote node. In loop-back mode, the CANFD module ignores the bit sent during the ACK slot in the CAN frame acknowledge field, generating an internal acknowledge bit to ensure proper reception of its own message. Both transmit and receive interrupts are generated. The CANFD_CTL1.LBEN bit can only be written in freeze mode and is blocked by hardware in other modes. Note that in loop-back mode, the CANFD_CFG.SRXDIS bit cannot be asserted, because it impedes the self reception of a transmitted message. Also, note that the CANFD_FD_CTL.TDCOMPEN bit must be 0 (transceiver delay compensation feature disabled) when the CANFD_CTL1.LBEN bit is asserted.	
11 (R/W)	TWRNMSK	Tx Warning Interrupt Mask. The CANFD_CTL1.TWRNMSK bit provides a mask for the Tx warning interrupt (CANFD_ESR1.TXWRNINT) The CANFD_CTL1.TWRNMSK bit is read as zero when CAN_MCR.WRNEN is negated. The CANFD_CTL1.TWRNMSK bit can only be written when the CANFD_CFG.WRNEN bit is enabled.	
		0	Tx Warning Interrupt Disabled
		1	Tx Warning Interrupt Enabled

Table 16-35: CANFD_CTL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
10 (R/W)	RWRNMSK	Rx Warning Interrupt Mask. The CANFD_CTL1.RWRNMSK bit provides a mask for the Rx warning interrupt (CANFD_ESR1.RXWRNINT) The CANFD_CTL1.RWRNMSK bit is read as zero when the CANFD_CFG.WRNEN bit is negated. It can only be written only if the CANFD_CFG.WRNEN bit is enabled.	
		0	Rx Warning Interrupt Disabled
		1	Rx Warning Interrupt Enabled
7 (R/W)	SMP	CAN Bit Sampling. The CANFD_CTL1.SMP bit defines the sampling mode of CAN bits at the Rx input. When the CANFD_CTL1.SMP bit is disabled, one sample determines the bit value. When it is enabled three samples determine the value of the received bit: the regular sample (sample point) and the two preceding samples; a majority rule is used. The CANFD_CTL1.SMP bit can only be written in freeze mode and is blocked by hardware in other modes. Note that for proper operation, when enabling CAN bit sampling, guarantee a minimum value of 2 time quanta in the CANFD_CTL1.PSEG1 (or CANFD_TIMING.EPSEG1) bit field. SMP cannot be asserted when CAN FD is enabled (CANFD_CFG.FDEN = 1).	
		0	Disable
		1	Enable

Table 16-35: CANFD_CTL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W)	BOFFREC	Bus-Off Recovery. The CANFD_CTL1.BOFFREC bit defines how the CANFD module recovers from bus off state. When the CANFD_CTL1.BOFFREC bit is enabled, automatic recovering from the bus off state occurs according to the CAN Specification 2.0B. When the CANFD_CTL1.BOFFREC bit is disabled, automatic recovering from the bus off state is disabled and the CANFD module remains in the bus off state until the CANFD_CTL1.BOFFREC bit is enabled by software. If this occurs before 128 sequences of 11 recessive bits are detected on the CAN bus, then the bus off recovery happens as if the CANFD_CTL1.BOFFREC bit was never disabled. If the bit is enabled after 128 sequences of 11 recessive bits occurred, then the CANFD module will re-synchronize to the bus by waiting for 11 recessive bits before joining the bus. After being enabled, the CANFD_CTL1.BOFFREC bit can be disabled again during the bus off state, but it will be effective only the next time the CANFD module enters the bus off state. If CANFD_CTL1.BOFFREC bit was enabled when the CANFD module entered the bus off state, disabling the CANFD_CTL1.BOFFREC bit during the bus off state will not be effective for the current bus off recovery.	
		0	Enable
		1	Disable
5 (R/W)	TSYNEN	Timer Sync. The CANFD_CTL1.TSYNEN bit enables a mechanism that resets the free-running timer each time a message is received in message buffer 0. The timer sync feature provides a means to synchronize multiple CANFD stations with a special "SYNC" message (global network time). If the CANFD_CFG.RFEN bit is set (Rx FIFO enabled), the first available mailbox, according to the CANFD_CTL2.RFFNUM setting, is used for timer synchronization instead of MB0. The CANFD_CTL1.TSYNEN bit can only be written in freeze mode and is blocked by hardware in other modes.	
		0	Disable
		1	Enable

Table 16-35: CANFD_CTL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W)	LBUF	Lowest Buffer Transmitted First. The CANFD_CTL1.LBUF bit defines the ordering mechanism for message buffer transmission. When the CANFD_CTL1.LBUF bit is enabled, the lowest number buffer is transmitted first and when it is disabled the buffer with highest priority is transmitted first. When the CANFD_CTL1.LBUF bit is enabled, the CANFD_CFG.LPRIOEN bit does not affect the arbitration priority. The CANFD_CTL1.LBUF bit can only be written in freeze mode and is blocked by hardware in other modes.	
		0	Disable
		1	Enable
3 (R/W)	LOMEN	Listen-Only Mode. The CANFD_CTL1.LOMEN bit configures the CANFD module to operate in listen-only mode. When the CANFD_CTL1.LOMEN is enabled to be in listen-only mode, transmission is disabled, all error counters in the CANFD_ECR register are frozen, and the CANFD module operates in the CAN error passive mode. Only messages acknowledged by another CAN station will be received. If the CANFD module detects a message that has not been acknowledged, it flags a BIT0 error without changing the receive error counter (CANFD_ECR.RXERRCNT), as if it were trying to acknowledge the message. Listen-Only mode is acknowledged by the state of the CANFD_ESR1.FLTCONF bit field indicating a passive error. There can be some delay between the listen-only mode request and acknowledge. The CANFD_CTL1.LOMEN bit can only be written in freeze mode and is blocked by hardware in other modes.	
		0	Disable
		1	Enable
2:0 (R/W)	PROPSEG	Propagation Segment. The CANFD_CTL1.PROPSEG bit field defines the length of the propagation segment in the bit time. The valid programmable values are 0-7. The CANFD_CTL1.PROPSEG bit can only be written in freeze mode and is blocked by hardware in other modes. Propagation Segment Time = (PROPSEG + 1) x Time-Quanta. Time-Quantum = One SCLOCK Period.	

Pretended Networking Control1 Register

The CANFD_PN_CTL1 register contains control bits for pretended networking mode filtering selection. Configure this register with the filter criteria to receive wakeup messages. Bits other than CANFD_PN_CTL1.WTOFMSK and CANFD_PN_CTL1.WUMFMSK can only be written in freeze mode.

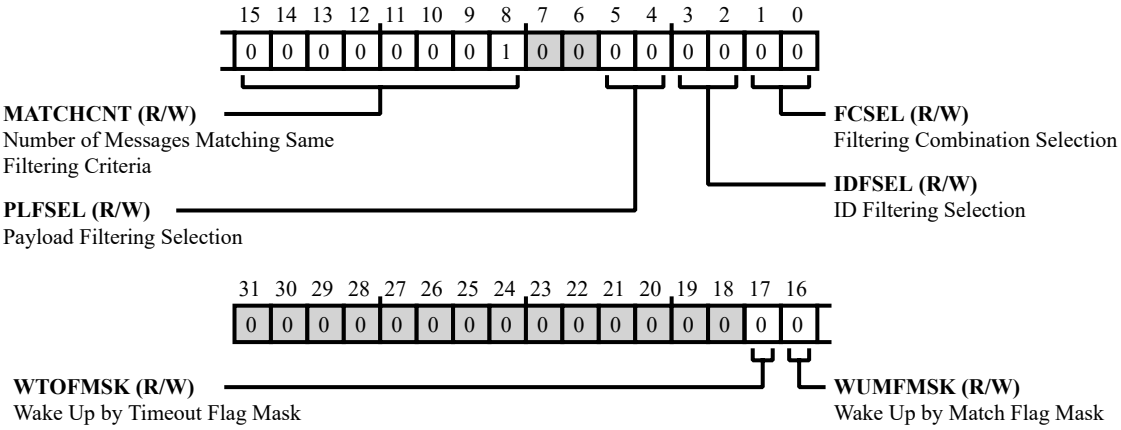

Figure 16-18: CANFD_PN_CTL1 Register Diagram

Table 16-36: CANFD_PN_CTL1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W)	WTOFMSK	Wake Up by Timeout Flag Mask. The CANFD_PN_CTL1.WTOFMSK bit masks the generation of a wakeup event originated by a timeout:	
		0	Timeout Event Disabled
		1	Timeout Event Enabled
16 (R/W)	WUMFMSK	Wake Up by Match Flag Mask. The CANFD_PN_CTL1.WUMFMSK bit masks the generation of a wakeup event originated by a successfully filtered Rx message.	
		0	Wakeup match disabled
		1	Wakeup match enabled

Table 16-36: CANFD_PN_CTL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15:8 (R/W)	MATCHCNT	Number of Messages Matching Same Filtering Criteria. The CANFD_PN_CTL1.MATCHCNT bit field defines the number of times a given message must match the predefined filtering criteria for ID and/or PL before generating a wakeup event. This quantity is configured in the 1 to 255 range. For example, if the received message must match the predefined filtering criteria for ID and/or PL once before generating a wakeup event, the CANFD_PN_CTL1.MATCHCNT bit field value is 0x01; if it must match twice before generating a wakeup event, the bit field value is 0x02; and if it must match 255 times generating a wakeup event, the CANFD_PN_CTL1.MATCHCNT bit field value is 0xFF.	
5:4 (R/W)	PLFSEL	Payload Filtering Selection. The CANFD_PN_CTL1.PLFSEL bit field selects the level of payload filtering to be applied when the CANFD module is under pretended networking mode. Filtering does not accept remote messages (RTR=1) when payload filtering is active.	
		0	Match the payload contents against an exact target value
		1	Match if a payload value is greater than or equal to a specific target value
		2	Match if a payload value is less than or equal to a specific target value
		3	Match if a payload value is inside a range, greater than or equal to a specified lower limit and smaller than or equal a specified upper limit
3:2 (R/W)	IDFSEL	ID Filtering Selection. The CANFD_PN_CTL1.IDFSEL bit field selects the level of ID filtering to be applied when the CANFD module is under pretended networking mode. In ID filtering, if the CANFD_FLTR_ID2_IDMSK.IDE and CANFD_FLTR_ID2_IDMSK.RTR bits are set, the IDE and RTR bits are also considered part of the reception filter.	
		0	Match the ID contents against an exact target value
		1	Match if the ID value is greater than or equal to a specific target value
		2	Match if the ID value is less than or equal to a specific target value
		3	Match if the ID value is inside a range, greater than or equal to a specified lower limit and smaller than or equal a specified upper limit

Table 16-36: CANFD_PN_CTL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1:0 (R/W)	FCSEL	Filtering Combination Selection. The `CANFD_PN_CTL1.FCSEL` bit field selects elects the filtering criteria to be applied when the CANFD module is in pretended networking mode.	
		0	Message ID filtering only
		1	Message ID filtering and payload filtering
		2	Message ID filtering occurring a specified number of times
		3	Message ID filtering and payload filtering a specified number of times

Control 2 Register

The CANFD_CTL2 register complements CANFD_CTL1, providing control bits for memory write accesses in freeze mode, for extending FIFO filter quantity, and for adjusting the operation of internal CANFD processes like matching and arbitration.

The contents of the CANFD_CTL2 register are not affected by soft reset.

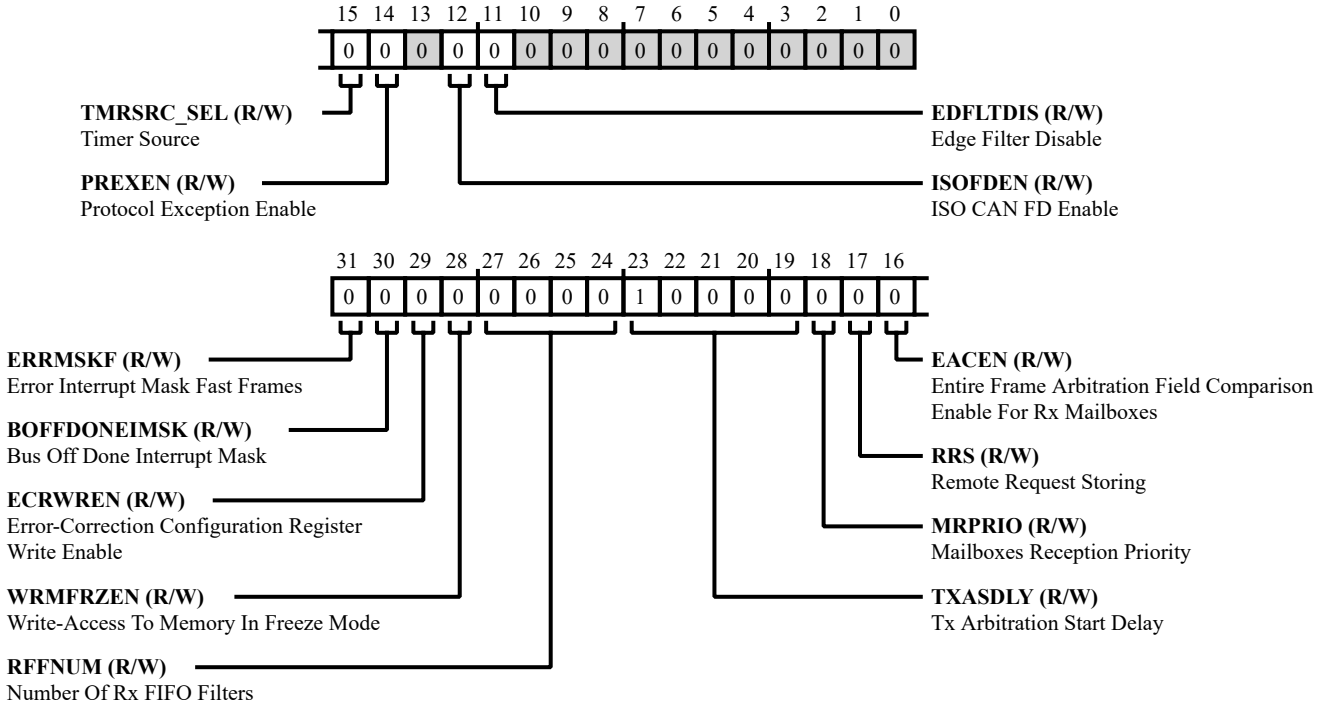

Figure 16-19: CANFD_CTL2 Register Diagram

Table 16-37: CANFD_CTL2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	ERRMSKF	Error Interrupt Mask Fast Frames. The CANFD_CTL2.ERRMSKF bit is the error interrupt mask for errors detected in the data phase of fast CAN FD frames. It provides a mask for the CANFD_ESR1.ERRINTF interrupt. When the CANFD_CTL2.ERRMSKF bit is set, the error interrupt is enabled. When the bit is cleared the error interrupt is disabled.
30 (R/W)	BOFFDONEIMSK	Bus Off Done Interrupt Mask. The CANFD_CTL2.BOFFDONEIMSK bit provides a mask for the bus off done interrupt in the CANFD_ESR1 register. When the CANFD_CTL2.BOFFDONEIMSK bit is set, the bus off done interrupt is enabled. When the bit is cleared the bus off done interrupt is disabled.

Table 16-37: CANFD_CTL2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
29 (R/W)	ECRWREN	Error-Correction Configuration Register Write Enable. The CANFD_CTL2.ECRWREN bit enables the MECR register to be updated. Setting the CANFD_CTL2.ECRWREN bit is set, enables updates. Clearing the bit disables updates. The CANFD_CTL2.ECRWREN bit is automatically set to zero if the protocol described in the "Detection and Correction of Memory Errors" section of the CANFD chapter is not followed.
28 (R/W)	WRMFRZEN	Write-Access To Memory In Freeze Mode. The CANFD_CTL2.WRMFRZEN bit enables unrestricted write access to the CANFD memory in freeze mode. Clear the CANFD_CTL2.WRMFRZEN bit to maintain the write access restrictions. Set the CANFD_CTL2.WRMFRZEN bit to enable unrestricted write access to the CANFD memory. The CANFD_CTL2.WRMFRZEN bit can only be written in freeze mode and has no effect out of freeze mode. The CANFD_CFG.RFEN bit must not be set during CANFD memory initialization.

Table 16-37: CANFD_CTL2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
27:24 (R/W)	RFFNUM	Number Of Rx FIFO Filters. The CANFD_CTL2.RFFNUM bit field defines the number of Rx FIFO filters. For more details, see the Number of Rx FIFO Filters table in the CANFD chapter. The maximum selectable number of filters is a function of configuration parameter NUMBER_OF_MB. Do not program the CANFD_CTL2.RFFNUM bit field with values that make the number of message buffers occupied by the Rx FIFO and ID Filter exceed the number of mailboxes present, defined by the CANFD_CFG.MAXMB bit field. Each group of eight filters occupies a memory space equivalent to two message buffers, which means that as more filters are implemented fewer mailboxes are available. Considering that the Rx FIFO occupies the memory space originally reserved for MB0-5, program the CANFD_CTL2.RFFNUM bit with a value corresponding to a number of filters not greater than the number of available memory words. Calculate this as follows: (SETUP_MB - 6) x 4 where SETUP_MB is the lower value between parameter NUMBER_OF_MB and register field CANFD_CFG.MAXMB. The number of remaining mailboxes available is (SETUP_MB - 8) - (RFFN x 2) If the number of Rx FIFO filters programmed through the CANFD_CTL2.RFFNUM bit field exceeds the SETUP_MB value (memory space available), the exceeding ones are not functional. Note that the number of the last remaining available mailbox is defined by the least value between (NUMBER_OF_MB - 1) and the CANFD_CFG.MAXMB field. If the individual Rx mask registers are not enabled, all Rx FIFO filters are affected by the Rx FIFO global mask. The CANFD_CTL2.RFFNUM bit field can only be written in freeze mode as it is blocked by hardware in other modes.
23:19 (R/W)	TXASDLY	Tx Arbitration Start Delay. The CANFD_CTL2.TXASDLY bit field indicates how many CAN bits the Tx arbitration process start point can be delayed from the first bit of CRC field on the CAN bus. The CANFD_CTL2.TXASDLY bit field can only be written in freeze mode and it is blocked by hardware in other modes.
18 (R/W)	MRPRIO	Mailboxes Reception Priority. The CANFD_CTL2.MRPRIO bit defines the mailboxes reception priority. If the CANFD_CTL2.MRPRIO bit is set, the matching process starts from the mailboxes and if no match occurs the matching continues on the Rx FIFO. If the bit is cleared, matching starts from Rx FIFO and continues on mailboxes. The CANFD_CTL2.MRPRIO bit can only be written only in freeze mode and it is blocked by hardware in other modes.

Table 16-37: CANFD_CTL2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W)	RRS	Remote Request Storing. If the CANFD_CTL2.RRS bit is set, a remote request frame is submitted to a matching process and stored in the corresponding message buffer in the same fashion of a data frame. No automatic remote response frame is generated. If the CANFD_CTL2.RRS bit is cleared, the remote request frame is submitted to a matching process and an automatic remote response frame is generated if a message buffer with CODE=0b1010 is found with the same ID. The CANFD_CTL2.RRS bit can only be written in freeze mode and it is blocked by hardware in other modes.	
16 (R/W)	EACEN	Entire Frame Arbitration Field Comparison Enable For Rx Mailboxes. The CANFD_CTL2.EACEN bit controls the comparison of IDE and RTR bits within Rx mailboxes filters with their corresponding bits in the incoming frame by the matching process. The CANFD_CTL2.EACEN bit does not affect matching for the Rx FIFO. When the CANFD_CTL2.EACEN bit is set it enables the comparison of both the IDE and RTR bits of an Rx mailbox filter with the corresponding bits of the incoming frame. Mask bits do apply. When the CANFD_CTL2.EACEN bit is cleared the IDE bit of the Rx mailbox filter is always compared and RTR is never compared, regardless of mask bits. EACEN can be only written only in freeze mode and it is blocked by hardware in other modes.	
15 (R/W)	TMRSRC_SEL	Timer Source. The CANFD_CTL2.TMRSRC_SEL bit selects the time tick source used for incrementing the free running timer counter. When the CANFD_CTL2.TMRSRC_SEL bit is set, the free running timer is clocked by an external time tick. The period can be either adjusted to be equal to the baud rate on the CAN bus or a different value as required. When the CANFD_CTL2.TMRSRC_SEL bit is cleared, the free running timer is clocked by the CAN bit clock, which defines the baud rate on the CAN bus. The CANFD_CTL2.TMRSRC_SEL bit can only be written in freeze mode.	
14 (R/W)	PREXEN	Protocol Exception Enable. The CANFD_CTL2.PREXEN bit enables the protocol exception feature. The CANFD_CTL2.PREXEN bit can only be written in freeze mode.	
		0	Disable
		1	Enable

Table 16-37: CANFD_CTL2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	ISOFDEN	ISO CAN FD Enable. The `CANFD_CTL2.ISOFDEN` bit controls ISO CAN FD compliant operation. Setting the bit enables ISO CAN FD compliant operation by enabling the following features, which are part of the ISO 11898 standard and not included in the original (Bosch) CAN FD protocol specification: The count of variable stuff bits inserted from the start of frame bit to the last bit of data field. Also, the modulo 8 count of variable stuff bits plus the respective parity bit (even parity calculated over the 3-bit modulo 8 count) are combined as the 4-bit stuff count field and inserted before the CRC sequence field. CRC calculation extends beyond the end of data field and takes the stuff count field bits into account. Clearing the `CANFD_CTL2.ISOFDEN` bit disables ISO CAN FD specific features (non-ISO CAN FD operation). The `CANFD_CTL2.ISOFDEN` bit is only writable in freeze mode.	
11 (R/W)	EDFLTDIS	Edge Filter Disable. The `CANFD_CTL2.EDFLTDIS` bit controls the edge filter used during the bus integration state. When the edge filter is enabled, two consecutive nominal time quanta with dominant bus state are required to detect an edge that causes synchronization. When synchronization occurs, the counting of the sequence of eleven consecutive recessive bits is restarted. The edge filter prevents the dominant pulses that are shorter than a nominal bit time (present during the data phase of an FD frame) from being mistaken for an idle condition. The `CANFD_CTL2.EDFLTDIS` bit is only writable in freeze mode.	
		0	Enable
		1	Disable

Pretended Networking Control2 Register

The CANFD_PN_CTL2 register contains configuration bits for the timeout value under pretended networking mode. Only write to this register in freeze mode.

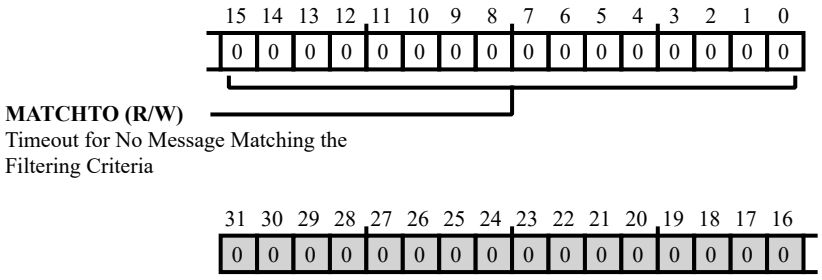

Figure 16-20: CANFD_PN_CTL2 Register Diagram

Table 16-38: CANFD_PN_CTL2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	MATCHTO	Timeout for No Message Matching the Filtering Criteria. The CANFD_PN_CTL2.MATCHTO bit field defines a timeout value that generates a wakeup event when the CANFD_CFG.PNETEN bit is enabled. If the timeout counter reaches the target value when the CANFD module is in pretended networking mode, a wakeup event is generated. The timeout limit value is configured from 1 to 65535 to control an internal 16-bit up-count timer to produce a trigger upon reaching this configured value. The internal timer is incremented based on periodic time ticks, with a period 64 times the CAN bit time unit. When the CANFD_PN_CTL2.MATCHTO bit field is 0x0000, the timeout is disabled.

Error Counter Register

The CANFD_ECR register has four 8-bit fields reflecting the value of the CANFD error counters:

• Transmit error counter (CANFD_ECR.TXERRCNT field)

• Receive error counter (CANFD_ECR.RXERRCNT field)

• Transmit error counter for errors detected in the data phase of CAN FD messages with the BRS bit set (CANFD_ECR.TXERRCNTF field)

• Receive error counter for errors detected in the data phase of CAN FD messages with the BRS bit set (CANFD_ECR.RXERRCNTF field)

The TXERRCNT and RXERRCNT counters take into account all errors in both CAN FD and non-FD message formats. The TXERRCNTF and RXERRCNT_FAST counters only count the errors that occur in the data phase of CAN FD frames with the BRS bit set.

The fault confinement state (CANFD_ESR1.FLTCONF) is only updated based on the TXERRCNT and RXERRCNT counters. The TXERRCNT and RXERRCNT counters can only be written in freeze mode. The TXERRCNTF and RXERRCNT_FAST counters are read-only except in freeze mode, where the processor can write a zero value. The rules for incrementing and decrementing these counters are described in the CAN protocol and are completely implemented in the CANFD module.

The basic rules for the CANFD bus state transitions are as follows:

• If the value of TXERRCNT or RXERRCNT increases to be greater than or equal to 128, the CANFD_ESR1.FLTCONF field updates to reflect the error passive state.

• If the CANFD state is error passive, and either TXERRCNT or RXERRCNT decrements to a value less than or equal to 127 while the other already satisfies this condition, the CANFD_ESR1.FLTCONF field updates to reflect the error active state.

• If the value of TXERRCNT increases to be greater than 255, the CANFD_ESR1.FLTCONF field updates to reflect the bus off state and an interrupt may be issued. The value of TXERRCNT is then reset to zero.

• If the CANFD is in the bus off state, then TXERRCNT is cascaded together with another internal counter to count the 128 occurrences of 11 consecutive recessive bits on the bus. Hence, TXERRCNT is reset to zero and counts in a manner where the internal counter counts 11 such bits and then wraps around while incrementing TXERRCNT. When TXERRCNT reaches the value of 128, the CANFD_ESR1.FLTCONF field is updated to be error active and both error counters are reset to zero. At any instance of dominant bit following a stream of less than 11 consecutive recessive bits, the internal counter resets itself to zero without affecting the TXERRCNT value. The TXERRCNTF counter is frozen during bus off.

• If during system start-up, only one node is operating, then its TXERRCNT increases in each message it is trying to transmit, as a result of acknowledge errors (indicated by the CANFD_ESR1.ACKERR bit). After the transition to the error passive state, TXERRCNT is no longer incremented by acknowledge errors. Therefore, the device never goes to the bus off state.

• If RXERRCNT increases to a value greater than 127, it is not incremented further, even if more errors are detected while being a receiver. At the next successful message reception, the counter is set to a value between 119 and 127 to resume to the error active state.

• The TXERRCNTF and RXERRCNT_FAST error counters values increment and decrement based on errors detected only in the data phase of CAN FD frames with the BRS bit set, following the same increment and decrement rules as the TXERRCNT and RXERRCNT counters. These counters do not wrap around and get stuck at their maximum value (255). They stop counting and keep their values frozen while the CANFD is in the bus off state. They are reset when the CANFD leaves the bus off state and restart counting once the CANFD resumes to the error active state.

• When the CANFD module is in pretended networking mode, RXERRCNT and RXERRCNT_FAST keep counting errors and error flags are stored. TXERRCNT and TXERRCNTF preserve their values and do not change since no transmission occurs under pretended networking mode. Error counters and error flags that changed values while in pretended networking mode are updated in the CANFD_ECR and CANFD_ESR1 registers when the CANFD module resumes normal mode. The FAST error flags in the CANFD_ESR1 register are not set if the CANFD is in pretended networking mode.

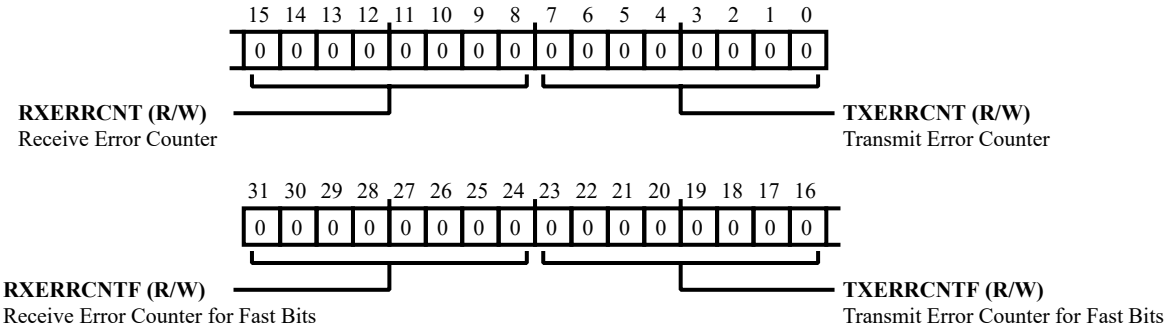

Figure 16-21: CANFD_ECR Register Diagram

Table 16-39: CANFD_ECR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	RXERRCNTF	Receive Error Counter for Fast Bits. The CANFD_ECR.RXERRCNTF bit field is for errors detected in the data phase of received CAN FD messages with the BRS bit set. The CANFD_ECR.RXERRCNTF bit field is read-only except in freeze mode. In freeze mode the processor can only write a 8-bit zero value.
23:16 (R/W)	TXERRCNTF	Transmit Error Counter for Fast Bits. The CANFD_ECR.TXERRCNTF bit field is for errors detected in the data phase of received CAN FD messages with the BRS bit set. The CANFD_ECR.TXERRCNTF bit field is read-only except in freeze mode. In freeze mode the processor can only write a 8-bit zero value.

Table 16-39: CANFD_ECR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W)	RXERRCNT	Receive Error Counter. The `CANFD_ECR.RXERRCNT` bit field is for all errors detected in received messages. The `CANFD_ECR.RXERRCNT` bit field is read-only except in freeze mode, where the processor can write it.
7:0 (R/W)	TXERRCNT	Transmit Error Counter. The `CANFD_ECR.TXERRCNT` bit field is for all errors detected in transmitted messages. The `CANFD_ECR.TXERRCNT` bit field is read-only except in freeze mode, where the processor can write it.

Error Injection Address Register

The CANFD_ERR_IADDR register holds the address where a memory read error is injected.

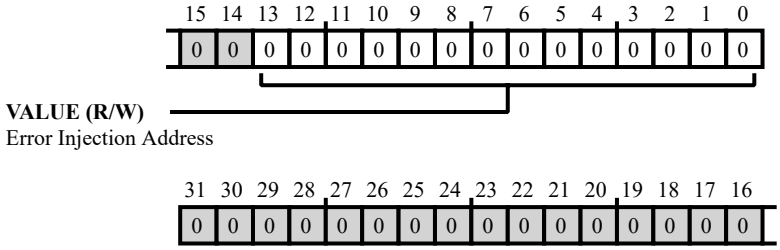

Figure 16-22: CANFD_ERR_IADDR Register Diagram

Table 16-40: CANFD_ERR_IADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
13:0 (R/W)	VALUE	Error Injection Address. The CANFD_ERR_IADDR.VALUE bit field defines the physical RAM address where a memory read error is to be injected. See the Error Injection Address Mapping table in the CANFD chapter for more details. Note that the two least significant bits are always read as zero.

Error Injection Data Pattern Register

The CANFD_ERR_IDP register holds the error pattern injected in the data word that is read from memory.

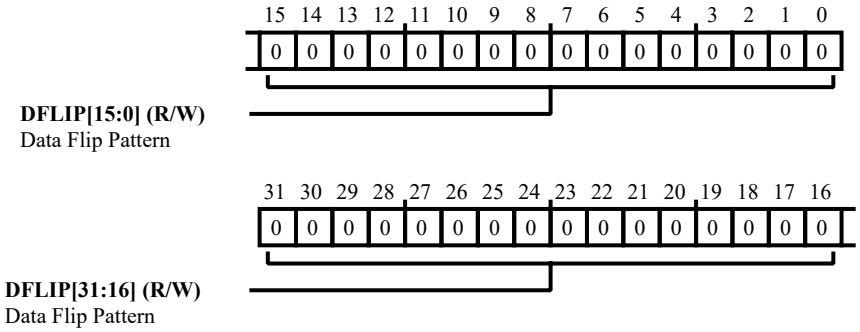

Figure 16-23: CANFD_ERR_IDP Register Diagram

Table 16-41: CANFD_ERR_IDP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DFLIP	Data Flip Pattern. The CANFD_ERR_IDP.DFLIP bit field determines the data flip pattern. Bits set to one in the flip pattern cause the corresponding data bit in the word read from memory to invert.

Error Injection Parity Pattern Register

The CANFD_ERR_IPP register holds the error pattern that is injected in the parity bits read from memory along with data word. Bits set to one in the flip pattern cause the corresponding parity bit, in the word read from memory, to invert.

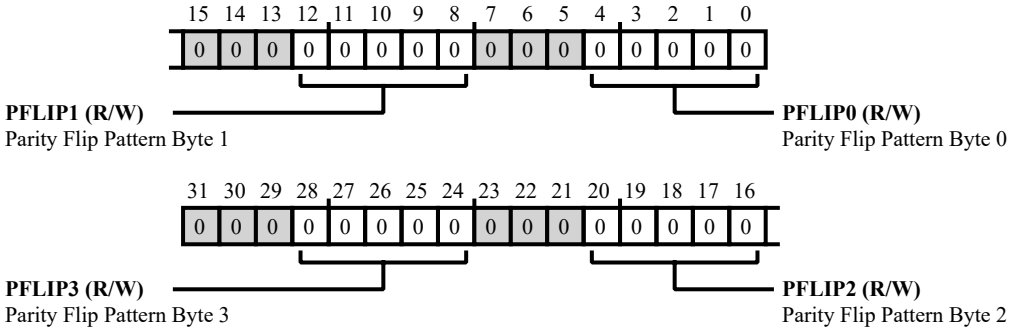

Figure 16-24: CANFD_ERR_IPP Register Diagram

Table 16-42: CANFD_ERR_IPP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
28:24 (R/W)	PFLIP3	Parity Flip Pattern Byte 3. The CANFD_ERR_IPP.PFLIP3 bit field is for the parity flip pattern for byte 3 (most significant).
20:16 (R/W)	PFLIP2	Parity Flip Pattern Byte 2. The CANFD_ERR_IPP.PFLIP2 bit field is for the parity flip pattern for byte 2.
12:8 (R/W)	PFLIP1	Parity Flip Pattern Byte 1. The CANFD_ERR_IPP.PFLIP1 bit field is for the parity flip pattern for byte 1.
4:0 (R/W)	PFLIP0	Parity Flip Pattern Byte 0. The CANFD_ERR_IPP.PFLIP0 bit field is for the parity flip pattern for byte 0 (least significant).

Error Status Register

The CANFD_ERR_STAT register holds the status bits of the error correction and detection operations. Clear these flags by writing them with a one. Writing a zero to the flags has no effect.

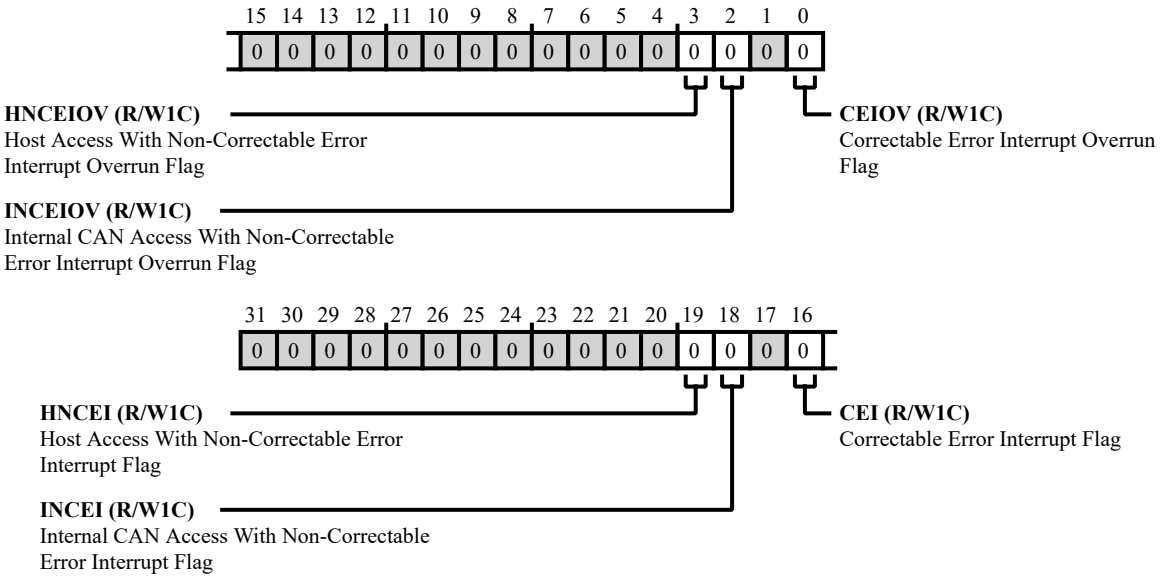

Figure 16-25: CANFD_ERR_STAT Register Diagram

Table 16-43: CANFD_ERR_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
19 (R/W1C)	HNCEI	Host Access With Non-Correctable Error Interrupt Flag. The CANFD_ERR_STAT.HNCEI bit indicates if a non-correctable error is detected in a host access. If the CANFD_ERR_STAT.HNCEI bit is set, a non-correctable error was detected in a memory read initiated by the host. A bus transfer error is asserted for that access. If the CANFD_MEC.HNCIMSK bit is set, the interrupt is asserted. If the CANFD_ERR_STAT.HNCEI bit is cleared, no non-correctable errors were detected in host accesses so far.	
		0	No Non-Correctable Error Detected
		1	Non-Correctable Error Detected

Table 16-43: CANFD_ERR_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
18 (R/W1C)	INCEI	Internal CAN Access With Non-Correctable Error Interrupt Flag. The CANFD_ERR_STAT.INCEI bit indicates if a non-correctable error is detected in a CAN access. If the CANFD_ERR_STAT.INCEI bit is set, a non-correctable error was detected in a memory read initiated by a CANFD internal process. A bus transfer error is asserted for that access. If the CANFD_MEC.INCEMSK bit is set, the interrupt is asserted. If the CANFD_ERR_STAT.INCEI bit is cleared, no non-correctable errors were detected in CAN accesses so far.	
		0	No Non-Correctable Error Detected
		1	Non-Correctable Error Detected
16 (R/W1C)	CEI	Correctable Error Interrupt Flag. The CANFD_ERR_STAT.CEI bit indicates if a correctable error is detected. If the CANFD_ERR_STAT.CEI bit is set, a correctable error was detected in a memory read. If the CANFD_MEC.CEIMSK bit is set, the interrupt is asserted. If the CANFD_ERR_STAT.CEI bit is cleared, no correctable errors were detected so far.	
		0	No Correctable Error Detected
		1	Correctable Error Detected
3 (R/W1C)	HNCEIOV	Host Access With Non-Correctable Error Interrupt Overrun Flag. The CANFD_ERR_STAT.HNCEIOV bit indicates if an overrun on non-correctable error is detected in a host access. If the CANFD_ERR_STAT.HNCEIOV bit is set, a non-correctable error was detected in a memory read initiated by the host when the CANFD_ERR_STAT.HNCEI bit is set. No interrupt is associated with this flag. If the CANFD_ERR_STAT.HNCEIOV bit is cleared, no overrun on non-correctable errors were detected in a host access.	
		0	No Overrun Detected
		1	Overrun Detected

Table 16-43: CANFD_ERR_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W1C)	INCEIOV	Internal CAN Access With Non-Correctable Error Interrupt Overrun Flag. The `CANFD_ERR_STAT.INCEIOV` bit indicates if an overrun on non-correctable error is detected in a CAN access. If the `CANFD_ERR_STAT.INCEIOV` bit is set, a non-correctable error was detected in a memory read initiated by a CANFD internal process when the `CANFD_ERR_STAT.INCEI` bit is set. No interrupt is associated with this flag. If the `CANFD_ERR_STAT.INCEIOV` bit is cleared, no overrun on non-correctable errors were detected in a CAN access.	
		0	No Overrun Detected
		1	Overrun Detected
0 (R/W1C)	CEIOV	Correctable Error Interrupt Overrun Flag. The `CANFD_ERR_STAT.CEIOV` bit indicates if an overrun on correctable errors is detected. If the `CANFD_ERR_STAT.CEIOV` bit is set, a overrun on a correctable error was detected in a memory read while the `CANFD_ERR_STAT.CEI` bit was set. No interrupt is associated with this flag. If the `CANFD_ERR_STAT.CEIOV` bit is cleared, no overrun on correctable errors were detected.	
		0	No Overrun Detected
		1	Overrun Detected

Error and Status 1 Register

The CANFD_ESR1 register reports various error conditions detected in the reception and transmission of a CAN frame, some general status of the device, and is the source of some interrupts to the processor.

The reported error conditions are:

• CANFD_ESR1.B1ERR, CANFD_ESR1.B0ERR, CANFD_ESR1.ACKERR, CANFD_ESR1.CRCERR, CANFD_ESR1.FRMERR, and CANFD_ESR1.STFERR, for errors detected in CAN frames of any format.

• CANFD_ESR1.B1ERRF, CANFD_ESR1.B0ERRF, CANFD_ESR1.CRCERRF, CANFD_ESR1.FRMERRF, and CANFD_ESR1.STFERRF for errors detected in the data phase of CAN FD frames with the BRS bit set.

An error detected in a single CAN frame is reported by one or more error flags. Error reporting is cumulative in case additional error events occur in subsequent frames before the processor reads the CANFD_ESR1 register.

CANFD_ESR1.TXWRN, CANFD_ESR1.RXWRN, CANFD_ESR1.IDLE, CANFD_ESR1.TXINPROG, CANFD_ESR1.FLTCONF, CANFD_ESR1.RXINPROG, and CANFD_ESR1.SYNC are status bits.

CANFD_ESR1.BOFFINT, CANFD_ESR1.BOFFDONEINT, CANFD_ESR1.ERRINT, CANFD_ESR1.ERRINTF, CANFD_ESR1.WAKINT,CANFD_ESR1.TXWRNINT, and CANFD_ESR1.RXWRNINT are interrupt bits. When servicing interrupt requests generated by these bits use the following procedure:

• Read the CANFD_ESR1 register to capture all error condition and status bits. This action clears the respective bits set since the last read access.

• Write 1 to clear the interrupt bit that triggered the interrupt request.

• Write 1 to clear the CANFD_ESR1.ERROVR bit if it is set.

Starting from all error flags cleared, a first error event sets either the CANFD_ESR1.ERRINT or the CANFD_ESR1.ERRINTF bits (provided the corresponding mask bit is asserted). If other error events in subsequent frames occur before the processor services the interrupt request, the CANFD_ESR1.ERROVR bit is set to indicate that errors from different frames have accumulated.

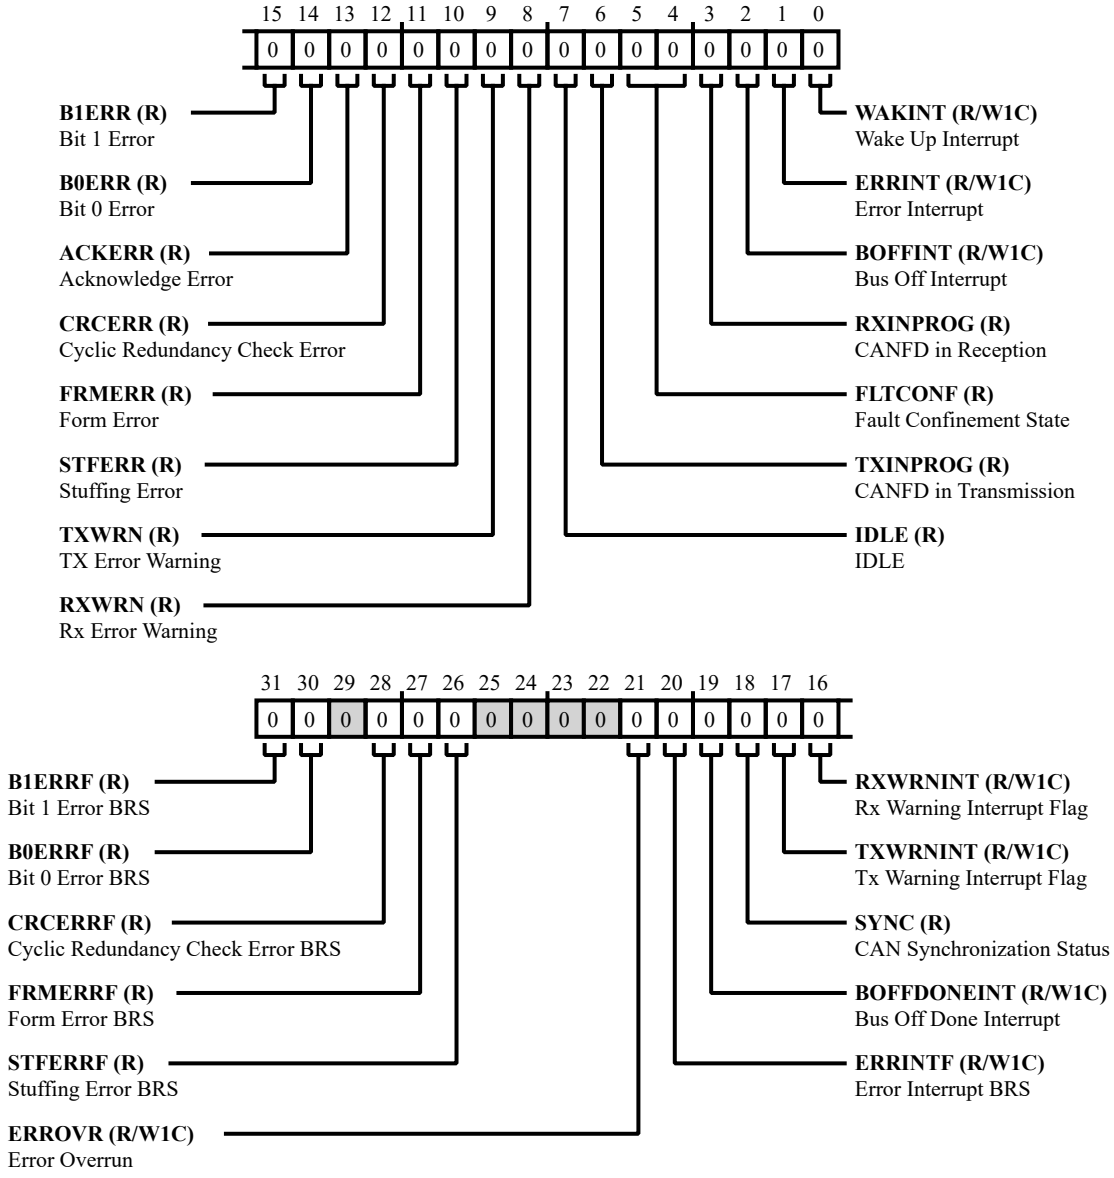

Figure 16-26: CANFD_ESR1 Register Diagram

Table 16-44: CANFD_ESR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/NW)	B1ERRF	Bit 1 Error BRS. The CANFD_ESR1.B1ERRF bit indicates when an inconsistency occurs between the transmitted and the received bit in the data phase of CAN FD frames with the BRS bit set. When the CANFD_ESR1.B1ERRF bit is enabled, at least one bit sent as recessive is received as dominant. When the bit is disabled, there is no such occurrence.	
		0	Disable
		1	Enable
30 (R/NW)	B0ERRF	Bit 0 Error BRS. The CANFD_ESR1.B0ERRF bit indicates when an inconsistency occurs between the transmitted and the received bit in the data phase of CAN FD frames with the BRS bit set. When the CANFD_ESR1.B0ERRF bit is enabled, at least one bit sent as recessive is received as dominant. When the bit is disabled, there is no such occurrence.	
		0	Disable
		1	Enable
28 (R/NW)	CRCERRF	Cyclic Redundancy Check Error BRS. The CANFD_ESR1.CRCERRF bit indicates if a CRC error is detected by the receiver node in the CRC field of CAN FD frames with the BRS bit set. The calculated CRC is different from the received CRC. When the CANFD_ESR1.CRCERRF bit is enabled, a CRC error occurred since the last read of the register. When the bit is disabled, there is no such occurrence.	
		0	Disable
		1	Enable
27 (R/NW)	FRMERRF	Form Error BRS. The CANFD_ESR1.FRMERRF bit indicates that a form error is detected by the receiver node in the data phase of CAN FD frames with the BRS bit set. A fixed-form bit field contains at least one illegal bit. When the CANFD_ESR1.FRMERRF bit is enabled, a form error occurred since the last read of the register. When the bit is disabled, there is no such occurrence.	
		0	Disable
		1	Enable

Table 16-44: CANFD_ESR1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
26 (R/NW)	STFERRF	Stuffing Error BRS. The CANFD_ESR1.STFERRF bit indicates that a stuffing error is detected in the data phase of CAN FD frames with the BRS bit set. When the CANFD_ESR1.STFERRF bit is enabled, a stuffing error occurred since the last read of the register. When the bit is disabled, there is no such occurrence.	
		0	Disable
		1	Enable
21 (R/W1C)	ERROVR	Error Overrun. The CANFD_ESR1.ERROVR bit indicates that an error condition occurred when any error flag is already set. When the CANFD_ESR1.ERROVR bit is enabled an overrun has occurred. When it is disabled, an overrun has not occurred. Clear the CANFD_ESR1.ERROVR bit by writing a one to it.	
		0	Disable
		1	Enable
20 (R/W1C)	ERRINTF	Error Interrupt BRS. The CANFD_ESR1.ERRINTF bit indicates an error interrupt is detected in the data phase of CAN FD frames with the BRS bit set. When the CANFD_ESR1.ERRINTF bit is enabled it indicates setting the of any error bit detected in the data phase of CAN FD frames with the BRS bit set. When it is disabled, there is no such occurrence. The CANFD_ESR1.ERRINTF bit indicates that at least one of the error bits detected in the data phase of CAN FD frames with the BRS bit set (CANFD_ESR1.B1ERRF, CANFD_ESR1.B0ERRF, CANFD_ESR1.CRCERRF, CANFD_ESR1.FRMERRF, or CANFD_ESR1.STFERRF) is set. If the CANFD_CTL2.ERRMSKF is set, an interrupt is generated to the processor. Clear the CANFD_ESR1.ERRINTF bit by writing a one to it. Writing a zero has no effect.	
		0	Disable
		1	Enable

Table 16-44: CANFD_ESR1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
19 (R/W1C)	BOFFDONEINT	Bus Off Done Interrupt. When the CANFD_ESR1.BOFFDONEINT bit is enabled it indicates the CANFD module has completed the bus off process. When it is disabled, there is no such occurrence. The CANFD_ESR1.BOFFDONEINT bit is set when the Tx Error Counter (CANFD_ECR.TXERRCNT) finishes counting 128 occurrences of 11 consecutive recessive bits on the CAN bus and is ready to leave bus off mode. If the CANFD_CTL2.BOFFDONEIMSK is set, an interrupt is generated to the processor. Clear the CANFD_ESR1.BOFFDONEINT bit by writing a one to it. Writing a zero has no effect.	
		0	Disable
		1	Enable
18 (R/NW)	SYNC	CAN Synchronization Status. The CANFD_ESR1.SYNC bit is a read-only flag that indicates whether the CANFD module is synchronized to the CAN bus and able to participate in the communication process. It is set and cleared by the CANFD module. When the CANFD_ESR1.SYNC bit is enabled, the CANFD module is synchronized to the CAN bus. When it is disabled, the CANFD module is not synchronized to the CAN bus.	
		0	Disable
		1	Enable

Table 16-44: CANFD_ESR1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W1C)	TXWRNINT	Tx Warning Interrupt Flag. When the CANFD_ESR1.TXWRNINT bit is enabled, the Tx error counter transitioned from less than 96 to greater than or equal to 96. When the bit is disabled, there is no such occurrence. If the CANFD_CFG.WRNEN bit is enabled, the CANFD_ESR1.TXWRNINT bit is set when the CANFD_ESR1.TXWRN bit transitions from 0 to 1, meaning that the Tx error counter reached 96. If the CANFD_CTL1.TWRNMSK bit is set, an interrupt is generated to the processor. The CANFD_ESR1.TXWRNINT bit is cleared by writing a one to it. Writing a zero has no effect. When the CANFD_CFG.WRNEN bit is disabled, the CANFD_ESR1.TXWRNINT flag is masked. The processor must clear the CANFD_ESR1.TXWRNINT flag before disabling the CANFD_CFG.WRNEN bit or the CANFD_ESR1.TXWRNINT bit will be set when the CANFD_CFG.WRNEN bit is enabled again. The CANFD_ESR1.TXWRNINT bit is not generated during the bus off state and is not updated during freeze mode. When the CANFD module returns to normal mode from pretended networking mode, the CANFD_ESR1.TXWRNINT bit does not update.	
		0	Disable
		1	Enable
16 (R/W1C)	RXWRNINT	Rx Warning Interrupt Flag. When the CANFD_ESR1.RXWRNINT bit is enabled, it indicates that the Rx error counter transitioned from less than 96 to greater than or equal to 96. When the bit is disabled, there is no such occurrence. If the CANFD_CFG.WRNEN bit is enabled, the CANFD_ESR1.RXWRNINT bit is set when the CANFD_ESR1.RXWRN bit transitions from 0 to 1, meaning that the Rx error counter reached 96. If the CANFD_CTL1.RWRNMSK bit is set, an interrupt is generated to the processor. The CANFD_ESR1.RXWRNINT bit is cleared by writing a one to it. Writing a zero has no effect. When the CANFD_CFG.WRNEN bit is disabled, the CANFD_ESR1.RXWRNINT flag is masked. The processor must clear the CANFD_ESR1.RXWRNINT flag before disabling the CANFD_CFG.WRNEN bit or the CANFD_ESR1.RXWRNINT bit will be set when the CANFD_CFG.WRNEN bit is enabled again. The CANFD_ESR1.RXWRNINT bit is not updated during freeze mode. When the CANFD module returns to normal mode from pretended networking mode, the CANFD_ESR1.RXWRNINT bit does not update to reflect the Rx error counter state.	
		0	Disable
		1	Enable

Table 16-44: CANFD_ESR1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/NW)	B1ERR	Bit 1 Error. The CANFD_ESR1.B1ERR bit indicates when an inconsistency occurs between the transmitted and the received bit in a non-CAN FD message or in the arbitration or data phase of a CAN FD message. When the CANFD_ESR1.B1ERR bit is enabled, at least one bit sent as recessive is received as dominant. When the bit is disabled, there is no such occurrence. The CANFD_ESR1.B1ERR bit updates when the CANFD module returns to normal mode from pretended networking mode. Note that the CANFD_ESR1.B1ERR bit is not set by a transmitter in case of arbitration field or ACK slot, or in case of a node sending a passive error flag that detects dominant bits.	
		0	Disable
		1	Enable
14 (R/NW)	B0ERR	Bit 0 Error. The CANFD_ESR1.B0ERR bit indicates when an inconsistency occurs between the transmitted and the received bit in a non-CAN FD message or in the arbitration or data phase of a CAN FD message. When the CANFD_ESR1.B0ERR bit is enabled, at least one bit sent as recessive is received as dominant. When the bit is disabled, there is no such occurrence. The CANFD_ESR1.B0ERR bit updates when the CANFD module returns to normal mode from pretended networking mode.	
		0	Disable
		1	Enable
13 (R/NW)	ACKERR	Acknowledge Error. The CANFD_ESR1.ACKERR bit indicates an acknowledge error is detected by the transmitter node (a dominant bit detected during the ACK SLOT) When the CANFD_ESR1.ACKERR bit is enabled an ACK error occurred since the last read of this register.When the bit is disabled, there is no such occurrence. The CANFD_ESR1.ACKERR bit updates when the CANFD module returns to normal mode from pretended networking mode.	
		0	Disable
		1	Enable

Table 16-44: CANFD_ESR1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/NW)	CRCERR	Cyclic Redundancy Check Error. The CANFD_ESR1.CRCERR bit indicates if a CRC error is detected by the receiver node in a non-FD message or in the arbitration or data phase of a frame in CAN FD format (the calculated CRC is different from the received CRC) When the CANFD_ESR1.CRCERR bit is enabled, a CRC error occurred since the last read of the register. When the bit is disabled, there is no such occurrence. The CANFD_ESR1.CRCERR bit updates when the CANFD module returns to normal mode from pretended networking mode.	
		0	Disable
		1	Enable
11 (R/NW)	FRMERR	Form Error. The CANFD_ESR1.FRMERR bit indicates that a form error is detected by the receiver node in a non-FD message or in a CAN FD message in the arbitration or data phase. A fixed-form bit field contains at least one illegal bit. When the CANFD_ESR1.FRMERR bit is enabled, a form error occurred since the last read of the register. When the bit is disabled, there is no such occurrence. The CANFD_ESR1.FRMERR bit updates when the CANFD module returns to normal mode from pretended networking mode.	
		0	Disable
		1	Enable
10 (R/NW)	STFERR	Stuffing Error. The CANFD_ESR1.STFERR bit indicates that a stuffing error is detected by the receiver node in a non-FD message or in a CAN FD message in the arbitration or data phase. When the CANFD_ESR1.STFERR bit is enabled, a stuffing error occurred since the last read of the register. When the bit is disabled, there is no such occurrence. The CANFD_ESR1.STFERR bit updates when the CANFD module returns to normal mode from pretended networking mode.	
		0	Disable
		1	Enable

Table 16-44: CANFD_ESR1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/NW)	TXWRN	TX Error Warning. The CANFD_ESR1.TXWRN bit indicates when repetitive errors are occurring during message transmission. When the CANFD_ESR1.TXWRN bit is enabled, the CANFD_ECR.TXERRCNT value is greater than or equal to 96. When it is disabled, there is no such occurrence. The CANFD_ESR1.TXWRN bit is only affected by the CANFD_ECR.TXERRCNT value. It does not update during freeze mode.	
		0	Disable
		1	Enable
8 (R/NW)	RXWRN	Rx Error Warning. The CANFD_ESR1.RXWRN bit indicates when repetitive errors are occurring during message transmission. When the CANFD_ESR1.RXWRN bit is enabled, the CANFD_ECR.TXERRCNT value is greater than or equal to 96. When it is disabled, there is no such occurrence. The CANFD_ESR1.RXWRN bit is only affected by the CANFD_ECR.RXERRCNT value. It does not update during freeze mode. It updates when the CANFD returns to normal mode from pretended networking mode.	
		0	Disable
		1	Enable
7 (R/NW)	IDLE	IDLE. The CANFD_ESR1.IDLE bit indicates when the CAN bus is in the IDLE state. When the CANFD_ESR1.IDLE bit is enabled, the CAN bus is IDLE. When it is disabled, there is no such occurrence.	
		0	Disable
		1	Enable
6 (R/NW)	TXINPROG	CANFD in Transmission. The CANFD_ESR1.TXINPROG bit indicates if the CANFD module is transmitting a message. When the CANFD_ESR1.TXINPROG bit is enabled, the CANFD module is transmitting a message. When it is disabled, the CANFD module is not transmitting a message.	
		0	Disable
		1	Enable

Table 16-44: CANFD_ESR1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5:4 (R/NW)	FLTCONF	Fault Confinement State. The CANFD_ESR1.FLTCONF bit field indicates the fault confinement state of the CANFD module. If the CANFD_CTL1.LOMEN bit is enabled, after some delay that depends on the CAN bit timing, the CANFD_ESR1.FLTCONF bit field will indicate the error passive state. The same delay affects how the CANFD_ESR1.FLTCONF bit field reflects an update to the CANFD_ECR register by the processor. It may take up to one CAN bit time to get them coherent again. The CANFD_ESR1.FLTCONF bit field is affected by soft reset. However, if the CANFD_CTL1.LOMEN bit is enabled, the CANFD_ESR1.FLTCONF reset value lasts just one CAN bit. After this time, the CANFD_ESR1.FLTCONF bit field indicates the error passive state.	
		0	Error Active
		1	Error Passive
		2	Bus Off
		3	Bus Off
3 (R/NW)	RXINPROG	CANFD in Reception. The CANFD_ESR1.RXINPROG bit indicates if the CANFD module is receiving a message. When the CANFD_ESR1.RXINPROG bit is enabled the CANFD module is receiving a message and when it is disabled the CANFD module is not receiving a message.	
		0	Disable
		1	Enable
2 (R/W1C)	BOFFINT	Bus Off Interrupt. The CANFD_ESR1.BOFFINT bit is enabled when the CANFD module enters the bus off state. If the corresponding mask bit (CAN_CTRL1.BOFFMSK) is set, an interrupt is generated to the processor. When the CANFD_ESR1.BOFFINT bit is disabled, there is no such occurrence. The CANFD_ESR1.BOFFINT bit is cleared by writing one to it. Writing zero has no effect.	
		0	Disable
		1	Enable

Table 16-44: CANFD_ESR1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W1C)	ERRINT	Error Interrupt. The CANFD_ESR1.ERRINT bit indicates that at least one of the error bits (CANFD_ESR1.B1ERR, CANFD_ESR1.B0ERR, CANFD_ESR1.CRCERR, CANFD_ESR1.FRMERR, or CANFD_ESR1.STFERR) is set. If the corresponding mask bit (CANFD_CTL1.ERRMSK) is set, an interrupt is generated to the processor. The CANFD_ESR1.ERRINT bit is cleared by writing a one to it. Writing a zero has no effect.	
		0	Disable
		1	Enable
0 (R/W1C)	WAKINT	Wake Up Interrupt. The CANFD_ESR1.WAKINT bit applies when the CANFD module is in low-power mode under a self wake up mechanism (doze or stop mode). When the CANFD_ESR1.WAKINT bit is enabled it indicates a recessive-to-dominant transition was received on the CAN bus. When a recessive-to-dominant transition is detected on the CAN bus and the CANFD_CFG.WAKMSK bit is set, an interrupt is generated to the processor. This bit is cleared by writing it to one. When the bit is disabled, there is no such occurrence. When the CANFD_CFG.SLFWAKEN bit is disabled, the CANFD_ESR1.WAKINT flag is masked. The processor must clear the CANFD_ESR1.WAKINT flag before disabling the CANFD_CFG.SLFWAKEN bit. Otherwise, he CANFD_ESR1.WAKINT is set when the CANFD_CFG.SLFWAKEN bit is set again. Writing zero has no effect. The CANFD_ESR1.WAKINT bit is cleared by writing one to it. Writing zero has no effect.	
		0	Disable
		1	Enable

Error and Status 2 Register

The CANFD_ESR2 register reports general status information.

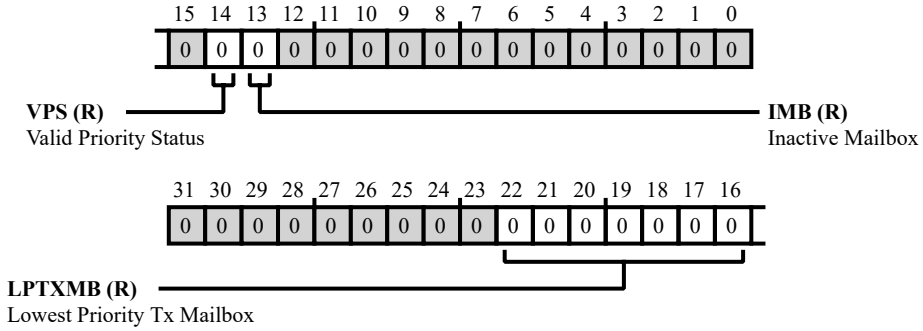

Figure 16-27: CANFD_ESR2 Register Diagram

Table 16-45: CANFD_ESR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
22:16 (R/NW)	LPTXMB	Lowest Priority Tx Mailbox. If the CANFD_ESR2.VPS bit is set, the CANFD_ESR2.LPTXMB bit field indicates the lowest number inactive mailbox, per the CANFD_ESR2.IMB bit. If there is no inactive mailbox, then the mailbox indicated depends on the CANFD_CTL1.LBUF bit value. If the CANFD_CTL1.LBUF bit bit is cleared, the mailbox indicated is the one that has the greatest arbitration value. If the CANFD_CTL1.LBUF bit bit is set, the mailbox indicated is the highest number active Tx mailbox. If a Tx mailbox is being transmitted, it is not considered in the CANFD_ESR2.LPTXMB bit field calculation. If the CANFD_ESR2.IMB bit is not set and a frame is transmitted successfully, the CANFD_ESR2.LPTXMB bit field is updated with the mailbox number.

Table 16-45: CANFD_ESR2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/NW)	VPS	Valid Priority Status. The CANFD_ESR2.VPS bit indicates whether the CANFD_ESR2.IMB and CANFD_ESR2.LPTXMB contents are currently valid. If the CANFD_ESR2.VPS bit is set, the contents of the CANFD_ESR2.IMB and CANFD_ESR2.LPTXMB bits are valid. If the bit is cleared, the contents of the CANFD_ESR2.IMB and CANFD_ESR2.LPTXMB bits are invalid. The CANFD_ESR2.VPS bit is set upon every complete Tx arbitration process unless the processor writes to the C/S word of a mailbox that has already been scanned (is behind Tx Arbitration Pointer during the Tx arbitration process). If there is no inactive mailbox and only one Tx mailbox that is being transmitted, then the CANFD_ESR2.VPS bit is not set. The CANFD_ESR2.VPS bit is cleared upon the start of every Tx arbitration process or upon a write to the C/S word of any mailbox. Note that the CANFD_ESR2.VPS bit is not affected by any processor write into the C/S of a MB that is blocked by the abort mechanism. When the CANFD_CFG.ABORTEN bit is set, the abort code write into the C/S of an MB that is being transmitted (pending abort), or any write attempt into a Tx MB with the interrupt flag set is blocked.
13 (R/NW)	IMB	Inactive Mailbox. If the CANFD_ESR2.VPS bit is set, the CANFD_ESR2.IMB bit indicates whether there is any inactive mailbox (CODE field is either 0b1000 or 0b0000). If the CANFD_ESR2.IMB bit is set and the CANFD_ESR2.VPS bit is set and there is at least one inactive mailbox. The CANFD_ESR2.LPTXMB bit field content is the number of the first one. If the CANFD_ESR2.IMB bit is cleared and the CANFD_ESR2.VPS bit is set, the CANFD_ESR2.LPTXMB bit field is not an inactive mailbox. The CANFD_ESR2.IMB bit is set during arbitration, if a CANFD_ESR2.LPTXMB value is found and it is inactive. The CANFD_ESR2.IMB bit is also set if CAN_ESR2.MB is not set and a frame is transmitted successfully. The CANFD_ESR2.IMB bit is cleared at the start of arbitration. Note that if an MB is successfully transmitted and The CANFD_ESR2.IMB bit is zero (no inactive mailbox), then the CANFD_ESR2.VPS and CANFD_ESR2.IMB bits are set and the index related to the MB just transmitted is loaded into the CANFD_ESR2.LPTXMB bit field.

CANFD Bit Timing Register

The CANFD_FD_TIMING register stores the CAN bit timing variables for use in the data phase of CAN FD messages when the CANFD_FD_CTL.BRSEN bit is set, compatible with CAN FD specification. The CANFD_FD_TIMING.FPRESDIV, CANFD_FD_TIMING.FPROPSEG, CANFD_FD_TIMING.FPSEG1, CANFD_FD_TIMING.FPSEG2, and CANFD_FD_TIMING.FRJW bit fields define the time quantum duration, the number of time quanta per CAN bit, and the sample point position for the data bit rate portion of a CAN FD message with the BRS bit set.

The contents of the CANFD_FD_TIMING register are not affected by soft reset.

Note that the sum of values in the CANFD_FD_TIMING.FPROPSEG and CANFD_FD_TIMING.FPSEG1 bit fields must be at least two time quanta.

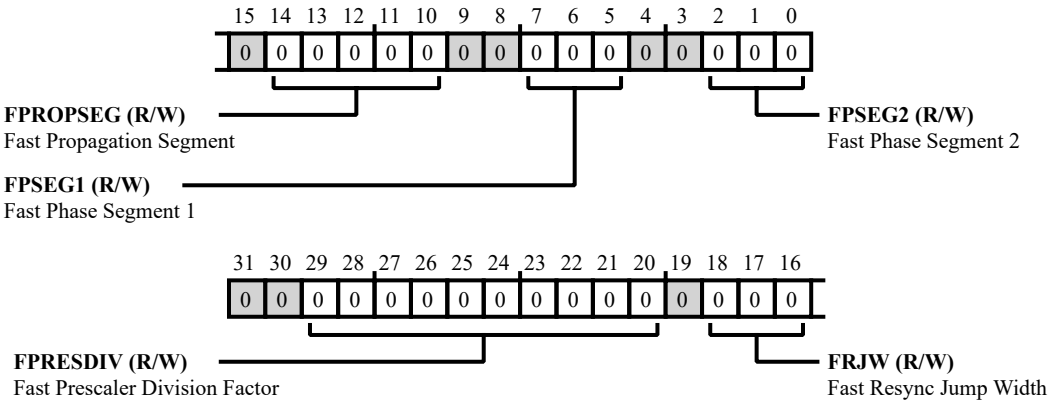

Figure 16-28: CANFD_FD_TIMING Register Diagram

Table 16-46: CANFD_FD_TIMING Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:20 (R/W)	FPRESDIV	Fast Prescaler Division Factor. The CANFD_FD_TIMING.FPRESDIV bit field defines the ratio between the PE clock frequency and the Serial Clock (Sclock) frequency. This is in the data bit rate portion of a CAN FD message with the BRS bit set. The Sclock period defines the time quantum of the CAN FD protocol for the data bit rate. Sclock frequency = PE clock frequency / (FPRESDIV + 1). To minimize errors when processing FD frames, use the same value for the CANFD_FD_TIMING.FPRESDIV and CANFD_CTL1.PRESDIV bit fields The CANFD_FD_TIMING.FPRESDIV bit field can only be written in freeze mode and is blocked by hardware in other modes.

Table 16-46: CANFD_FD_TIMING Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
18:16 (R/W)	FRJW	Fast Resync Jump Width. The `CANFD_FD_TIMING.FRJW` bit field defines the maximum number of time quanta that a bit time can be changed by one re-synchronization. This is in the data bit rate portion of a CAN FD message with the BRS bit set. Resync Jump Width = FSJW + 1. One time quantum is equal to the Sclock period. The `CANFD_FD_TIMING.FRJW` bit field can only be written in freeze mode and is blocked by hardware in other modes.
14:10 (R/W)	FPROPSEG	Fast Propagation Segment. The `CANFD_FD_TIMING.FPROPSEG` bit field defines the length of the propagation segment in the bit time. This is in the data bit rate portion of a CAN FD message with the BRS bit set. Propagation Segment Time = FPROPSEG x Time-Quanta One time quantum is equal to the Sclock period. The `CANFD_FD_TIMING.FPROPSEG` bit field can only be written in freeze mode and is blocked by hardware in other modes.
7:5 (R/W)	FPSEG1	Fast Phase Segment 1. The `CANFD_FD_TIMING.FPSEG1` bit field defines the length of phase segment 1 in the bit time. This is in the data bit rate portion of a CAN FD message with the BRS bit set. Phase Segment 1 = (FPSEG1 + 1) x Time-Quanta One time quantum is equal to the Sclock period. FPSEG1 can be written only in Freeze mode because it is blocked by hardware in other modes.
2:0 (R/W)	FPSEG2	Fast Phase Segment 2. The `CANFD_FD_TIMING.FPSEG2` bit field defines the length of phase segment 2. This is in the data bit rate portion of a CAN FD message with the BRS bit set. Phase Segment 2 = (FPSEG2 + 1) x Time-Quanta One time quantum is equal to the Sclock period. FPSEG1 can be written only in Freeze mode because it is blocked by hardware in other modes.

CANFD CRC Register

The CANFD_FD_CRC register provides information about the CRC of transmitted messages. The CANFD module uses different CRC polynomials for different frame formats as follows:

- The CRC_15 polynomial is used for all frames in CAN format.
- The CRC_17 polynomial is used for frames in CAN FD format with a data field up to sixteen bytes.
- The CRC_21 polynomial is used for frames in CAN FD format with a data field longer than sixteen bytes.

Each polynomial shown below results in a Hamming distance of 6. The CANFD_FD_CRC register updates when the Tx interrupt flag is asserted.

CRC_15 = 0xC599:$(x^{15}+x^{14}+x^{10}+x^{8}+ x^{7}+x^{4}+x^{3}+1)$

CRC_17 = 0x3685B:$(x^{17}+x^{16}+x^{14}+x^{13}+x^{11}+x^{6}+x^{4}+x^{3}+x^{1}+1)$

CRC_21 = 0x302899:$(x^{21}+x^{20}+x^{13}+x^{11}+x^{7}+x^{4}+x^{3}+1)$

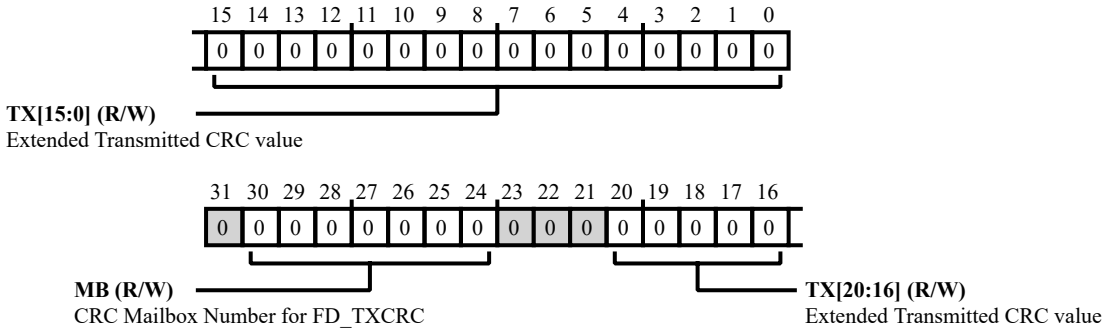

Figure 16-29: CANFD_FD_CRC Register Diagram

Table 16-47: CANFD_FD_CRC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
30:24 (R/W)	MB	CRC Mailbox Number for FD_TXCRC. The CANFD_FD_CRC.MB bit field indicates the number of the mailbox corresponding to the value in the FD_TXCRC field, for both FD and non-FD frames.

Table 16-47: CANFD_FD_CRC Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
20:0 (R/W)	TX	Extended Transmitted CRC value. The `CANFD_FD_CRC.TX` bit field contains the CRC value calculated over the most recent transmitted message. There are different CRC polynomials for different frame formats. All frames in CAN format use a 15-bit polynomial, CRC_15. CRC_17 is for frames in CAN FD format with a data field up to sixteen bytes long. The 21-bit polynomial, CRC_21, is for frames in CAN FD format with a data field longer than sixteen bytes. For CRC_15 and CRC_17, the six most significant bits and the four most significant bits are reported as zeros, respectively. For CRC_15, this register has the same content as the `CANFD_CRC` register.

CANFD Control Register

The CANFD_FD_CTL register contains control bits for CAN FD operation. It also defines the data size of message buffers allocated in different partitions of RAM (memory blocks).

When 8 bytes of payload is selected, block R0 allocates MB0 to MB31 and block R1 allocates MB32 to MB63.

When more than 8 bytes of payload is selected, the maximum number of MBs in a block is limited as described as follows:

Payload Size => Maximum Number of Message Buffers per RAM Block

8 bytes => 32

16 bytes => 21

32 bytes => 12

64 bytes => 7

Note that one memory block fits exactly 32 MBs with 8 bytes payload. For the other options of payload sizes, empty memory may exist between last MB in a block and the beginning of the next block. This empty memory corresponds to less than one MB, and must not be used.

The contents of CANFD_FD_CTL register are not affected by soft reset.

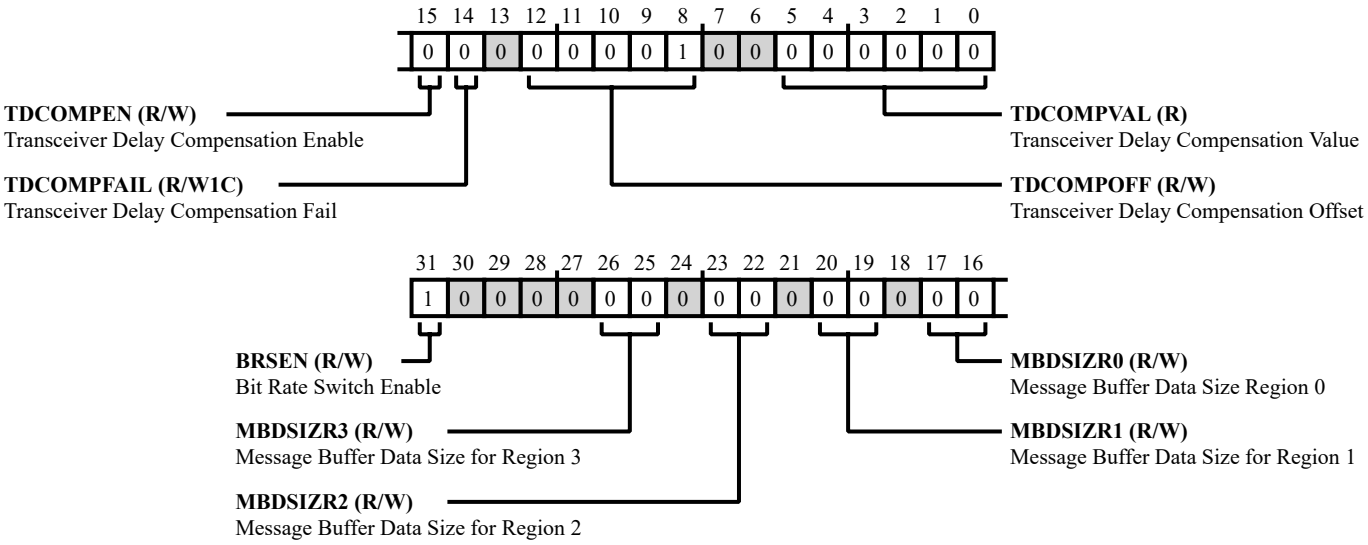

Figure 16-30: CANFD_FD_CTL Register Diagram

Table 16-48: CANFD_FD_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	BRSEN	Bit Rate Switch Enable. The CANFD_FD_CTL.BRSEN bit enables the effect of the bit rate switch (BRS) bit during the data phase of Tx messages. When the CANFD_FD_CTL.BRSEN bit is set, if the BRS bit in the Tx MB is recessive, the CANFD module transmits a frame with bit rate switching. When the CANFD_FD_CTL.BRSEN bit is clear, the BRS bit in the Tx MB has no effect and the CANFD module transmits a frame with the nominal rate. The processor can write the CANFD_FD_CTL.BRSEN bit any time, however, the effect only becomes active when the CAN bus is in the wait for bus idle, bus idle, bus off state, or when the current frame under reception or transmission reaches the inter-frame space. By negating the CANFD_FD_CTL.BRSEN bit, the processor can force all bits in CAN FD messages to be transmitted with a nominal bit rate, despite the value in the BRS bit of the Tx MBs.	
		0	Nominal Rate
		1	Bit Rate Switching
26:25 (R/W)	MBDSIZR3	Message Buffer Data Size for Region 3. The CANFD_FD_CTL.MBDSIZR3 field selects the data size for the region R3 of message buffers allocated in RAM. The CANFD_FD_CTL.MBDSIZR3 bit field can only be written in freeze mode.	
		0	8 bytes per message buffer
		1	16 bytes per message buffer
		2	32 bytes per message buffer
		3	64 bytes per message buffer
23:22 (R/W)	MBDSIZR2	Message Buffer Data Size for Region 2. The CANFD_FD_CTL.MBDSIZR2 field selects the data size for the region R2 of message buffers allocated in RAM. The CANFD_FD_CTL.MBDSIZR2 bit field can only be written in freeze mode.	
		0	8 bytes per message buffer
		1	16 bytes per message buffer
		2	32 bytes per message buffer
		3	64 bytes per message buffer

Table 16-48: CANFD_FD_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
20:19 (R/W)	MBDSIZR1	Message Buffer Data Size for Region 1. The CANFD_FD_CTL.MBDSIZR1 bit field selects the data size for the region R1 of message buffers allocated in RAM. The CANFD_FD_CTL.MBDSIZR1 bit field can only be written in freeze mode.	
		0	8 bytes per message buffer
		1	16 bytes per message buffer
		2	32 bytes per message buffer
		3	64 bytes per message buffer
17:16 (R/W)	MBDSIZR0	Message Buffer Data Size Region 0. The CANFD_FD_CTL.MBDSIZR0 bit field selects the data size for the region R0 of message buffers allocated in RAM. The CANFD_FD_CTL.MBDSIZR0 bit field can only be written in freeze mode.	
		0	8 bytes per message buffer
		1	16 bytes per message buffer
		2	32 bytes per message buffer
		3	64 bytes per message buffer
15 (R/W)	TDCOMPEN	Transceiver Delay Compensation Enable. The CANFD_FD_CTL.TDCOMPEN bit enables or disables the TDC feature. The CANFD_FD_CTL.TDCOMPEN bit can only be written in freeze mode. Note that when loop-back mode is enabled (CANFD_CTL1.LBEN), the CANFD_FD_CTL.TDCOMPEN bit must be disabled.	
		0	Disable
		1	Enable
14 (R/W1C)	TDCOMPFAIL	Transceiver Delay Compensation Fail. The CANFD_FD_CTL.TDCOMPFAIL bit indicates when the transceiver delay compensation (TDC) mechanism is out of range. When the TDC is out of range it is unable to compensate for the loop delay of the transceiver and successfully compare the delayed received bits to the transmitted ones. The CANFD_FD_CTL.TDCOMPFAIL bit is set the first time the CANFD module detects the out of range condition. To clear the CANFD_FD_CTL.TDCOMPFAIL bit, write a one to it.	
		0	Measured loop delay is in range
		1	Measured loop delay is out of range

Table 16-48: CANFD_FD_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
12:8 (R/W)	TDCOMPOFF	Transceiver Delay Compensation Offset. The `CANFD_FD_CTL.TDCOMPOFF` bit field contains the offset value that must be added to the loop delay of the measured transceiver. This defines the position of the delayed comparison point when bit rate switching is active. The `CANFD_FD_CTL.TDCOMPOFF` bit field can only be written in freeze mode. The bit field value is defined in PE clock periods and must be smaller than the CAN bit duration in the data bit rate. Do not set the `CANFD_FD_CTL.TDCOMPOFF` bit field to zero.
5:0 (R/NW)	TDCOMPVAL	Transceiver Delay Compensation Value. The `CANFD_FD_CTL.TDCOMPVAL` bit field contains the value of the transceiver loop delay measured from the transmitted EDL to R0 transition edge to the respective received one added to the value in the `CANFD_FD_CTL.TDCOMPOFF` bit field. This value is an integer multiple of the PE clock period.

Pretended Networking DLC Filter Register

The CANFD_FLTR_DLC register contains the DLC inside range target values (CANFD_FLTR_DLC.HI and CANFD_FLTR_DLC.LO) for filtering incoming messages. The DLC range is only for payload filtering. The CANFD_FLTR_DLC register can only be written in freeze mode.

Note that when a fixed quantity of data bytes is required, both the CANFD_FLTR_DLC.HI and CANFD_FLTR_DLC.LO bit fields must have the same value; otherwise, a range of DLC is considered for filtering.

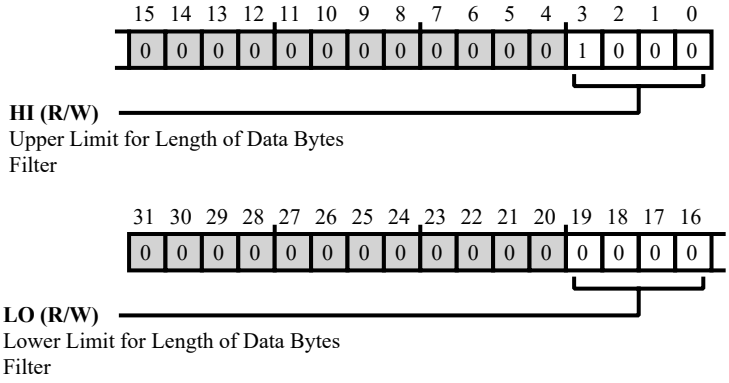

Figure 16-31: CANFD_FLTR_DLC Register Diagram

Table 16-49: CANFD_FLTR_DLC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19:16 (R/W)	LO	Lower Limit for Length of Data Bytes Filter. The CANFD_FLTR_DLC.LO bit field specifies the lower limit on the number of data bytes considered valid for payload comparison. The CANFD_FLTR_DLC.LO bit field is part of payload reception filter.
3:0 (R/W)	HI	Upper Limit for Length of Data Bytes Filter. The CANFD_FLTR_DLC.HI bit field specifies the upper limit on the number of data bytes considered valid for payload comparison. The CANFD_FLTR_DLC.HI bit field is part of payload reception filter.

Pretended Networking ID Filter1 Register

The CANFD_FLTR_ID1 register contains the FLT_ID1 target value and the IDE and RTR target values for filtering the incoming message ID. This register is for equal to, smaller than, greater than comparisons, or as the lower limit value in an ID range detection. The CANFD_FLTR_ID1 register is only written in freeze mode.

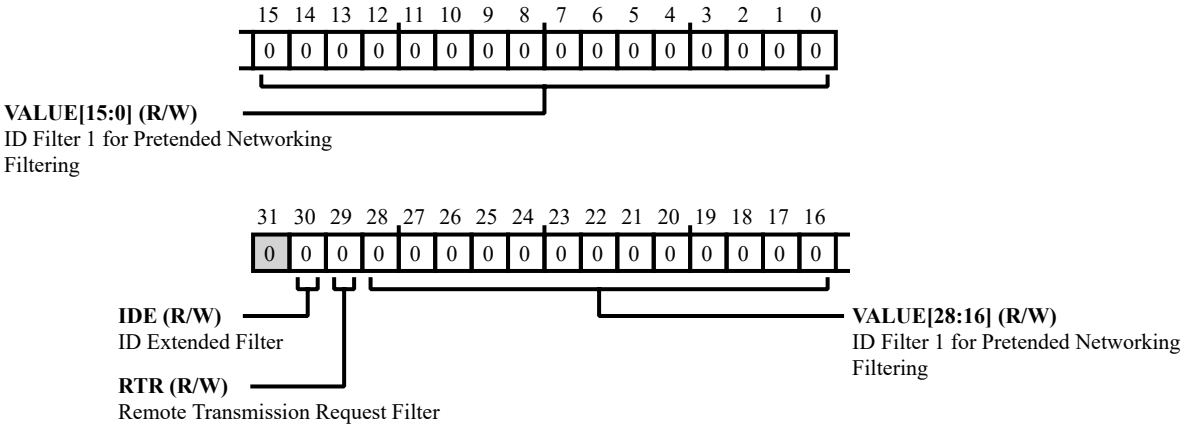

Figure 16-32: CANFD_FLTR_ID1 Register Diagram

Table 16-50: CANFD_FLTR_ID1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
30 (R/W)	IDE	ID Extended Filter. The CANFD_FLTR_ID1.IDE bit identifies if the frame format is standard or extended. It is part of the ID reception filter.	
		0	Accept Standard Frame Format
		1	Accept Extended Frame Format
29 (R/W)	RTR	Remote Transmission Request Filter. The CANFD_FLTR_ID1.RTR bit identifies if the frame is remote. It is part of the ID reception filter.	
		0	Reject remote frame (accept data frame)
		1	Accept remote frame
28:0 (R/W)	VALUE	ID Filter 1 for Pretended Networking Filtering. The CANFD_FLTR_ID1.VALUE bit field defines either the 29 bits of a extended frame format, considering all bits, or the 11 bits of a standard frame format, considering just the 11 leftmost bits.	

Pretended Networking ID Filter2 / IDMask Register

The CANFD_FLTR_ID2_IDMSK register contains the FLT_ID2 target value for use as the upper limit value in ID range detection. When exact ID filtering criteria is selected, the CANFD_FLTR_ID2_IDMSK register is also for storing the ID mask. The CANFD_FLTR_ID2_IDMSK.IDE and CANFD_FLTR_ID2_IDMSK.RTR bits are for ID filtering (exact and range) as part of the ID reception filter.

The CANFD_FLTR_ID2_IDMSK register can only be written in freeze mode.

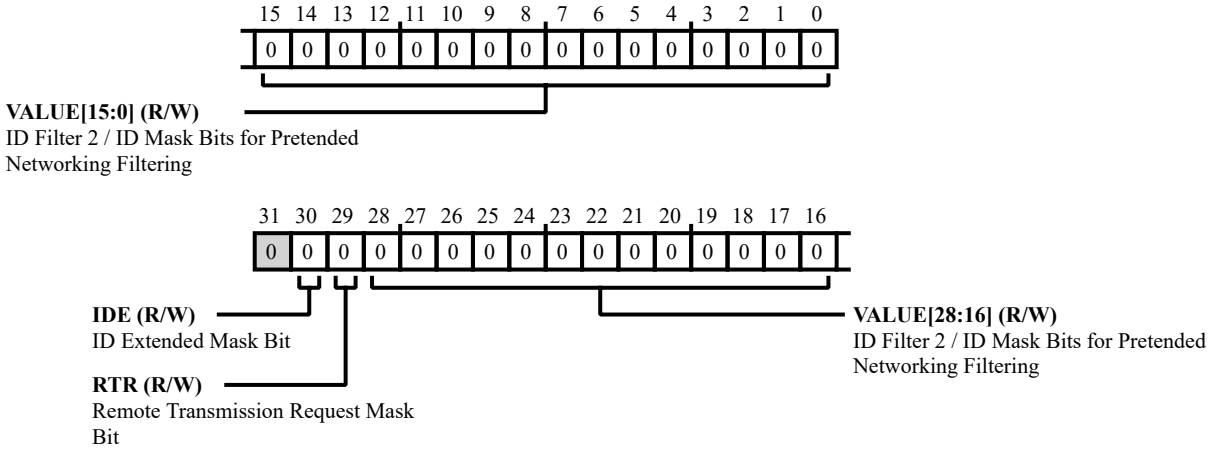

Figure 16-33: CANFD_FLTR_ID2_IDMSK Register Diagram

Table 16-51: CANFD_FLTR_ID2_IDMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
30 (R/W)	IDE	ID Extended Mask Bit. The CANFD_FLTR_ID2_IDMSK.IDE bit indicates whether the frame format (standard/extended) is used as part of the ID reception filter. If the CANFD_FLTR_ID2_IDMSK.IDE bit is set, the corresponding bit in the filter is checked. If it is cleared, the corresponding bit in the filter is a don't care.	
		0	Don't Care
		1	Checked
29 (R/W)	RTR	Remote Transmission Request Mask Bit. The CANFD_FLTR_ID2_IDMSK.RTR bit indicates if the frame type (data/remote) is part of the ID reception filter. If the CANFD_FLTR_ID2_IDMSK.RTR bit is set, the corresponding bit in the filter is checked. If it is cleared, the corresponding bit in the filter is a don't care.	
		0	Don't Care
		1	Checked

Table 16-51: CANFD_FLTR_ID2_IDMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
28:0 (R/W)	VALUE	ID Filter 2 / ID Mask Bits for Pretended Networking Filtering. The `CANFD_FLTR_ID2_IDMSK.VALUE` bit field defines the ID filter value (FLT_ID2). In extended frame format, use all 29 bits (FLT_ID2[28:0]) in the field. In standard frame format, use the upper 11 bits (FLT_ID2[28:18]) and the lower 18 bits (FLT_ID2[17:0]) have no meaning. The `CANFD_FLTR_ID2_IDMSK.VALUE` bit field can also be IDMASK in exact ID filtering to define the mask value. In extended frame format, use all 29 bits (IDMASK[28:0]) in the field. In standard frame format, use the upper 11 bits (IDMASK[28:18]) and the lower 18 bits (IDMASK[17:0]) have no meaning.

Mailbox Interrupt Flag 1 Register

The CANFD_IFLG1 register defines the flags for the 32 message buffer interrupts for MB31 to MB0. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding bit in the CANFD_IFLG1 register. If the corresponding bit in the CANFD_IMSK1 register is set, an interrupt is generated. The interrupt flag must be cleared by writing a 1 to it. Writing a zero has no effect.

Before updating the CANFD_CFG.MAXMB field, the processor must service the CANFD_IFLG1 bits whose MB value is greater than the CANFD_CFG.MAXMB to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

There is an exception is when DMA for Rx FIFO is enabled, as described below.

Rx FIFO:

The BUF7I to BUF5I flags are also used to represent FIFO interrupts when the Rx FIFO is enabled. When the CANFD_CFG.RFEN bit is set and the CANFD_CFG.DMAEN bit is cleared, the function of the 8 least significant interrupt flags changes as follows:

- BUF7I, BUF6I, and BUF5I indicate operating conditions of the FIFO.
- BUF0I is used to empty the FIFO.
- BUF4I to BUF1I are reserved.

Before setting the CANFD_CFG.RFEN bit, the processor must service the IFLAG bits asserted in the Rx FIFO region or these IFLAG bits will mistakenly show the related MBs now belonging to the FIFO as having contents to be serviced. When the CANFD_CFG.RFEN bit is negated, the FIFO flags must be cleared. The same care must be taken when a CANFD_CTL2.RFFNUM value is selected extending Rx FIFO filters beyond MB7. For example, when the CANFD_CTL2.RFFNUM value is 0x8, the MB0–23 range is occupied by Rx FIFO filters and related IFLAG bits must be cleared.

The Rx FIFO must be disabled when the CANFD_CFG.FDEN bit is enabled.

Rx FIFO with DMA:

When both the CANFD_CFG.RFEN bit and the CANFD_CFG.DMAEN bits are set (DMA feature for Rx FIFO enabled), the function of the 8 least significant interrupt flags (BUF7I–BUF0I) are changed to support the DMA operation:

- BUF7I, BUF6I, and BUF4I–BUF1I are not used.
- BUF5I indicates operating condition of FIFO.
- BUF5I does not generate a CPU interrupt, but generates a DMA request.
- BUF0I is used to empty FIFO.

The CANFD_IMSK1 register bits in the Rx FIFO region are not considered when the CANFD_CFG.DMAEN bit is asserted. In addition, the processor must not clear the flag BUF5I when DMA is enabled. Before setting the

CANFD_CFG.DMAEN bit, the processor must service the IFLAGs asserted in the Rx FIFO region. When the CANFD_CFG.DMAEN bit is cleared, the FIFO must be empty.

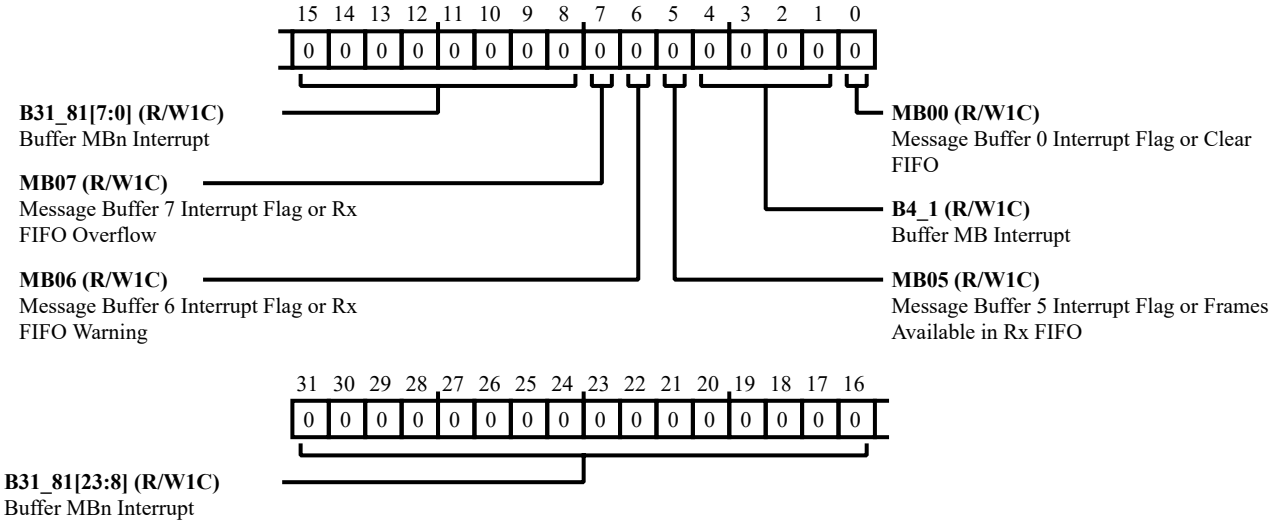

Figure 16-34: CANFD_IFLG1 Register Diagram

Table 16-52: CANFD_IFLG1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:8 (R/W1C)	B31_81	Buffer MBn Interrupt. Each bit in the CANFD_IFLG1.B31_81 bit field flags the corresponding CANFD Message Buffer Interrupt for MB31 to MB8. Only the lower 8 bits are available when parameter NUMBER_OF_MB = 16.	
		0	No occurrence of successful transmission or reception
		1	Successful transmission or reception

Table 16-52: CANFD_IFLG1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
7 (R/W1C)	MB07	Message Buffer 7 Interrupt Flag or Rx FIFO Overflow. The CANFD_IFLG1.MB07 bit flags the CANFD module message buffer interrupt for MB7 or Rx FIFO overflow. When the CANFD_IFLG1.MB07 bit is set and CANFD_CFG.RFEN is disabled, MB7 completed transmission or reception. When the CANFD_IFLG1.MB07 bit is set and CANFD_CFG.RFEN is enabled, there is an Rx FIFO overflow. When the CANFD_IFLG1.MB07 bit is cleared and CANFD_CFG.RFEN is disabled, the corresponding buffer has no occurrence of successfully completed transmission or reception.When the CANFD_IFLG1.MB07 bit is cleared and CANFD_CFG.RFEN is enabled, there is no occurrence of Rx FIFO overflow. When the CANFD_CFG.RFEN bit is cleared (Rx FIFO disabled), the CANFD_IFLG1.MB07 bit flags the interrupt for MB7. When the CANFD_CFG.RFEN bit is set (Rx FIFO enabled), the CANFD_IFLG1.MB07 bit represents the Rx FIFO overflow. In this case, the CANFD_IFLG1.MB07 bit indicates that a message was lost because the Rx FIFO is full. Note that the CANFD_IFLG1.MB07 bit is not asserted when the Rx FIFO is full and the message was captured by a mailbox. Note that the CANFD_IFLG1.MB07 bit is cleared by the CANFD module whenever the CANFD_CFG.RFEN bit is changed by a processor write.
6 (R/W1C)	MB06	Message Buffer 6 Interrupt Flag or Rx FIFO Warning. The CANFD_IFLG1.MB06 bit flags the CANFD module message buffer interrupt for MB6 or Rx FIFO warning. When the CANFD_IFLG1.MB06 bit is set and CANFD_CFG.RFEN is disabled, MB6 completed transmission or reception. When the CANFD_IFLG1.MB06 bit is set and CANFD_CFG.RFEN is enabled, the Rx FIFO is almost full. When the CANFD_IFLG1.MB06 bit is cleared and CANFD_CFG.RFEN is disabled, the corresponding buffer has no occurrence of successfully completed transmission or reception.When the CANFD_IFLG1.MB06 bit is cleared and CANFD_CFG.RFEN is enabled, the Rx FIFO is not almost full. When the CANFD_CFG.RFEN bit is cleared (Rx FIFO disabled), the CANFD_IFLG1.MB06 bit flags the interrupt for MB6. When the CANFD_CFG.RFEN bit is set (Rx FIFO enabled), the CANFD_IFLG1.MB06 bit represents the Rx FIFO warning. In this case, BUF6I indicates when the number of unread messages in the Rx FIFO increases from 4 to 5 due to the reception of a new message, meaning that the Rx FIFO is almost full. Note that if the CANFD_IFLG1.MB06 bit is cleared while the number of unread messages is greater than 4, the CANFD_IFLG1.MB06 bit is not asserted again until the number of unread messages in the Rx FIFO decreases to 4 or less. Note that the CANFD_IFLG1.MB06 bit is cleared by the CANFD module whenever the CANFD_CFG.RFEN bit is changed by a processor write.

Table 16-52: CANFD_IFLG1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W1C)	MB05	Message Buffer 5 Interrupt Flag or Frames Available in Rx FIFO. The CANFD_IFLG1.MB05 bit flags the CANFD module message buffer interrupt for MB5 or Rx FIFO frames available. When the CANFD_IFLG1.MB05 bit is set and CANFD_CFG.RFEN is disabled, MB5 completed transmission or reception. When the CANFD_IFLG1.MB05 bit is set and CANFD_CFG.RFEN is enabled, the Rx FIFO has frames available. BUF5I generates a DMA request when both the CANFD_CFG.RFEN and CANFD_CFG.DMAEN bits are set. When the CANFD_IFLG1.MB05 bit is cleared and CANFD_CFG.RFEN is disabled, the corresponding buffer has no occurrence of successfully completed transmission or reception. When the CANFD_IFLG1.MB05 bit is cleared and CANFD_CFG.RFEN is enabled, no frames are available in the Rx FIFO. When the CANFD_CFG.RFEN bit is cleared (Rx FIFO disabled), CANFD_IFLG1.MB05 bit flags the interrupt for MB5. When the CANFD_CFG.RFEN bit is set (Rx FIFO enabled), the CANFD_IFLG1.MB05 bit represents the frames available in the Rx FIFO and indicates that at least one frame is available to be read from the Rx FIFO. When the CANFD_CFG.DMAEN bit is set, the CANFD_IFLG1.MB05 bit generates a DMA request and the processor must not clear the CANFD_IFLG1.MB05 bit by writing one to it. Note that the CANFD_IFLG1.MB05 bit is cleared by the CANFD module whenever the CANFD_CFG.RFEN bit is changed by a processor write.	
4:1 (R/W1C)	B4_1	Buffer MB Interrupt. The CANFD_IFLG1.B4_1 bit field indicates whether the corresponding buffer has successfully completed transmission or reception (when CAN_MCR.RFEN=0). When CAN_MCR.RFEN is cleared (=0) (Rx FIFO disabled), the BUF4TO1I flags the interrupts for MB4 to MB1. When CAN_MCR.RFEN is set (=1)(Rx FIFO enabled), BUF4TO1I flags are reserved. Note: BUF4TO1I are cleared by the CANFD module whenever CAN_MCR.RFEN is changed by a CPU write.	
		0	No occurrence of successful completed transmission or reception
		1	Successful transmission or reception

Table 16-52: CANFD_IFLG1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W1C)	MB00	Message Buffer 0 Interrupt Flag or Clear FIFO. The CANFD_IFLG1.MB00 bit flags the interrupt for MB0, when the CANFD_CFG.RFEN bit is cleared (Rx FIFO disabled). When the CANFD_IFLG1.MB00 bit is set, the corresponding buffer successfully completed transmission or reception. When the bit is cleared, the corresponding buffer has no occurrence of successfully completed transmission or reception. When the CANFD_CFG.RFEN bit is set (Rx FIFO enabled), the CANFD_IFLG1.MB00 bit triggers the clear FIFO operation. This operation empties FIFO contents. Before performing this operation, the processor must service all FIFO related IFLAGs. When the CANFD_CFG.DMAEN bit is set (DMA is enabled), this operation also clears the CANFD_IFLG1.MB05 flag and consequently aborts the DMA request. The clear FIFO operation occurs when the processor writes a one to the CANFD_IFLG1.MB00 bit, which is only allowed in freeze mode and is blocked by hardware in other conditions.

Mailbox Interrupt Flag 2 Register

The CANFD_IFLG2 register defines the flags for the 32 message buffer interrupts for MB63 to MB32. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the respective bit in the CANFD_IFLG2 bit. If the corresponding bit is set, an interrupt is generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect.

Before updating the CANFD_CFG.MAXMB field, the processor must service the CANFD_IFLG2 bits whose MB value is greater than the CANFD_CFG.MAXMB to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

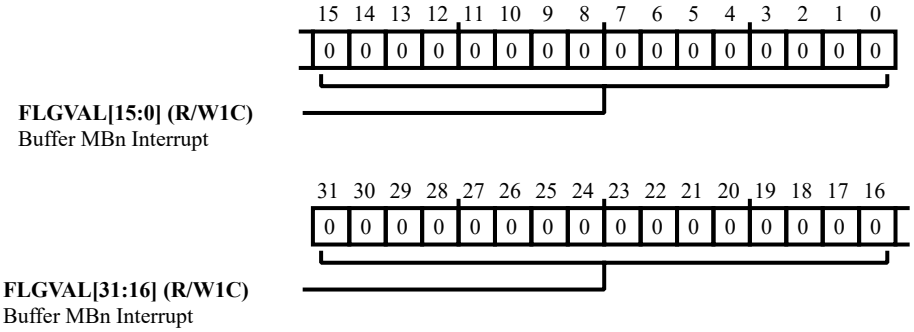

Figure 16-35: CANFD_IFLG2 Register Diagram

Table 16-53: CANFD_IFLG2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:0 (R/W1C)	FLGVAL	Buffer MBn Interrupt. The CANFD_IFLG2.FLGVAL bit field flags the corresponding buffer (MB63 to MB32) indicating whether there has been a successfully completed transmission or reception.	
		0	No occurrence of successful transmission or reception
		1	Successful transmission or reception

Mailbox Interrupt Mask 1 Register

The CANFD_IMSK1 register allows any number of the 32 message buffer interrupts to be enabled or disabled for MB31 to MB. The CANFD_IMSK1 register contains one interrupt mask bit per buffer, enabling the CPU to determine which buffer generates an interrupt after a successful transmission or reception (as indicated by the corresponding bit in the register).

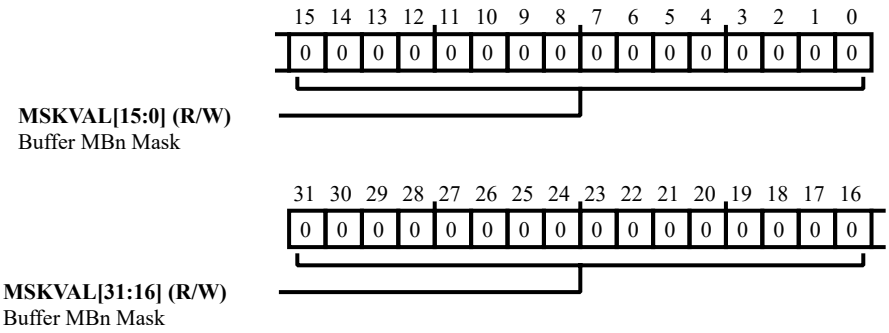

Figure 16-36: CANFD_IMSK1 Register Diagram

Table 16-54: CANFD_IMSK1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:0 (R/W)	MSKVAL	Buffer MBn Mask. Each CANFD_IMSK1.MSKVAL bit enables or disables the corresponding CANFD Message Buffer Interrupt for MB31 to MB0. Note: Setting or clearing a bit in CAN_IMASK1 can assert or negate an interrupt request if the corresponding CAN_IFLAG1 bit is set.	
		0	Disabled
		1	Enabled

Mailbox Interrupt Mask 2 Register

The CANFD_IMSK2 register allows any number of the 32 message buffer interrupts to be enabled or disabled for MB63 to MB32. The CANFD_IMSK2 register contains one interrupt mask bit per buffer, enabling the processor to determine which buffer generates an interrupt after a successful transmission or reception (as indicated by the corresponding bit in the register).

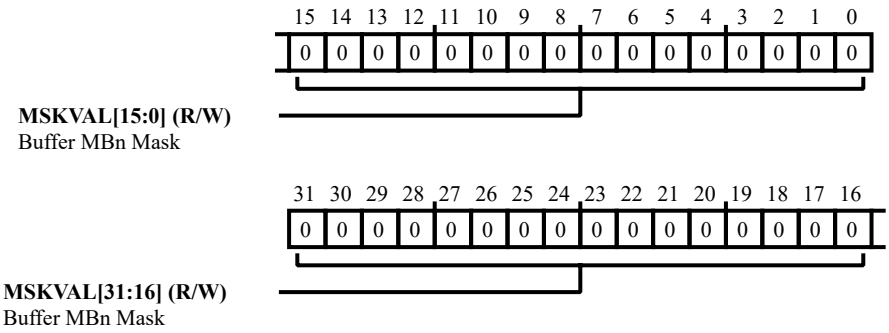

Figure 16-37: CANFD_IMSK2 Register Diagram

Table 16-55: CANFD_IMSK2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	MSKVAL	Buffer MBn Mask. Each CANFD_IMSK2.MSKVAL bit enables or disables the corresponding CANFD Message Buffer Interrupt for MB63 to MB32. : Note: Setting or clearing a bit in CAN_IMASK2 can assert or negate an interrupt request if the corresponding CAN_IFLAG2 bit is set.

Module Configuration Register

The CANFD_CFG register configures the operation modes and settings for the CANFD module. This register defines global system configurations, such as the module operation modes and the maximum message buffer configuration.

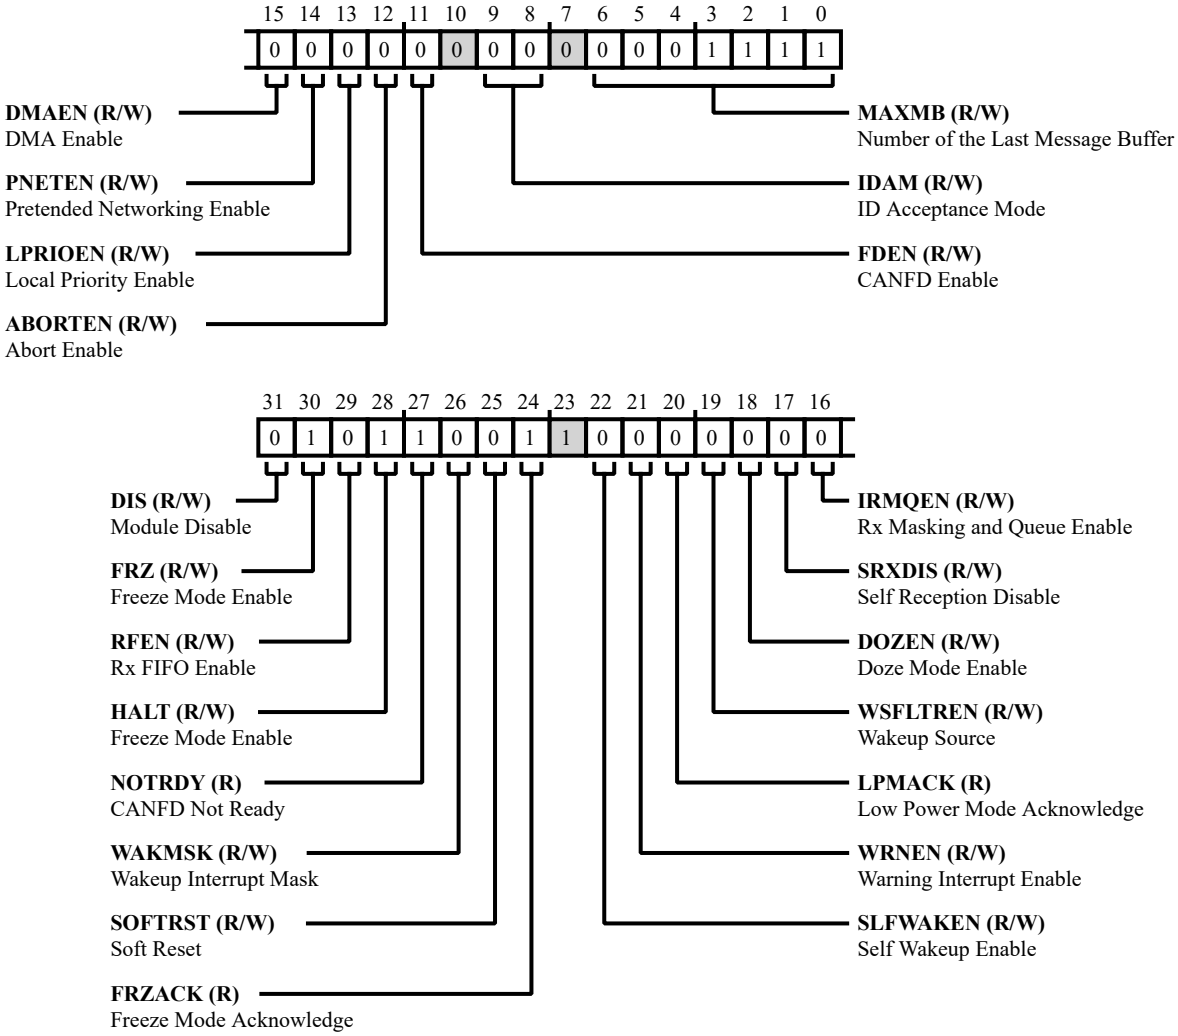

Figure 16-38: CANFD_CFG Register Diagram

Table 16-56: CANFD_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	DIS	Module Disable. The CANFD_CFG.DIS bit disables or enables the CANFD module. When the CANFD_CFG.DIS bit is set, the CANFD module disables the clocks to the PE and CHI submodules. This bit is not affected by a soft reset.	
		0	Enable
		1	Disable
30 (R/W)	FRZ	Freeze Mode Enable. The CANFD_CFG.FRZ bit specifies the CANFD module behavior when the CANFD_CFG.HALT bit is set or when there is a debug mode request at the chip level. When the CANFD_CFG.FRZ bit is set, the CANFD module enters freeze mode. Negation of the CANFD_CFG.FRZ bit causes the CANFD module to exit from freeze mode. The CANFD_CFG.FRZ bit is set by hardware when a non-correctable error is detected and the CANFD_MEC.NCERRFRZEN bit is set.	
		0	Disable
		1	Enable
29 (R/W)	RFEN	Rx FIFO Enable. The CANFD_CFG.RFEN bit enables the Rx FIFO. When the CANFD_CFG.RFEN bit is set, do not use MBs 0-5 for normal reception and transmission. The corresponding memory region (0x80-0xDC) is used by the FIFO engine and additional MBs (up to 32, depending on the CANFD_CTL2.RFFNUM bit setting) are used as Rx FIFO ID filter table elements. The CANFD_CFG.RFEN bit also impacts the minimum number of peripheral clocks per CAN bit. The CANFD_CFG.RFEN bit can only be written in freeze mode because it is blocked by hardware in other modes. Note that the CANFD_CFG.RFEN bit cannot be set when the CANFD_CFG.FDEN bit is set.	
		0	Disable
		1	Enable

Table 16-56: CANFD_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
28 (R/W)	HALT	Freeze Mode Enable. Setting the CANFD_CFG.HALT bit puts the CANFD module into freeze mode. The processor clears the CANFD_CFG.HALT bit after initializing the message buffers, the CANFD_CTL1 register, and the CANFD_CTL2 register. The CANFD module does not receive or transmit data before the CANFD_CFG.HALT bit is cleared. The CANFD module cannot enter freeze mode while it is in a low-power mode. The CANFD_CFG.HALT bit is set by hardware when a non-correctable error is detected and the CANFD_MEC.NCERRFRZEN bit is set.	
		0	Disable
		1	Enable
27 (R/NW)	NOTRDY	CANFD Not Ready. The CANFD_CFG.NOTRDY bit is a read-only bit that indicates the CANFD module is either in module disable, doze, stop, or freeze mode. The CANFD_CFG.NOTRDY bit is negated once the CANFD module exits these modes. Soft reset does not affect the CANFD_CFG.NOTRDY bit.	
		0	Normal, Listen-Only, or Loop-Back Mode
		1	Module Disable, Doze, Stop, or Freeze Mode
26 (R/W)	WAKMSK	Wakeup Interrupt Mask. The CANFD_CFG.WAKMSK bit enables the wakeup interrupt using the self wakeup mechanism.	
		0	Disable
		1	Enable
25 (R/W)	SOFTRST	Soft Reset. When the CANFD_CFG.SOFTRST bit is set, the internal state machines and some of the memory mapped registers of the CANFD module reset. For the processor to directly assert a soft reset, write to the CANFD_CFG.SOFTRST bit. A soft reset can also occur when a global soft reset is requested at the chip level. Soft reset is synchronous and has to follow a request/acknowledge procedure across clock domains, so it takes time to fully propagate the effect. The CANFD_CFG.SOFTRST bit remains set while reset is pending and is automatically negated when the reset completes. Poll the CANFD_CFG.SOFTRST bit to know when the soft reset has completed. Soft reset cannot be applied while clocks are shut down in a low-power mode. Remove the CANFD module from low-power mode before applying soft reset. A soft reset does not affect the CANFD_CFG.SOFTRST bit.	

Table 16-56: CANFD_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
24 (R/NW)	FRZACK	Freeze Mode Acknowledge. The CANFD_CFG.FRZACK bit is a read-only bit that indicates the CANFD module is in freeze mode and the prescaler is stopped. A freeze mode request is only granted after the current transmission or reception processes completes. Poll the CANFD_CFG.FRZACK bit in software to know when the CANFD module enters freeze mode. If a freeze mode request is negated, the CANFD_CFG.FRZACK bit is negated after the CANFD module prescaler is running again. If freeze mode is requested while the CANFD module is in a low-power mode, the CANFD_CFG.FRZACK bit sets only when the module exits the low-power mode. Soft reset does not affect the CANFD_CFG.FRZACK bit. Note that the CANFD_CFG.FRZACK bit is set within 178 CAN bits of the freeze mode request. It is negated within 2 CAN bits after a freeze mode request removal.	
		0	No Freeze Mode Prescaler is running.
		1	Freeze Mode The prescaler stopped.
22 (R/W)	SLFWAKEN	Self Wakeup Enable. The CANFD_CFG.SLFWAKEN bit enables the self wakeup feature when the CANFD module is in a low-power mode other than module disable. When the self wakeup feature is enabled, the CANFD module monitors the bus for a wakeup event (a recessive-to-dominant transition). If a wake up event is detected during doze mode, the CANFD module requests resumption of the clocks and when the CANFD_CFG.SLFWAKEN bit is enabled generates a wakeup interrupt to the processor. If a wakeup event is detected during stop mode, the CANFD module, when the CANFD_CFG.SLFWAKEN bit is enabled, generates a wake up interrupt to the processor so that it can exit stop mode globally and the CANFD module can request to resume the clocks. When the CANFD module is in a low-power mode other than module disable, the CANFD_CFG.SLFWAKEN bit cannot be written as it is blocked by hardware. Disable self wakeup when pretended networking mode is set.	
		0	Disable
		1	Enable

Table 16-56: CANFD_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
21 (R/W)	WRNEN	Warning Interrupt Enable. The CANFD_CFG.WRNEN bit enables the generation of the TWRNINT and RWRNINT flags in the CANFD_ESR1 register. If the CANFD_CFG.WRNEN bit is negated, the TWRNINT and RWRNINT flags will always be zero, independent of the values of the error counters. No warning interrupt is generated. The CANFD_CFG.WRNEN bit can only be written in freeze mode and is blocked by hardware in other modes.	
		0	Disable
		1	Enable
20 (R/NW)	LPMACK	Low Power Mode Acknowledge. The CANFD_CFG.LPMACK bit is a read-only bit that indicates that the CANFD module is in a low-power mode (module disable, doze, or stop). The module can only enter a low-power mode when all current transmission or reception processes have finished. Poll the CANFD_CFG.LPMACK bit to know when the CANFD module is in low-power mode. The CANFD_CFG.LPMACK bit is not affected by soft reset. Note that the CANFD_CFG.LPMACK bit is set within 180 CAN bits of the low-power mode request by the processor. It is negated within 2 CAN bits after removing the low-power mode request. When the CANFD module is in pretended networking mode, the CANFD_CFG.LPMACK bit is negated within 180 CAN bits from the removal of the low-power mode request.	
		0	Disable Not in low-power mode
		1	Enable In low-power mode
19 (R/W)	WSFLTREN	Wakeup Source. The CANFD_CFG.WSFLTREN bit controls whether the integrated low-pass filter is applied to protect the Rx CAN input from spurious wakeup. When enabled, the CANFD module uses the filtered Rx input to detect recessive-to-dominant edges on the CAN bus. When disabled the CANFD module uses the unfiltered Rx input to detect recessive-to-dominant edges on the CAN bus. The CANFD_CFG.WSFLTREN bit can only be written in freeze mode and is blocked by hardware in other modes.	
		0	Disable
		1	Enable

Table 16-56: CANFD_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
18 (R/W)	DOZEN	Doze Mode Enable. The CANFD_CFG.DOZEN bit controls whether the CANFD module can enter low-power mode when doze mode is requested at the chip level. When the CANFD_CFG.DOZEN bit is set the CANFD module can enter low-power mode and when it is cleared the module cannot. The CANFD_CFG.DOZEN bit is automatically reset when the CANFD module wakes up from doze mode upon detecting activity on the CAN bus (CANFD_CFG.SLFWAKEN enabled).	
		0	Disable
		1	Enable
17 (R/W)	SRXDIS	Self Reception Disable. The CANFD_CFG.SRXDIS bit controls whether the CANFD module can receive frames transmitted from itself. When the CANFD_CFG.SRXDIS bit is set, frames transmitted by the CANFD module are not stored in any MB, regardless of whether the MB is programmed with an ID that matches the transmitted frame. No interrupt flag or interrupt signal is generated due to the frame reception. The CANFD_CFG.SRXDIS bit can only be written in freeze mode and is blocked by hardware in other modes.	
		0	Enable
		1	Disable
16 (R/W)	IRMQEN	Rx Masking and Queue Enable. The CANFD_CFG.IRMQEN bit controls whether the Rx matching process is based on individual masking and queue or on a masking scheme with the CANFD_RX_MB_GMSK, CANFD_RX_14_MSK, CANFD_RX_15_MSK, and CANFD_RX_FIFO_GMSK registers. The CANFD_CFG.IRMQEN bit can only be written in freeze mode and is blocked by hardware in other modes. For backward compatibility, when CANFD_CFG.IRMQEN is disabled, reading a C/S word locks the MB even when it is empty.	
		0	Disable
		1	Enable

Table 16-56: CANFD_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	DMAEN	DMA Enable. The CANFD_CFG.DMAEN bit enables or disables the DMA feature. The DMA feature is only for use with the Rx FIFO and the CANFD_CFG.RFEN bit must be set. When both the CANFD_CFG.DMAEN and CANFD_CFG.RFEN bits are set, CANFD_IFLG1.MB05 generates the DMA request and no Rx FIFO interrupt is generated. The CANFD_CFG.DMAEN bit can only be written in freeze mode and is blocked by hardware in other modes.	
		0	Disable
		1	Enable
14 (R/W)	PNETEN	Pretended Networking Enable. The CANFD_CFG.PNETEN bit enables the pretended networking mode. When pretended networking is enabled, the PE submodule is kept operational in doze mode and stop mode. It is able to process Rx message filtering as defined by the pretended networking configuration registers. The CANFD_CFG.PNETEN bit can be only be written in freeze mode.	
		0	Disable
		1	Enable
13 (R/W)	LPRIOEN	Local Priority Enable. The CANFD_CFG.LPRIOEN bit controls whether the local priority feature is enabled and is provided for backward compatibility with legacy applications. Local priority expands the arbitration ID. With this expanded ID concept, the arbitration process is based on the full 32-bit word, but the actual transmitted ID still has 11 bits for standard frames and 29 bits for extended frames. The CANFD_CFG.LPRIOEN bit can only be written only in freeze mode and is blocked by hardware in other modes.	
		0	Disable
		1	Enable

Table 16-56: CANFD_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	ABORTEN	Abort Enable. The CANFD_CFG.ABORTEN bit enables the Tx abort mechanism. The Tx abort mechanism ensures a safe procedure for aborting a pending transmission, so that no frame is sent on the CAN bus without notification. The CANFD_CFG.ABORTEN bit can only be written only in freeze mode and is blocked by hardware in other modes. Note that when the CANFD_CFG.ABORTEN bit is set, the abort mechanism must only be used for updating mailboxes configured for transmission. Writing the abort code into Rx mailboxes can cause unpredictable results when the CANFD_CFG.ABORTEN bit is enabled.	
		0	Disable
		1	Enable
11 (R/W)	FDEN	CANFD Enable. The CANFD_CFG.FDEN bit enables CAN with Flexible Data rate (CAN FD) operation. When the CANFD_CFG.FDEN bit is enabled, the CANFD module can receive and transmit messages in both CAN FD and CAN 2.0 formats. When it is disabled, the CANFD module can only receive and transmit messages in CAN 2.0 format. The CANFD_CFG.FDEN bit can only be written in freeze mode only. Note that the CANFD_CFG.RFEN bit cannot be set if the CANFD_CFG.FDEN bit is set.	
		0	Disable
		1	Enable
9:8 (R/W)	IDAM	ID Acceptance Mode. The CANFD_CFG.IDAM bit field identifies the format of the Rx FIFO ID filter table elements (ID acceptance mode). All elements of the table are configured at the same time by the CANFD_CFG.IDAM bit field (they are all the same format). The CANFD_CFG.IDAM bit field can only be written in freeze mode and is blocked by hardware in other modes.	
		0	Format A. There is one full ID (standard and extended) per ID filter table element.
		1	Format B. There are two full standard IDs or two partial 14-bit (standard and extended) IDs per ID filter table element.
		2	Format C. There are four partial 8-bit standard IDs per ID filter table element.
		3	Format D. All frames are rejected.

Table 16-56: CANFD_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
6:0 (R/W)	MAXMB	Number of the Last Message Buffer. The CANFD_CFG.MAXMB bit field defines the number of the last message buffer that will take part in the matching and arbitration processes. The reset value (0x0F) is equivalent to a 16 message buffer configuration. The CANFD_CFG.MAXMB bit field can only be written in freeze mode and is blocked by hardware in other modes. Note that the CANFD_CFG.MAXMB bit field must be programmed with a value smaller than or equal to the number of available message buffers. Additionally, the definition of the CANFD_CFG.MAXMB bit value must take into account the region of MBs occupied by Rx FIFO and the ID filters table space defined by the CANFD_CTL2.RFFNUM bit. The CANFD_CFG.MAXMB bit field impacts the minimum number of peripheral clocks per CAN bit.

Memory Error Control Register

The CANFD_MEC register contains control bits for memory error detection and correction (ECC).

Note that when the CANFD_CTL2.ECRWREN bit is disabled, writes to the CANFD_MEC register are blocked, with the exception of the CANFD_MEC.ECRWRDIS bit.

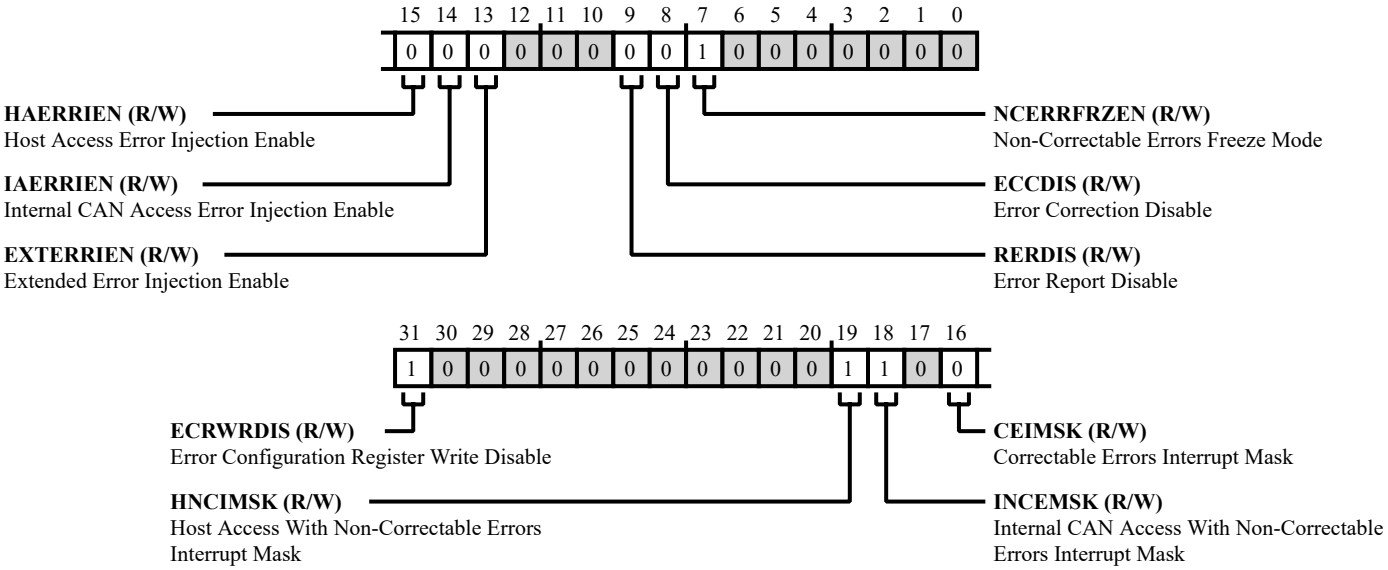

Figure 16-39: CANFD_MEC Register Diagram

Table 16-57: CANFD_MEC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	ECRWRDIS	Error Configuration Register Write Disable. The CANFD_MEC.ECRWRDIS bit disables writes to the CANFD_MEC register. The CANFD_MEC.ECRWRDIS bit is automatically set to 1 (disabled) when the CANFD_CTL2.ECRWREN bit is enabled. See the protocol described in the Detection and Correction of Memory Errors section of the CANFD chapter.	
		0	Enable
		1	Disable
19 (R/W)	HNCIMSK	Host Access With Non-Correctable Errors Interrupt Mask. The CANFD_MEC.HNCIMSK bit enables the interrupt in case of non-correctable errors detected in memory reads issued by the host.	
		0	Disable
		1	Enable

Table 16-57: CANFD_MEC Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
18 (R/W)	INCEMSK	Internal CAN Access With Non-Correctable Errors Interrupt Mask. The `CANFD_MEC.INCEMSK` bit enables the interrupt in case of non-correctable errors detected in memory reads issued by the CAN internal processes.	
		0	Disable
		1	Enable
16 (R/W)	CEIMSK	Correctable Errors Interrupt Mask. The `CANFD_MEC.CEIMSK` bit enables the interrupt in case of correctable errors detected in memory reads issued by the host or CANFD module internal processes.	
		0	Disable
		1	Enable
15 (R/W)	HAERRIEN	Host Access Error Injection Enable. The `CANFD_MEC.HAERRIEN` bit enables the injection of errors for memory reads issued by the host.	
		0	Disable
		1	Enable
14 (R/W)	IAERRIEN	Internal CAN Access Error Injection Enable. The `CANFD_MEC.IAERRIEN` bit enables the injection of errors for memory reads issued by the CAN internal processes.	
		0	Disable
		1	Enable
13 (R/W)	EXTERRIEN	Extended Error Injection Enable. Memory accesses performed by internal CANFD processes are 64-bit accesses. The `CANFD_MEC.EXTERRIEN` bit extends the error injection on 32-bit memory accesses to the complementary 32-bit word using the same 32-bit error injection data and parity words. When the `CANFD_MEC.EXTERRIEN` bit is enabled, the error injection is applied to the 64-bit word. When the bit is disabled, error injection is only applied to the 32-bit word. See the descriptions of the `CANFD_ERR_IDP` and `CANFD_ERR_IPP` registers.	
		0	Disable
		1	Enable

Table 16-57: CANFD_MEC Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	RERDIS	Error Report Disable. The `CANFD_MEC.RERDIS` bit disables the update of the error report registers. When the error report registers are disabled, the update of error-related flags and the generation of bus transfer errors are still active. Note that when reading the report registers, the `CANFD_MEC.RERDIS` bit must be set to ensure coherence on the consecutive register reads.	
		0	Enable
		1	Disable
8 (R/W)	ECCDIS	Error Correction Disable. The `CANFD_MEC.ECCDIS` bit disables the memory detection and correction mechanism. In addition to disabling the error report mechanism, when the `CANFD_MEC.ECCDIS` bit is set, the update of the error-related flags and generation of bus transfer errors also stops. The parity bits continue to be calculated and written into memory on write transactions.	
		0	Enable
		1	Disable
7 (R/W)	NCERRFRZEN	Non-Correctable Errors Freeze Mode. The `CANFD_MEC.NCERRFRZEN` bit determines the response when a non-correctable error is detected in a memory read performed by CANFD module internal processes. Enabling the `CANFD_MEC.NCERRFRZEN` bit puts the CANFD module in freeze mode, preventing corrupted data from being treated as valid by CANFD internal processes. Disabling the bit maintains normal operation.	
		0	Disable
		1	Enable

Pretended Networking Payload Low Filter2 Register

The CANFD_FLTR_DATA1_HI register contain Payload Filter 1 high order bits of the target value. This is for filtering the incoming message payload in pretended networking mode. It is for =, ≤, or ≥ to comparisons; or as the lower limit value in payload range detection.

The CANFD_FLTR_DATA1_HI register can only be written in freeze mode.

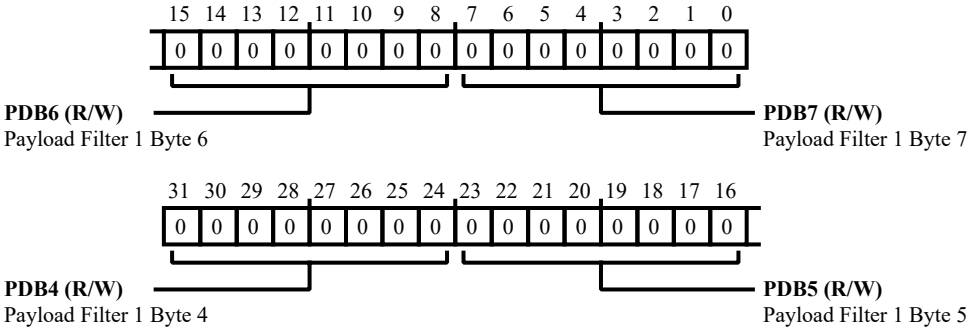

Figure 16-40: CANFD_FLTR_DATA1_HI Register Diagram

Table 16-58: CANFD_FLTR_DATA1_HI Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	PDB4	Payload Filter 1 Byte 4. The CANFD_FLTR_DATA1_HI.PDB4 bit field contains the payload filter 1 high order bits for pretended networking payload filtering corresponding to data byte 4.
23:16 (R/W)	PDB5	Payload Filter 1 Byte 5. The CANFD_FLTR_DATA1_HI.PDB5 bit field contains the payload filter 1 high order bits for pretended networking payload filtering corresponding to data byte 5.
15:8 (R/W)	PDB6	Payload Filter 1 Byte 6. The CANFD_FLTR_DATA1_HI.PDB6 bit field contains the payload filter 1 high order bits for pretended networking payload filtering corresponding to data byte 6.
7:0 (R/W)	PDB7	Payload Filter 1 Byte 7. The CANFD_FLTR_DATA1_HI.PDB7 bit field contains the payload filter 1 high order bits for pretended networking payload filtering corresponding to data byte 7.

Pretended Networking Payload Low Filter1 Register

The CANFD_FLTR_DATA1_LO register contain Payload Filter 1 low order bits of the target value. This is for filtering the incoming message payload in pretended networking mode. It is for =, ≤, or ≥ to comparisons; or as the lower limit value in payload range detection.

The CANFD_FLTR_DATA1_LO register can only be written in freeze mode.

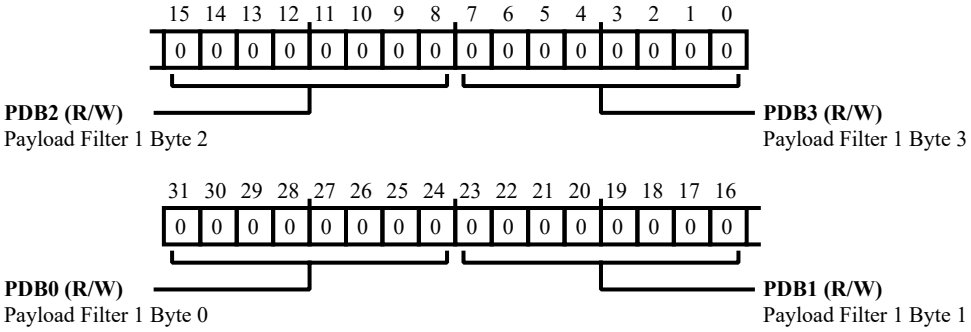

Figure 16-41: CANFD_FLTR_DATA1_LO Register Diagram

Table 16-59: CANFD_FLTR_DATA1_LO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	PDB0	Payload Filter 1 Byte 0. The CANFD_FLTR_DATA1_LO.PDB0 bit field contains the payload filter 1 low order bits for pretended networking payload filtering corresponding to data byte 0.
23:16 (R/W)	PDB1	Payload Filter 1 Byte 1. The CANFD_FLTR_DATA1_LO.PDB1 bit field contains the payload filter 1 low order bits for pretended networking payload filtering corresponding to data byte 1.
15:8 (R/W)	PDB2	Payload Filter 1 Byte 2. The CANFD_FLTR_DATA1_LO.PDB2 bit field contains the payload filter 1 low order bits for pretended networking payload filtering corresponding to data byte 2.
7:0 (R/W)	PDB3	Payload Filter 1 Byte 3. The CANFD_FLTR_DATA1_LO.PDB3 bit field contains the payload filter 1 low order bits for pretended networking payload filtering corresponding to data byte 3.

Pretended Networking Payload High Filter2 High Order Bits / Payload High Mask Register

The CANFD_FLTR_DATA2_DMSK_HI register has two functions:

It contains the high order bits for the Payload Filter 2 value for use as the upper limit in payload range detection.

When exact payload filtering criteria is selected, the CANFD_FLTR_DATA2_DMSK_HI register is the payload mask.

Otherwise, the CANFD_FLTR_DATA2_DMSK_HI register is not used. It can only be written in freeze mode.

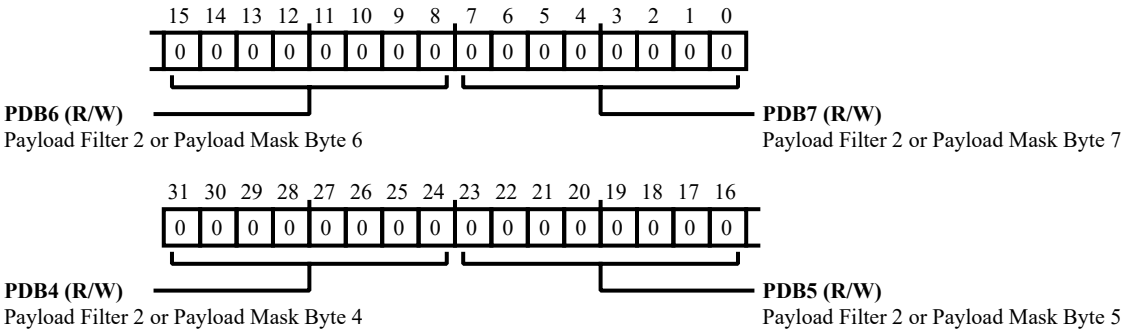

Figure 16-42: CANFD_FLTR_DATA2_DMSK_HI Register Diagram

Table 16-60: CANFD_FLTR_DATA2_DMSK_HI Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	PDB4	Payload Filter 2 or Payload Mask Byte 4. The CANFD_FLTR_DATA2_DMSK_HI.PDB4 bit field contains the payload filter 2 high order bits or payload mask high order bits for pretended networking payload filtering corresponding to data byte 4.
23:16 (R/W)	PDB5	Payload Filter 2 or Payload Mask Byte 5. The CANFD_FLTR_DATA2_DMSK_HI.PDB5 bit field contains the payload filter 2 high order bits or payload mask high order bits for pretended networking payload filtering corresponding to data byte 5.
15:8 (R/W)	PDB6	Payload Filter 2 or Payload Mask Byte 6. The CANFD_FLTR_DATA2_DMSK_HI.PDB6 bit field contains the payload filter 2 high order bits or payload mask high order bits for pretended networking payload filtering corresponding to data byte 6.
7:0 (R/W)	PDB7	Payload Filter 2 or Payload Mask Byte 7. The CANFD_FLTR_DATA2_DMSK_HI.PDB7 bit field contains the payload filter 2 high order bits or payload mask high order bits for pretended networking payload filtering corresponding to data byte 7.

Pretended Networking Payload Low Filter2 / Payload Low Mask Register

The CANFD_FLTR_DATA2_DMSK_LO register has two functions:

It contains the low order bits for the Payload Filter 2 value for use as the upper limit in payload range detection.

When exact payload filtering criteria is selected, the CANFD_FLTR_DATA2_DMSK_LO register is the payload mask.

Otherwise, the CANFD_FLTR_DATA2_DMSK_LO register is not used. It can only be written in freeze mode.

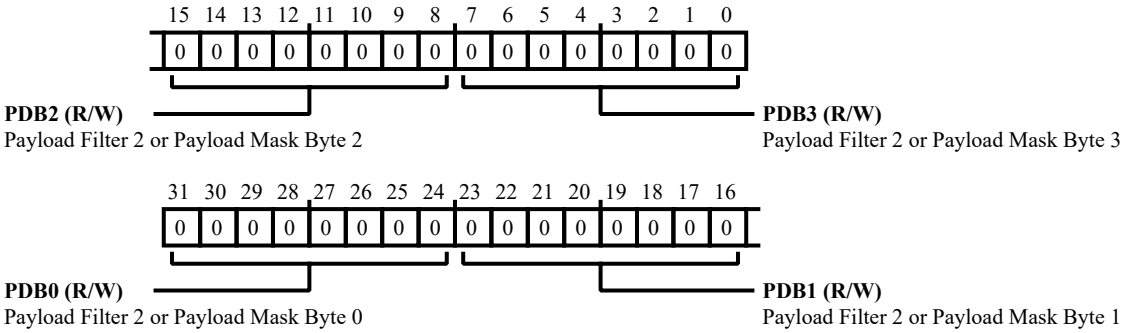

Figure 16-43: CANFD_FLTR_DATA2_DMSK_LO Register Diagram

Table 16-61: CANFD_FLTR_DATA2_DMSK_LO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	PDB0	Payload Filter 2 or Payload Mask Byte 0. The CANFD_FLTR_DATA2_DMSK_LO.PDB0 bit field contains the payload filter 2 low order bits or payload mask low order bits for pretended networking payload filtering corresponding to data byte 0.
23:16 (R/W)	PDB1	Payload Filter 2 or Payload Mask Byte 1. The CANFD_FLTR_DATA2_DMSK_LO.PDB1 bit field contains the payload filter 2 low order bits or payload mask low order bits for pretended networking payload filtering corresponding to data byte 1.
15:8 (R/W)	PDB2	Payload Filter 2 or Payload Mask Byte 2. The CANFD_FLTR_DATA2_DMSK_LO.PDB2 bit field contains the payload filter 2 low order bits or payload mask low order bits for pretended networking payload filtering corresponding to data byte 2.
7:0 (R/W)	PDB3	Payload Filter 2 or Payload Mask Byte 3. The CANFD_FLTR_DATA2_DMSK_LO.PDB3 bit field contains the payload filter 2 low order bits or payload mask low order bits for pretended networking payload filtering corresponding to data byte 3.

Error Report Address Register

The CANFD_ERR_RADDR register reports the address of an access with an error (correctable or non-correctable) and reports the identification of the source of that access.

The address is 32-bit aligned. Non-aligned accesses, where the CANFD_ERRADDR[1:0] bits are non-zero, are reported with the address aligned and the data in the CANFD_ERR_RDAT register shifted accordingly. If there is an error in an access that is larger than 32 bits (as performed by CANFD internal processes), the address of the 32-bit word with the error is reported. In case of errors detected in more than one 32-bit word, only the least significant address is reported.

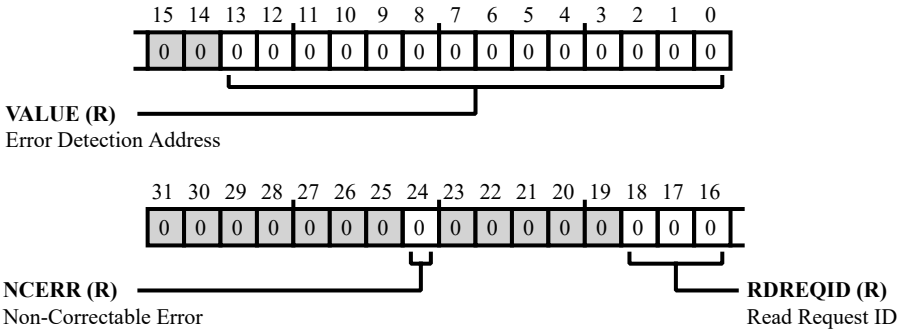

Figure 16-44: CANFD_ERR_RADDR Register Diagram

Table 16-62: CANFD_ERR_RADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
24 (R/NW)	NCERR	Non-Correctable Error. The CANFD_ERR_RADDR.NCERR bit indicates that a report is due to an non-correctable error. When the CANFD_ERR_RADDR.NCERR bit is set, it is reporting a non-correctable error. When it is cleared, it is reporting a correctable-error.	
18:16 (R/NW)	RDREQID	Read Request ID. The CANFD_ERR_RADDR.RDREQID bit field identifies the details of a memory read request.	
		0	Move-Out CANFD Access
		1	Move-In CANFD Access
		2	TX Arbitration
		3	Rx Matching
		4	Move-Out Host Access
		5	Reserved
		6	Reserved
		7	Reserved

Table 16-62: CANFD_ERR_RADDR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
13:0 (R/NW)	VALUE	Error Detection Address. The `CANFD_ERR_RADDR.VALUE` bit field contains the address where the error was detected. See the description of the Error Injection Address Register (`CANFD_ERR_IADDR`).

Error Report Data Register

The CANFD_ERR_RDAT register reports the raw data (unmodified by the ECC logic correction) read from the memory with the error. The value reported does not represent the transient values of the BUSY bit when reading a message buffer.

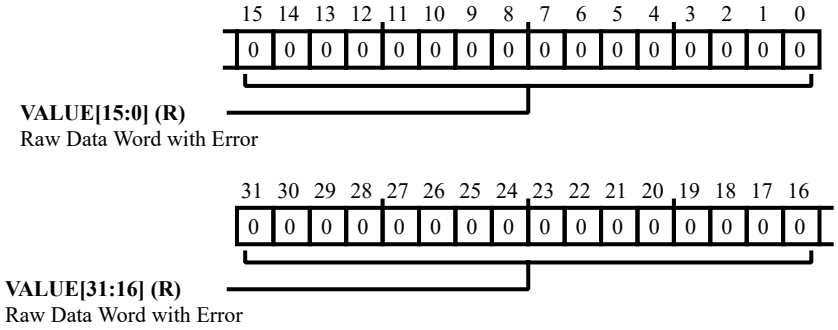

Figure 16-45: CANFD_ERR_RDAT Register Diagram

Table 16-63: CANFD_ERR_RDAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Raw Data Word with Error. The CANFD_ERR_RDAT.VALUE bit field contains the raw data word read from memory with error. This data word is unmodified by the correction performed by ECC logic and does not represent the transient values of the BUSY bit when reading the message buffer.

Error Report Syndrome Register

The CANFD_ERR_RSYN register holds the syndrome detected in a memory read with an error. It reports the bytes that are read in the 32-bit read transaction.

Each SYNDn field indicates the type of error and which bit in byte (n) is affected by the error. The CANFD_ERR_RSYN.SYND3 bit field corresponds to the most significant byte in the data word read from memory and the CANFD_ERR_RSYN.SYND0 bit field corresponds to the least significant.

Each BEn field indicates which byte in the 32-bit word reported was effectively read. The syndrome bits are calculated for all bytes, even for the non-read ones. Errors detected in non-read bytes are indicated and reported.

See the Detection and Correction of Memory Errors section of the CANFD chapter for more details.

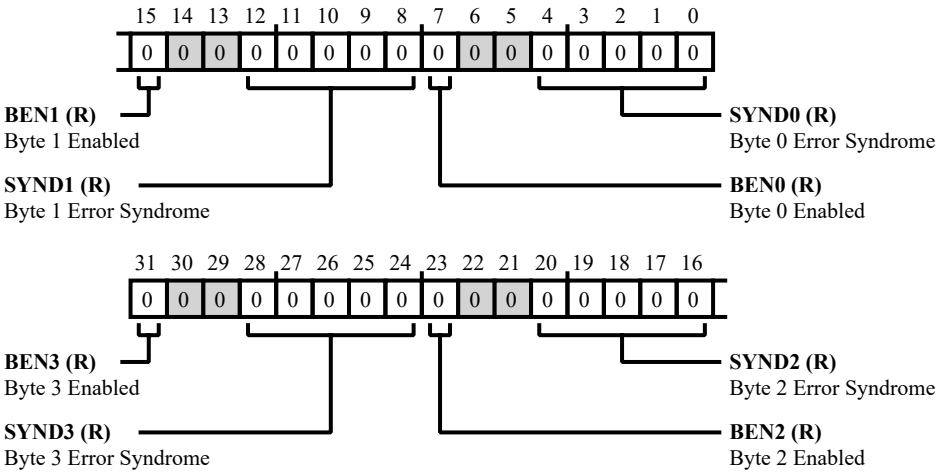

Figure 16-46: CANFD_ERR_RSYN Register Diagram

Table 16-64: CANFD_ERR_RSYN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/NW)	BEN3	Byte 3 Enabled. The CANFD_ERR_RSYN.BEN3 bit indicates if byte 3 (most significant) was read. If the CANFD_ERR_RSYN.BEN3 bit is enabled the byte was read, and if it is disabled then it was not read.	
		0	Disable
		1	Enable
28:24 (R/NW)	SYND3	Byte 3 Error Syndrome. The CANFD_ERR_RSYN.SYND3 bit field contains the error syndrome for byte 3. The Syndrome Definition table in the CANFD chapter defines the values for the CANFD_ERR_RSYN.SYND3 bit field.	

Table 16-64: CANFD_ERR_RSYN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
23 (R/NW)	BEN2	Byte 2 Enabled. The CANFD_ERR_RSYN.BEN2 bit indicates if byte 2 was read. If the CANFD_ERR_RSYN.BEN2 bit is enabled the byte was read, and if it is disabled then it was not read.	
		0	Disable
		1	Enable
20:16 (R/NW)	SYND2	Byte 2 Error Syndrome. The CANFD_ERR_RSYN.SYND2 bit field contains the error syndrome for byte 2. The Syndrome Definition table in the CANFD chapter defines the values for the CANFD_ERR_RSYN.SYND2 bit field.	
15 (R/NW)	BEN1	Byte 1 Enabled. The CANFD_ERR_RSYN.BEN1 bit indicates if byte 1 was read. If the CANFD_ERR_RSYN.BEN1 bit is enabled the byte was read, and if it is disabled then it was not read.	
		0	Disable
		1	Enable
12:8 (R/NW)	SYND1	Byte 1 Error Syndrome. The CANFD_ERR_RSYN.SYND1 bit field contains the error syndrome for byte 1. The Syndrome Definition table in the CANFD chapter defines the values for the CANFD_ERR_RSYN.SYND1 bit field.	
7 (R/NW)	BEN0	Byte 0 Enabled. The CANFD_ERR_RSYN.BEN0 bit indicates if byte 2 (least significant) was read. If the CANFD_ERR_RSYN.BEN0 bit is enabled the byte was read, and if it is disabled then it was not read.	
		0	Disable
		1	Enable
4:0 (R/NW)	SYND0	Byte 0 Error Syndrome. The CANFD_ERR_RSYN.SYND0 bit field contains the error syndrome for byte 0 (least significant). The Syndrome Definition table in the CANFD chapter defines the values for the CANFD_ERR_RSYN.SYND0 bit field.	

Receive Mailbox14 Mask Register

The CANFD_RX_14_MSK register is located in RAM.

When the CANFD_CFG.IRMQEN bit is asserted, the CANFD_RX_14_MSK register has no effect.

The CANFD_RX_14_MSK register is used to mask the filter fields of message buffer 14.

This register can only be programmed while the CANFD module is in freeze mode as it is blocked by hardware in other modes.

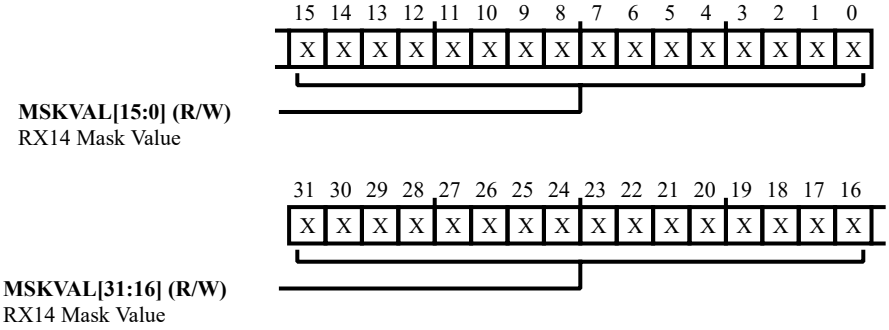

Figure 16-47: CANFD_RX_14_MSK Register Diagram

Table 16-65: CANFD_RX_14_MSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	MSKVAL	RX14 Mask Value. In the CANFD_RX_14_MSK.MSKVAL bit field, if a bit is a zero the corresponding bit in the filter is a don't care. If it is a one, the corresponding bit in the filter is checked. Each mask bit masks the corresponding mailbox 14 filter field in the same way that the CANFD_RX_MB_GMSK register masks other mailbox filters.

Receive Mailbox15 Mask Register

The CANFD_RX_15_MSK register is located in RAM.

When the CANFD_CFG.IRMQEN bit is asserted, the CANFD_RX_15_MSK register has no effect.

The CANFD_RX_15_MSK register is used to mask the filter fields of message buffer 15.

This register can only be programmed while the CANFD module is in freeze mode as it is blocked by hardware in other modes.

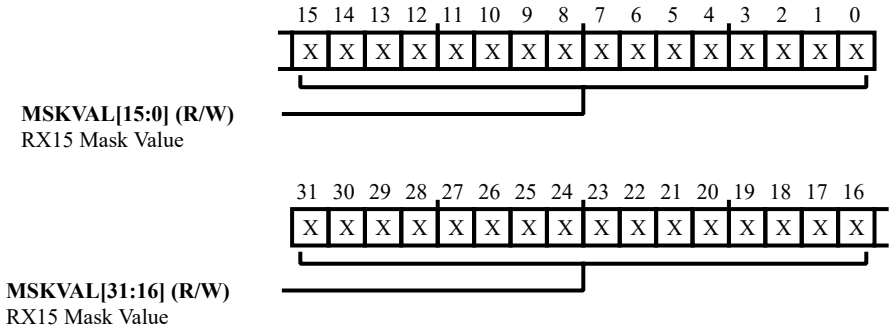

Figure 16-48: CANFD_RX_15_MSK Register Diagram

Table 16-66: CANFD_RX_15_MSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	MSKVAL	RX15 Mask Value. In the CANFD_RX_15_MSK.MSKVAL bit field, if a bit is a zero the corresponding bit in the filter is a don't care. If it is a one, the corresponding bit in the filter is checked. Each mask bit masks the corresponding mailbox 15 filter field in the same way that the CANFD_RX_MB_GMSK register masks other mailbox filters.

Receive FIFO Global Mask Register

The CANFD_RX_FIFO_GMSK register is located in RAM.

If the Rx FIFO is enabled, the CANFD_RX_FIFO_GMSK register is used to mask the Rx FIFO ID filter table elements that do not have a corresponding CANFD_RX_IMSK according to the CANFD_CTL2.RFFNUM bit field setting.

The CANFD_RX_FIFO_GMSK register can only be written in freeze mode as it is blocked by hardware in other modes.

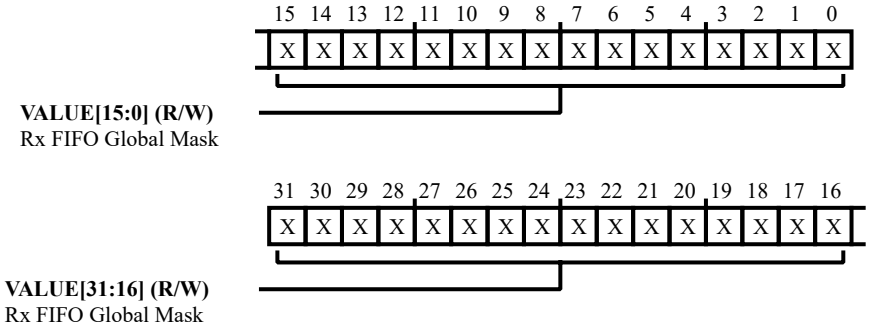

Figure 16-49: CANFD_RX_FIFO_GMSK Register Diagram

Table 16-67: CANFD_RX_FIFO_GMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:0 (R/W)	VALUE	Rx FIFO Global Mask. The bits in this field mask the ID filter table elements bits in a perfect alignment.	
		0	Corresponding bit in the filter is checked
		1	Corresponding bit in the filter is don't care

Receive FIFO Information Register

The CANFD_RX_FIFO register provides information on the Rx FIFO.

The CANFD_RX_FIFO register is the port through which the processor accesses the output of the RXFIR FIFO located in RAM. The CANFD_RX_FIFO register is written by the CANFD module whenever a new message is moved into the Rx FIFO and the register output is updated whenever the output of the Rx FIFO is updated with the next message.

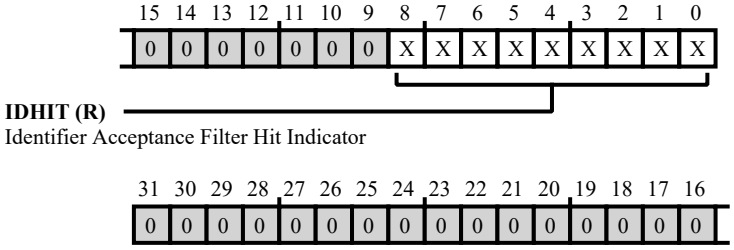

Figure 16-50: CANFD_RX_FIFO Register Diagram

Table 16-68: CANFD_RX_FIFO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
8:0 (R/NW)	IDHIT	Identifier Acceptance Filter Hit Indicator. The CANFD_RX_FIFO.IDHIT bit field indicates which identifier acceptance filter was hit by the received message that is in the output of the Rx FIFO. If multiple filters match the incoming message ID, the first matching IDAF found (lowest number) by the matching process is indicated. The CANFD_RX_FIFO.IDHIT bit field is valid only while the CANFD_IFLG1.MB05 bit is set.

Receive Individual Mask Register

The CANFD_RX_IMSK[n] registers are used to store the acceptance masks for ID filtering in Rx MBs and the Rx FIFO.

When the Rx FIFO is disabled (CANFD_CFG.RFEN is disabled), an individual mask is provided for each available Rx mailbox on a one-to-one correspondence. When the Rx FIFO is enabled (CANFD_CFG.RFEN is enabled), an individual mask is provided for each Rx FIFO ID Filter table element on a one-to-one correspondence depending on the setting of the CANFD_CTL2.RFFNUM bit.

The CANFD_RX_IMSK0 register stores the individual mask associated with either MB0 or ID Filter Table Element 0, CANFD_RX_IMSK1 stores the individual mask associated with either MB1 or ID Filter Table Element 1, and so on.

The CANFD_RX_IMSK[n] registers are only be accessed by the processor while the CANFD is in freeze mode and are otherwise blocked by hardware.

The CANFD_RX_IMSK[n] registers are not affected by reset. They are located in RAM and must be explicitly initialized prior to any reception.

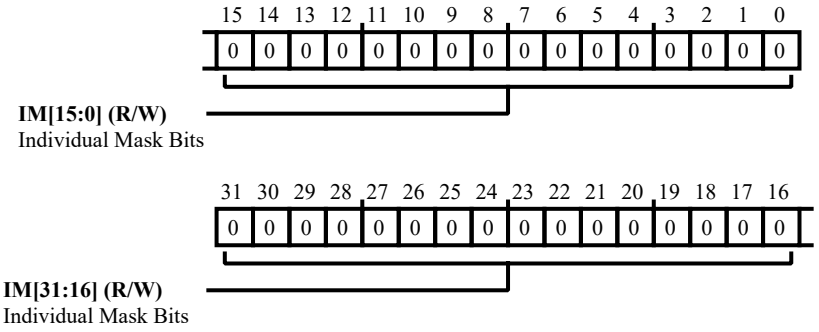

Figure 16-51: CANFD_RX_IMSK[n] Register Diagram

Table 16-69: CANFD_RX_IMSK[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	IM	Individual Mask Bits. The CANFD_RX_IMSK[n].IM bits masks the corresponding bit in both the mail-box filter and Rx FIFO ID filter table element in distinct ways. For mailbox filters, see the CANFD_RX_MB_GMSK register description. For Rx FIFO ID filter table elements, see the CANFD_RX_FIFO_GMSK register description. If a bit in the CANFD_RX_IMSK[n].IM field is set, the corresponding bit in the filter is checked. If it is cleared, the corresponding bit in the filter is a don't care.

Receive Mailbox Global Mask Register

The CANFD_RX_MB_GMSK register is located in RAM.

When the CANFD_CFG.IRMQEN bit is disabled, the CANFD_RX_MB_GMSK register is always in effect (the bits in the MG field will mask the mailbox filter bits).

When the CANFD_CFG.IRMQEN bit is enabled, the CANFD_RX_MB_GMSK register has no effect (the bits in the MG field will not mask the mailbox filter bits).

The CANFD_RX_MB_GMSK register is used to mask the filter fields of all Rx MBs, excluding MBs 14–15, which have individual mask registers.

The CANFD_RX_MB_GMSK register can only be written in freeze mode and is blocked by hardware in other modes.

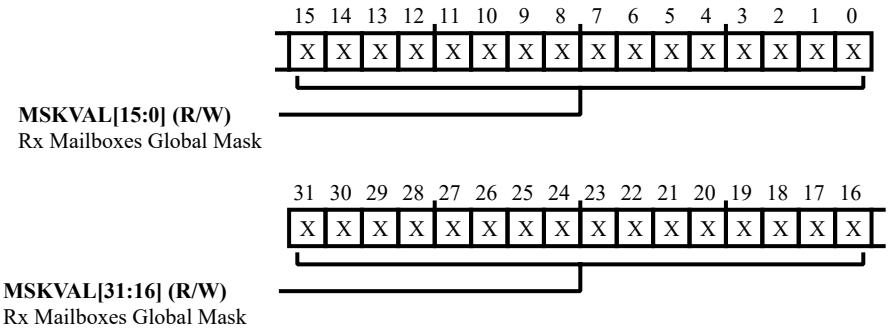

Figure 16-52: CANFD_RX_MB_GMSK Register Diagram

Table 16-70: CANFD_RX_MB_GMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:0 (R/W)	MSKVAL	Rx Mailboxes Global Mask. The CANFD_RX_MB_GMSK.MSKVAL bits mask the mailbox filter bits. Note that the alignment with the ID word of the mailbox is not perfect as the two most significant MG bits affect the fields RTR and IDE, which are located in the Control and Status (C/S) word of the mailbox.	
		0	Don't care
		1	Filter is checked

Free Running Timer Register

The CANFD_TMR register is a 16-bit free running counter. The timer starts from 0x0 after reset, counts linearly to 0xFFFF, and wraps around.

The timer is incremented by the CAN bit clock, which defines the baud rate on the CAN bus. During a message transmission/reception, the timer increments by one for each bit that is received or transmitted. When there is no message on the bus, the timer counts using the previously programmed baud rate. The timer is not incremented during module disable, doze, stop, pretended networking, and freeze modes.

The timer value is captured when the second bit of the identifier field of any frame is on the CAN bus. This captured value is written into the time stamp entry in a message buffer after the successful reception or transmission of a message.

If the CANFD_CTL1.TSYNEN bit is enabled, the timer is reset whenever a message is received in the first available mailbox, according to the CANFD_CTL2.RFFNUM setting.

The processor can write to this register anytime. However, if the write occurs at the same time that the timer is being reset by a reception in the first mailbox, then the write value is discarded.

Reading this register affects the mailbox unlocking procedure.

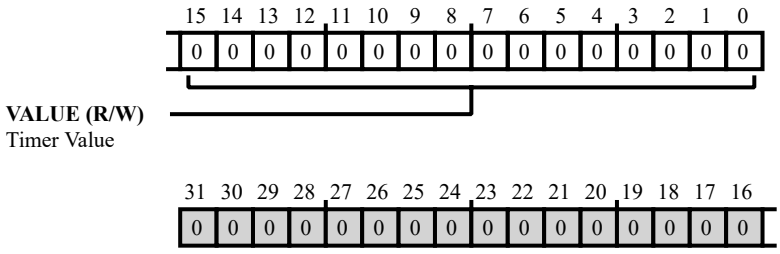

Figure 16-53: CANFD_TMR Register Diagram

Table 16-71: CANFD_TMR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Timer Value. The CANFD_TMR.VALUE bit field contains the free-running counter value.

Pretended Networking Wake Up Message Buffer 0 Control Status Register

The CANFD_WMB0_CS register stores control and status information for an incoming Rx message.

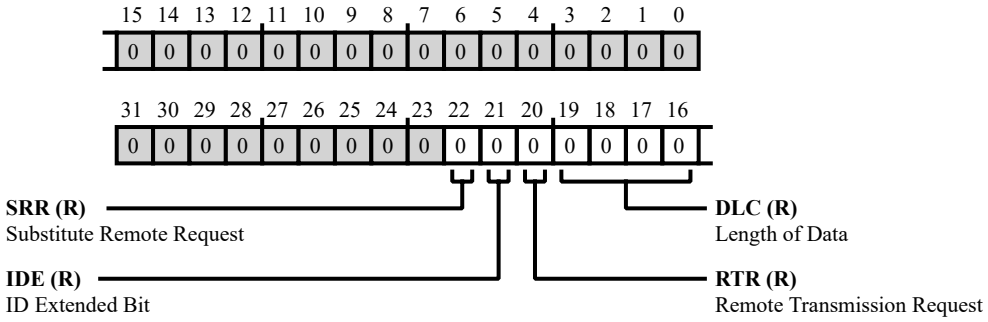

Figure 16-54: CANFD_WMB0_CS Register Diagram

Table 16-72: CANFD_WMB0_CS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
22 (R/NW)	SRR	Substitute Remote Request. The CANFD_WMB0_CS.SRR bit is received as either recessive or dominant.	
21 (R/NW)	IDE	ID Extended Bit. The CANFD_WMB0_CS.IDE bit identifies whether the frame format is standard or extended.	
		0	Standard Frame Format
		1	Extended Frame Format
20 (R/NW)	RTR	Remote Transmission Request. The CANFD_WMB0_CS.RTR bit indicates whether the frame is remote.	
		0	Data Frame (Not Remote)
		1	Remote Frame
19:16 (R/NW)	DLC	Length of Data. The CANFD_WMB0_CS.DLC field represents the length (in bytes) of the Rx data received when the module is in pretended networking mode. The CANFD_WMB0_CS.DLC field is written by the CANFD module, copied from the DLC (data length code) field of the received frame. The field indicates which data bytes are valid.	

Pretended Networking Wake Up Message Buffer 0 Data 0-3 Register

The CANFD_WMB0_D03 register stores the data bytes 0 to 3 of the payload information of the incoming Rx message. This register content is cleared when the incoming matched message is either a remote frame (RTR=1) or a data frame with DLC=0.

Note that the data 0-3 registers are located at 0xB48 for WMB0.

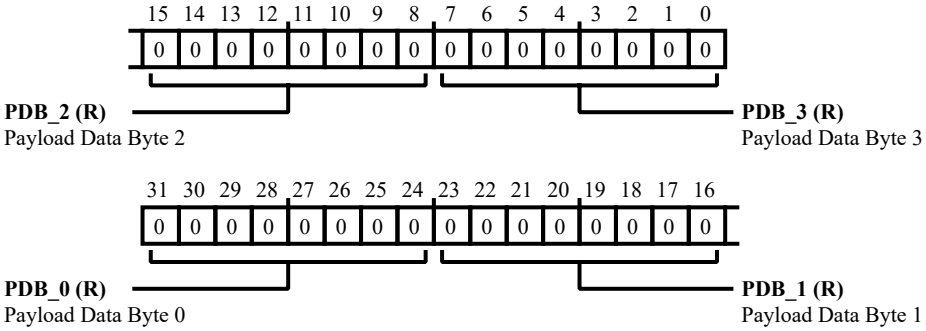

Figure 16-55: CANFD_WMB0_D03 Register Diagram

Table 16-73: CANFD_WMB0_D03 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/NW)	PDB_0	Payload Data Byte 0. The CANFD_WMB0_D03.PDB_0 bit field contains the received payload corresponding to data byte 0 in pretended networking mode.
23:16 (R/NW)	PDB_1	Payload Data Byte 1. The CANFD_WMB0_D03.PDB_1 bit field contains the received payload corresponding to data byte 1 in pretended networking mode.
15:8 (R/NW)	PDB_2	Payload Data Byte 2. The CANFD_WMB0_D03.PDB_2 bit field contains the received payload corresponding to data byte 2 in pretended networking mode.
7:0 (R/NW)	PDB_3	Payload Data Byte 3. The CANFD_WMB0_D03.PDB_3 bit field contains the received payload corresponding to data byte 3 in pretended networking mode.

Wakeup Message Buffer Data 4-7 Register

The CANFD_WMB0_D47 register stores the data bytes 4 to 7 of the payload information of an incoming Rx message.T his register content is cleared when the incoming matched message is either a remote frame (RTR=1) or a data frame with DLC=0.

Note that the data 4-7 registers are located at 0xB4C for WMB0.

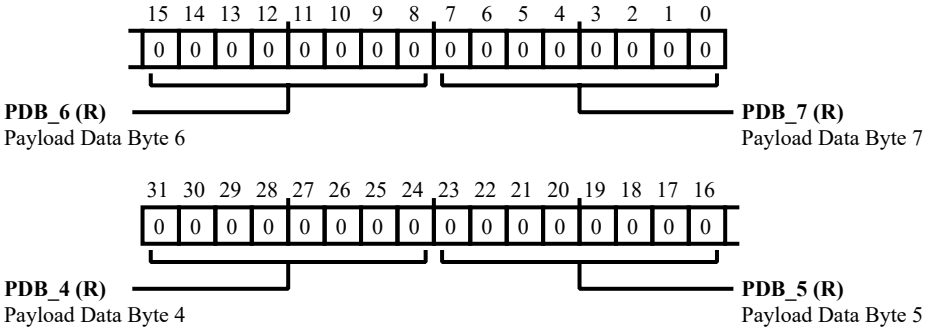

Figure 16-56: CANFD_WMB0_D47 Register Diagram

Table 16-74: CANFD_WMB0_D47 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/NW)	PDB_4	Payload Data Byte 4. The CANFD_WMB0_D47.PDB_4 bit field contains the received payload corresponding to data byte 4 in pretended networking mode.
23:16 (R/NW)	PDB_5	Payload Data Byte 5. The CANFD_WMB0_D47.PDB_5 bit field contains the received payload corresponding to data byte 5 in pretended networking mode.
15:8 (R/NW)	PDB_6	Payload Data Byte 6. The CANFD_WMB0_D47.PDB_6 bit field contains the received payload corresponding to data byte 6 in pretended networking mode.
7:0 (R/NW)	PDB_7	Payload Data Byte 7. The CANFD_WMB0_D47.PDB_7 bit field contains the received payload corresponding to data byte 7 in pretended networking mode.

Pretended Networking Wake Up Message Buffer ID 0 Register

The CANFD_WMB0_ID register stores the ID information of an incoming Rx message.

Note that the WMB0 ID registers is located at 0xB44.

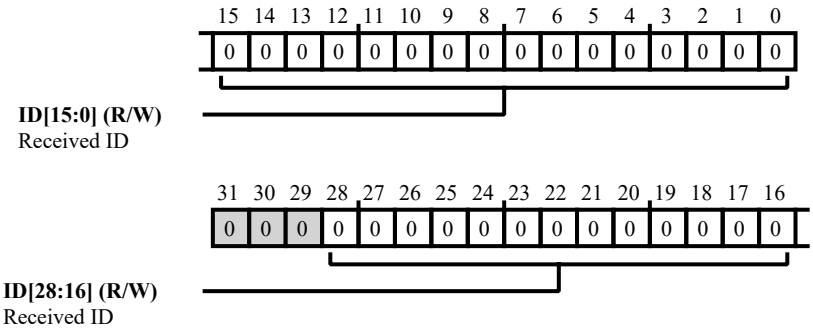

Figure 16-57: CANFD_WMB0_ID Register Diagram

Table 16-75: CANFD_WMB0_ID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
28:0 (R/W)	ID	Received ID. The CANFD_WMB0_ID.ID bit field stores the received ID as either, the 29 bits of the extended frame format (considering the ID[28:0] field) or the 11 bits of the standard frame format (considering the ID[28:18] field only). In the standard frame format, the remaining bits in the ID[17:0] range have no meaning.

Pretended Networking Wake Up Message Buffer 1 Control Status Register

The CANFD_WMB1_CS register stores control and status information for an incoming Rx message.

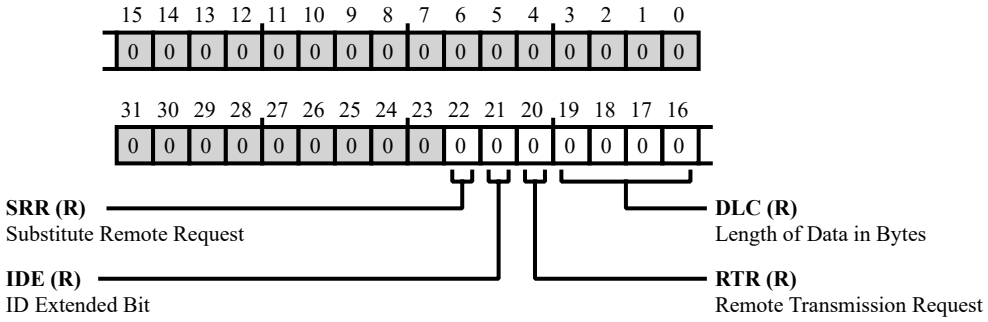

Figure 16-58: CANFD_WMB1_CS Register Diagram

Table 16-76: CANFD_WMB1_CS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
22 (R/NW)	SRR	Substitute Remote Request. The CANFD_WMB1_CS.SRR bit is received as either recessive or dominant.	
21 (R/NW)	IDE	ID Extended Bit. The CANFD_WMB1_CS.IDE bit identifies whether the frame format is standard or extended.	
		0	Standard Frame Format
		1	Extended Frame Format
20 (R/NW)	RTR	Remote Transmission Request. The CANFD_WMB1_CS.RTR bit indicates whether the frame is remote.	
		0	Data Frame (Not Remote)
		1	Remote Frame
19:16 (R/NW)	DLC	Length of Data in Bytes. The CANFD_WMB1_CS.DLC field represents the length (in bytes) of the Rx data received when the module is in pretended networking mode. The CANFD_WMB1_CS.DLC field is written by the CANFD module, copied from the DLC (data length code) field of the received frame. The field indicates which data bytes are valid.	

Pretended Networking Wake Up Message Buffer 1 Data 0-3 Register

The CANFD_WMB1_D03 register stores the data bytes 0 to 3 of the payload information of the incoming Rx message. This register content is cleared when the incoming matched message is either a remote frame (RTR=1) or a data frame with DLC=0.

Note that the data 0-3 registers are located at 0xB58 for WMB1.

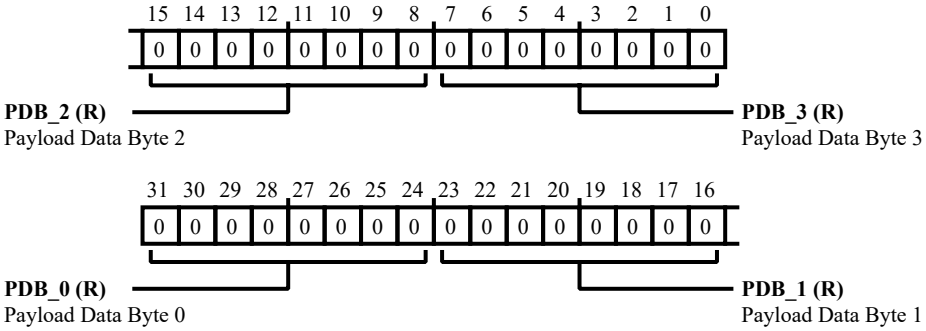

Figure 16-59: CANFD_WMB1_D03 Register Diagram

Table 16-77: CANFD_WMB1_D03 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/NW)	PDB_0	Payload Data Byte 0. The CANFD_WMB1_D03.PDB_0 bit field contains the received payload corresponding to data byte 0 in pretended networking mode.
23:16 (R/NW)	PDB_1	Payload Data Byte 1. The CANFD_WMB1_D03.PDB_1 bit field contains the received payload corresponding to data byte 1 in pretended networking mode.
15:8 (R/NW)	PDB_2	Payload Data Byte 2. The CANFD_WMB1_D03.PDB_2 bit field contains the received payload corresponding to data byte 2 in pretended networking mode.
7:0 (R/NW)	PDB_3	Payload Data Byte 3. The CANFD_WMB1_D03.PDB_3 bit field contains the received payload corresponding to data byte 3 in pretended networking mode.

Pretended Networking Wake Up Message Buffer 1 Data 4-7 Register

The CANFD_WMB1_D47 register stores the data bytes 4 to 7 of the payload information of an incoming Rx message.T his register content is cleared when the incoming matched message is either a remote frame (RTR=1) or a data frame with DLC=0.

Note that the data 4-7 registers are located at 0xB5C for WMB1.

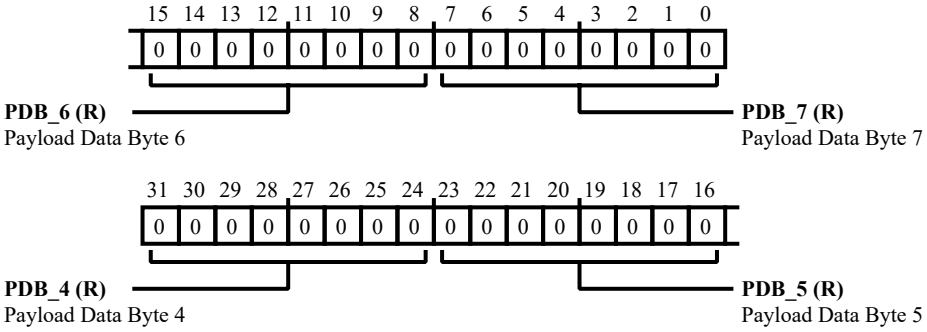

Figure 16-60: CANFD_WMB1_D47 Register Diagram

Table 16-78: CANFD_WMB1_D47 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/NW)	PDB_4	Payload Data Byte 4. The CANFD_WMB1_D47.PDB_4 bit field contains the received payload corresponding to data byte 4 in pretended networking mode.
23:16 (R/NW)	PDB_5	Payload Data Byte 5. The CANFD_WMB1_D47.PDB_5 bit field contains the received payload corresponding to data byte 5 in pretended networking mode.
15:8 (R/NW)	PDB_6	Payload Data Byte 6. The CANFD_WMB1_D47.PDB_6 bit field contains the received payload corresponding to data byte 6 in pretended networking mode.
7:0 (R/NW)	PDB_7	Payload Data Byte 7. The CANFD_WMB1_D47.PDB_7 bit field contains the received payload corresponding to data byte 7 in pretended networking mode.

Pretended Networking Wake Up Message Buffer ID 1 Register

The CANFD_WMB1_ID register stores the ID information of an incoming Rx message.

Note that the WMB1 ID registers is located at 0xB54.

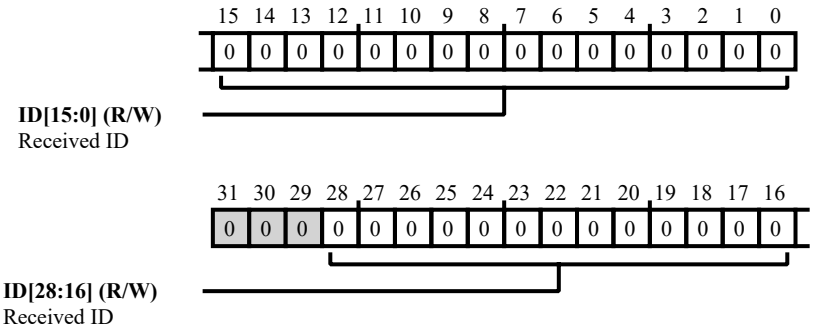

Figure 16-61: CANFD_WMB1_ID Register Diagram

Table 16-79: CANFD_WMB1_ID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
28:0 (R/W)	ID	Received ID. The CANFD_WMB1_ID.ID bit field stores the received ID as either, the 29 bits of the extended frame format (considering the ID[28:0] field) or the 11 bits of the standard frame format (considering the ID[28:18] field only). In the standard frame format, the remaining bits in the ID[17:0] range have no meaning.

Pretended Networking Wake Up Message Buffer 2 Control Status Register

The CANFD_WMB2_CS register stores control and status information for an incoming Rx message.

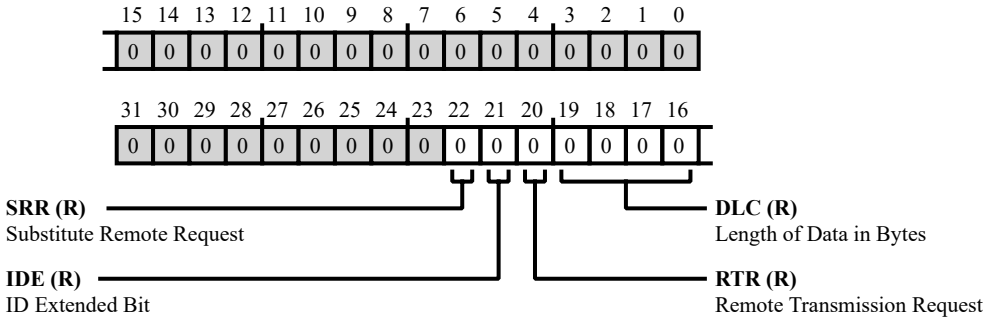

Figure 16-62: CANFD_WMB2_CS Register Diagram

Table 16-80: CANFD_WMB2_CS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
22 (R/NW)	SRR	Substitute Remote Request. The CANFD_WMB2_CS.SRR bit is received as either recessive or dominant.	
21 (R/NW)	IDE	ID Extended Bit. The CANFD_WMB2_CS.IDE bit identifies whether the frame format is standard or extended.	
		0	Standard Frame Format
		1	Extended Frame Format
20 (R/NW)	RTR	Remote Transmission Request. The CANFD_WMB2_CS.RTR bit indicates whether the frame is remote.	
		0	Data Frame (Not Remote)
		1	Remote Frame
19:16 (R/NW)	DLC	Length of Data in Bytes. The CANFD_WMB2_CS.DLC field represents the length (in bytes) of the Rx data received when the module is in pretended networking mode. The CANFD_WMB2_CS.DLC field is written by the CANFD module, copied from the DLC (data length code) field of the received frame. The field indicates which data bytes are valid.	

Pretended Networking Wake Up Message Buffer 2 Data 0-3 Register

The CANFD_WMB2_D03 register stores the data bytes 0 to 3 of the payload information of the incoming Rx message. This register content is cleared when the incoming matched message is either a remote frame (RTR=1) or a data frame with DLC=0.

Note that the data 0-3 registers are located at 0xB68 for WMB2.

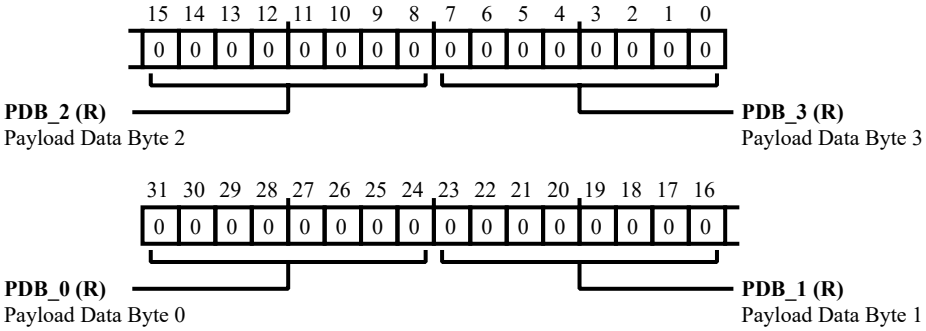

Figure 16-63: CANFD_WMB2_D03 Register Diagram

Table 16-81: CANFD_WMB2_D03 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/NW)	PDB_0	Payload Data Byte 0. The CANFD_WMB2_D03.PDB_0 bit field contains the received payload corresponding to data byte 0 in pretended networking mode.
23:16 (R/NW)	PDB_1	Payload Data Byte 1. The CANFD_WMB2_D03.PDB_1 bit field contains the received payload corresponding to data byte 1 in pretended networking mode.
15:8 (R/NW)	PDB_2	Payload Data Byte 2. The CANFD_WMB2_D03.PDB_2 bit field contains the received payload corresponding to data byte 2 in pretended networking mode.
7:0 (R/NW)	PDB_3	Payload Data Byte 3. The CANFD_WMB2_D03.PDB_3 bit field contains the received payload corresponding to data byte 3 in pretended networking mode.

Pretended Networking Wake Up Message Buffer 2 Data 4-7 Register

The CANFD_WMB2_D47 register stores the data bytes 4 to 7 of the payload information of an incoming Rx message.T his register content is cleared when the incoming matched message is either a remote frame (RTR=1) or a data frame with DLC=0.

Note that the data 4-7 registers are located at 0xB6C for WMB2.

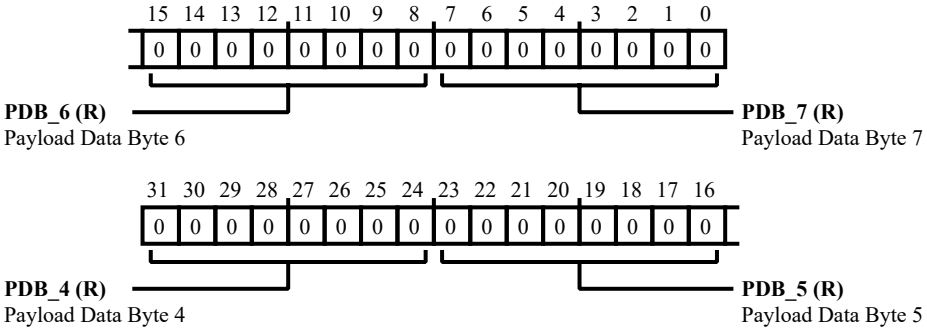

Figure 16-64: CANFD_WMB2_D47 Register Diagram

Table 16-82: CANFD_WMB2_D47 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/NW)	PDB_4	Payload Data Byte 4. The CANFD_WMB2_D47.PDB_4 bit field contains the received payload corresponding to data byte 4 in pretended networking mode.
23:16 (R/NW)	PDB_5	Payload Data Byte 5. The CANFD_WMB2_D47.PDB_5 bit field contains the received payload corresponding to data byte 5 in pretended networking mode.
15:8 (R/NW)	PDB_6	Payload Data Byte 6. The CANFD_WMB2_D47.PDB_6 bit field contains the received payload corresponding to data byte 6 in pretended networking mode.
7:0 (R/NW)	PDB_7	Payload Data Byte 7. The CANFD_WMB2_D47.PDB_7 bit field contains the received payload corresponding to data byte 7 in pretended networking mode.

Pretended Networking Wake Up Message Buffer ID 2 Register

The CANFD_WMB2_ID register stores the ID information of an incoming Rx message.

Note that the WMB2 ID registers is located at 0xB64.

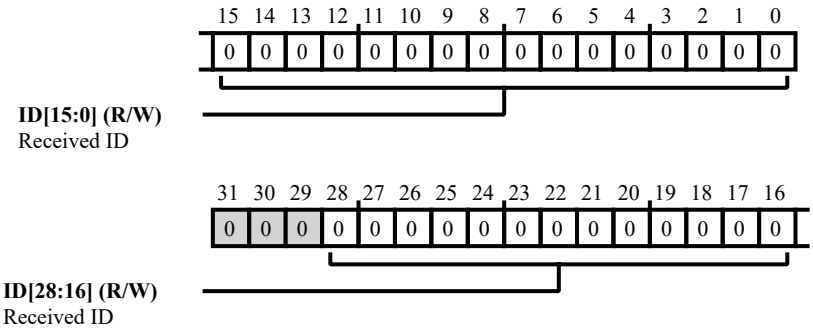

Figure 16-65: CANFD_WMB2_ID Register Diagram

Table 16-83: CANFD_WMB2_ID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
28:0 (R/W)	ID	Received ID. The CANFD_WMB2_ID.ID bit field stores the received ID as either, the 29 bits of the extended frame format (considering the ID[28:0] field) or the 11 bits of the standard frame format (considering the ID[28:18] field only). In the standard frame format, the remaining bits in the ID[17:0] range have no meaning.

Pretended Networking Wake Up Message Buffer 3 Control Status Register

The CANFD_WMB3_CS register stores control and status information for an incoming Rx message.

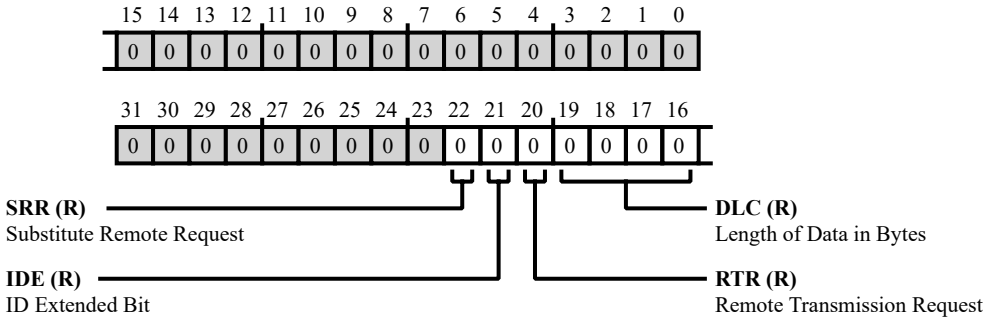

Figure 16-66: CANFD_WMB3_CS Register Diagram

Table 16-84: CANFD_WMB3_CS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
22 (R/NW)	SRR	Substitute Remote Request. The CANFD_WMB3_CS.SRR bit is received as either recessive or dominant.	
21 (R/NW)	IDE	ID Extended Bit. The CANFD_WMB3_CS.IDE bit identifies whether the frame format is standard or extended.	
		0	Standard Frame Format
		1	Extended Frame Format
20 (R/NW)	RTR	Remote Transmission Request. The CANFD_WMB3_CS.RTR bit indicates whether the frame is remote.	
		0	Data Frame (Not Remote)
		1	Remote Frame
19:16 (R/NW)	DLC	Length of Data in Bytes. The CANFD_WMB3_CS.DLC field represents the length (in bytes) of the Rx data received when the module is in pretended networking mode. The CANFD_WMB3_CS.DLC field is written by the CANFD module, copied from the DLC (data length code) field of the received frame. The field indicates which data bytes are valid.	

Pretended Networking Wake Up Message Buffer 3 Data 0-3 Register

The CANFD_WMB3_D03 register stores the data bytes 0 to 3 of the payload information of the incoming Rx message. This register content is cleared when the incoming matched message is either a remote frame (RTR=1) or a data frame with DLC=0.

Note that the data 0-3 registers are located at 0xB78 for WMB3.

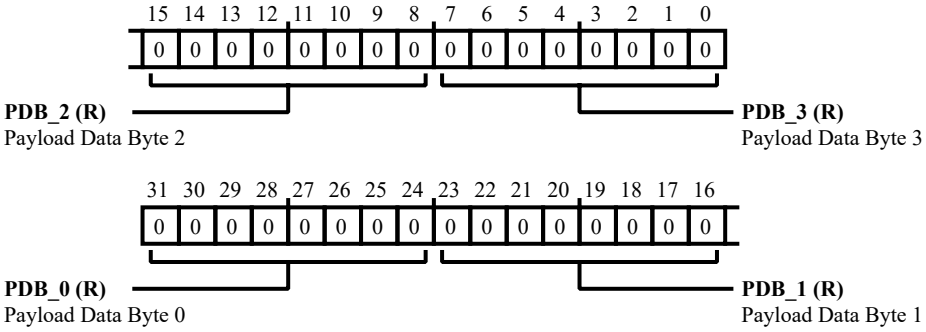

Figure 16-67: CANFD_WMB3_D03 Register Diagram

Table 16-85: CANFD_WMB3_D03 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/NW)	PDB_0	Payload Data Byte 0. The CANFD_WMB3_D03.PDB_0 bit field contains the received payload corresponding to data byte 0 in pretended networking mode.
23:16 (R/NW)	PDB_1	Payload Data Byte 1. The CANFD_WMB3_D03.PDB_1 bit field contains the received payload corresponding to data byte 1 in pretended networking mode.
15:8 (R/NW)	PDB_2	Payload Data Byte 2. The CANFD_WMB3_D03.PDB_2 bit field contains the received payload corresponding to data byte 2 in pretended networking mode.
7:0 (R/NW)	PDB_3	Payload Data Byte 3. The CANFD_WMB3_D03.PDB_3 bit field contains the received payload corresponding to data byte 3 in pretended networking mode.

Pretended Networking Wake Up Message Buffer 3 Data 4-7 Register

The CANFD_WMB3_D47 register stores the data bytes 4 to 7 of the payload information of an incoming Rx message.T his register content is cleared when the incoming matched message is either a remote frame (RTR=1) or a data frame with DLC=0.

Note that the data 4-7 registers are located at 0xB7C for WMB3.

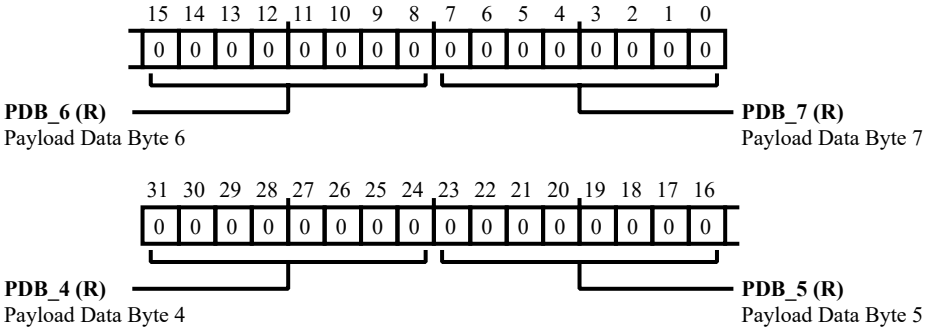

Figure 16-68: CANFD_WMB3_D47 Register Diagram

Table 16-86: CANFD_WMB3_D47 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/NW)	PDB_4	Payload Data Byte 4. The CANFD_WMB3_D47.PDB_4 bit field contains the received payload corresponding to data byte 4 in pretended networking mode.
23:16 (R/NW)	PDB_5	Payload Data Byte 5. The CANFD_WMB3_D47.PDB_5 bit field contains the received payload corresponding to data byte 5 in pretended networking mode.
15:8 (R/NW)	PDB_6	Payload Data Byte 6. The CANFD_WMB3_D47.PDB_6 bit field contains the received payload corresponding to data byte 6 in pretended networking mode.
7:0 (R/NW)	PDB_7	Payload Data Byte 7. The CANFD_WMB3_D47.PDB_7 bit field contains the received payload corresponding to data byte 7 in pretended networking mode.

Pretended Networking Wake Up Message Buffer ID 3 Register

The CANFD_WMB3_ID register stores the ID information of an incoming Rx message.

Note that the WMB3 ID registers is located at 0xB74.

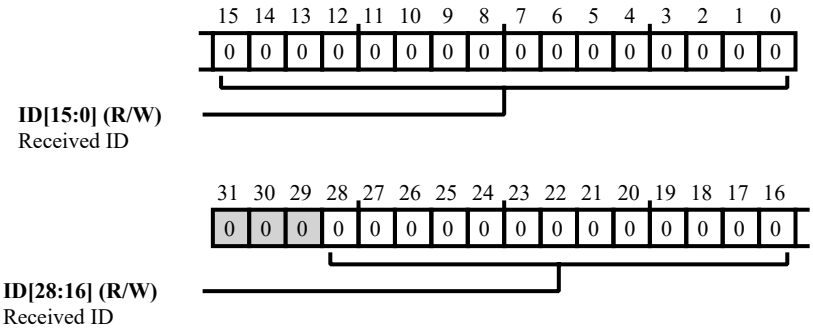

Figure 16-69: CANFD_WMB3_ID Register Diagram

Table 16-87: CANFD_WMB3_ID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
28:0 (R/W)	ID	Received ID. The CANFD_WMB3_ID.ID bit field stores the received ID as either, the 29 bits of the extended frame format (considering the ID[28:0] field) or the 11 bits of the standard frame format (considering the ID[28:18] field only). In the standard frame format, the remaining bits in the ID[17:0] range have no meaning.

Pretended Networking Wakeup Match Register

The CANFD_WUM register contains wake up information related to the matching processes performed while the CANFD module receives frames under pretended networking mode.

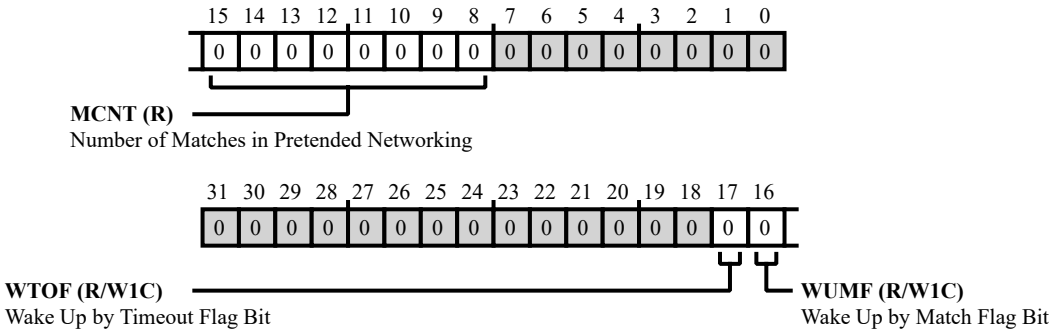

Figure 16-70: CANFD_WUM Register Diagram

Table 16-88: CANFD_WUM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W1C)	WTOF	Wake Up by Timeout Flag Bit. The CANFD_WUM.WTOF bit indicates if the CANFD module detects a timeout event during a time interval defined by the CANFD_PN_CTL2.MATCHTO bit field. WTOF generates a wakeup event if the CANFD_PN_CTL1.WTOFMSK enabled.	
		0	No event detected
		1	Wakeup event detected
16 (R/W1C)	WUMF	Wake Up by Match Flag Bit. The CANFD_WUM.WUMF bit indicates whether the CANFD module detects a matching Rx incoming message passing the filtering criteria specified in the CANFD_PN_CTL1 register. WUMF generates a wakeup event if the CANFD_PN_CTL1.WUMFMSK bit is enabled.	
		0	No event detected
		1	Wakeup event detected
15:8 (R/NW)	MCNT	Number of Matches in Pretended Networking. The CANFD_WUM.MCNT bit field reports the number of times a given message matches the predefined filtering criteria for ID and/or PL before a wake up event. The CANFD_WUM.MCNT bit field is reset by the CANFD module when it enters pretended networking mode. This bit field and is not affected by a soft reset.	

17 Watchdog Timer (WDOG)

The processor has a 32-bit watchdog timer that can be used to verify system reliability by generating an event to the processor core when the watchdog expires before software updates it.

The ADSP-2184x has four watchdog timers, providing more options to monitor different parts of the system separately.

WDOG Features

The watchdog timer has the following features:

- Programmable 32-bit watchdog count value
- 8-bit disable bit pattern
- General-purpose core event generation

The watchdog timer can supervise system software stability by periodically reloading it to prevent expiration of the downward-counting timer (such that the count never becomes 0). When used in this fashion, an expiring timer can indicate the system software is not running normally.

Expiration of the WDOG counter generates a general-purpose interrupt, which can be used in a variety of ways:

- as an interrupt vector sent through the System Event Controller (SEC) to the core to be serviced by a handler function, providing full software control of device resources (for example, GPIO management and reset control).
- as a fault condition through the SEC to provide hardware-automated:
    - signaling of the fault condition on external pins to the system,
    - system reset requests to the Reset Control Unit (RCU), and/or
    - trigger outputs (SEC0_FAULT trigger generator) through the Trigger Routing Unit (TRU) to initiate activities in a variety of potential trigger receiver (for example, GPIO control).

To help debugging, the watchdog timer does not decrement (even when enabled) if the processor is in emulation mode.

WDOG Functional Description

When enabled, the 32-bit watchdog timer counts downward every SCLK0_0 cycle. If it reaches zero, the watchdog expiration event is generated, which can be used in many ways.

To start the watchdog timer:

1. Program the watchdog timeout period (in SCLK0_0 cycles) in the WDOG_CNT register. With the watchdog disabled, this write also preloads the WDOG_STAT register.
2. Enable the watchdog timer by writing any value other than 0xAD to the WDOG_CTL.WDEN field.

Once the watchdog is enabled, writes to the WDOG_CNT register are ignored. The counter begins decrementing, and the current counter value can be read from the 32-bit WDOG_STAT register at any time.

To prevent the counter from expiring, software must "kick" the watchdog by writing any value to the WDOG_STAT register while the current count is non-zero. While the value written is irrelevant and ignored, this action resets the current counter in the WDOG_STAT register to the programmed WDOG_CNT value, and decrementing continues. The internal counter continues decrementing until it reaches zero, at which point the expiration event is generated, and the WDOG_CTL.WDRO rollover bit is set.

Watchdog operation continues in this manner unless disabled by explicitly writing 0xAD to the WDOG_CTL.WDEN field.

The watchdog expiration event can be used in a variety of ways, as listed below.

- The watchdog expiration event itself is one of numerous interrupt sources that is managed by the System Event Controller. Like other peripheral sources, this event can be used to cause a vector to a handler function that executes based on interrupt priority.
- The watchdog expiration event can be used to initiate automated hardware response through the SEC Fault Interface (SFI).

For this, the WDOG expiry must be configured as the fault source in the SEC. Then the response to the WDOG expiry can be set to any of the following actions:

- Signaling through the external fault pin.
- System reset.
- Trigger outputs to numerous potential trigger completers.

ADSP-2184x WDOG Register List

The Watchdog Timer unit (WDOG) provides a software-based watchdog timer that can improve system reliability by generating an event to the processor core if the watchdog expires before being updated by software. A set of registers governs WDOG operations. For more information on WDOG functionality, see the WDOG register descriptions.

Table 17-1: ADSP-2184x WDOG Register List

WDOG Block Diagram

The *Watchdog Timer Block Diagram* figure shows the detailed block diagram for the watchdog timer.

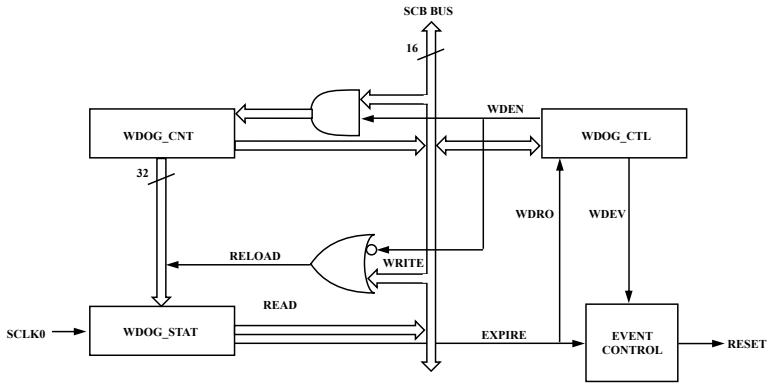

Figure 17-1: Watchdog Timer Block Diagram

Internal Interface

The system clock (SCLK) clocks the watchdog timer. The registers are accessed through the peripheral MMR access bus. 32-bit read/write operations always access the 32-bit `WDOG_CNT` and `WDOG_STAT` registers. Hardware ensures that those accesses are atomic. When the counter expires, the WDOG expiration event is generated.

External Interface

The watchdog timer does not directly interact with any external pins.

ADSP-2184x WDOG Register Descriptions

Watchdog Timer Unit (WDOG) contains the following registers.

Table 17-5: ADSP-2184x WDOG Register List

Name	Description
`WDOG_CNT`	Count Register
`WDOG_CTL`	Control Register
`WDOG_STAT`	Watchdog Timer Status Register
`WDOG_WIN`	Watchdog Timer Window Register

Count Register

The WDOG_CNT register holds the programmable, unsigned count value. A valid write to this register also pre-loads the WDOG counter. For added safety, the WDOG_CNT register can be updated only when the WDOG timer is disabled. A write to the WDOG_CNT register while the timer is enabled does not modify the contents of this register. This register must be accessed with 32-bit read/writes only.

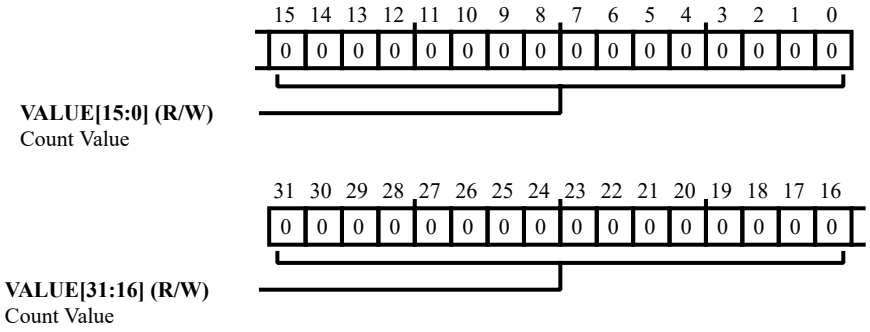

Figure 17-2: WDOG_CNT Register Diagram

Table 17-6: WDOG_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Count Value. The WDOG_CNT.VALUE bit field holds the programmable, unsigned count value.

Control Register

The WDOG_CTL register controls the watchdog timer. This register supports enabling/disabling the watchdog timer and supports checking the timer rollover status. Note that when the processor is in emulation mode, the watchdog timer counter will not decrement even if it is enabled.

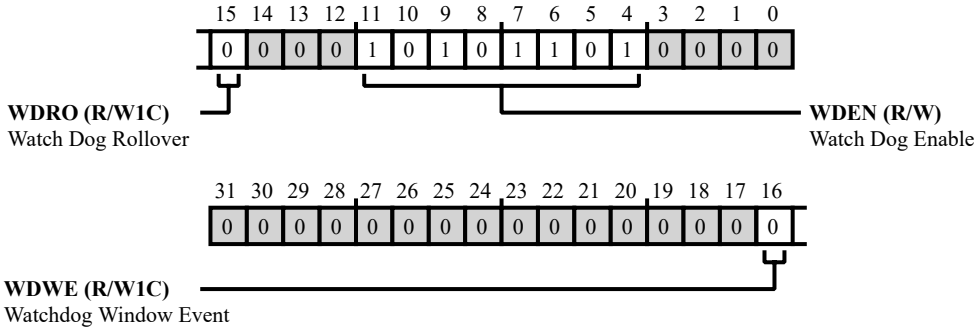

Figure 17-3: WDOG_CTL Register Diagram

Table 17-7: WDOG_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W1C)	WDWE	Watchdog Window Event. Software can determine whether the timer has been serviced unexpectedly early by interrogating the WDOG_CTL.WDWE status bit. This is a sticky bit that is set whenever the watchdog is serviced and the WDOG_STAT value is greater than the WDOG_WIN value. It is cleared only by disabling the watchdog timer and by writing a 1 to the bit.	
		0	Window Event has not occurred
		1	Window Event has occurred
15 (R/W1C)	WDRO	Watch Dog Rollover. Software can determine whether the timer has rolled over by interrogating the WDOG_CTL.WDRO status bit. This is a sticky bit that is set whenever the watch dog timer count reaches 0 and cleared only by disabling the watch dog timer and then writing a 1 to the bit.	
		0	WDT Has Not Expired
		1	WDT Has Expired
11:4 (R/W)	WDEN	Watch Dog Enable. The WDOG_CTL.WDEN field is used to enable and disable the watchdog timer. Writing any value other than the disable value into this field enables the watchdog timer. This multi-bit disable key minimizes the chance of inadvertently disabling the watchdog timer.	
		173	Counter Disabled. All other values mean that the counter is enabled.

Watchdog Timer Status Register

The WDOG_STAT register contains the current count value of the watchdog timer. Reads of this register return the current count value. When the watchdog timer is enabled, the WDOG_STAT register is decremented by 1 on each SCLK cycle. When the count value reaches 0, the watchdog timer stops counting, and the expiry event is generated. The WDOG_STAT register is a 32-bit unsigned system MMR that must be accessed with 32-bit reads and writes.

Values cannot be stored directly in this register but are instead copied from the WDOG_CNT register. This copy process can happen in two ways:

- While the watchdog timer is disabled, writing the WDOG_CNT register pre-loads the WDOG_STAT register.
- While the watchdog timer is enabled, writing the WDOG_STAT register loads it with the value in the WDOG_CNT register.
- While the watchdog timer is disabled, writing to the WDOG_STAT register also reloads it with the value in the WDOG_CNT register.

When the processor executes a write (of an arbitrary value) to the WDOG_STAT register, the value in the WDOG_CNT register is copied into the WDOG_STAT register. Typically, software sets the value of WDOG_CNT at initialization, then periodically writes to the WDOG_STAT register before the watchdog timer expires. This reloads the watchdog timer with the value from WDOG_CNT and prevents generation of the expiry event.

If the program does not reload the counter before SCLK x count register cycles, an expiry event is generated, and the WDOG_CTL.WDRO bit is set. When this happens, the counter stops decrementing and remains at zero. If the counter is enabled with a zero loaded to the counter, the WDOG_CTL.WDRO bit is set immediately and the counter remains at zero and does not decrement.

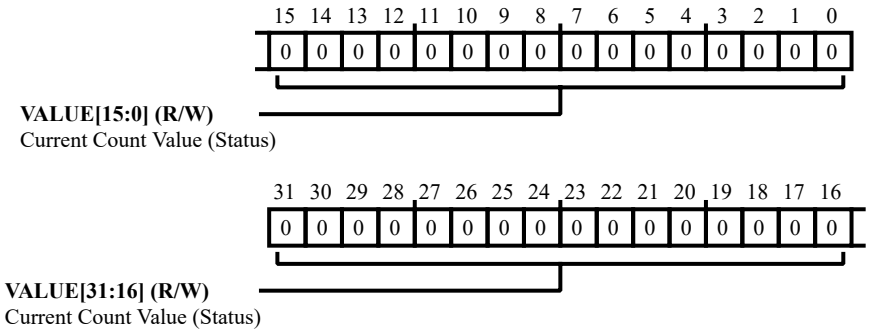

Figure 17-4: WDOG_STAT Register Diagram

Table 17-8: WDOG_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Current Count Value (Status). The `WDOG_STAT.VALUE` bit field contains the current count value of the watchdog timer.

Watchdog Timer Window Register

Watchdog window register holds the unsigned window value programmed. The window register can be programmed while the WDOG is disabled; any write to the register when WDOG is enabled doesn't alter the contents of the register. When the WDOG is enabled and the core services the WDOG by doing a write to `WDOG_STAT` register while the `WDOG_STAT` value is greater than `WDOG_WIN`, the WDWE event is generated and also the counter stops decrementing.

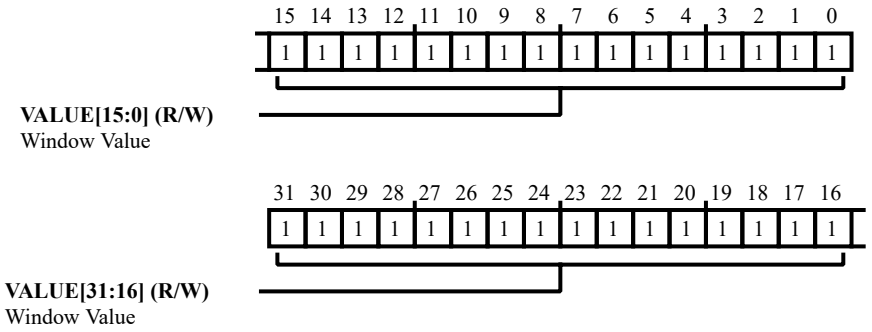

Figure 17-5: WDOG_WIN Register Diagram

Table 17-9: WDOG_WIN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Window Value. The `WDOG_WIN.VALUE` bit field contains the unsigned window value.

18 Link Port (LP)

Link ports allow the processor to connect to other processors or peripheral link ports using a simple communication protocol for high-speed parallel data transfer. This peripheral allows various I/O peripheral interconnection schemes to I/O peripheral devices as well as co-processing and multiprocessing schemes.

The link ports of the processor support 2- and 4-bit wide data transfers DDR mode. The link port pins are multiplexed in the GPIO ports. For information on processor multiplexing, see the data sheet for the specific processor.

Link ports can operate independently and simultaneously, allowing glueless high-speed connectivity of up to four external processors.

NOTE: Reference to SCLK in this chapter can be considered as OCLK0_0.

LP Features

All link ports are identical in their design and have the following common features.

- Bidirectional ports with four data signals (`LP_D0` - `LP_D3`), an acknowledge signal (`LP_ACK`), and a clock signal (`LP_CLK`).
- Provide high-speed, point-to-point data transfers to other processors, allowing different types of interconnections between multiple processors.
- Pack data into 32-bit words. The processor can directly read this data or transfer it through DMA to or from on-chip memory.
- Support for data buffering through a 2-deep FIFO for transmit and a 4-deep FIFO for receive.
- Programmable clock and acknowledge based handshake mechanism for efficient communication.
- A dedicated DMA channel.
- Support for data transfer in 2-bit mode (DDR) and 4-bit mode (DDR)

LP Functional Description

This section provides a description of the link port, including a list of its registers and a functional block diagram.

ADSP-2184x LP Register List

The Link Port LP is an 8-bit wide parallel port that can connect to another processor's LP or another LP-compatible device. This port allows a variety of interconnection schemes to I/O peripheral devices as well as co-processing and multiprocessing schemes. A set of registers governs LP operations. For more information on LP functionality, see the LP register descriptions.

Table 18-1: ADSP-2184x LP Register List

Name	Description

Block Diagram

The ***Link Port Block Diagram*** shows the block diagram of a link port.

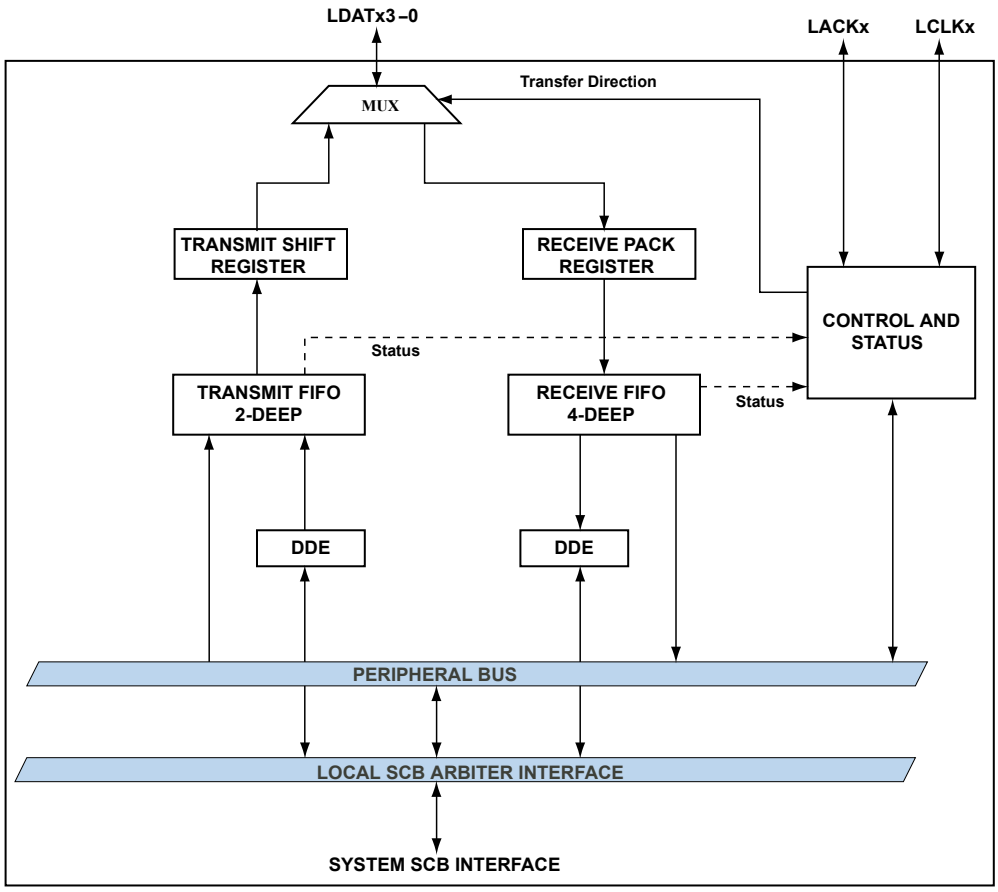

Figure 18-1: Link Port Block Diagram

External Connections

As shown in the ***Link Port Pin Connections*** figure, a link port has four data lines (LP_D0 – LP_D3), a clock line (LP_CLK), and an acknowledge line (LP_ACK). A link port can act as either a transmitter or a receiver but not both at the same time.

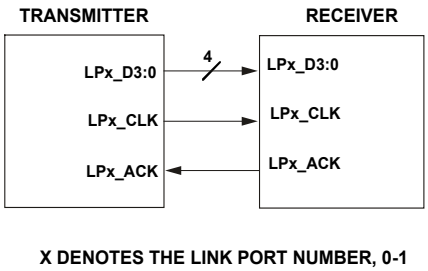

Figure 18-2: Link Port Pin Connections

Use external pull-downs for the LP_CLK and LP_ACK pins so that the link port can enable the transmitter and receiver, irrespective of the state of the other.

Internal Blocks

As shown in the block diagram, the link ports have independent modules for transmit and receive. If enabled as transmitter, the link port uses a 2 deep 32-bit FIFO. If enabled as a receiver, the port uses a 4 deep 32-bit FIFO. The core MMR access bus interfaces with these FIFOs. The distributed DMA engines (DDE) use the system cross bar (SCB) interface to access the FIFO. The link port uses the LP_CTL.TRAN bit to determine whether the module is enabled for transmit or receive operation.

Architectural Concepts

The following sections describe the architectural concepts of the link port.

- FIFO Buffers
- Handshake for Link Port Enable Process
- Multi-Processor Connectivity

FIFO Buffers

When a link port is configured as transmitter, the link port uses a 2-deep FIFO buffer. A shift register unpacks the single 32-bit word to either eight 4-bit data bytes or sixteen 2-bit data bytes, based on the selected transfer mode. As the FIFO has space for more data, the link port makes a new DMA request. If the FIFO becomes empty, the LP_CLK signal is deasserted. The core can access FIFO through the LP_TX register.

The core or DMA makes three writes (2-stage FIFO and 1 shift register) to the transmit buffer before it signals a full condition. The link port uses the LP_STAT.FFST bit field to reflect the status of the FIFO but not the shift register full or empty condition. However, the program can poll the LP_STAT.LPBS bit to discover whether the link port is driving data from the shift register to the pins. The LP_STAT.LPBS bit is also set when receiver has held off transmission by driving LP_ACK low.

NOTE: When the 2-deep FIFO and the output shift-register overflow, any further write to the link port buffer overwrites the input stage of the FIFO.

NOTE: The core can also read the transmit FIFO through the data LP_TX register.

NOTE: If the transmitter is disabled while performing writes to the transmit FIFO, a FIFO full condition is signaled after two writes.

The transmit buffer registers have shadow registers. Using these shadow registers, both stages of the 2-deep FIFO can be read without updating the status registers. The LP_TXIN_SHDW register corresponds to the input stage of the FIFO. The LP_TXOUT_SHDW register corresponds to the output stage of the FIFO as shown in the ***Transmit FIFO path*** figure.

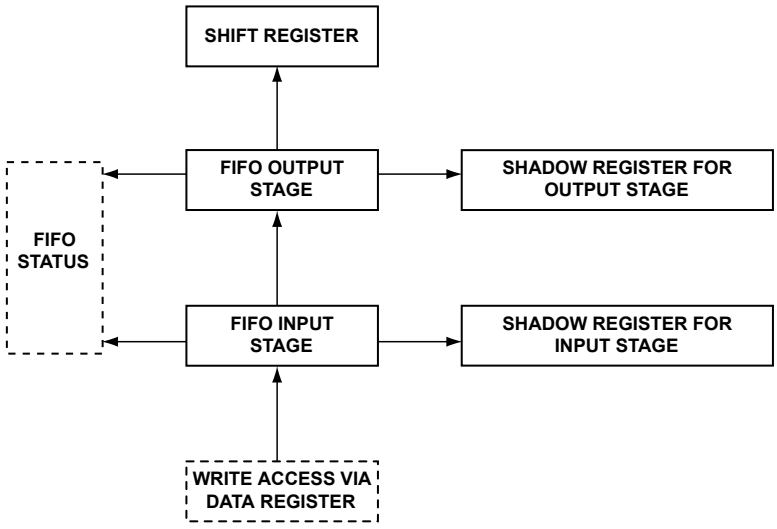

Figure 18-3: Transmit FIFO path

When a link port is configured as receiver, data transfers to the core or DMA from the full 4-deep receive FIFO. An internal packing register packs data to 32 bits. Four reads can occur from the receive buffer by the core or DMA before it signals an empty condition. The link port uses the LP_STAT.FFST bits to reflect the status of the 4-deep read buffer FIFO. The core can access this FIFO through the LP_RX register.

NOTE: When receive FIFO overflows (LP_STAT.ROVF bit=1), any further data from the transmitter is lost. Only the data retained in the receive FIFO can be retrieved further.

The receiver drives the LP_ACK output signal low, after the first byte of data for the next-to-last empty slot (in the 4-deep FIFO) is received. This functionality prevents data loss due to the transmitter starting transmission of the next word before the LP_ACK signal reaches the transmitter. (The timing is due to the larger delay in synchronization.) This functionality guarantees that even after allowing for the extra synchronization cycle in the transmitter and receiver, there is no overflow in the receive FIFO. The ***LACK Generation Based on Receive FIFO Status*** figure shows how FIFO slots influence the acknowledge signal generation. The grayed sections show received data. The white sections show empty locations where the decision to pull LP_ACK high is taken.

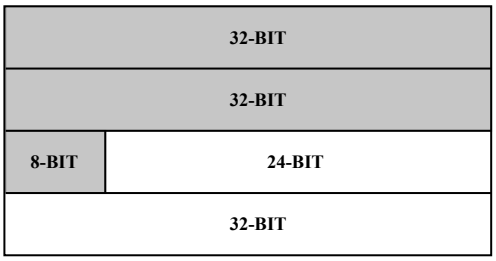

Figure 18-4: LACK Generation Based on Receive FIFO Status

NOTE: The link port uses a 4-deep receive FIFO only under a worst case situation, as mentioned. In all other cases, respond as if the FIFO has only a 3-deep stage. The LP_ACK signal is pulled high before the last stage of the FIFO.

The link port has memory-mapped buffers for both receive and transmit operations. A JTAG-based emulator can read the FIFO which can cause unexpected problems in data transfers. This activity can only happen during an emulation event (typically hitting a breakpoint or single-stepping). The emulator issues core reads through JTAG. To work around this issue, see the tools documentation for more information.

Handshake for Link Port Enable Process

In a link port-based system, the transmitter and the receiver can be enabled at different times. Use external pull-downs for the LP_CLK and LP_ACK signals.

If the receiver is enabled before the transmitter, the external pull-down holds the LP_CLK signal of the transmitter low. The receiver is held off. The receiver can wait for a rising edge on the LP_CLK signal to assert its receive service request interrupt. This rising edge occurs only when transmitter starts driving the first data on to the bus, after the application enables it.

If the transmitter is enabled before the receiver, the external pull-down holds the LP_ACK signal of the receiver low. Transmission is held off. Refer to the ***Enable the Transmitter Before the Receiver*** figure. The transmitter can wait for a rising edge on the LP_ACK signal to assert its transmit service request interrupt. This rising edge is asserted as soon as the receiver is enabled after the hardware drives the LP_ACK high.

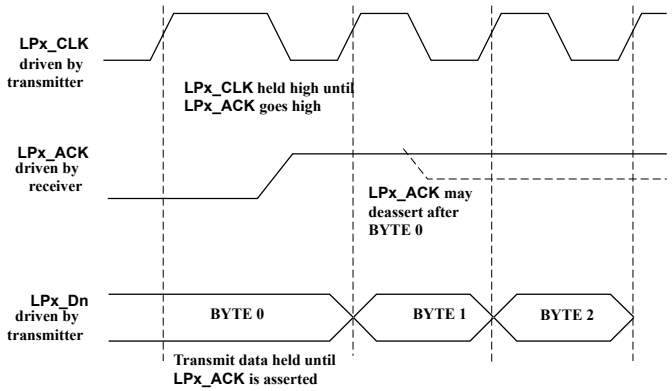

Figure 18-5: Enable the Transmitter Before the Receiver

NOTE: Service request interrupts or status are asserted only when the link port (receiver or transmitter) is disabled.

Multi-Processor Connectivity

Link ports can operate independently, allowing glueless connection with external processors. Link ports have dedicated DMA channels, allowing independent data transfers. The following group of figures shows some examples of different bus connection topology that can be used in multi-processor system design. The inter-connection methods are not limited to these examples.

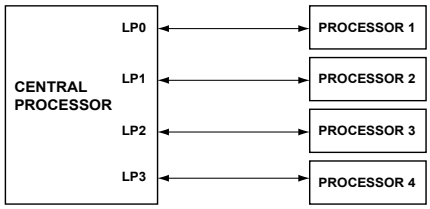

Figure 18-6: Central Processor-Based Model

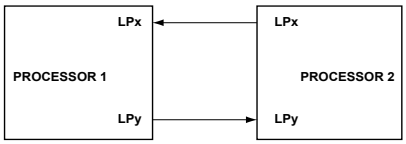

Figure 18-7: Link Port Full-Duplex Transfer Model

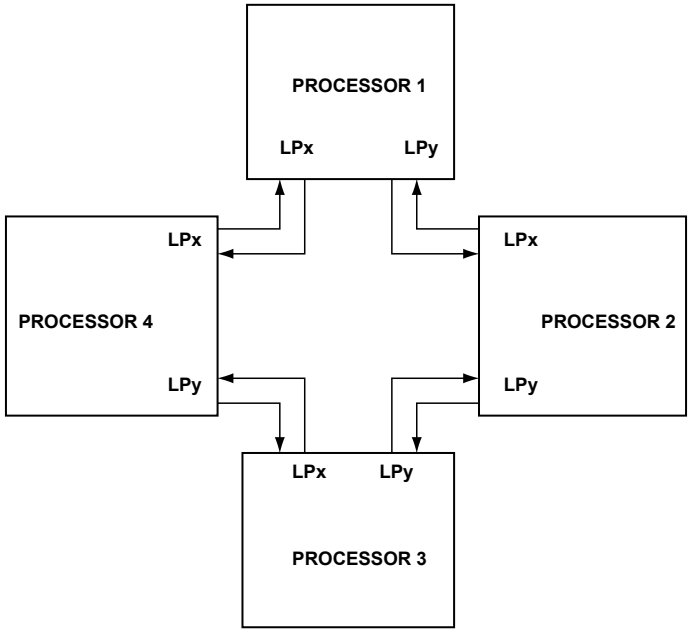

Figure 18-8: Link Port Ring Model

The link port protocol does not include built-in support for multiple requesters. However, there can be situations where multiple devices try to become the bus requester at the same time. Multi-requester conflicts can be resolved using token passing. In token passing, the token is a software flag that passes between processors.

At reset, the token is set to reside in the link port of one device, making it the requester and the transmitter. When a receiver (completer) wants to become the requester, it can assert its LP_ACK signal to get the attention of the requester. The requester knows, through the software protocol, whether to respond with actual data or whether the token is requested. If the requester wishes to give up the token, it can send back a user-defined token release word and thereafter clear its token flag.

Simultaneously, the completer sets its token and can thereafter transmit. The token release word can be any user-defined value. Because the transmitter and receiver expect a code word, this word does not need to be exclusive of normal data transmission. If the requester wishes to give up the token, it can send back a user-defined token release word and thereafter clear its token flag. Simultaneously, the completer examines the data sent back and if it is the token release word, the completer sets its token, and can thereafter transmit.

The link port protocol includes handshake mechanism to inform the other end of transfer (transmit or receive) of an enable instance. However, it does not support handshakes to inform a disabled instance, while a chunk of data transfers. The application must assume the disabled state of the other end and take appropriate action.

For example, in a multi-processing environment, a receiver did not read its full FIFO for an extended time due to internal bus arbitrations. The transmitter can require software or a peripheral timer-based timeout to inform the application that the LP_ACK signal is low for an extended period.

LP Operating Modes

The link port does not have particular modes of operation, as the peripheral is based on a simple protocol. The following sections explain the data transfer modes, using the core and using DMA.

- Core Data Transfers
- DMA Data Transfers

LP Data Transfer Modes

This section describes link port DMA and core data transfers.

Core Data Transfers

If DMA is disabled for a link port buffer, the processor core can write or read internal FIFO buffers as a memory-mapped register through the MMR access bus. To avoid FIFO overflow or underflow, the core can access the FIFO registers in one of the following ways.

- Access link port registers using an interrupt service routine (ISR) mapped to the data request interrupt of the link port. The interrupt request remains high only when the FIFO is accessible (when the FIFO is not full in transmit mode and not empty in receive mode).
- Poll the FIFO status bits of the LP_STAT register. Write to the transmit FIFO if not full or read from the receive FIFO if not empty.

DMA Data Transfers

Dedicated DMA channels are available for each link port. DMA-related activity is explained in the following steps.

1. Data Receive – Once the DMA channel and link port module are configured and enabled, the external device begins writing data to the FIFO through the data pins of the link port. The FIFO detects this activity and in turn sends a DMA request. After the request is granted, the DMA transfer progresses until the FIFO is empty.
2. Data Transmit – Once the DMA channel and link port module are configured and enabled, setting the `LP_CTL.EN` bit automatically asserts a DMA request when the transmit FIFO is empty. After the request is granted, DMA fills the FIFO. The external device begins reading data from the FIFO through the data pins of the link port. The FIFO detects that there is room in the buffer and asserts another DMA request, continuing the process.

LP Event Control

This section describes how the link port uses interrupts and status signals.

Interrupt Signals

Each link port has two dedicated interrupt lines—a data request interrupt and a status interrupt. Data request interrupts are asserted based on FIFO conditions for data transfer. Status interrupts are asserted when a service request status or an overflow status is set. The following list explains each of these interrupts.

- ***Data Request Interrupt.*** Asserted if the FIFO is not full in transmission mode and the FIFO is not empty in reception mode. This functionality serves as a core triggered interrupt in non-DMA mode and as the DMA interrupt request in DMA mode. Generation of this interrupt is based on the `LP_STAT.FFST` (status bit of the link port buffer).
- ***Link Port Transmit Service Request Interrupt (LTRQ)***. Allow a disabled link port to generate an interrupt when an external access is attempted. When a link port is configured as transmitter, the transmit service request interrupt is enabled by setting the `LP_CTL.TRQMSK` bit. When set, an external receiver can indicate to the disabled transmitter that it must receive data through the connected link port. The receiver does so by driving a high level on the `LP_ACK` line. When the `LP_ACK` of the disabled transmitter link port is detected high, a `LP_STAT.LTRQ` interrupt is generated. The transmitter can enable itself for data transfer with the receiver. The link port needs a pull-down on `LP_ACK` for this feature to function properly.
- ***Link Port Receive Service Request Interrupt (LRRQ)***. When a link port is configured as receiver, this interrupt is enabled by setting the `LP_CTL.RRQMSK` bit. When set, an external transmitter can indicate to the disabled receiver that it must receive data through the connected link port. The transmitter does so by driving out the first data. When the `LP_CLK` of the disabled receiver link port is detected high, a `LP_STAT.LRRQ` interrupt is generated. The receiver can further enable itself for data transfer with the transmitter. The link port needs a pull-down on the `LP_CLK` signal for this feature to function properly.
- ***Link Port Receive Overflow Interrupt (LPOVF)***. Generated when the receiver FIFO overflows and is enabled by setting the `LP_CTL.ROVFMSK` bit. This interrupt can happen if the transmitter continues to transmit data even though the receiver has deasserted `LP_ACK` signal causing the receive FIFO to overflow.

Enabling Link Port Interrupts

A data request interrupt is a direct interrupt and can be controlled separately from the application.

To mask the interrupt, set the mask bits in LP_CTL register corresponding to service interrupts and the overflow interrupt. These interrupts are ORed and fed to the SIC as a single LP_STAT interrupt. These interrupts are latched and stored in the associated bits of LP_STAT register. If an LP_STAT interrupt occurs, in the ISR, programs can read the LP_STAT register bits to determine the type of interrupt. These bits are write-one-to-clear (W1C); writing one to the bit resets the bit and disables the corresponding interrupt.

Status and Error Signals

This section explains the various status signals in the LP_STAT register.

- ***Transfer Status signals***. The link port uses the bus status bit (LP_STAT.LPBS) to give the status of the bus condition (busy or idle) when the link port is configured as transmitter. The LP_STAT.LPBS is high if the link port drives data into the link port pins. Programs can poll this bit after polling the LP_STAT.FFST bit to disable the link port safely.

  The link buffer status (LP_STAT.FFST) field directly indicates the status of the FIFO (including empty or full conditions) during data transfer. Software can poll this field in the LP_STAT register before writing to the FIFO (in case of transmission) or reading from the FIFO (in case of reception). The LP_STAT.FFST bit is automatically cleared when the link port is disabled.

- ***Transfer Request Status signals***. The link port uses the receive request status (LP_STAT.LRRQ) bit to indicate that an external receiver wants to receive data (in case the link port is a disabled transmitter). The link port uses the transmit request status (LP_STAT.LTRQ) bit to indicate that an external transmitter wants to send data (in case the link port is a disabled receiver). Software can poll these bits to enable the transmitter or receiver accordingly.

- ***Error Status signals***. In receive mode 32-bit data is received in eight chunks of 4-bit data. This data is then packed to a single 32-bit data before loading the FIFO. The link buffer error status (LP_STAT.LPACK) bit is high during this packing process and goes low after packing.

  The link port overflow status (LP_STAT.ROVF) bit is set when the receive FIFO overflows. This event can occur if the transmitter continues to transmit data even though the receiver has deasserted LP_ACK causing the receiver FIFO to overflow.

- *Link Port Clock Division signals*. In the SC84x family of processors, the Linkport peripheral is configured to use CLK_09 as its input clock source from the Clock Division Unit (CDU). The CDU0 input clocks can be one of the following: DCLK_0, CCLK2_0, DCLK_1, or CCLK2_1.

  The clock signal provided through CLK_09 undergoes an internal division by 4 before reaching the link port peripheral. This division occurs in two stages, with the clock being divided by 2 at each stage.

  After this division, the resulting clock serves as the input to the link port block. To further reduce the clock frequency, program the LP_DIV register using the following equation:

  LP_DIV = 0 →; LP_CLK = SCLK

LP_DIV not equal to 0; → LP_CLK = SCLK / (2 × DIV)

Here, SCLK refers to the clock entering the link port block after the initial division by 4 from CLK_09.

LP Programming Model

The following sections provide information on configuring the operating mode and enabling the link ports.

- Setting Up a DMA Transmit Operation
- Setting Up a DMA Receive Operation
- Setting Up a Core Transmit Operation
- Setting Up a Core Receive Operation

Setting Up a DMA Transmit Operation

This following procedure describes the typical steps for configuring the link ports in DMA transmit mode.

1. Enable the link port pins in the GPIO port mux using the appropriate `PORT_FER` and `PORT_MUX` registers.
2. Install interrupt handlers for DMA and for transfer status (service request interrupt).
3. Configure the link port to transmit by setting the `LP_CTL` bit and enable the transmit request interrupt mask by setting the `LP_CTL.TRQMSK` bit.
4. Program the link port clock divider by writing a value to the `LP_DIV` register.
5. If using DMA stop mode or auto buffer mode, program the appropriate DMA registers.

   ADDITIONAL INFORMATION: An example configuration is: `DMA_ADDRSTART`, `DMA_XCNT`, `DMA_XMOD`, and `DMA_CFG` registers (Stop/Auto, `DMA_CFG.PSIZE` =1, `DMA_CFG.MSIZE` =4, interrupt generation and memory read).
6. Wait for the link port receiver (connected externally) to be enabled. The application can wait for the transmit service request interrupt to assert.
7. Clear the transmit service request interrupt status by writing 1 to the `LP_STAT.LTRQ` bit.
8. Enable DMA by setting the `DMA_CFG.EN` bit.
9. Enable the link port by setting the `LP_CTL.EN` bit.
10. Wait for DMA to assert a transfer completion interrupt.
11. Clear the DMA interrupt source by writing 1 to the `DMA_STAT.IRQDONE` bit.

Setting Up a DMA Receive Operation

This section describes the typical steps for using the link ports in DMA receive mode.

1. Enable the link port pins in GPIO port mux using the appropriate PORT_FER and PORT_MUX registers.
2. Install interrupt handlers for DMA and for transfer status (service request interrupt).
3. Configure the link port for reception (clear the LP_CTL.TRAN bit) and enable the receive request interrupt mask by setting the LP_CTL.RRQMSK bit.
4. If using DMA stop mode or auto buffer mode, program the DMA registers.

   ADDITIONAL INFORMATION: An example configuration is: DMA_ADDRSTART, DMA_XCNT, DMA_XMOD, and DMA_CFG registers (Stop/Auto, DMA_CFG.PSIZE=1, DMA_CFG.MSIZE=4, interrupt generation and memory write).
5. If using DMA array mode or list mode, create DMA configuration data structures filled with components.

   ADDITIONAL INFORMATION: An example configuration is: DMA_ADDRSTART, DMA_XCNT, DMA_XMOD, and DMA_CFG registers (Array/List, DMA_CFG.PSIZE =1, DMA_CFG.MSIZE =4, interrupt generation, memory write and fetch =4/5) and DMA_DSCPTR_NXT register (if list mode). Further, program DMA configuration register (Array/List, DMA_CFG.PSIZE =1, DMA_CFG.MSIZE =4, Memory Write and Fetch =4/5) and program the DMA_DSCPTR_NXT register (if list mode).
6. Wait for the link port transmitter (connected externally) to be enabled with subsequent data transmission. The application can wait for the receive service request interrupt to assert.
7. Clear the receive service request interrupt status by writing 1 to the LP_STAT.LRRQ bit.
8. Enable DMA by setting the DMA_CFG.EN bit.
9. Enable the link port by setting the LP_CTL.EN bit.
10. Wait for DMA to assert the transfer complete interrupt.
11. Clear the DMA interrupt source by writing 1 to the DMA_STAT.IRQDONE bit of the DMA status register.

Setting Up a Core Transmit Operation

This section describes the typical steps for using the link ports in processor core based transmission.

1. Enable the link port pins in the GPIO port mux using the appropriate PORT_FER and PORT_MUX registers.
2. Install interrupt handlers for data transfer and for transfer status (service request interrupt). The interrupt handlers for data transfer are the same source or ID as the DMA interrupt line in the SEC.
3. Configure the link port for transmission by setting the LP_CTL.TRAN bit) and enable the transmit request interrupt mask by setting the LP_CTL.TRQMSK bit).
4. Program the link port clock divider by writing a value in to the LP_DIV register.
5. Wait for the link port receiver (connected externally) to be enabled. The application can wait for a transmit service request interrupt to assert.
6. Clear the transmit service request interrupt status by writing 1 to the LP_STAT.LTRQ bit.

7. Enable the link port by setting the LP_CTL.EN bit.
8. The data request interrupt is asserted whenever there is free space in the FIFO. The application can write to the LP_TX register based on the FIFO conditions (half or empty) reflected in the LP_STAT.FFST bit field.

Setting Up a Core Receive Operation

This section describes the typical steps for using the link ports in processor core-based reception.

1. Enable the link port pins in the GPIO port mux using the appropriate PORT_FER and PORT_MUX registers.
2. Install interrupt handlers for data transfer and for transfer status (service request interrupt). The interrupt handlers for data transfer are the same source or ID as the DMA interrupt line in the SEC).
3. Configure link port for reception (clear LP_CTL.TRAN bit). Enable the receive request interrupt mask bit (set LP_CTL.RRQMSK).
4. Wait for the link port transmit (connected externally) to be enabled with subsequent transmission of data. The application can wait for receive service request interrupt to be asserted.
5. Clear the receive service request interrupt status by writing 1 to the LP_STAT.LRRQ bit.
6. Enable the link port by setting the LP_CTL.EN bit.
7. The data request interrupt is asserted whenever there is free space in the FIFO. The application can read from the LP_RX register based on the FIFO conditions (1 or 2 or 3 data available) which is reflected in the LP_STAT.FFST bit field.

ADSP-2184x LP Register Descriptions

Link Port (LP) contains the following registers.

Table 18-6: ADSP-2184x LP Register List

Name	Description
LP_CTL	Control Register
LP_DIV	Clock Divider Value Register
LP_RX	Receive Buffer Register
LP_STAT	Status Register
LP_TX	Transmit Buffer Register
LP_TXIN_SHDW	Shadow Input Transmit Buffer Register
LP_TXOUT_SHDW	Shadow Output Transmit Buffer Register

Control Register

The LP_CTL register provides LP interrupt masking, selection of transfer direction, and link port enable.

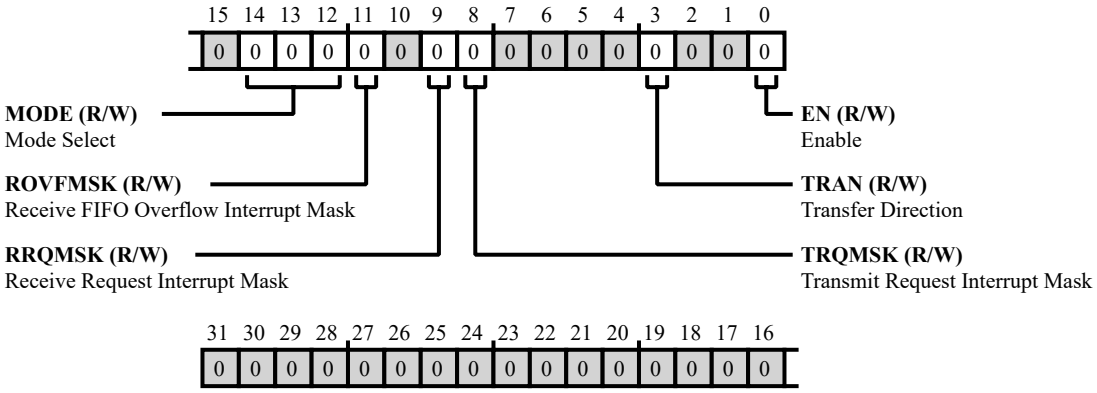

Figure 18-9: LP_CTL Register Diagram

Table 18-7: LP_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
14:12 (R/W)	MODE	Mode Select. The LP_CTL.MODE field indicates the mode of operation for double data rates (DDR). Note that the LRRQ interrupt is not supported in DDR mode. The LP receiver must be enabled by the user before starting the LP transmitter. For LP DDR mode, the value of LP DDR clock should be twice that of LP clock. CDU CLKO9 is used for the LP DDR clock.	
		5	4 bit DDR. (D0, D1, D2 and D3 data pins are used)
		6	2 bit DDR. (D0 and D1 data pins are used)
11 (R/W)	ROVFMSK	Receive FIFO Overflow Interrupt Mask.	
		0	Mask Disable Receive FIFO Overflow Interrupt
		1	Unmask Enable Receive FIFO Overflow Interrupt
9 (R/W)	RRQMSK	Receive Request Interrupt Mask. Link Port Receive Request Mask	
		0	Mask Disable Receive Request interrupt.
		1	Unmask Enable Receive Request interrupt.
8 (R/W)	TRQMSK	Transmit Request Interrupt Mask. Link Port Transmit Request Mask	
		0	Mask Disable Transmit Request interrupt.
		1	Unmask Enable Transmit Request interrupt.

Table 18-7: LP_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	TRAN	Transfer Direction. The `LP_CTL.TRAN` bit selects the transfer direction as transmit (if set) or receive (if cleared) for link buffer.	
		0	Receive Direction transfer is receive
		1	Transmit Direction transfer is transmit
0 (R/W)	EN	Enable. The `LP_CTL.EN` enables or disables the link port. When the processor disables the port (`LP_CTL.EN` transitions from high to low), the processor clears the corresponding `LP_STAT` bits.	
		0	Disable Disable linkport
		1	Enable linkport Enable linkport

Clock Divider Value Register

The LP_DIV register selects the divisor for ratio between the internal LP clock (LCLK) and system clock (SCLK). This programming is applicable only for the transmitter. The receiver can operate at any asynchronous frequency up to the maximum frequency independent of the ratio programmed.

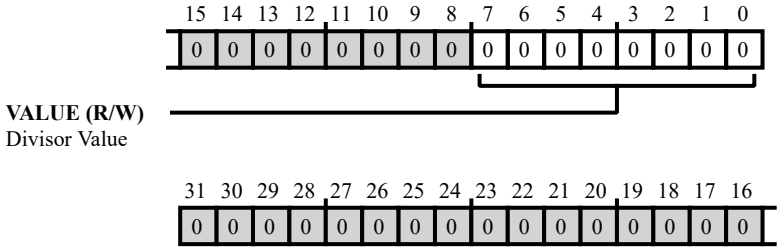

Figure 18-10: LP_DIV Register Diagram

Table 18-8: LP_DIV Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	Divisor Value. The LP_DIV.VALUE bits select the clock divider (relating the LP' internally generated clock (LCLK) to the system clock (SCLK). The LP_DIV.VALUE should be programmed prior to LP enable. For LP_DIV.VALUE = 0, LCLK = SCLK For LP_DIV.VALUE = xxxxxxxx, LCLK = SCLK / (2 x DIV)

Receive Buffer Register

The LP_RX register buffers the receive data flow through the LP. The receive buffer is a four-location deep FIFO. In the receive buffer, data is transferred to the core or DMA from the receive FIFO where an internal register does the packing. This packing register is not software accessible. For more information on LP buffer features and operations, see the LP functional description.

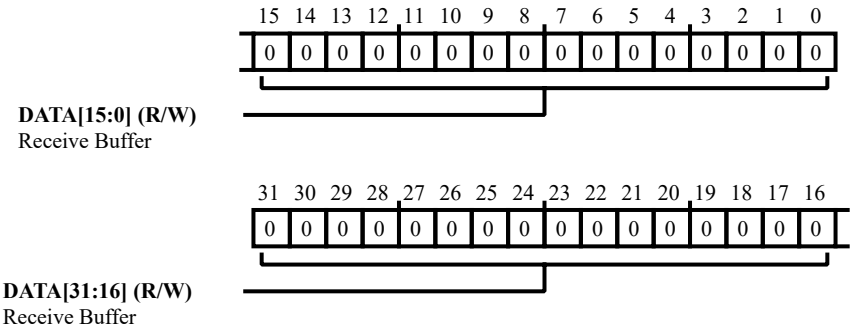

Figure 18-11: LP_RX Register Diagram

Table 18-9: LP_RX Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DATA	Receive Buffer.

Status Register

The LP_STAT register provides status information on link port interrupts, FIFO, buses, and receive/transmit requests.

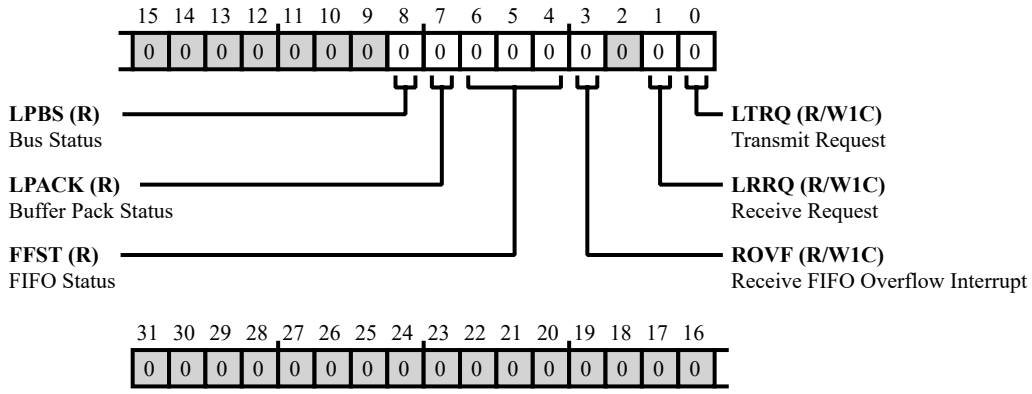

Figure 18-12: LP_STAT Register Diagram

Table 18-10: LP_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/NW)	LPBS	Bus Status. The LP_STAT.LPBS bit indicates the LPDAT bus status. LP_STAT.LPBS is kept high if data is being driven by the link port into the LP_D[n] pins.	
		0	Link port bus is idle
		1	Link port bus is busy
7 (R/NW)	LPACK	Buffer Pack Status. The LP_STAT.LPACK bit indicates packing status. In receive mode, 32-bit data is received in the block size configured in the LP_CTL.MODE bit field. Then, the data is packed to get a single 32-bit data before loading the FIFO. The LP_STAT.LPACK bit is high during this packing process and goes low after packing. In transmit mode, 32-bit data in the FIFO is unpacked to the appropriate data width before sending. The LP_STAT.LPACK is high during unpacking.	
		0	Packing Complete Packing done
		1	Packing Incomplete Packing is in progress
6:4 (R/NW)	FFST	FIFO Status. The LP_STAT.FFST bits indicate the FIFO status. These bits are cleared when the LP is disabled.	
		0	TX - Empty; RX - Empty Link buffer (TX OR RX) empty

Table 18-10: LP_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		1	TX - Reserved ; RX - Has 1 data word RX has 1 word of data. TX reserved
		2	TX - Reserved; RX - Has 2 data words RX has 2 word of data. TX reserved.
		3	TX - Reserved; RX - Has 3 data words RX has 3 word of data. TX reserved.
		4	TX - One Word; RX -Has 4 data words RX has 4 word of data. TX 1 word of data.
		5	Reserved
		6	TX - FIFO Full; RX - Reserved RX reserved. TX reserved.
		7	Reserved
3 (R/W1C)	ROVF	Receive FIFO Overflow Interrupt. This interrupt is generated when the receiver FIFO overflows. This overflow may happen if the transmitter continues to transmit data even though the receiver has de-asserted the LP_ACK pin.	
1 (R/W1C)	LRRQ	Receive Request. The LP generates this interrupt when the LP_CLK pin of a disabled link port (the receiver) is forced high by another link port (the transmitter). Note that the LRRQ interrupt is not supported in DDR mode.	
0 (R/W1C)	LTRQ	Transmit Request. The LP generates this interrupt when the LP_ACK pin of a disabled link port (the transmitter) is forced high by another link port (the receiver).	

Transmit Buffer Register

The LP_TX register buffers the transmit data flow through the LP. The transmit buffer is two words deep. In the transmit buffer, the input stage of the FIFO is used to accept core data or DMA data from internal memory, and the data is transferred to the link port interface from the output stage of the FIFO. The output stage performs the unpacking in the transmit buffer. The least significant byte is transmitted first. As each word is unpacked and transmitted, the next location in FIFO becomes available and a new DMA request is made if DMA is enabled. If the register becomes empty, the LP asserts the LP_CLK signal. For more information on LP buffer features and operations, see the LP functional description.

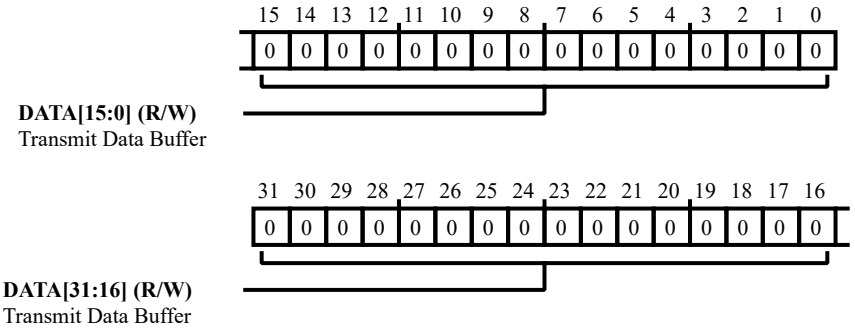

Figure 18-13: LP_TX Register Diagram

Table 18-11: LP_TX Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DATA	Transmit Data Buffer.

Shadow Input Transmit Buffer Register

The LP_TXIN_SHDW register contains the same data as the input stage of the transmit buffer. Read of this shadow transmit buffer does not update the LP_STAT register.

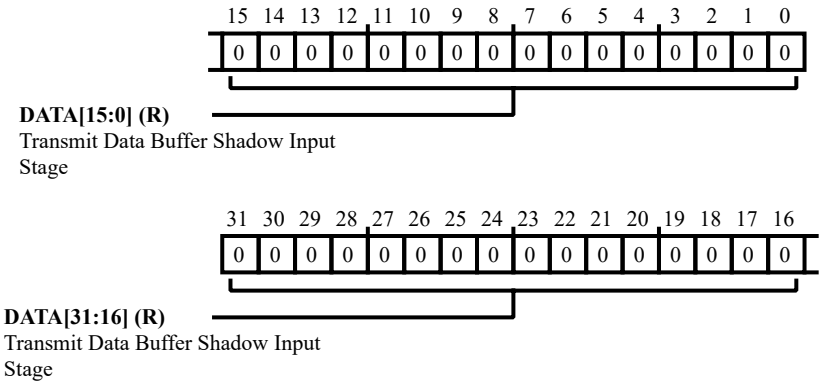

Figure 18-14: LP_TXIN_SHDW Register Diagram

Table 18-12: LP_TXIN_SHDW Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	DATA	Transmit Data Buffer Shadow Input Stage.

Shadow Output Transmit Buffer Register

The LP_TXOUT_SHDW register contains the same data as the output stage of the transmit buffer. Read of this shadow transmit buffer does not update the LP_STAT register.

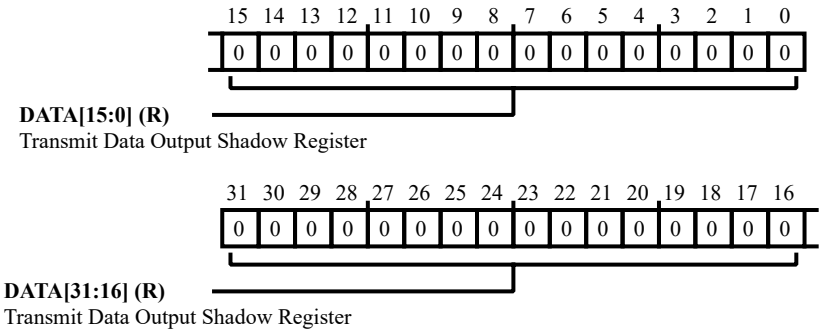

Figure 18-15: LP_TXOUT_SHDW Register Diagram

Table 18-13: LP_TXOUT_SHDW Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	DATA	Transmit Data Output Shadow Register.

19 Pulse Density Modulation (PDM) Microphone Interface

The pulse density modulation (PDM) microphone interface converts digital PDM microphone data to I^2S/TDM format. The microphone data in I^2S/TDM format is then routed internally to the SPORT/ASRC or externally via the DAI pins. Each DAI unit has one PDM interface.

PDM Features

The PDM interface includes the following features:

- Four channels of PDM audio inputs from digital microphones
- 16×, 32×, or 64× decimation ratio of PDM to pulse code modulation (PCM) audio data
- 24-bit resolution to support high sound pressure level (SPL) microphones
- 126 dB A-weighted SNR
- 4 kHz to 192 kHz output sampling rate
- Bit clock rates of 64×, 128×, 192×, 256×, 384×, or 512× the output sampling rate

  NOTE: Refer to the product data sheet for the maximum BCLK frequency.
- Automatic PDM clock generation
- Target I^2S or TDM output interface
- Supports up to 16 TDM slots
- Configurable TDM slot routing and sizes

PDM Functional Description

The following are the typical connections for the PDM module:

- PDM interface–PDM clock (PDM_CLK0) and PDM data (PDM_DAT0 and PDM_DAT1) are typically routed to DAI pins via the Signal Routing Unit (SRU) which is in turn connected to a PDM data source, for example, PDM microphones.
- Target I^2S/TDM interface –Bit clock (BCLK), frame sync (LRCLK), and serial data (SDATA) signals are typically routed internally to the SPORT using the SRU for the microphone data to reach memory in PCM format.
- Control registers–All PDM related control registers are included in the DAI MMR system.

ADSP-2184x PDM Register List

Pulse Density Modulation interface block

Table 19-1: ADSP-2184x PDM Register List

Name	Description
PDM_CTL0	PDM Control Register
PDM_HPF_CTL	High Pass Filter Control Register
PDM_RESET	Software Reset Register
PDM_SP_CTL0	Serial Port Control0 Register
PDM_SP_CTL1	Serial Port Control1 Register

PDM Block Diagram

The *PDM Interface Block Diagram* figure illustrates the interconnection of PDM block in the DAI subsystem.

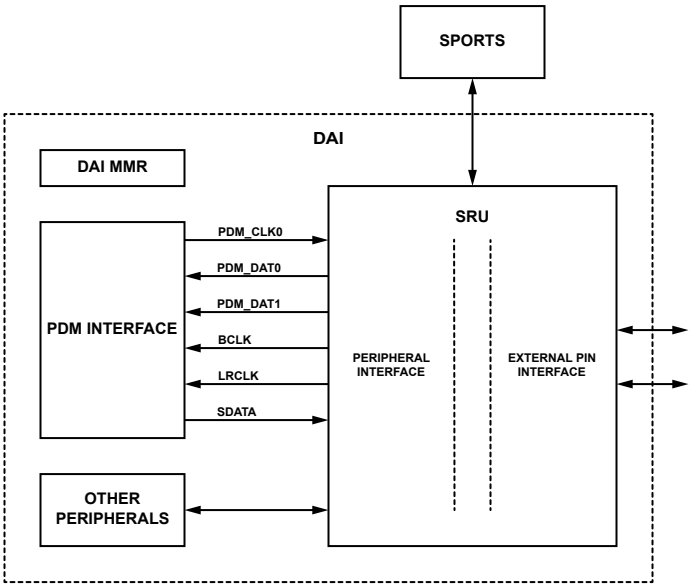

Figure 19-1: PDM Interface Block Diagram

PDM Architectural Concepts

The PDM interface provides up to four channels of decimation from a 1-bit PDM source to a 24-bit PCM audio stream. The down sampling ratio is typically 64 × f_S, where f_S is the PCM output sampling rate. The down sampling ratio can also be set at 32 × f_S or 16 × f_S, to facilitate higher output sampling rates. All channels decimate at the same ratio. The 24-bit down-sampled PCM audio data is output via standard stereo (I^2S, left justified, right justified) or TDM format. The input sources for the PDM interface can be any device that has a target PDM output, such as a digital microphone.

Internally, there are four channels. The *PDM Channel Mapping* table details the mapping of the PDM_DATx input pins to the internal channels. If a channel is not in use, the associated PDM_DATx pin can be disabled to save power.

Table 19-2: PDM Channel Mapping

Input Pin	PDM_CLK Edge	Internal Channel
PDM_DAT0	Falling	0
PDM_DAT0	Rising	1
PDM_DAT1	Falling	2
PDM_DAT1	Rising	3

PDM Initialization and Clocking

After I^2S clocks are applied, there are 16 full frame sync cycles of initialization time before the PDM clocks start. Once the PDM clocks start running, 48 additional frame sync cycles elapse before the PDM data is driven on the SDATA pin.

During normal operation, if the bit clock or frame sync is removed then the PDM clock output stops immediately and the PDM interface enters a lower power state. If the clocks resume, the PDM interface relocks to the bit clock and frame sync signals and adjusts the PDM clock output accordingly. The length of time before the PDM clock outputs resume is 4 frames ± 1 frame to lock to the incoming signal. If the format of the clock signals change, the PDM interface detects this change at the end of the frame and stops the PDM clock outputs. Then, the device reconfigures and resumes sending PDM clocks with no user intervention. Again, the PDM clock outputs resume after 4 frames ±1 frame to lock to the incoming signal.

The PDM interface requires a clock rate that is a minimum of 64× the frame sync sample rate. Bit clock rates of 128×, 192×, 256×, 384×, and 512× the frame sync rate are also supported. The PDM interface automatically detects the ratio between the bit clock and frame sync signals and generates a PDM clock output at 64 × the frame synce rate by default. If lower decimation ratios are selected in the `PDM_CTL0` register, the PDM output clock rate corresponds to the configuration set in the `PDM_CTL0.DEC_RATIO` bit field. The minimum sampling rate is 4 kHz and the maximum sampling rate is 192 kHz. The PDM clock range is 256 kHz to 6.144 MHz. Internally, all processing is done at the PDM clock rate.

SPORT Interface

The PDM interface supports I^{2}S and TDM serial output formats. It supports up to 16 TDM slots, with slot widths of 16, 24, or 32-bits. Internal channels are connected to output slots by configuring the appropriate channel slot bit fields in the PDM_SP_CTL1 register. By default, each channel is routed to the slot with the same number. For example, the reset value of the PDM_SP_CTL1.CH3_SLOT bit field is 0x0011, connecting channel 3 to slot 3.

Each channel has a drive select bit: PDM_SP_CTL1.CH0_DRV, PDM_SP_CTL1.CH1_DRV, PDM_SP_CTL1.CH2_DRV, or PDM_SP_CTL1.CH3_DRV. If the drive select bit is set to one, the channel is driven on the serial port in the appropriate output slot; and if it is cleared to zero, the channel does not drive (tristate high impedance mode). Note that this feature is useful only when the SPORT data is driven out of the processor via a DAI pin buffer and not when the data is routed internally to the SPORT or ASRC. To use this feature, tie the PDMx_SDATA_OE_O signal to the DAIx_PBENxx_I signal of the DAI pin buffer.

It is possible to erroneously configure more than one channel to drive on a single TDM slot. There is no cross-checking of register settings to prevent this configuration, but it will not damage the device. In this case, only the data from the lowest channel number is driven into the slot and the data from the higher channels will not be driven.

The PDM_SP_CTL0.SAI_MODE bit configures the SPORT interface mode. The two modes are stereo and TDM. The primary difference between these two modes is the format of the frame sync clock that is expected and the polarity of the active edge of the clock.

With the PDM_SP_CTL0.SAI_MODE bit and the PDM_SP_CTL0.LRCLK_POL bit set to zero, the serial port is in stereo mode with the clock polarity set to normal. In this mode, there must be only two channels of data sent. The frame starts with the falling edge of the frame sync, with an expected cycle of 50% high and 50% low. Channel 0 sends out data when the clock is low. As soon as the frame sync goes high the data from channel 0 stops and channel 1 begins sending data. Both edges of the frame sync clock are used. If the duty cycle is not 50/50, there may be errors in the resulting data. In this mode of operation, the PDM interface does not expect 32-bit clock transitions for each channel. All bit clock to frame sync ratios are supported.

With the PDM_SP_CTL0.SAI_MODE bit set to one and the PDM_SP_CTL0.LRCLK_POL bit set to zero, the serial port is in TDM mode with the clock polarity set to normal. In this mode, it can transmit anywhere from one channel to as many as four channels spread out across 16 data slots in TDM-16 format.

The PDM interface supports bit clock rates of 64×, 128×, 192×, 256×, 384×, or 512× the output sampling rate. The BCLK frequency however, must not exceed the maximum value specified in the data sheet. These bit clock rates are combined with the three different TDM slot sizes of 16-bit, 24-bit, or 32-bit slots, selected by the PDM_SP_CTL0.CH0_SLOT_WIDTH bit field. Note that as soon as the next frame sync edge is detected, the PDM interface restarts from slot 0 and any unreceived data from the previous frame is lost. This is how to achieve unusual TDM formats like TDM-5 or TDM-10. In addition, there is only support for TDM-16 or less for placing data into a TDM slot. Data cannot be placed into slots above 16, however it is possible to configure the PDM interface to tristate all unused TDM slots, which includes all the slots above the first 16 slots for modes that have more than 16 slots.

In TDM mode, the frame sync is expected to be a positive going pulse that is at least one-bit clock period wide. A falling edge is not necessary, it is only important that the signal is low long enough to meet the timing specification for a read before transitioning from low to high. The frame starts with the rising edge of this pulse. The data is clocked out according to the slot width and using the data format specified in the PDM_SP_CTL0 register. The PDM interface continues to send data until all active channels are sent and then the device waits for the next frame sync clock edge to start sending the next set of frame samples.

In TDM-8 format, when the PDM interface is set to output channel 0 through channel 3 into slot 0 to slot 3, the PDM interface can tristate for the remainder of the frame. This allows another PDM to output four channels onto slot 4 through slot 7. These slots do not have to be consecutive, and the two devices can be configured to interleave their respective data. The serial port can be set up to drive only when there is data to drive into a data slot. If all eight channels are not in use, configuring the drive select bit in the PDM_SP_CTL1 for the unused channels will assign those slots to drive or tristate in the TDM data stream. Note that this feature is useful only when the SPORT data is driven out of the chip via a DAI pin buffer and not when the data is routed internally to the SPORT or ASRC. To use this feature, tie the PDMx_SDATA_OE_O signal to the DAIx_PBENxx_I signal of the DAI pin buffer.

To invert the IRCLK polarity, set the PDM_SP_CTL0.LRCLK_POL bit to one. With inverted clock polarity in stereo mode, channel 0 is sent out when the frame sync is high, so the start of the frame is a low to high transition. With inverted clock polarity in TDM mode, the frame sync pulse is negative, so the frame starts with the high to low transition.

Configure the PDM_SP_CTL0.DATA_FORMAT bit field to align data within the 32-bit data slot. There is support for left justified mode, delayed by one-bit clock period; and right justified modes for 24-bit, 20-bit, and 16-bit data word sizes.

SPORT Timing

The *Stereo Mode* figure is a timing diagram for I^{2}S mode with 24-bit data.

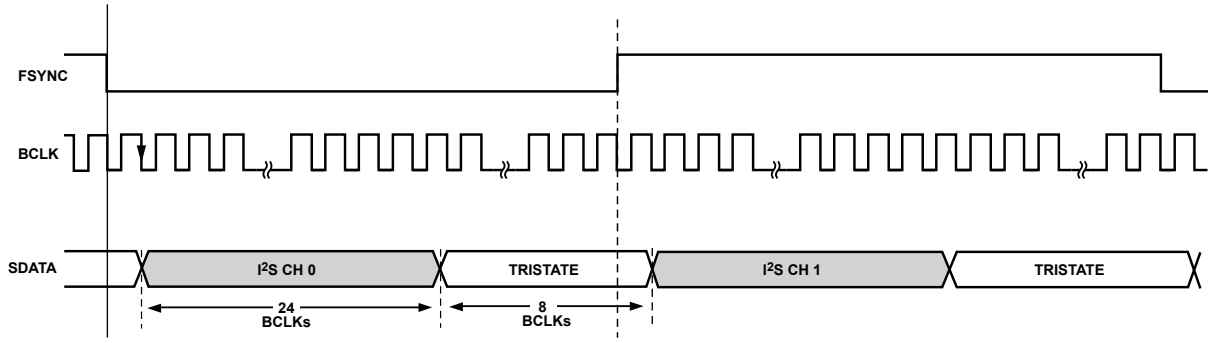

Figure 19-2: Stereo Mode

The *TDM4 Mode Four Channel* figure is a timing diagram for TDM4 mode with default channel assignments, 24-bit data, and 32-bit slots, and normal polarity clocks.

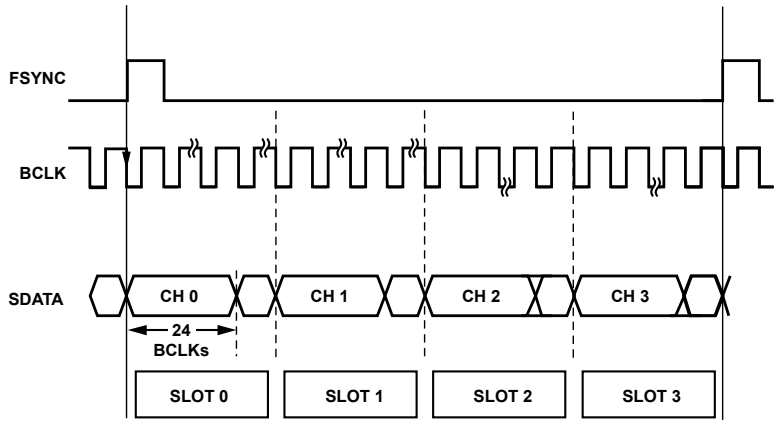

Figure 19-3: TDM4 Four Channel

The ***TDM4 Mode Two Channel*** figure is a timing diagram that shows TDM4 mode with only two channels enabled, 24-bit data delayed by zero BCLK, 32-bit slots, and normal polarity clocks.

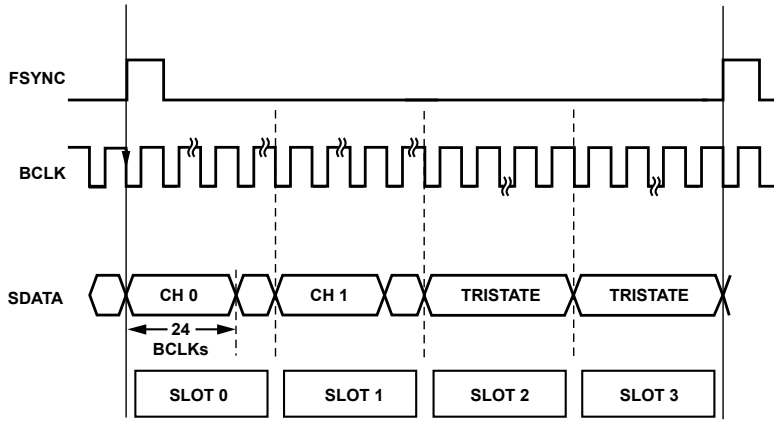

Figure 19-4: TDM4 Two Channel

The ***TDM8 Mode Four Channel*** figure is a timing diagram that shows TDM8 mode with all the four channels enabled, 24-bit data delayed by zero BCLK, 32-bit slots, and normal polarity clocks.

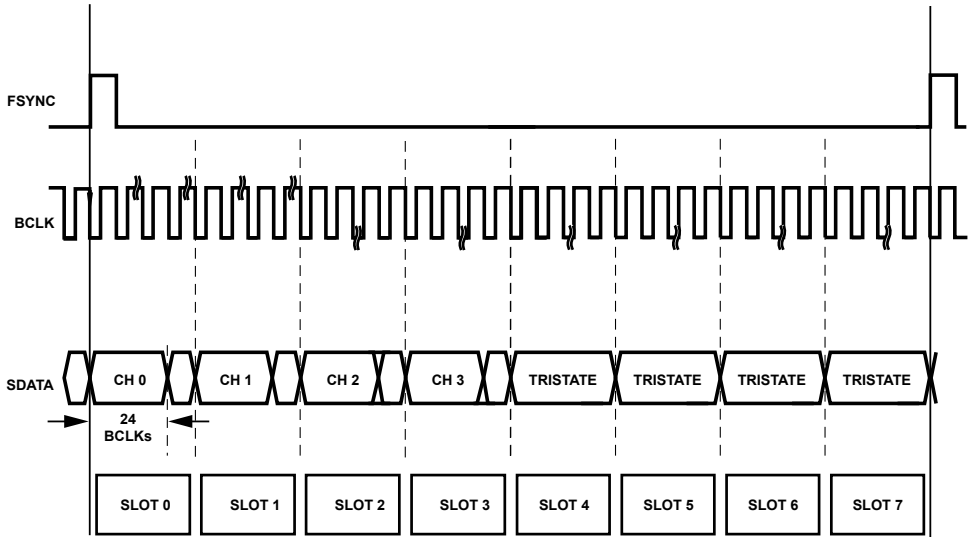

Figure 19-5: TDM8 Four Channels

The *TDM2 Mode Two Channel* figure is a timing diagram that shows TDM2 mode with two channels enabled, 24-bit data delayed by one BCLK, 32-bit slots, and normal polarity clocks.

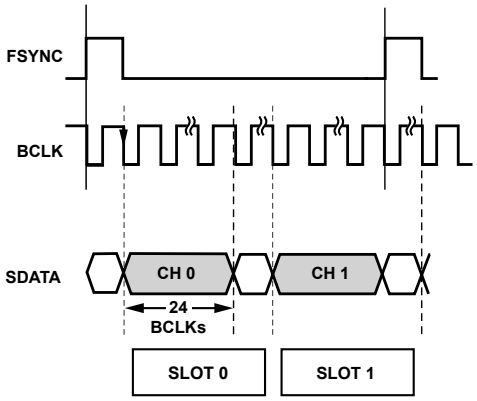

Figure 19-6: TDM2 Two Channels

High Pass Filter

There is a first order high-pass filter in the signal path. It is disabled by default and can be enabled by setting the `PDM_HPF_CTL.EN` bit. To adjust the cutoff frequency, configure the `PDM_HPF_CTL.FC` bit field. The settings are relative to the output sampling rate.

The *HPF Cutoff Frequency Selection* table shows the setting and the cutoff frequency for common sampling rates.

Table 19-3: HPF Cutoff Frequency Selections

PDM_HPF_CTL.HPF_FC	Multiplication Factor	48 kHz Sampling Rate Cutoff Frequency (Hz)	32 kHz Sampling Rate Cutoff Frequency (Hz)
0101	0.00505	242.4	161.6
1001	0.00251	120.48	80.32

Table 19-3: HPF Cutoff Frequency Selections (Continued)

PDM_HPF_CTL.HPF_FC	Multiplication Factor	48 kHz Sampling Rate Cutoff Frequency (Hz)	32 kHz Sampling Rate Cutoff Frequency (Hz)

PDM Programming Model

The following section provides information on configuring the PDM interface.

Configuring the PDM Interface

Use the following steps to configure the PDM interface:

Optional high pass filter configuration:

- Configure the PDM_HPF_CTL register to enable the high pass filter using the PDM_HPF_CTL.EN bit and set the cutoff frequency by programming the PDM_HPF_CTL.FC bit field.

1. Configure PDM_SP_CTL0 register to set the following parameters:
    a. SPORT mode (Stereo/TDM) with the PDM_SP_CTL0.SAI_MODE bit
    b. SPORT data format (BCLK delay) with PDM_SP_CTL0.DATA_FORMAT bit field
    c. SPORT slot width (16, 24, or 32 bits) with PDM_SP_CTL0.CH0_SLOT_WIDTH bit field – applicable only for the TDM mode
    d. BCLK capture edge (rising/falling) with the PDM_SP_CTL0.BCLK_POL bit
    e. LRCLK polarity (normal/inverted) with the PDM_SP_CTL0.LRCLK_POL bit
2. Configure the PDM_SP_CTL1 register to set the following parameters:
    a. PDM to SPORT channel slot mapping with serial port channel slot bit fields (CHx_SLOT)
    b. To select if the PDM channel will get driven to the associated SPORT channel slot with the serial port channel drive select bit (CHx_DRV).

3. Configure the PDM_CTL0 register to configure the decimation ratio with the PDM_CTL0.DEC_RATIO bit field and finally enable the PDM clock with the PDM_CTL0.CLK0_EN bit.

Software Reset

The PDM_RESET.SOFT bit is set to perform a soft reset of the PDM block. Setting this bit resets internal bit clock counters and audio data, but it does not reset the PDM register settings. This bit is self-clearing.

ADSP-2184x PDM Register Descriptions

Pulse Density Modulation interface block (PDM) contains the following registers.

Table 19-4: ADSP-2184x PDM Register List

Name	Description
PDM_CTL0	PDM Control Register
PDM_HPF_CTL	High Pass Filter Control Register
PDM_RESET	Software Reset Register
PDM_SP_CTL0	Serial Port Control0 Register
PDM_SP_CTL1	Serial Port Control1 Register

PDM Control Register

The PDM_CTL0 register (read/write) controls the channel activation, clock enable and Decimation ratio.

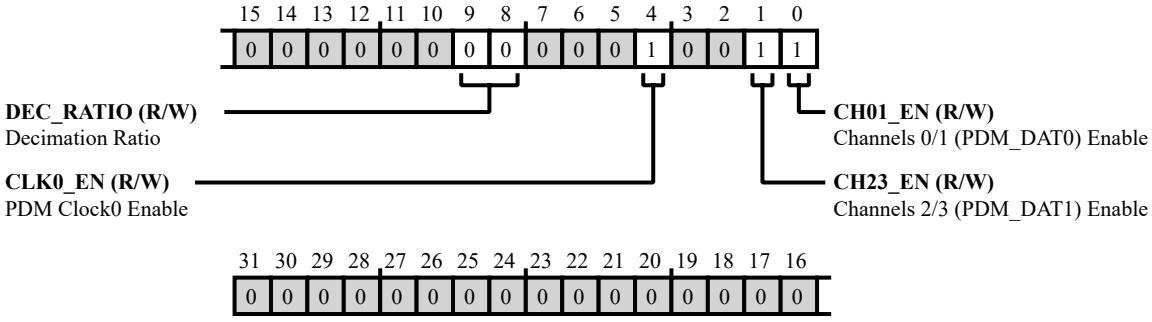

Figure 19-7: PDM_CTL0 Register Diagram

Table 19-5: PDM_CTL0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
9:8 (R/W)	DEC_RATIO	Decimation Ratio.	
		0	64 times decimation
		1	32 times decimation
		2	16 times decimation
4 (R/W)	CLK0_EN	PDM Clock0 Enable.	
		0	PDM_CLK0 output disabled
		1	PDM_CLK0 output enabled
1 (R/W)	CH23_EN	Channels 2/3 (PDM_DAT1) Enable.	
		0	PDM channels 2/3 disabled
		1	PDM channels 2/3 enabled
0 (R/W)	CH01_EN	Channels 0/1 (PDM_DAT0) Enable.	
		0	PDM channels 0/1 disabled
		1	PDM channels 0/1 enabled

High Pass Filter Control Register

The PDM_HPF_CTL register (read/write) controls the High Pass Filter.

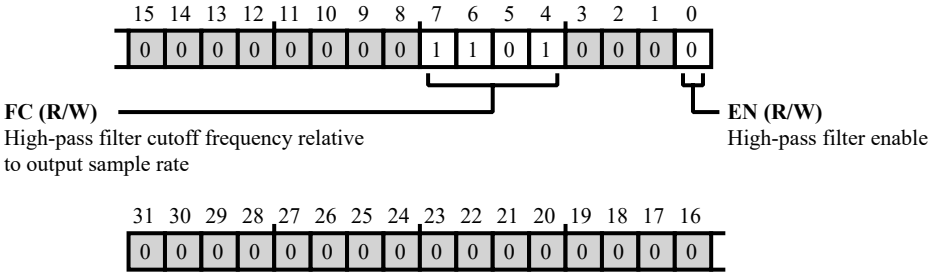

Figure 19-8: PDM_HPF_CTL Register Diagram

Table 19-6: PDM_HPF_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
7:4 (R/W)	FC	High-pass filter cutoff frequency relative to output sample rate.	
		0	Reserved
		1	Reserved
		2	Reserved
		3	Reserved
		4	Reserved
		5	0.00505
		6	0.00251
		7	0.00125
		8	0.000623
		9	0.000311
		10	0.000155
		11	0.0000777
		12	0.0000389
		13	0.0000194
		14	0.00000971
		15	0.00000486
0 (R/W)	EN	High-pass filter enable.	
		0	High Pass Filter Off
		1	High Pass Filter On

Software Reset Register

The PDM_RESET register (read/write) controls the software reset operations.

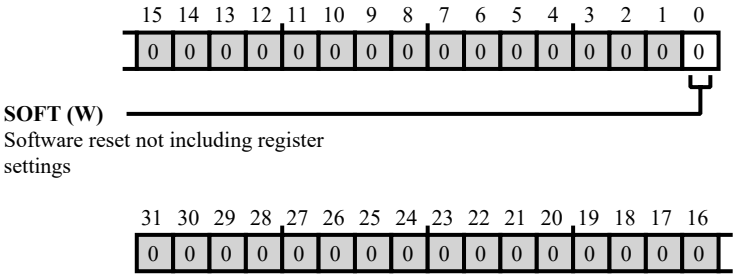

Figure 19-9: PDM_RESET Register Diagram

Table 19-7: PDM_RESET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (RX/W)	SOFT	Software reset not including register settings.	
		0	N/A
		1	Write once to soft reset

Serial Port Control0 Register

The PDM_SP_CTL0 register (read/write) controls serial port mode, data format and slot width.

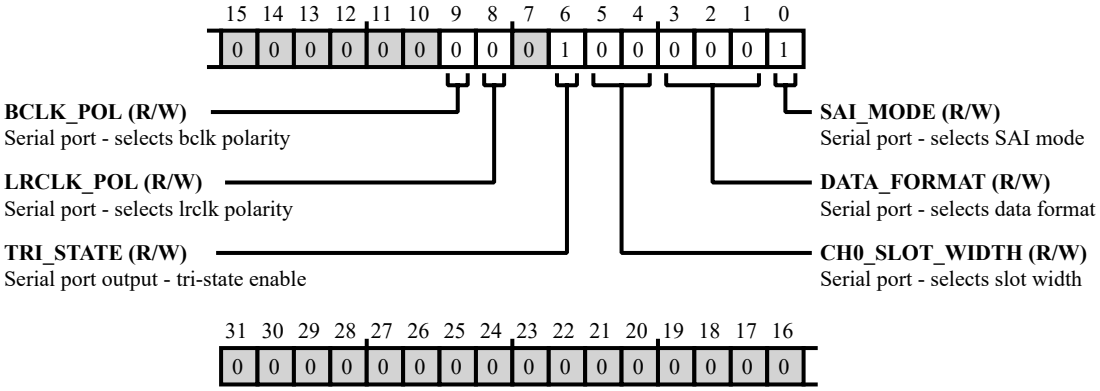

Figure 19-10: PDM_SP_CTL0 Register Diagram

Table 19-8: PDM_SP_CTL0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	BCLK_POL	Serial port - selects bclk polarity.	
		0	Capture on rising edge
		1	Capture on falling edge
8 (R/W)	LRCLK_POL	Serial port - selects lrclk polarity.	
		0	Normal Polarity
		1	Inverted Polarity
6 (R/W)	TRI_STATE	Serial port output - tri-state enable.	
		0	tri-state disabled
		1	tri-state enabled
5:4 (R/W)	CH0_SLOT_WIDTH	Serial port - selects slot width.	
		0	32 BCLK's per slot
		1	16 BCLK's per slot
		2	24 BCLK's per slot
3:1 (R/W)	DATA_FORMAT	Serial port - selects data format.	
		0	Typical I2S mode, delay by 1
		1	Left Justified,delay by 0
		2	Delay by 8
		3	Delay by 12

Table 19-8: PDM_SP_CTL0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		4	Delay by 16
0 (R/W)	SAI_MODE	Serial port - selects SAI mode.	
		0	STEREO (I2S, LJ or RJ)
		1	TDM

Serial Port Control1 Register

The PDM_SP_CTL1 register (read/write) controls the mapping of channel 0/1/2/3 to TDM slots.

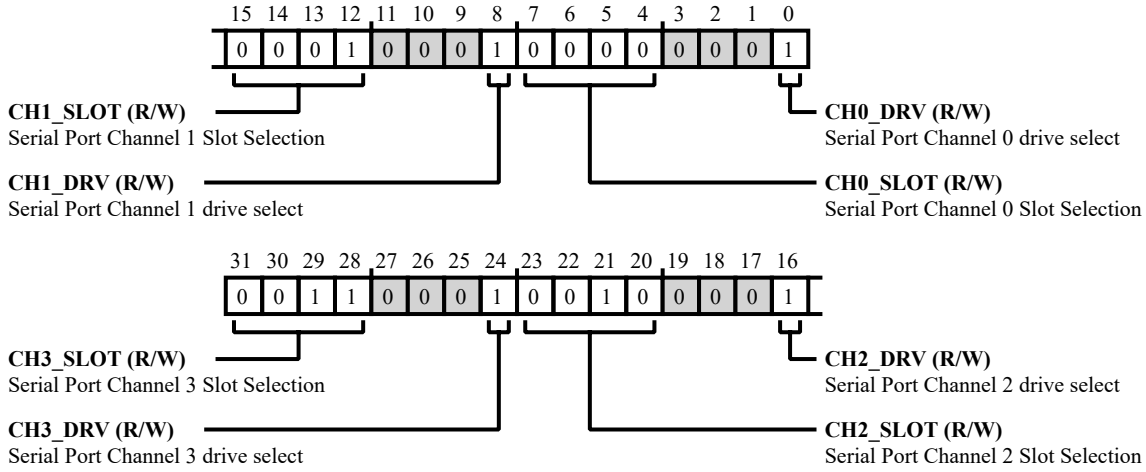

Figure 19-11: PDM_SP_CTL1 Register Diagram

Table 19-9: PDM_SP_CTL1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration

		0	Channel will not be driven on serial port
		1	Channel will be driven on serial port in selected output slot.

20 Serial Peripheral Interface (SPI)

The serial peripheral interface is an industry-standard synchronous serial link that supports communication with multiple SPI-compatible devices. The baseline SPI peripheral is a synchronous, four-wire interface consisting of two data pins, one device select pin, and a gated clock pin. The two data pins allow full-duplex operation to other SPI-compatible devices. Two extra (optional) data pins are provided on specific SPIs to support quad SPI operation. Enhanced modes of operation such as flow control, fast mode, and dual-I/O mode (DIOM) are also supported. In addition, a direct memory access (DMA) mode allows for transferring several words with minimal CPU interaction.

With a range of configurable options, the SPI ports provide a glueless hardware interface with other SPI-compatible devices in controller mode, target mode, and multi-controller environments. The SPI peripheral includes programmable baud rates, clock phase, and clock polarity. The peripheral can operate in a multi-controller environment by interfacing with several other devices, acting as either a controller device or a target device. In a multi-controller environment, the SPI peripheral uses open-drain outputs to avoid data bus contention. The flow control features enable slow target devices to interface with fast controller devices by providing an SPI ready pin which flexibly controls the transfers.

NOTE: SPI peripherals on the processor operate in the CLKO6 domain. For more details on CLKO6 programming, refer the *Clock Generation Unit (CGU)* chapter.

SPI Features

The SPI module supports the following features:

- Full-duplex, synchronous serial interface
- 8, 16-bit and 32-bit word sizes
- Programmable baud rate, clock phase, and polarity
- Programmable interframe latency
- Flow control
- Support for Fast and DIOM modes
- SPI1 and SPI2 support quad mode and memory-mapped mode. Memory-mapped mode is only supported by SPI1/SPI2.

- Independent receive and transmit DMA channels
- Burst transfer mode for non-DMA write accesses

SPI Functional Description

This section provides information on the function of the SPI module.

Shift register functionality

The SPI is a shift register that serially transmits and receives data bits to or from other SPI devices. During an SPI transfer, data is simultaneously transmitted (shifted out serially) and received (shifted in serially). A serial clock line synchronizes shifting and sampling of the information on the two serial data lines.

Controller/target functionality

During a data transfer, one SPI system acts as the link controller which controls the data flow. The other system acts as the target, which has data shifted into and out of it by the controller. Different devices can take turn being controllers, and one controller can simultaneously shift data into multiple targets (broadcast mode). However, only one target can drive its output to write data back to the controller at any given time. This rule must be enforced in the broadcast mode. Several targets can be selected to receive data from the controller in this mode. But, only one target can be enabled to send data back to the controller.

Enhanced operating modes

SPI supports enhanced modes of operation like fast mode, DIOM, and Quad-SPI, and optional flow control. In fast mode, received data is sampled on the transmit edge instead of the standard receive edge, thus enabling a full-cycle path for the received data. In DIOM, both COTI and CITO are configured as input or output pins, and 2 bits are shifted in or out on each receive or transmit edge. In Quad-SPI mode, SPI_D3:0 are configured as input or output pins and 4 bits are shifted in or out on each receive or transmit edge. A slower target can use flow control to stall a faster controller device.

Single and multi-controller use

The SPI can be used in a single controller as well as multi-controller environment. The `SPI_COTI`, `SPI_CITO`, and the `SPI_CLK` signals are all tied together in both configurations. SPI transmission and reception can be enabled simultaneously or individually, depending on `SPI_RXCTL` and `SPI_TXCTL` settings. In broadcast mode, several target can be enabled to receive, but only one target must be in transmit mode and driving the `SPI_CITO` line.

ADSP-2184x SPI Register List

The Serial Peripheral Interface (SPI) provides a full-duplex, synchronous serial interface, which supports both controller/target modes and multi-controller environments. The SPI baud rate and clock phase/polarities are

programmable, and it has integrated DMA channels for both transmit and receive data streams. A set of registers governs SPI operations. For more information on SPI functionality, see the SPI register descriptions.

Table 20-1: ADSP-2184x SPI Register List

Name	Description
SPI_CLK	Clock Rate Register
SPI_CTL	Control Register
SPI_DLY	Delay Register
SPI_ILAT	Masked Interrupt Condition Register
SPI_ILAT_CLR	Masked Interrupt Clear Register
SPI_IMSK	Interrupt Mask Register
SPI_IMSK_CLR	Interrupt Mask Clear Register
SPI_IMSK_SET	Interrupt Mask Set Register
SPI_MMRDH	Memory Mapped Read Header
SPI_MMTOP	SPI Memory Top Address

SPI Block Diagram

The ***SPI Controller Block Diagram*** illustrates the blocks of the SPI module. The module is comprised of three primary parts:

- SPI core contains the receive and transmit FIFOs and their associated shift registers
- Control blocks contain the synchronizer and logic to control the data flow through the data pipelines

- Register block

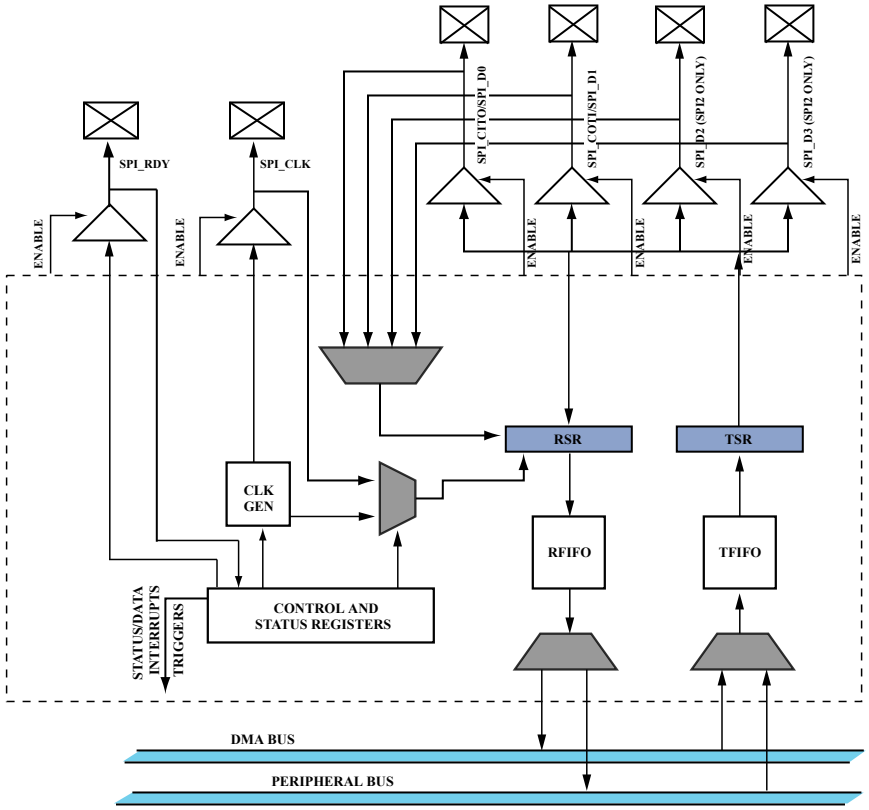

Figure 20-1: SPI Controller Block Diagram, Quad Mode

Transfer Protocol

The SPI module implements two channels that are independent of each other. The SPI module uses the SPI_RXCTL and SPI_TXCTL dedicated control registers to control these channels. Except in dual and quad modes, SPI can enable and use both channels simultaneously.

The SPI protocol supports four different combinations of serial clock phase and polarity. These combinations are selected through the SPI_CTL.CPOL and SPI_CTL.CPHA bits.

The ***SPI Transfer Protocol*** figures demonstrate the two basic transfer formats as defined by the CPHA bit. Two waveforms are shown for SPI_CLK; one for SPI_CTL.CPOL=0 and the other for SPI_CTL.CPOL=1. The diagrams can be interpreted as controller or target timing diagrams since the SPI_CLK, SPI_CITO, and SPI_COTI pins are directly connected between the controller and the target. The SPI_CITO signal is the output from the target (target transmission), and the SPI_COTI signal is the output from the controller (controller transmission). The controller generates the SPI_CLK signal. The SPI_TS signal is the target device select input to the target from the controller. The diagrams represent an 8-bit transfer (SPI_CTL.SIZE=0) with the MSB first (SPI_CTL.LSBF=0). Any combination of the SPI_CTL.SIZE and SPI_CTL.LSBF bits is permissible. For example, a 16-bit transfer with the LSB first is another possible configuration.

The clock polarity and the clock phase could be identical for the controller device and the target device involved in the communication link. The transfer format from the controller can be changed between transfers to adjust for various requirements of a target device.

The SPI module uses the SPI_CTL.ATSEL bit to determine when the SPI hardware or software control the SPI_SEL[n] line. When SPI_CTL.ATSEL=1, the target select line must be set to the polarity set in the SPI_CTL.POLSEL field between each serial transfer. The actual behavior of SPI_SEL[n] also depends on the parameters programmed into the SPI_DLY register. The SPI hardware logic automatically controls this functionality. When SPI_CTL.ATSEL=0, SPI_SEL[n] can either remain active between successive transfers or be inactive. The software must control this activity through manipulation of the SPI_TSEL register.

The ***SPI Transfer Protocol*** pair of figures illustrates the case when SPI_CTL.ATSEL = 1 and the SPI_SEL[n] line is inactive between frames. If ASSEL = 0, the SPI_SEL[n] line can remain active between frames; however, the first bit is only driven when an active transition of SPI_CLK occurs.

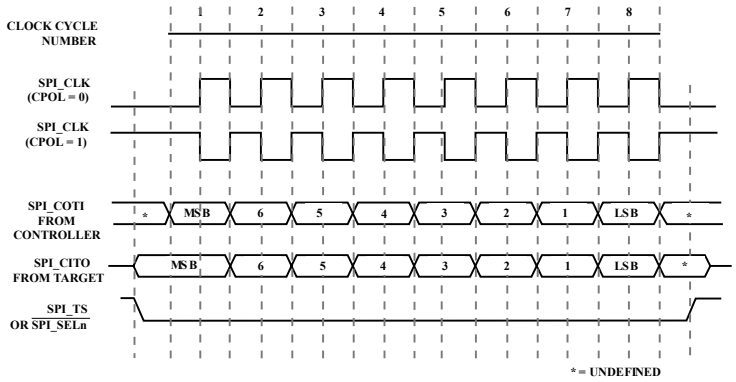

Figure 20-2: SPI Transfer Protocol for CPHA=0

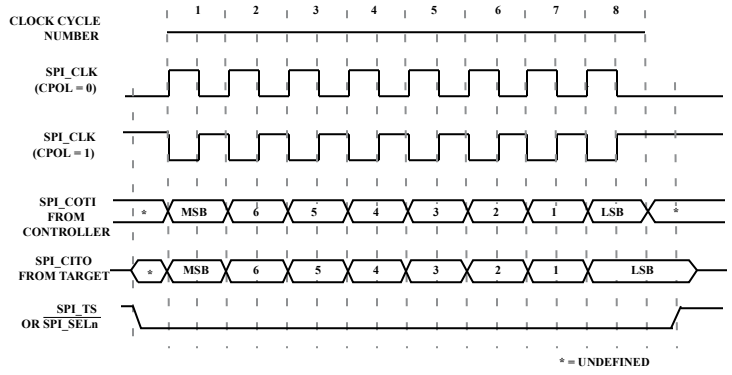

Figure 20-3: SPI Transfer Protocol for CPHA=1

Clock Considerations

The SPI_CLK signal is a gated clock that is only active during data transfers, for the time of the transferred word. In normal mode, the number of active edges is equal to the number of bits to be transmitted or received. In

dual-I/O mode, it is half of the number of bits to be transmitted or received, and in quad-SPI mode it is one-fourth of the number. The clock rate can be derived using both even and odd dividers from SCLK.

For controller devices, the SPI uses the SPI_CLK register value to determine the clock rate, whereas this value is ignored for target devices.

When the SPI controller is a controller, SPI_CLK is an output signal. Conversely, when the SPI controller is a target, SPI_CLK is an input signal. Peripheral devices ignore the SPI clock when the target select input is driven inactive. The SPI uses the SPI_CLK signal to shift out and shift in the data driven onto the SPI_CITO and SPI_COTI lines. The data is always shifted out on one edge of the clock (the active edge) and sampled on the opposite edge of the clock (the sampling edge). Clock polarity and clock phase relative to data are programmable through the SPI_CTL register and define the transfer format.

Controlling Delay Between Frames

The ***SPI Timing with Lead and Lag Programming (Independent of SPI_CTL.CPHA Setting)*** figure illustrates SPI timing using the SPI_DLY.LEADX and SPI_DLY.LAGX programming. The SPI uses the SPI_DLY.LAGX bits to control the timing between the chip select (SPI_TS) signal assertion and the first SPI_CLK edge. The SPI uses the SPI_DLY.LEADX bits to control the timing between the last SPI_CLK edge and deassertion of the SPI_TS signal. The lead and lag timing can be extended by a 1 SPI_CLK duration to ease timing restrictions on the target device.

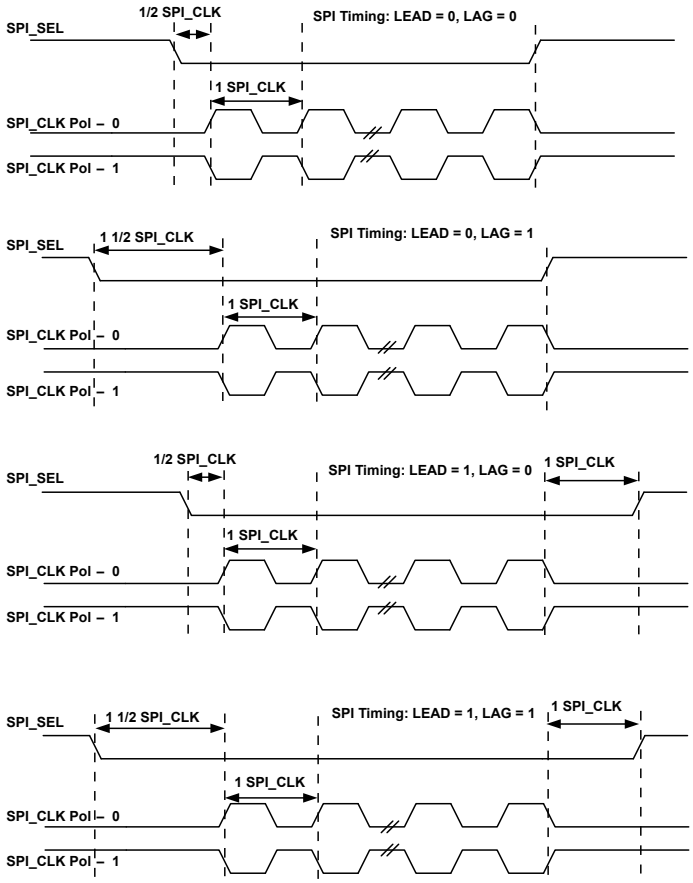

Figure 20-4: SPI Timing with Lead and Lag Programming (Independent of SPI_CTL.CPHA Setting)

The ***SPI Timing with SPI_DLY.STOP Programming (Independent of SPI_CTL.CPHA Setting)*** figure illustrates SPI timing with STOP programming. The SPI module uses this timing to insert multiples of `SPI_CLK` period delays between transfers. The `SPI_TS` line is deasserted for the duration specified in the `SPI_DLY.STOP` bit field, assuming the `SPI_CTL.POLSEL` bit is configured for deassertion between transfers.

If the `SPI_DLY.STOP` bit =0, the controller operates in a *continuous mode*. This mode causes an immediate start of the second word after the last bit is transferred from the first word. During this mode of operation, the chip select line is continuously asserted.

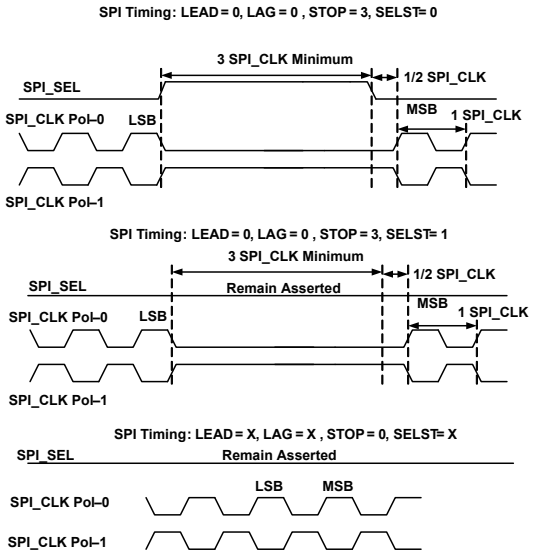

Figure 20-5: SPI Timing with SPI_DLY.STOP Programming (Independent of SPI_CTL.CPHA Setting)

When the SPI_DLY.STOP bit =0 and initial conditions for a transfer are not met, the interface pauses before the next transfer. During this pause, the SPI uses the SPI_CTL.POLSEL bit to determine the state of the chip select pin. The SPI uses the SPI_DLY.LEADX and SPI_DLY.LAGX bits to determine the timing between SPI_CLK edges and the chip select line.

Flow Control

In controller mode, the target device must drive the SPI_RDY pin. The pin acts as an input signal. The target can deassert the SPI_RDY pin to stop the controller from initiating any new transfer. If SPI_RDY is deasserted in the middle of a transfer, the current transfer continues, and the next transfer will not start unless the target asserts the SPI_RDY signal. Whenever the target deasserts SPI_RDY and stalls the controller, the SPI controller goes into a waiting state, and the SPI_STAT.FCS bit is set. When the target asserts SPI_RDY, the SPI controller resumes operation, and the SPI_STAT.FCS bit is cleared.

In target mode, the SPI_RDY pin acts as an output signal. Flow control can be configured on either the TX channel or the RX channel. The SPI uses the SPI_CTL.FCCH bit to control this configuration. If flow control is configured on the TX channel, as the SPI_TFIFO status nears the empty condition, the SPI_RDY pin is deasserted. If flow control is configured on the RX channel, as the SPI_RFIFO status nears the full condition, the SPI_RDY pin is deasserted. The SPI uses the SPI_CTL.FCWM bits to control the FIFO status at which SPI_RDY deassertion takes place. Flow control in target mode is purely based on the FIFO status and does not depend on the word counters.

The ***SPI Flow Control Timing in Controller Mode*** figure illustrates this timing.

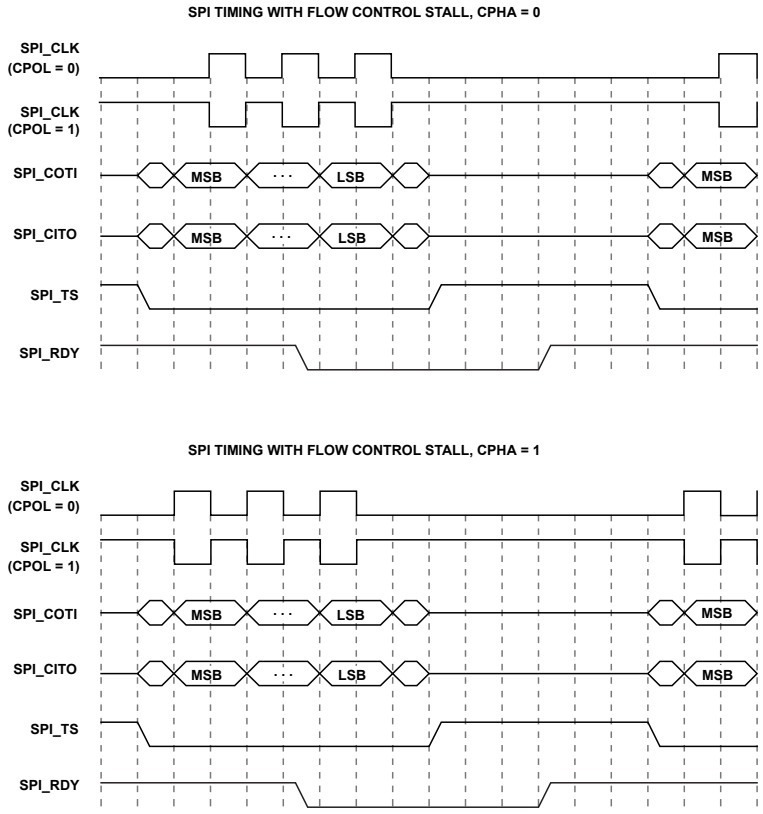

Figure 20-6: SPI Flow Control Timing in Controller Mode.

Target Select Operation

If the SPI is in target mode, $\overline{\texttt{SPI_TS}}$ acts as the target select input. When SPI is enabled as a controller, $\overline{\texttt{SPI_TS}}$ can serve as an error detection input for the SPI in a multi-controller environment. The `SPI_CTL.PTSE` bit enables this feature. When `SPI_CTL.PTSE`=1, the $\overline{\texttt{SPI_TS}}$ input is the controller mode error input. Otherwise, $\overline{\texttt{SPI_TS}}$ is ignored.

The $\overline{\texttt{SPI_TS}}$ signal is an active-low signal. The controller asserts the signal during the transfer. The signal can be deasserted or remain asserted between transfers. When $\overline{\texttt{SPI_TS}}$ is deasserted, `SPI_CLK` and inputs are ignored, and outputs are three-stated.

The target select bits (`SPI_TSEL.TSEL1` – `SPI_TSEL.TSEL7`) are used in a multiple-target SPI environment. For example, if there are eight SPI devices in the system including a processor controller, the controller processor can support the SPI mode transactions across the other seven devices. This configuration requires only one controller processor in this multi-target environment.

For example, assume that the SPI of the processor is the controller. The `SPI_TSEL.TSEL1` – `SPI_TSEL.TSEL7` bits on the processor can be connected to the target select pin of each target device. In this configuration, the target select bits can be used in three ways. In cases 1 and 2, the processor is the controller and the seven microcontrollers or targets with SPI interfaces are targets. The processor can do one of the following:

1. Transmit to all seven SPI devices at the same time in a broadcast mode. Here, all target select bits are set.

2. Receive and transmit from one SPI device by enabling only one target SPI device at a time.
3. If all the targets are also processors, then the requester can receive data from only one processor at a time. (The functionality is enabled by clearing the SPI_CTL.ECITO bit in the six other target processors.) The requester can transmit broadcast data to all seven at the same time. This CITO enabling feature is available in some other microcontrollers. Therefore, it is possible to use the CITO enabling feature with any other SPI device that includes this functionality.

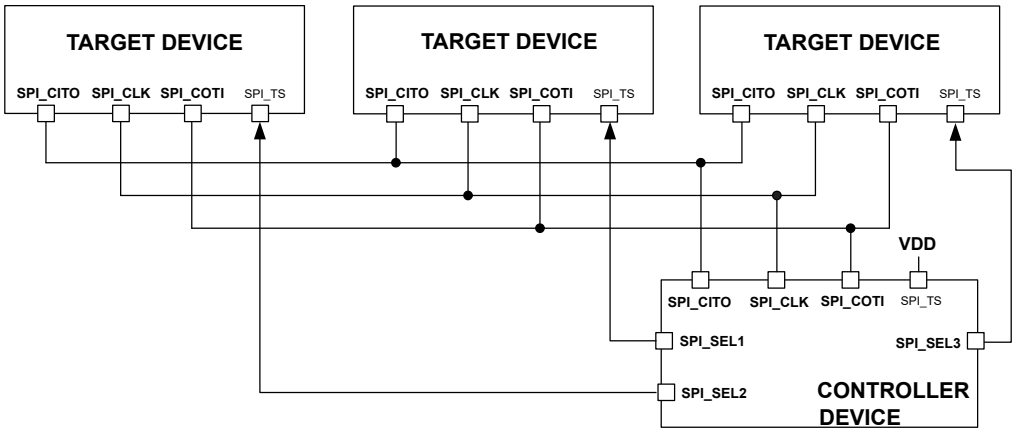

Figure 20-7: Single-Controller, Multiple-Target Configuration

Beginning and Ending a Non-DMA SPI Transfer

The start and finish of a non-DMA SPI transfer depend on the following settings.

1. Whether the device is configured as a controller or a target.
2. The state of the SPI_CTL.ATSEL bit, which selects between hardware and software control over SPI_TSEL.

When SPI_CTL.CPHA=0, the enabled target select outputs are driven active. However, the SPI_CLK signal remains inactive for the first half of the first cycle of SPI_CLK. For a target with SPI_CTL.CPHA=0, the transfer starts as soon as the SPI_TS input goes low.

When SPI_CTL.CPHA=1, a transfer starts with the first active edge of SPI_CLK for both target and controller devices. For a controller device, a transfer is complete after it sends the last data and simultaneously receives the last data bit. A transfer for a target device ends after the last sampling edge of SPI_CLK. If SPI_CTL.ATSEL=1, the hardware maintains responsibility for toggling SPI_TS between frames. If SPI_CTL.ATSEL=0, software controls the SPI_TS line and can keep it active between frames.

The SPI_STAT.RFE bit defines when the receive buffer can be read, indicating that SPI_RFIFO is not empty. The SPI_STAT.TFF bit defines when the transmit buffer can be written, indicating that the SPI_TFIFO is not full. The end of a single word transfer occurs when the SPI_STAT.RFE bit is cleared. The status indicates that a new word has been received and written into the receive FIFO. The SPI_STAT.RFE bit remains cleared when the receive FIFO has valid data.

To maintain software compatibility with other SPI devices, the SPI_STAT.SPIF bit is also available for polling. This bit can have a slightly different behavior from other commercially available devices.

In controller mode with the SPI_CTL.ATSEL bit cleared, software manually asserts the required target select signal before starting the transaction. After all data transfers, software typically releases the target select line.

When the receive or transmit word counters are enabled in the SPI_TXCTL or SPI_RXCTL registers, the SPI generates a finish interrupt at the end of the transfer. It signals the end of all transfers related to that transaction.

Transmit Operation in Non-DMA Mode

The transmit operation in non-DMA mode is enabled through the SPI_TXCTL.TEN bit. It can be enabled independently from the receive operation, and the transmit channel can become the initiating channel based on the SPI_TXCTL.TTI bit setting.

Transmit underrun is not possible in this mode, as no new transfer initiates unless the transmit FIFO is empty (in the case that SPI_TXCTL.TTI =1). A receive overflow is detected when data from a new frame transfer replaces older data in a full receive FIFO. This event can occur if SPI_TXCTL.TTI =1 and the receive channel is enabled in a non-initiating capacity.

An SPI transmit interrupt request is signaled once the transmit channel has been enabled and the transmit FIFO is not full. The SPI uses the SPI_TXCTL.TDR bit setting to control the frequency of the interrupt request.

Receive Operation in Non-DMA Mode

The receive operation in non-DMA mode is enabled through the SPI_RXCTL.REN bit. It can be enabled independently from the transmit operation, and the receive channel can become the initiating channel based on the SPI_RXCTL.RTI bit setting.

Receive overflow is not possible in this mode, as no new transfer initiates when the receive FIFO is full (in the case of SPI_RXCTL.RTI =1). A transmit underrun can occur (SPI_TXCTL.TDU bit) when no valid data is in the SPI_TFIFO register when a transfer is initiated. This event can occur if SPI_RXCTL.RTI =1 and the transmit channel is enabled in a non-initiating capacity.

An SPI receive interrupt request is signaled once the receive channel has been enabled and there is data waiting to be read. The SPI uses the SPI_RXCTL.RDR bit setting to control the frequency of the interrupt request.

Dual I/O Mode

In Dual I/O mode, the SPI_CITO and SPI_COTI pins are configured to operate in the same direction which doubles bandwidth. The SPI uses the SPI_CTL.SOTI bit to determine the order of bits on the pins. When set, the processor sends the first bit on the SPI_COTI pin and the second bit on the SPI_CITO pin. If the SPI_CTL.SOTI bit is cleared, the order is reversed. Since dual I/O mode uses both pins to transmit or receive data, only one channel can be enabled, either transmit or receive. Flow control through the SPI_RDY pin is supported. Interrupt request generation is unaffected by dual I/O mode. However, the interrupt service interval is reduced because the individual transfer latency is halved.

Changing to quad SPI mode must be done when the SPI is in a quiescent state.

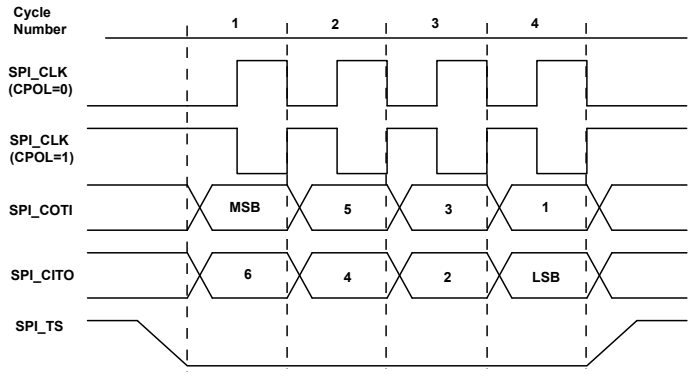

Figure 20-8: Dual I/O Mode Transfer Protocol for CPHA=0, SOSI=1, 8-Bit Transfer, LSBF=0.

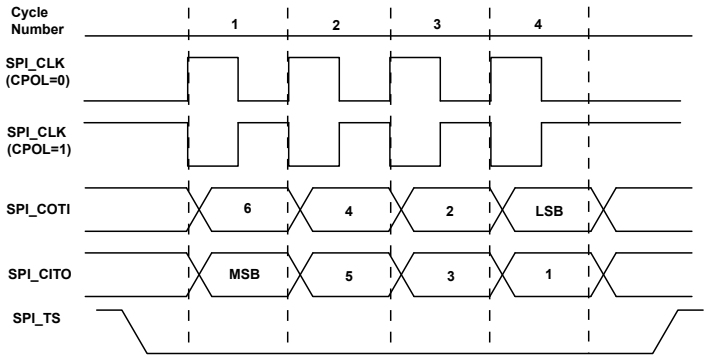

Figure 20-9: Dual I/O Mode Transfer Protocol for CPHA=1, SOSI=0, 8-Bit Transfer, LSBF=0.

Quad I/O Mode (SPI1/SPI2)

In quad SPI mode, the SPI_CITO and SPI_COTI pins, in tandem with the SPI_D2 and SPI_D3 pins, are configured to operate in the same direction. The SPI uses the SPI_CTL.SOTI bit to determine the order of bits on the pins. When set, the processor sends:

- The first bit on the SPI_COTI pin
- The second bit on the SPI_CITO pin
- The third bit on the SPI_D2 pin
- The fourth bit on the SPI_D3 pin

If the SPI_CTL.SOTI bit is cleared, the order is reversed. Since quad SPI mode uses all four pins to transmit or receive data, only one channel can be enabled as either transmit or receive. Flow control through the SPI_RDY pin is supported. Interrupt generation is unaffected by quad SPI mode.

Changing to quad SPI mode must be done when the SPI is in a quiescent state.

While using dual or quad I/O mode for communicating with flash devices, program the SPI_CTL.CPHA and the SPI_CTL.CPOL bits =1. This programming avoids bus contention during read operations, because the flash device starts driving out the bits immediately after dummy cycles in read header.

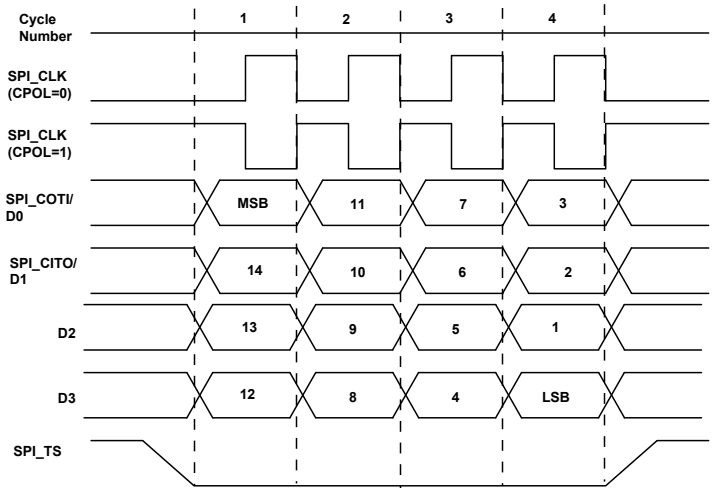

Figure 20-10: Quad Mode Timing for CPHA=0, SOSI=1, 16-Bit Transfer, LSBF=0.

NOTE: The SPI does support quad SPI 8-bit transfer in target continuous mode of operation with an SCLK:`SPI_CLK` ratio of less than 1:2. A minimum of 2 SCLK cycles is required between transfers in 8-bit quad SPI target mode with an SCLK:`SPI_CLK` ratio of less than 1:2.

Fast Mode

Fast mode is like the normal mode of operation when transmitting. When receiving, data is sampled at the next transmit edge allowing a full cycle of timing in the receive direction. This mode is valid in controller mode operation only. When the SPI operates in fast mode, the target drives the data for one full cycle.

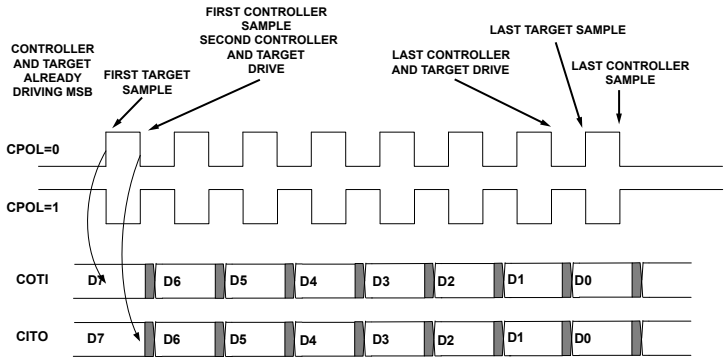

Figure 20-11: SPI Transfer Protocol in Fast Mode for SPI_CTL.CPHA = 0

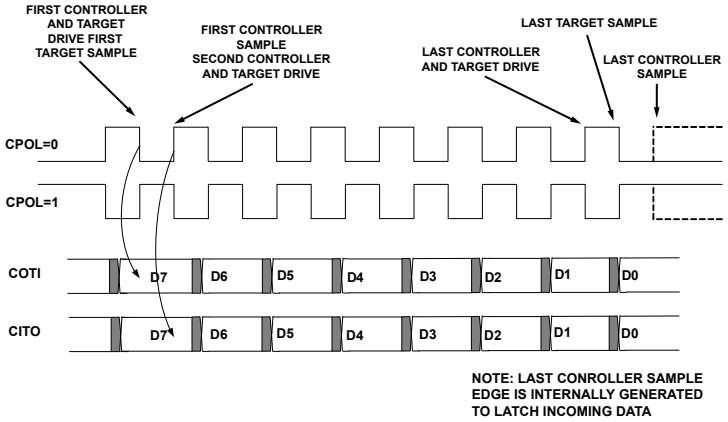

Figure 20-12: SPI Transfer Protocol in Fast Mode for SPI_CTL.CPHA = 1

Memory-Mapped Mode (SPI1/SPI2)

The SPI supports direct memory-mapped read accesses from a SPI memory device, enabled by setting the `SPI_CTL.MMSE` bit. This mode allows for direct execution of instructions from a SPI memory device without the need for a low-level software driver, as hardware handles all overhead tasks (for example, transmission of the read header, pin turnaround timing, and receive data sizing). The SPI features configurable options in the memory-mapped read header register (`SPI_MMRDH`) to provide compatibility with a wide range of SPI memory devices.

In non-memory-mapped mode, the software is responsible for providing the command and required dummy words for the read response, whereas this is all handled by hardware when the SPI is in memory-mapped mode. The memory of the SPI device is accessible directly through reads of the processor address space. The read accesses can be code or data accesses in core mode or when using memory DMA (MDMA). These accesses allow code to execute directly from SPI memory devices (true eXecute-In-Place operations), and the contents can be cached to improve performance. It is not necessary to access the SPI data buffer registers nor poll status bits; however, the hardware does not support peripheral DMA accesses nor write operations to the SPI memory space.

The ***Types of Operations*** table is a comparison of the permitted operations in the non-memory-mapped and memory-mapped modes supported by the SPI controller.

Table 20-6: Types of Operations

SPI Operation	Non-Memory-Mapped Mode	Memory-Mapped Mode
Core data write	Yes	No
Core data read	Yes	Yes
Code fetch: Execute-In-Place (XIP)	No	Yes
Read/Write accesses using SPI peripheral DMA	Yes	No
Read/Write accesses by other peripheral DMA channels	No	No

Table 20-6: Types of Operations (Continued)

SPI Operation	Non-Memory-Mapped Mode	Memory-Mapped Mode
MDMA read*	No	Yes
MDMA write	No	No

NOTE: MDMA read* - Only standard bandwidth MDMA (MDMA0 and MDMA1) and Enhanced Bandwidth MDMA (MDMA2) can be used for accessing flash address space in memory mapped mode. The maximum bandwidth MDMA (MDMA3) cannot access flash address space.

Memory-Mapped Description of Operation

Memory-mapped mode is enabled by setting the SPI_CTL.MMSE bit. When enabled, the SPI (if ready) accepts the read requests through a dedicated on-chip target interface. The memory subsystem controller drives this dedicated interface through the SCB fabric.

In a typical scenario, the memory subsystem controller issues read requests to the fabric, and the fabric routes these requests to the target port of the SPI peripheral. The controller describes the read access using a number of parameters such as starting address, transfer size, and burst type. The SPI responds to this read access request when it is ready for a new transfer. It loads the opcode, a specified number of address bytes, and an optional mode byte into the transmit FIFO. The SPI memory state machine begins when both the transmit and receive channels of the SPI are enabled with:

- the transmit transfer initiation bit is set (SPI_TXCTL.TTI=1), *and*
- the receive initiation bit is cleared (SPI_RXCTL.RTI=0)

The SPI memory read sequence starts with the assertion of $\overline{\text{SPI_SEL1}}$. If the SPI memory state machine is in the reset state, it looks for a command. The SPI hardware then sends the specific 8-bit read command (which can be optionally skipped), followed by the SPI memory read address. After this, a dummy period is inserted, in which a mode byte is optionally sent, and the pins are held or three-stated during the dummy clocking period.

NOTE: This read header is transmitted over the SPI standard protocol pins (SPI_CLK, SPI_COTI, SPI_CITO, $\overline{\text{SPI_SEL1}}$) or over the extended SPI protocol pins (SPI_CLK, SPI_COTI, SPI_CITO, SPI_D2, SPI_D3, $\overline{\text{SPI_SEL1}}$), based on the SPI_MMRDH.CMDPINS, SPI_MMRDH.ADRPINS, and SPI_CTL.MIOM bit settings. SPI memory devices usually support communication in MSB-first mode. In dual mode, the SPI typically uses SPI_CITO as IO1 and SPI_COTI as IO0. In quad mode, the SPI typically uses SPI_D3 pin as IO3, SPI_D2 as IO2, SPI_CITO as IO1, and SPI_COTI as IO0.

When all I/O data pins are three-stated, the SPI continues clocking the SPI memory device, which drives out the data bits at the addressed location, until all bytes are received. The SPI hardware reads the data as configured by the SPI_CTL.MIOM bit setting. Upon reception of the last byte, the SPI typically deasserts $\overline{\text{SPI_SEL1}}$ to prepare for the next requested read header.

Application code must ensure that the opcode sent is consistent with multiple I/O programming and that the parameters specified in the memory-mapped read header register are consistent with flash read access timing.

The *SPI Memory-Mapped Register Operations Flow* diagram shows how the fields of the SPI_MMRDH register determine the read header while initiating transfers in memory-mapped mode.

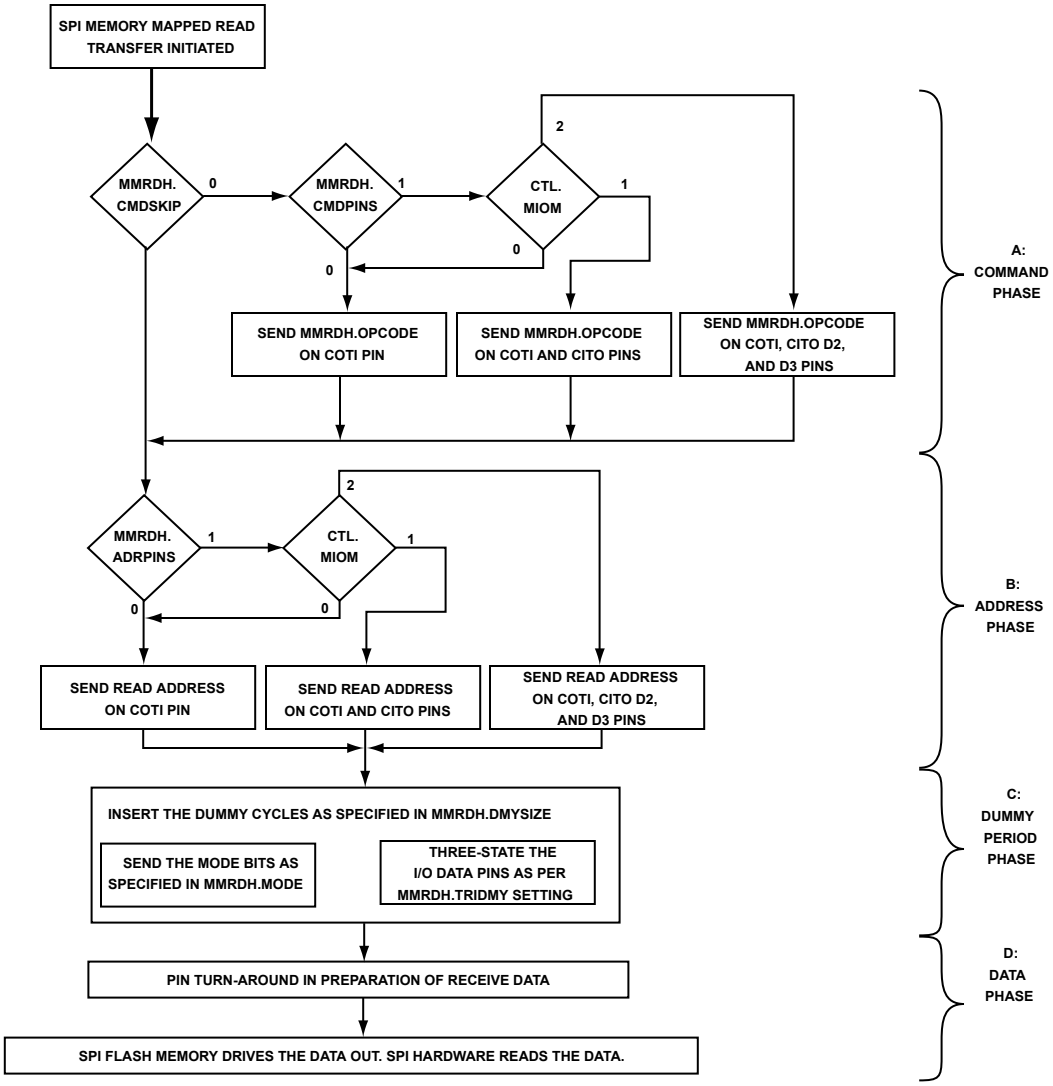

Figure 20-13: SPI Memory-Mapped Register Operations Flow

Memory-Mapped Architectural Concepts

In memory-mapped mode, the SPI accepts read requests through a dedicated on-chip target interface. The SPI (when ready) accepts these requests and begins the process of assembling the read header based on access attributes described in both the SPI_MMRDH register and the internal bus request. After the read header transmission completes, a pin turnaround period is timed, and the receiver is enabled. The SPI continues clocking the SPI memory device until all bytes are received.

The SPI memory-mapped hardware accommodates various memory devices with different read timing. The capabilities include extra mode bits, flexible dummy period timing, and three-state control, as configured in the SPI_MMRDH register.

The *Memory-Mapped Protocol* figure shows the protocol for the SPI controller in memory-mapped mode.

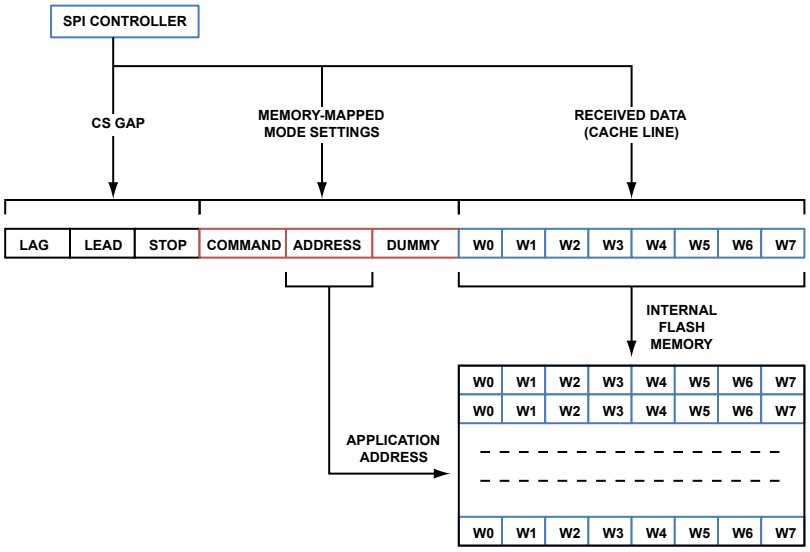

Figure 20-14: Memory-Mapped Protocol

As shown in the figure, the COMMAND field (`SPI_MMRDH.OPCODE`) is transmitted upon assertion of the `SPI_SEL[n]` signal. The SPI memory interprets this 8-bit value as a read command. Any 8-bit read opcode whose timing is compliant with the processor SPI and features provided by memory-mapped hardware is allowed, the most common being:

- Standard Read (0x03)
- Fast Read (0x0B)
- Fast Read Dual Output (0x3B)
- Fast Read Dual I/O (0x6B)
- Fast Read Quad Output (0xBB)
- Fast Read Quad I/O (0xEB)

NOTE: The SPI hardware does not validate the content of the `SPI_MMRDH.OPCODE` field prior to transmitting.

DMYSIZE (Number of Dummy Bytes)

When operating at a high clock frequency in multi-IO modes, most flash devices require some dummy clocks after the address bits. These dummy clock cycles allow the internal circuits of the device extra time for setting up the initial address. These bits specify the number of bytes separating address transmission and read data return.

The number of dummy cycles required varies per manufacturer, the read command used, and the SPI access time. The SPI hardware allows dummy cycles to be programmed in bytes in the `SPI_MMRDH.DMYSIZE` field, the value of which is a function of the number of pins used to transmit the address (`SPI_MMRDH.ADRPINS`), as shown in the *Pins Used to Transmit the Address (ADRPINS)* table.

Table 20-7: Pins Used to Transmit the Address (ADRPINS)

	Dummy clock cycles		
SPI_MMRDH.DMYSIZE	(**SPI_MMRDH.ADRPINS**=0, **SPI_CTL.MIOM**=x) Dummy bytes elapse over 1-pin	(**SPI_MMRDH.ADRPINS**=1, **SPI_CTL.MIOM**=1) Dummy bytes elapse over 2-pins	(**SPI_MMRDH.ADRPINS**=1, MIOM=2) Dummy bytes elapse over 4-pins
000	0	0	0
001	8	4	2
010	16	8	4
011	24	12	6
100	32	16	8
101	40	20	10
110	48	24	12
111	56	28	14

This dummy clocking period allows the mode bits to be sent, the pins to be three-stated, and the pins to be turned around in preparation for the receive data.

Memory-Mapped Read Accesses

The SPI hardware supports the most used read operations.

- Two standard SPI reads (read and read fast), which use the unidirectional `SPI_COTI` and `SPI_CITO` pins in addition to `SPI_SEL[n]` and `SPI_CLK`
- Four extended SPI multiple I/O reads: dual output, quad output, dual I/O, and quad I/O reads

The ***SPI Read Operations*** table and ***SPI Flash Fast Read Sequence*** figures summarize the types of read operations. Program each read operation in a way that is compatible with the description given in the SPI flash data sheet.

Table 20-8: SPI Read Operations

Operation	Read Command (Opcode)	CMDPIN	ADRPIN	DMYSIZE	Three-state	Multiple I/O Mode	Data Pins
Read	0x03	1	1	Zero	No	No	1
Fast Read	0x0B	1	1	Non-Zero	Yes	No	1
Dual Output Read	0x3B	1	1	Non-Zero	Yes	Yes(IO0-1)	2
Quad Output Read	0x6B	1	1	Non-Zero	Yes	Yes(IO0-3)	4
Dual I/O Read	0xBB	1, 2	2	Non-Zero	Yes	Yes (IO0-1)	2
Quad I/O Read	0xEB	1, 4	4	Non-Zero	Yes	Yes (IO0-3)	4

Some memory devices also support word quad I/O read (0xE7) and octal quad I/O read (0xE3) operations. These operations require fewer dummy cycles than normal quad I/O read operations.

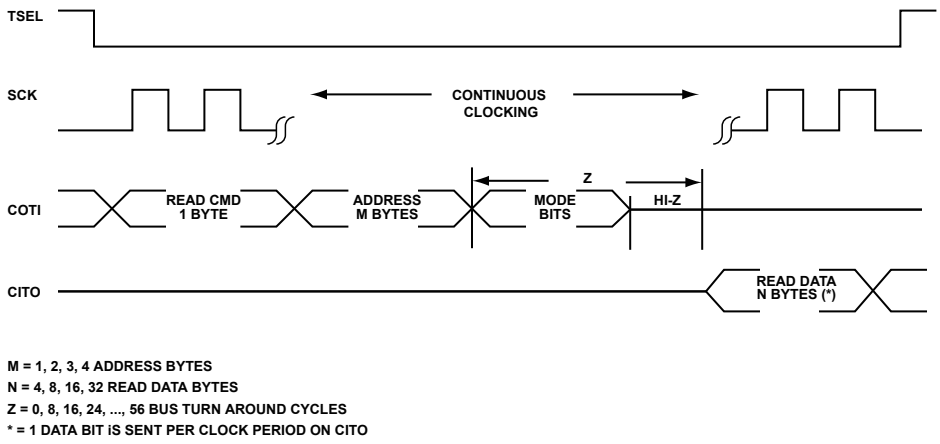

Figure 20-15: SPI Flash Fast Read Sequence

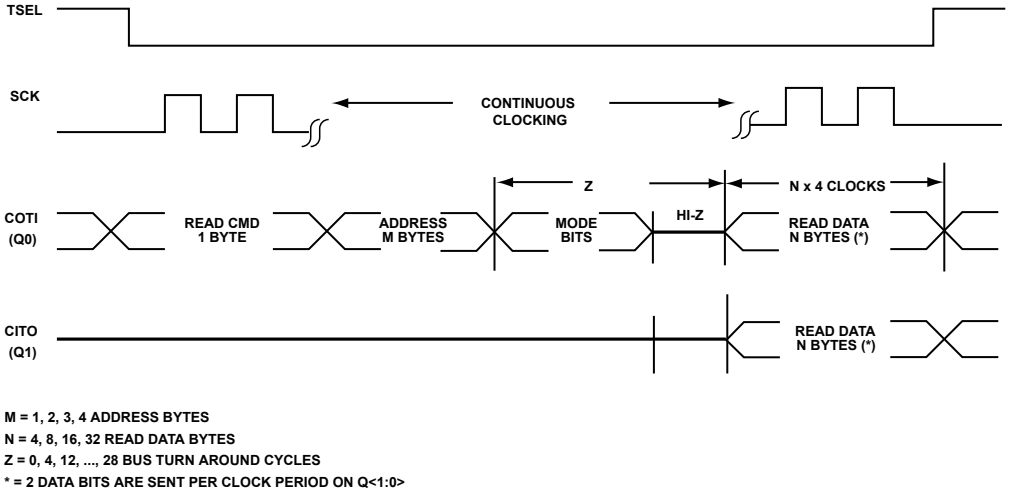

Figure 20-16: SPI Flash Fast Read (Dual Output) Sequence

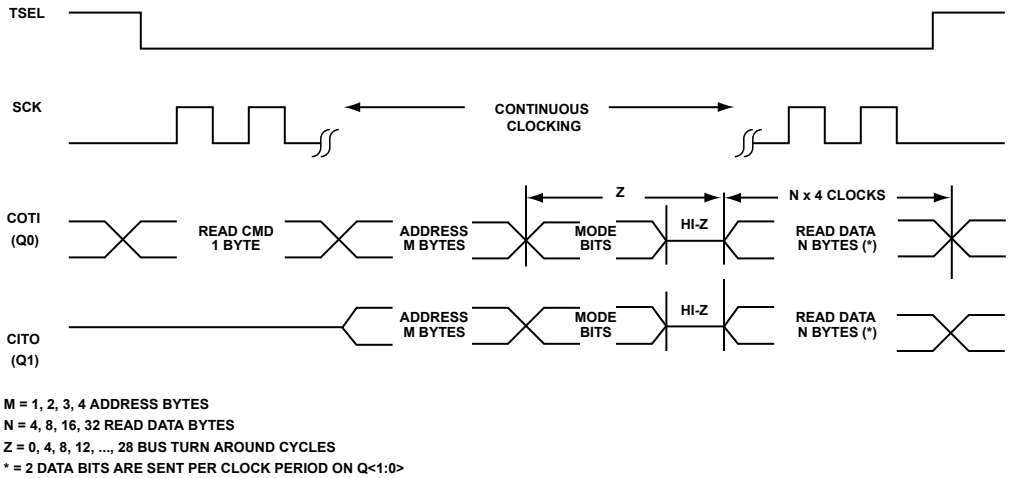

Figure 20-17: SPI Flash Fast Read (Dual I/O) Sequence

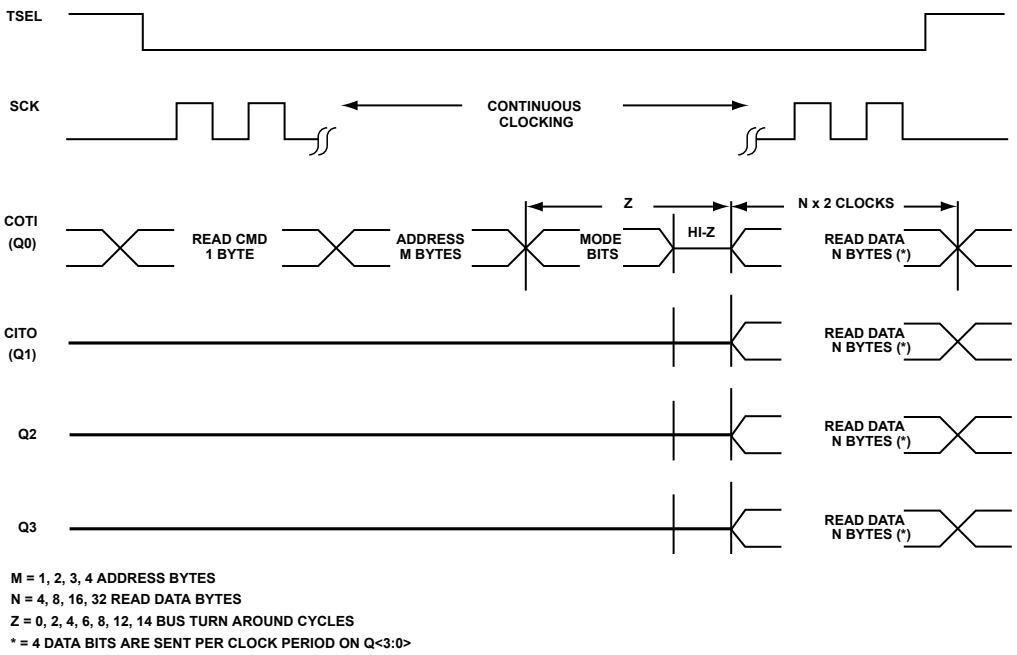

Figure 20-18: SPI Flash Quad Output Read Sequence

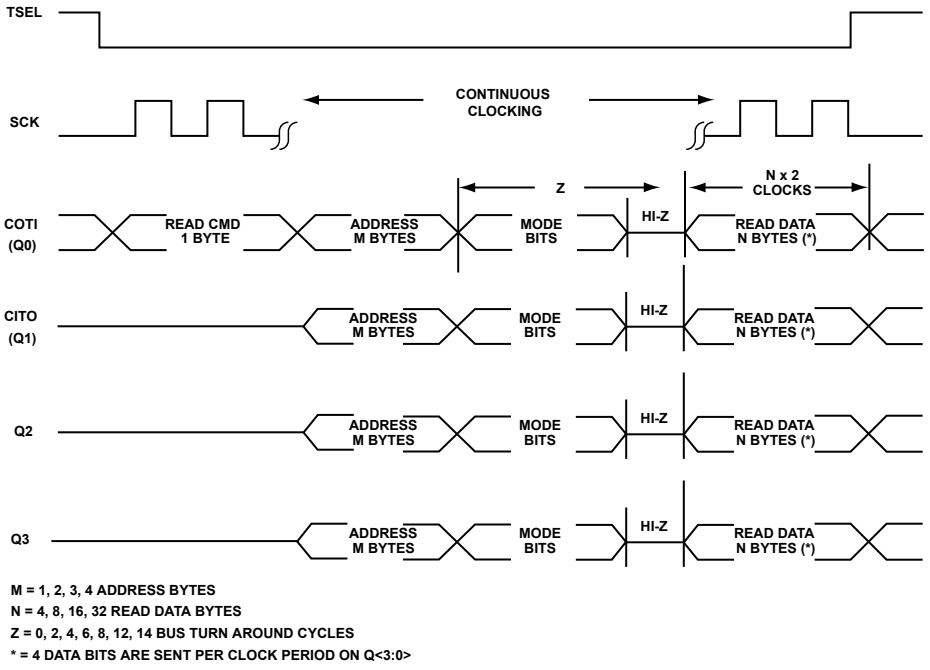

Figure 20-19: SPI Flash Quad I/O Read Sequence

SPI memory-mapped reads can be made cacheable in the core's internal memory by properly configuring the region as cacheable memory without bypass (see the related core's cache configuration documentation for details). In the figures, the number of read data bytes (N) is based on the following:

- For an instruction fetch by core (when in XIP mode); the number of instruction bytes to be fetched depends on the cache line size of the cache.

- For a data fetch by the core (data read), the number of data bytes to be fetched depends on the cache line size of the cache.

Although the minimum size of a memory-mapped data read transfer is 4 bytes, applications can fetch a single byte or a 2-byte data. (For example, it can fetch an unsigned char or short access in C code). In this case, only the required bytes are provided to the core and the other bytes are cached.

The on-chip memory subsystem controller provides a starting address for the burst and the SPI hardware issues this address as part of the read header. The address provided is N-byte aligned. For example, to read the 30th byte from SPI memory, then the typical address to provide is:

- 28 (0x0000_001C) for a 32-bit cache line
- 24 (0x0000_0018) for a 64-bit cache line
- 16 (0x0000_0010) for a 128-bit cache line
- 0 (0x0000_0000) for a 256-bit cache line

The read data is returned to the memory subsystem in the order provided by the SPI memory. There can be considerable delay for the expected data provided to the controller.

To minimize this delay, the wrap feature can be used where the memory subsystem provides the address of the critical word.

- For MDMA reads, the number of read data bytes (N) is always equal to 4 bytes. The MDMA read does not depend on the cache setting. For MDMA reads, limit the `DMA_CFG.MSIZE` field to one, two or four bytes. The address provided by the memory subsystem controller to the SPI hardware is always 4-bytealigned.

Memory-Mapped High-Performance Features

In addition to automating the SPI memory read accesses, the memory-mapped hardware also provides some features to improve SPI memory fetches and increase the system performance. The following sections describe these features.

Merged Read Accesses

It is common for the memory subsystem to fetch two or more cache lines from consecutive addresses (the address sequencing is linear without any jumps). To take advantage of this situation, the SPI memory-mapped hardware provides a feature called merging. Enable merging by setting the `SPI_MMRDH.MERGE` bit.

When enabled, the hardware compares the address of an incoming read request to the address of a request the SPI memory is actively servicing. It can decide to merge two accesses when the address for the second access is incremental. For example, if the first address of a 32-byte cache line fetch is 0x0000_0000 and the second fetch is to address 0x0000_0020, then these two accesses can be merged. Merging increases efficiency and overall fetch bandwidth by eliminating the read header for those accesses which only require continuation of the SPI clock.

Wrap Around Accesses

Many SPI flash memory devices support wrapping which is used to enhance critical word fetching of cache lines. In this mode, the SPI device automatically wraps the read address to the base of a cache line once the end of the cache line is reached.

Wrap around accesses are enabled by setting the SPI_MMRDH.WRAP bit.

Some flash devices require programs to send a ***Set Wrap*** command to place the device in wrap mode. Other flash devices provide a configuration register which must be programmed to set the flash in wrap mode. Since the SPI memory-mapped hardware does not support any write operations to flash, perform this step in non-memory-mapped mode (SPI_CTL.MMSE=0) by accessing the SPI registers.

Data access is limited to 8-byte, 16-byte, or 32-byte sections of flash page in wrap mode. The Arm core uses the Wrap 4 access (64-bit data) for L1 cache. The Arm core uses Wrap 4 and Wrap 8 accesses (64-bit data) for L2 cache. The cores use the Wrap 8 accesses for unaligned accesses. During the read request to the SPI memory-mapped hardware, the memory subsystem controller of the processor provides the address of a critical word instead of the line base. The read-data starts at the address specified in the instruction. Once it reaches the end boundary of the 8, 16, or 32-byte section, the output automatically wraps around to the beginning boundary to the line base address. The data fetch continues. It is not necessary to deassert the SPI SPI_SEL[n] signal or resend the read header to wrap to the cache line base when servicing misaligned cache fill requests.

The ***Byte Sequence in Wrap Modes*** table shows byte sequences in various wrap modes.

Table 20-9: Byte Sequence in Wrap Modes

Starting Address	8-Byte Wrap (cache_line = 8 byte)
0	0-1-2- . . . -6-7
1	1-2- 3-. . . -7-0
7	7-0-1- . . . -5-6
15	15-8-9- . . . -13-14
31	31-24-25-. . . .-29-30

The burst with wrap feature allows applications to fetch a critical address quickly. Applications then fill the cache afterwards within a fixed length (8/16/32-byte) of data without issuing multiple read commands. Certain applications can benefit from this feature to improve cache fill efficiency and overall performance of system code execution.

NOTE: Do not use the merge and wrap feature together. Using wrap bursts can unintentionally disable merging (merging cannot occur for unaligned wrapping bursts). A wrap burst can start fetching data words in the middle of the cache line and cannot be merged with the next access.

Execute-In-Place (XIP, SPI2 only)

Execute-In-Place, known as XIP, permits software code to execute directly from an SPI flash device rather than downloading the code and executing it out of RAM. XIP, also known as Command Skip mode, is a general term and can be applied to fetching data as well.

There is a difference between XIP mode and standard mode. In XIP mode, after the SPI memory device is selected (CS# =LOW), the memory device does not decode the first input byte as command code. Instead, it expects the read header to directly start with address bytes. In standard mode, the memory decodes the first input byte it receives as a command code.

The XIP mode dramatically reduces random access time for applications that require fast code execution without shadowing the memory content on a RAM. The SPI memory-mapped hardware provides a control bit, SPI_MMRDH.CMDSKIP to skip the command from read header.

Some SPI memory devices require configuration of their control register to enable the XIP mode of operation, using the non-memory-mapped mode of the processor SPI. Typically, during the dummy cycle period, the mode bits are used to confirm the XIP operation and the SPI_MMRDH.MODE field must be set appropriately. A dummy memory-mapped access may be needed before setting the SPI_MMRDH.CMDSKIP bit to set the SPI memory device in Command Skip mode.

For more details about how to configure SPI memories into XIP mode, refer to the device data sheet.

NOTE: When configuring the flash to XIP mode from the SHARC+ core, ensure that the routine that configures flash to XIP is not routed through the L2CC. This is accomplished by first configuring the flash to XIP mode, then enabling the L2CC from the core.

Memory-Mapped Mode Error Status Bits

The SPI memory-mapped hardware provides bits in the SPI_STAT register to report errors. It provides these bits for notification only and their state has no effect on SPI operations. The status register bits are sticky. A W1C (write-1-to-clear) operation clears the bits.

- Memory-Mapped Write Error (SPI_STAT.MMWE). This bit is set (=1) if an attempt is made to write to address space that is reserved for memory-mapped SPI memory. The SPI memory-mapped hardware does not support automated write access to SPI memory space.
- Memory-Mapped Read Error (SPI_STAT.MMRE). This bit is set (=1) if an attempt is made to read address space reserved for memory-mapped SPI memory while memory mapping is disabled (SPI_CTL.MMSE =0).
- Memory-Mapped Access Error (SPI_STAT.MMAE). This bit is set (=1) if an attempt is made to access either the TX or RX FIFO while memory-mapped access of SPI memory is enabled. In this case, attempts to communicate with the SPI device using legacy methods are blocked and receive fabric reports an error. Legacy methods include any direct access made to the TX and RX FIFOs, whether by DMA or processor MMR.
- Memory-Mapped Write Error Mask (SPI_CTL.MMWEM) bit specifies whether an error response is returned to the fabric on write attempts to address space that is reserved for memory-mapped SPI memory reads. Regardless of whether a write error response is masked using this bit, the memory-mapped write error (SPI_STAT.MMWE) sticky notification bit is still set.

  NOTE: Unlike other bits in the SPI_STAT register, these memory-mapped mode error bits do not have associated bits in the SPI interrupt mask (SPI_IMSK) and SPI interrupt condition (SPI_ILAT) registers.

The memory-mapped top register (SPI_MMTOP) is used to specify the upper limit of the SPI memory address. The memory-mapped accesses to SPI memory addresses equal to or above this range are considered illegal. The accesses are blocked, and a bus error response is generated.

This register is useful to block the invalid SPI memory address accesses. Some SPI memory vendors do not clearly specify (guarantee) that overrange address bits are ignored (address spaces can be wrapped).

Memory-Mapped Programming Guidelines

Setting the SPI_CTL.MMSE bit enables SPI memory-mapped mode. When enabled, the SPI interface is forced to be consistent with SPI memory requirements regardless the settings of certain control bits. The following tables specify typical settings for configuring the SPI in memory-mapped mode:

Table 20-10: SPI Control (SPI_CTL) Register

Bits	Typical values to set	Description	Comments
SPI_CTL.MODE	1	Controller mode enable	
SPI_CTL.PTSE	0	Protected target select enable	
SPI_CTL.ODM	0	Open-drain mode enable	
SPI_CTL.CPHASPI_CTL.CPOL	0–0 or 1–1	SPI mode of communication	Flash dependent, usually SPI flash supports mode-0 (CPHA=CPOL=0) and mode-3 (CPHA=CPOL=1)
SPI_CTL.ATSEL	1	Hardware target select pin control	
SPI_CTL.POLSEL	1	Target select asserted between transfers	
SPI_CTL.ECITO	1	CITO pin enable	
SPI_CTL.SIZE	2	32-bit transfer size	
SPI_CTL.LSBF	0	MSB bit first mode	Flash dependent, usually SPI flash communicates in MSB bit first mode
SPI_CTL.FCEN SPI_CTL.FCCH SPI_CTL.FCPL SPI_CTL.FCWM	0	Hardware flow control related bits	
SPI_CTL.FMODE	1	Fast mode enable	Typically set to 1 for full cycle timing, 0 only works at low speed
SPI_CTL.SOTI	0	Treat SPI_COTI pin as IO0 pin.	

Table 20-11: SPI Receive Control Register

Bits	Typical values to set	Description
SPI_RXCTL.REN	1	Receive channel enable
SPI_RXCTL.RTI	0	Receive transfer initiation disable
SPI_RXCTL.RWCEN	0	Receive word counter disable

Table 20-11: SPI Receive Control Register (Continued)

Bits	Typical values to set	Description
SPI_RXCTL.RDR	0	Receive data request disable
SPI_RXCTL.RDO	0	Discard incoming data if RFIFO is full
SPI_RXCTL.RRWM	0	Receive FIFO regular watermark
SPI_RXCTL.RUWM	0	Receive FIFO urgent watermark disable

Table 20-12: SPI Transmit Control Register

Bits	Typical values to set	Description
SPI_TXCTL.TEN	1	Transmit channel enable
SPI_TXCTL.TTI	1	Transmit transfer initiation disable
SPI_TXCTL.TWCEN	0	Transmit word counter disable
SPI_TXCTL.TDR	0	Transmit data request disable
SPI_TXCTL.TDU	0	Send last word when TFIFO is empty
SPI_TXCTL.TRWM	0	Transmit FIFO regular watermark
SPI_TXCTL.TUWM	0	Transmit FIFO urgent watermark disable

Table 20-13: SPI DLY Control Register

Bits	Typical Values to Set	Description	Comments See Flash data sheet for CS (for example, SSEL) Timing Specs
SPI_DLY.LAGX	1	Extended lag timing	
SPI_DLY.LEADX	1	Extended lead timing	
SPI_DLY.STOP	3	Stop bit between the transfers	Can be set to 1 at lower SPI clock frequencies.

The multiple I/O mode (SPI_CTL.MIOM) bits are partially ignored:

- The command (opcode) is transmitted using either just one or the number of pins specified by the SPI_CTL.MIOM bits, depending on SPI_MMRDH.CMDPINS bit setting.
- The address is then transmitted using either just one or the number of pins specified by the SPI_CTL.MIOM bits, depending on SPI_MMRDH.ADRPINS bit setting.
- The data is always read with the number of pins specified by the SPI_CTL.MIOM bits.

NOTE: Set the SPI module enable bits SPI_CTL.EN last after configuring all registers.

Use the following programming guidelines for memory-mapped mode:

- The SPI memory-mapped hardware does not check the flash status before initiating the access. It assumes that SPI memory is always able to respond to a read access. Before enabling memory-mapped mode (for example, setting the SPI_CTL.MMSE bit) ensure that SPI flash is ready for a read access. When using non-memory-mapped mode, a write-complete status can be examined prior to enabling the SPI in memory-mapped mode. (See the write in progress bit in the SPI flash memory status register.) Also, immediately after initial power-up, SPI memory devices can be inaccessible for a vendor-specified period.
- When SPI is enabled in memory-mapped mode, attempts to communicate with the SPI device using legacy methods are blocked. Legacy methods include any direct access made to the transmit or receive FIFOs, whether initiated by DMA or by a processor MMR access.
- To use some of the features offered by SPI memory devices, programs can first configure the SPI memory device by setting its control word or sending some commands. Because SPI memory-mapped hardware does not allow any type of SPI write operations, configure the SPI in non-memory-mapped mode prior to enabling memory-mapped mode.
- The memory-mapped hardware does not interpret the opcode. It does not check the validity of the timing that is specified in the SPI_MMRDH register for a particular opcode. Programs must set the fields of the SPI_MMRDH register to be consistent with the read-type selected.
- When the core requests the data or code fetch, the memory-mapped transfer depends on cache settings. The cache configuration register in the SPI memory device must be appropriately configured before enabling memory-mapped mode. Some of the high performance modes like merge, wrap, and transfer size depend on cache parameters.
- SPI memory-mapped MDMA reads do not support wrapping. For MDMA reads, limit the DMA_CFG.MSIZE field to 1 byte, 2 bytes or 4 bytes.
- There is not always tool support to change the SPI memory-mapped hardware setting or cache settings on-the-fly. Changing these settings can optimize the performance of code that accesses SPI memory in memory-mapped mode. It is expected that the SPI memory, SPI peripheral, and cache are programmed to one specific set of control settings for the whole application. Profiling or benchmarking of the actual application can be done to find the setting that works best.

SPI Interrupt Signals

The SPI controller supports three types of interrupt request signals that correspond to data, status, and error conditions.

Data Interrupts

The SPI target supports two data interrupt channels – receive and transmit. These interrupt signals are multiplexed into the DMA request lines. Since the target interfaces with separate read and write interfaces with DMA, the read and write data interrupts are independent. When the DMA channels are not used, the interrupts are routed directly to the system event controller. The interrupts occupy the same vector locations as the corresponding DMA channels.

Each of the data interrupt requests can be individually controlled. Program the SPI_RXCTL.RDR and SPI_TXCTL.TDR bit fields for receive and transmit, respectively. When receive is enabled, the RX interrupt request is issued whenever there is data available in the receive data path for reading. (The event occurs according to the SPI_RXCTL.RDR bit setting.) When transmit is enabled, the TX interrupt request is issued whenever the transmit data path can be written. (The event occurs according to the SPI_TXCTL.TDR setting.) DMA data interrupts are compatible with second-generation DMA to incorporate urgent data requests and transfer finish interrupt requests apart from the usual data request interrupts. Transmit interrupt requests operate independently from the word counter-value in the SPI_TWC register.

Status Interrupts

The SPI controller supports several status interrupt requests to indicate different conditions of the receiver and transmitter. All status interrupt requests can be masked. Status interrupt requests are signaled directly through a single SPI status IRQ line. The line cannot be combined with the SPI error IRQ line for some processors. The ***SPI Status Interrupts*** table describes the status interrupt requests that are available for the SPI controller.

Table 20-14: SPI Status Interrupts

SPI_STAT Bit	Description
SPI_STAT.RUWM	Receive FIFO urgent watermark interrupt request. Issued when the level of the RFIFO breaches the watermark set in the SPI_RXCTL.RUWM field. It is cleared when the level of the RFIFO reaches the watermark set in the SPI_RXCTL.RRWM field. If the RX channel is configured in DMA mode, SPI_RXCTL.RUWM is multiplexed with the data request.
SPI_STAT.TUWM	Transmit FIFO urgent watermark interrupt request. Issued when the level of the TFIFO breaches the watermark set using the SPI_TXCTL.TUWM bit. It is cleared when the level of the TFIFO reaches the watermark set in the SPI_TXCTL.TRWM field. If the TX channel is configured in DMA mode, SPI_STAT.TUWM is multiplexed with the data request.
SPI_STAT.TS	Transmit start interrupt request. Issued when the start of a transmit burst is detected by loading of the SPI_TWC register with the contents of the SPI_TWCR register.
SPI_STAT.RS	Receive start interrupt request. Issued when the start of a receive burst is detected by the loading of SPI_RWC with the contents of SPI_RWCR.
SPI_STAT.TF	Transmit finish interrupt request. Issued when a transmit burst completes (SPI_TWC decrements to zero).
SPI_STAT.RF	Receive finish interrupt request. Issued when a receive burst completes (SPI_RWC decrements to zero).

Error Conditions

The SPI controller supports interrupt requests upon several different error conditions. All interrupt requests are maskable. The individual error indications combine into a single SPI error IRQ signal, which can be multiplexed on some processors with the aggregated SPI status IRQ signal. The ***SPI Error Interrupts*** table details the possible error indications.

Error conditions arise depending on which of the channels (transmit or receive) are enabled. If a channel is disabled, all errors related to it are ignored. When both channels are enabled, errors from both channels are enabled.

Table 20-15: SPI Error Interrupts

Bit	Description
SPI_STAT.MF	Mode fault. Signaled when another device also tries to be a controller in a multi-controller system and drives the SPI_TS input low. This error is signaled in controller mode operation.
SPI_STAT.TUR	Transmission error. Signaled when an underflow condition occurs on the transmit channel. This event occurs when a new transfer starts but SPI_TFIFO is empty. This error does not occur in controller transmit initiating mode since SPI_TFIFO *Not Empty* is one of the conditions for transfer initiation.
SPI_STAT.ROR	Reception error. Signaled when an overflow condition occurs on the receive channel. This event occurs when a new data word is received, but the SPI_RFIFO is full. This error condition does not occur in controller receive initiating mode since SPI_RFIFO *Not Full* is one of the conditions for transfer initiation.
SPI_STAT.TC	Transmit collision error. Signaled when loading data to the transmit shift register happens near the first transmitting edge of SPI_CLK. In target mode of operation, the SPI controller is unaware of when the next transfer starts. Loading of data to the transmit shift register can happen just after the transmitting edge. This event results in the setup time not being met for the first bit transmitted. The transmitted data is corrupt. In SPI_CTL.CPHA 1 mode, the first SPI_CLK edge is taken as the first transmitting edge. If SPI_CTL.CPHA =0, then the last SPI_CLK edge of the last transmission (SPI_CTL.POLSEL =1) or target select deassertion (SPI_CTL.POLSEL =0) is taken as the first transmitting edge. This error is signaled only in the target mode of operation. In controller mode of operation, loading of data happens before the first transmitting edge of SPI_CLK.

SPI Programming Concepts

The following sections provide general programming guidelines and procedures.

Programming Guidelines

It is acceptable to program SPI_RXCTL and SPI_TXCTL registers after programming the SPI_CTL register. However, program the initiating mode register and its counter-register, if enabled, after the non-initiating mode register. For example, if transmit is the initiating mode and receive is the non-initiating mode, then program the SPI_RXCTL and SPI_RWC registers before the SPI_TXCTL and SPI_TWC registers. If enabling both transmit and receive in initiating mode, enable the SPI_CTL register after programming both the SPI_RXCTL and SPI_TXCTL registers.

These programming guidelines prevent SPI from starting a transfer when SPI registers are not fully programmed. Other ways of programming are also allowed when the initiating conditions prevent the start of communication until after programming of SPI registers is complete.

Avoid data corruption when changing the SPI module configuration. Do not change the configuration during a data transfer. Additionally, change the clock polarity only when no target is selected. However, an exception to this rule exists. When an SPI communication link consists of a single controller and target, SPI_CTL.ATSEL = 0. The target select input of the target is permanently tied low. In this case, the target is always selected. Avoid data corruption by enabling the target only after both the controller and target devices are configured.

The module supports 8, 16-bit and 32-bit word sizes. To ensure correct operation, configure both the controller and target with the same word size.

Controller Operation in Non-DMA Modes

This section describes the operation of the SPI as a controller in non-DMA mode.

1. Write to the SPI_TSEL register, setting one or more of the SPI select enable bits. This operation ensures that the desired targets are properly deselected while the controller is configured.
2. The SPI_RXCTL.RTI and SPI_TXCTL.TTI bits determine the SPI initiating mode. The initiating mode defines the primary transfer channel, and also the initiating condition for the transfer.
3. Write to the SPI_CLK, SPI_CTL, SPI_RXCTL, and SPI_TXCTL registers. This operation enables the device as a controller and configures the SPI system. It specifies the transfer modes and channels, appropriate word length, transfer format, baud rate, and other control information.

   ADDITIONAL INFORMATION: If SPI_RXCTL.RTI is enabled and SPI_TXCTL.TTI is not, write to the SPI_RXCTL register after writing into SPI_CTL, SPI_TXCTL, and SPI_TFIFO registers to prevent a transmit underrun for the first transfer.
4. If SPI_CTL.ATSEL=0, activate the desired targets by clearing one or more of the SPI_TSEL flag bits. Otherwise, the SPI hardware performs target activation.
5. The SPI controller then generates the programmed clock pulses on SPI_CLK and simultaneously shifts data out of SPI_COTI while shifting data in from SPI_CITO. Before a shift, the shift register is loaded with the contents of the SPI_TFIFO register. At the end of the transfer, the contents of the shift register are loaded into SPI_RFIFO.
6. Whenever the initiating conditions are satisfied, the SPI continues to send and receive words. If the transmit buffer remains empty or the receive buffer remains full, the device operates according to the states of the SPI_TXCTL.TDU and SPI_RXCTL.RDO bits.
7. It is possible to program a secondary channel in addition to the initiating channel. This feature allows usage of available channel resources for receives or transmits simultaneously with the initiating channel.

Target Operation in Non-DMA Modes

When a device is enabled as a target in a non-DMA mode, a transition of the $\overline{\text{SPI_TS}}$ select signal to the active state (low) triggers the start of a transfer. Or the first active edge of SPI_CLK triggers the start, depending on the state of SPI_CTL.CPHA bit. The interface operates in the following manner.

1. The core writes to the SPI_CTL, SPI_RXCTL, and SPI_TXCTL registers. The operation defines the mode of the serial link to be the same as the mode setup in the SPI controller.
2. To prepare for the data transfer, the core writes data to be transmitted into SPI_TFIFO.
3. Once the $\overline{\text{SPI_TS}}$ falling edge is detected, the target starts sending data on active SPI_CLK edges and sampling data on inactive SPI_CLK edges.
4. Reception or transmission continues until $\overline{\text{SPI_TS}}$ is released or until the target has received the proper number of clock cycles.

5. The target device continues to receive or transmit with each new falling edge transition on $\overline{\texttt{SPI_TS}}$ or active SPI_CLK edge. If the transmit buffer remains empty or the receive buffer remains full, the device operates according to the states of the SPI_TXCTL.TDU and SPI_RXCTL.RDO bits.

Configuring DMA Controller Mode

The SPI interface supports a write DMA channel and a read DMA channel. It can use these functions individually or in a lock-step manner in duplex mode (SPI_TXCTL.TTI= SPI_RXCTL.RTI=1).

1. Write to the appropriate DMA registers to enable the SPI DMA channel and to configure the necessary work units, access direction, word count, and so on.
2. Write to the SPI_TSEL register, setting one or more of the SPI flag select bits.
3. Write to the SPI_CLK and SPI_CTL registers, enabling the device as a controller and configuring the SPI system by specifying the appropriate word length, transfer format, baud rate, and so forth.
4. Write to SPI_RXCTL to configure SPI controller receive mode, or write to SPI_TXCTL to configure SPI controller transmit mode.
5. Finally, write to the SPI_RXCTL.REN bit to enable the receive channel, or write to SPI_TXCTL.TEN to enable the transmit channel.
6. When the SPI_RXCTL.RTI bit is enabled, a receive transfer is initiated upon enabling SPI_CTL.EN bit. If the receive word counter is enabled (SPI_RXCTL.RWCEN), then the SPI_RWC register must be non-zero for a transfer to initiate.

   ADDITIONAL INFORMATION: If enabling both receive and transmit DMA channels, but not enabling SPI_TXCTL.TTI, write to the SPI_RXCTL register after writing the SPI_CTL and SPI_TXCTL registers. In this way, a transmit underrun can be prevented for the first transfer. Subsequent transfers are initiated as the SPI reads data from the receive shift register and writes to the SPI receive FIFO. The SPI then requests a write from DMA to memory. Upon a DMA grant, the DMA engine reads a word from the SPI receive FIFO and writes to memory. New requests continue to be initiated as long as the receive FIFO does not fill up, when SPI_RWC does not become zero while SPI_RXCTL.RWCEN=1.
7. When SPI_TXCTL.TTI is enabled, the SPI controller requests DMA reads from memory when there is space for more data in the transmit pipe. Upon a DMA grant, the DMA engine reads a word from memory and writes to the transmit FIFO. As long as transmit data is available in the FIFO, and the SPI_TWC register is non-zero when SPI_TXCTL.TWCEN=1, the SPI continues to initiate transfers until disabled.
8. When both the SPI_TXCTL.TTI and SPI_RXCTL.RTI bits are enabled, the SPI controller requests a DMA read from memory. However, there must be space for more data in the transmit pipe and the number of words written into the SPI must be less than SPI_TWC if SPI_TXCTL.TWCEN=1. Upon a DMA grant, the DMA engine reads a word from memory and writes to the transmit FIFO.

   ADDITIONAL INFORMATION: As the SPI writes data from the transmit FIFO into the transmit shift register, it initiates a transfer on the SPI link. Data received from the transfer is moved from the SPI receive shift register to the receive FIFO. The SPI controller requests a write from DMA to memory. Upon a DMA

grant, the DMA engine reads a word from the receive FIFO and writes to memory. Transfer continues to be initiated when both receives and transmits can accommodate new data.

9. When the receive pipe fills up due to unavailability of DMA grants, the transmit pipe stalls until the pipe is drained. If the transmit pipe fills up, the SPI stops requesting for DMA writes. When the value in SPI_RWC expires, further write-requests to DMA stop. However, data already written into the transmit FIFO is sent, and read requests to DMA continue until the receive data is read from the receive FIFO.
10. The SPI then generates the programmed clock pulses on SPI_CLK and simultaneously shifts data out of SPI_COTI while shifting data in from SPI_CITO. For receive transfers, the value in the shift register is loaded into the SPI_RFIFO register at the end of the transfer. For transmit transfers, the value in the SPI_TFIFO register is loaded into the shift register at the start of the transfer.

Configuring DMA Target Mode Operation

This mode occurs when the SPI is enabled as a target and the DMA engine is configured to transmit or receive data. A transition of the SPI_TS signal to the active-low state triggers the start of a transfer. Or, the first active edge of SPI_CLK triggers the start of a transfer, depending on the state of the SPI_CTL.CPHA bit. The following steps illustrate the SPI receive or transmit DMA sequence in an SPI target (in response to a controller command). The SPI supports a receive DMA channel and a transmit DMA channel.

1. Write to the appropriate DMA registers to enable the SPI DMA channel and configure the necessary work units, access direction, word count, and so on.
2. Write to the SPI_CTL, SPI_RXCTL, and SPI_TXCTL registers to define the mode of the serial link to be the same as the mode configured in the SPI controller.
3. When the receive channel is enabled (SPI_RXCTL.REN is asserted), the following actions occur:
    a. Once the target select input is active, the target starts receiving and transmitting data on active SPI_CLK edges.
    b. The value in the shift register is loaded into the SPI_RFIFO register at the end of the transfer.
    c. Once SPI_RFIFO has valid data, it requests a write from DMA to memory.
    d. Upon a DMA grant, the DMA engine reads a word from the receive FIFO and writes to memory.
    e. When there is data in the receive FIFO, the SPI target continues to request a DMA write to memory. The DMA engine continues to read a word from the FIFO and writes to memory. The SPI target continues receiving words on active SPI_CLK edges when the SPI_TS input is active.
    f. When the data collected in the receive pipe breaches the set level, and the DMA engine cannot keep up with the receive rate, the target can deassert the SPI_RDY signal. This signaling throttles the controller. The receive pipe level is set according to the SPI_CTL.FCWM field. The signal is deasserted as the DMA drains the receive FIFO. Alternatively, the SPI can use the SPI_RXCTL.RDO bit to decide when the incoming data is discarded or overwritten into the receive FIFO (when SPI_CTL.FCEN is inactive).
4. When the transmit channel is enabled (SPI_TXCTL.TEN is asserted), the following actions occur:

a. The SPI requests a DMA read from memory.

b. Upon a DMA grant, the DMA engine reads a word from memory and writes to the transmit FIFO.

c. The SPI then reads DMA data from the transmit FIFO and writes to the transmit shift register, awaiting the start of the next transfer.

d. Once the target select input is active, the target starts receiving and transmitting data on active SPI_CLK edges.

e. When there is room in the transmit FIFO, the SPI target continues to request a DMA read from memory. The DMA engine continues to read a word from memory and write to the transmit FIFO. The SPI target continues transmitting words on active SPI_CLK edges as long as the SPI_TS input is active.

f. When the number of outstanding data entries in the transmit pipe breaches the level set and the DMA cannot keep up with the transmit rate, the target deasserts the SPI_RDY signal. This signaling throttles the controller. The transmit pipe level is set according to the SPI_CTL.FCWM field. The signal is deasserted as the DMA fills the transmit FIFO. Alternately, the SPI_TXCTL.TDU bit decides the state of the transmit data (when SPI_CTL.FCEN is deasserted).

5. When both receive and transmit channels are enabled, the following actions occur after the actions for each channel. Transfers continue when both receive and transmit channels can accommodate new data.

a. When the receive pipe fills up due to the unavailability of DMA grant, the SPI interface stalls the controller by asserting the SPI_RDY pin. This signal is deasserted as the DMA drains the receive FIFO. Alternately, the SPI uses the SPI_RXCTL.RDO bit to decide when the incoming data is discarded or overwritten in the receive FIFO (when SPI_CTL.FCEN is deasserted).

b. When the transmit pipe fills up, the SPI stops requesting DMA writes until the pipe clears.

c. When there is an underflow problem in the transmit pipe, the target stalls the controller by deasserting SPI_RDY while the DMA fills the transmit FIFO. Alternately, the SPI uses the SPI_TXCTL.TDU bit to decide the state of the transmit data (when SPI_CTL.FCEN is deasserted).

ADSP-2184x SPI Register Descriptions

Serial Peripheral Interface (SPI) contains the following registers.

Table 20-16: ADSP-2184x SPI Register List

Name	Description
SPI_CLK	Clock Rate Register
SPI_CTL	Control Register
SPI_DLY	Delay Register
SPI_ILAT	Masked Interrupt Condition Register
SPI_ILAT_CLR	Masked Interrupt Clear Register

Table 20-16: ADSP-2184x SPI Register List (Continued)

Name	Description
SPI_IMSK	Interrupt Mask Register
SPI_IMSK_CLR	Interrupt Mask Clear Register
SPI_IMSK_SET	Interrupt Mask Set Register
SPI_MMRDH	Memory Mapped Read Header
SPI_MMTOP	SPI Memory Top Address
SPI_RFIFO	Receive FIFO Data Register
SPI_RWC	Received Word Count Register
SPI_RWCR	Received Word Count Reload Register
SPI_RXCTL	Receive Control Register
SPI_TSEL	Target Select Register
SPI_STAT	Status Register
SPI_TFIFO	Transmit FIFO Data Register
SPI_TWC	Transmitted Word Count Register
SPI_TWCR	Transmitted Word Count Reload Register
SPI_TXCTL	Transmit Control Register

Clock Rate Register

The SPI_CLK register selects the baud rate for SPI data transfers, relating this rate to the SPI serial clock (SPI clock) and the system clock (SCLK).

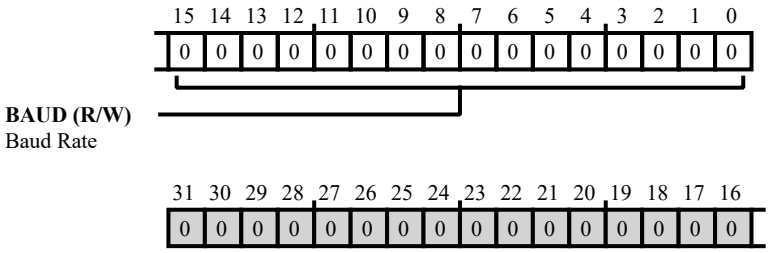

Figure 20-20: SPI_CLK Register Diagram

Table 20-17: SPI_CLK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	BAUD	Baud Rate. The SPI_CLK.BAUD bits set the SPI baud rate according to the formula: BAUD = (SCLK / SPI Clock) - 1

Control Register

The SPI_CTL register enables the SPI and configures settings for operating modes, communication protocols, and buffer operations.

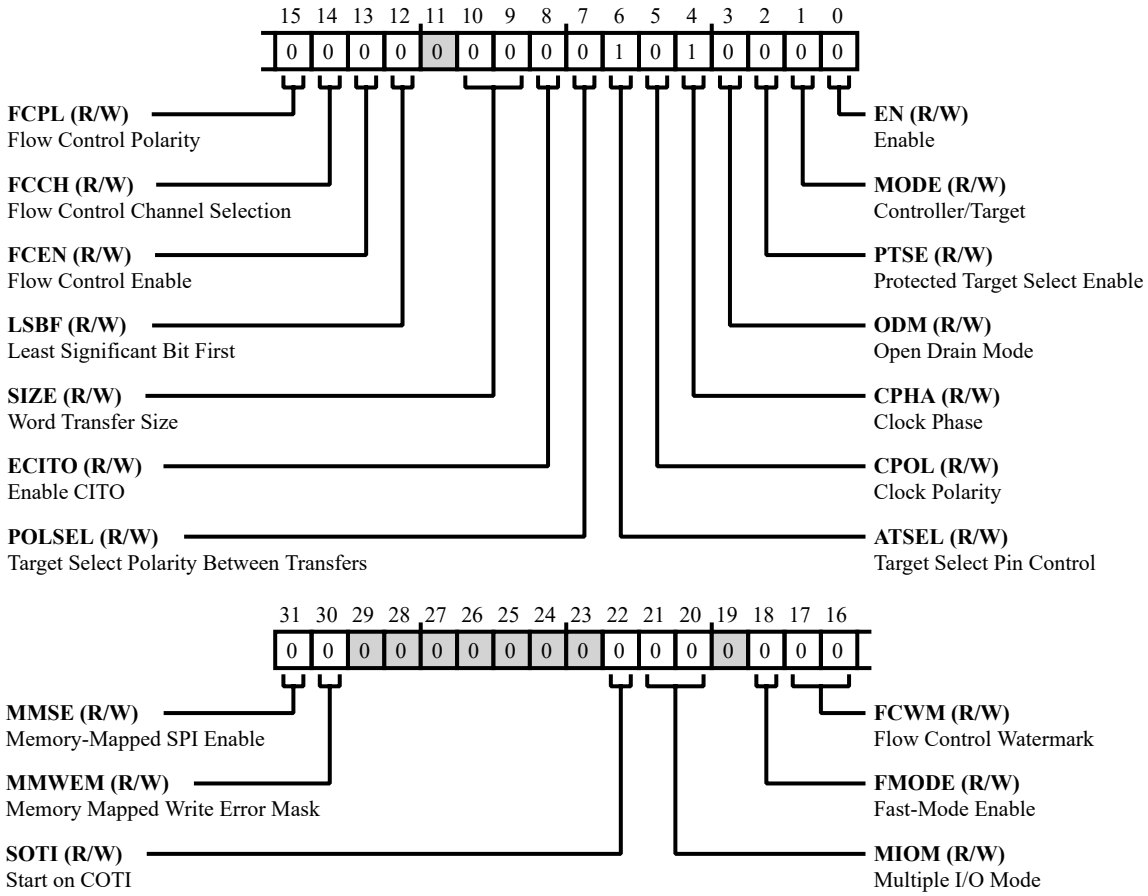

Figure 20-21: SPI_CTL Register Diagram

Table 20-18: SPI_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	MMSE	Memory-Mapped SPI Enable. When the SPI_CTL.MMSE bit is asserted, communication to an SPI memory device is automated such that the memory it contains is accessible directly through the read of processor address space assigned to it. (As far as the SPI peripheral is concerned, this includes all read accesses received by the SPI peripherals system crossbar port.) Note that when memory-mapped access of SPI memory is enabled, attempts to communicate with the SPI device using legacy methods are blocked and receive fabric error responses are generated. Legacy methods include any direct access made to the Tx and Rx FIFOs, whether initiated by DMA or processor MMR access.	
		0	Hardware automated access of memory-mapped SPI memory disabled.
		1	Hardware-automated access of memory-mapped SPI memory enabled.
30 (R/W)	MMWEM	Memory Mapped Write Error Mask. The SPI_CTL.MMWEM bit specifies whether an error response is returned to the fabric upon write attempts to address space reserved for memory-mapped reads of SPI memory.	
		0	Write error response returned upon write attempts to memory-mapped SPI memory
		1	Write error response masked (not returned) upon write attempts to memory-mapped SPI memory
22 (R/W)	SOTI	Start on COTI. The SPI_CTL.SOTI bit is valid only when SPI_CTL.MIOM is enabled for either DIOM or QIOM, and this bit selects the starting pin and the bit placement on pins for these modes. In DIOM, by default, (SPI_CTL.SOTI =0) SPI sends the first bit on the SPI_CITO pin and the second bit on the SPI_COTI pin. In QIOM, by default, the SPI sends the first bit on the SPI_D3 pin, the second bit on the SPI_D2 pin, the third bit on the SPI_CITO pin and the fourth bit on the SPI_COTI pin. This order can be reversed by setting the SPI_CTL.SOTI bit. When this bit is set, the SPI sends the first bit on the SPI_COTI pin. The first bit referred to here depends on the SPI_CTL.LSBF bit setting (MSB bit or LSB bit).	
		0	Start on CITO (DIOM) or Start on SPI_D3
		1	Start on COTI

Table 20-18: SPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
21:20 (R/W)	MIOM	Multiple I/O Mode. The SPI_CTL.MIOM bits enable SPI operation in dual I/O mode (DIOM) or quad I/O mode (QIOM). These bits can only be changed when the SPI is disabled (SPI_CTL.EN =0).	
		0	No MIOM (disabled)
		1	DIOM operation
		2	QIOM operation
		3	Reserved
18 (R/W)	FMODE	Fast-Mode Enable. The SPI_CTL.FMODE bit enables fast mode operation for SPI receive transfers. SPI transmit operations in fast mode are the same as normal mode.	
		0	Disable
		1	Enable
17:16 (R/W)	FCWM	Flow Control Watermark. The SPI_CTL.FCWM bits select the watermark level of the transmit channel (SPI_TFIFO buffer) or receive channel (SPI_RFIFO buffer) that triggers flow control operation. These bits are applicable only when the SPI is a target (SPI_CTL.MODE = 0) and flow control is enabled (SPI_CTL.FCEN =1). When the watermark condition is met, the SPI controller deasserts the SPI_RDY pin.	
		0	TFIFO empty or RFIFO full
		1	TFIFO 75% or more empty, or RFIFO 75% or more full
		2	TFIFO 50% or more empty, or RFIFO 50% or more full
		3	Reserved
15 (R/W)	FCPL	Flow Control Polarity. The SPI_CTL.FCPL bit selects flow control polarity for the SPI_RDY pin when flow control is enabled. When the SPI_RDY pin is active, the SPI is indicating it is ready for data transfer.	
		0	Active-low RDY
		1	Active-high RDY

Table 20-18: SPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
14 (R/W)	FCCH	Flow Control Channel Selection. The SPI_CTL.FCCH bit selects whether the SPI applies flow control to the transmit channel (SPI_TFIFO buffer) or receive channel (SPI_RFIFO buffer). This bit is applicable only when the SPI is a target and flow control is enabled.	
		0	Flow Control on RX Buffer
		1	Flow Control on TX Buffer
13 (R/W)	FCEN	Flow Control Enable. The SPI_CTL.FCEN bit enables SPI flow control operation, which permits slow target devices to interface with fast controller devices. This bit controls the operation of the SPI_RDY pin. Note that options for flow control operation are available using the SPI_CTL.FCCH, SPI_CTL.FCPL, and SPI_CTL.FCWM bits.	
		0	Disable
		1	Enable
12 (R/W)	LSBF	Least Significant Bit First. The SPI_CTL.LSBF bit selects whether the SPI transmits/receives data as LSB first (little endian) or MSB first (big endian). This bit can only be changed when the SPI is disabled.	
		0	MSB sent/received first (big endian)
		1	LSB sent/received first (little endian)
10:9 (R/W)	SIZE	Word Transfer Size. The SPI_CTL.SIZE bits select the SPI transfer word size as 8, 16 or 32 bits. To ensure correct operation, both the controller and target must be configured with the same word size. This bit can only be changed when the SPI is disabled (SPI_CTL.EN =0).	
		0	8-bit word
		1	16-bit word
		2	32-bit word
		3	Reserved
8 (R/W)	ECITO	Enable CITO. The SPI_CTL.ECITO bit enables controller-in-target-out (CITO) mode. This SPI mode is applicable only when the SPI is a target.	
		0	Disable
		1	Enable

Table 20-18: SPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	POLSEL	Target Select Polarity Between Transfers. The SPI_CTL.POLSEL bit selects the state (polarity) for the SPI_SEL[n] pin between SPI transfers when the SPI is a controller and hardware target select assertion is enabled (SPI_CTL.ATSEL =1). In target mode, this bit affects the detection of both transmit collision (SPI_STAT.TC and underrun (SPI_STAT.TUR) errors.	
		0	Deassert Target Select (high)
		1	Assert Target Select (low)
6 (R/W)	ATSEL	Target Select Pin Control. The SPI_CTL.ATSEL bit selects whether the SPI hardware sets the SPI_SEL[n] pin output value (ignoring the target select SPI_TSEL.TSEL1 - SPI_TSEL.TSEL7 bits) or whether software control of the target select bits set the SPI_SEL[n] pin output value. This feature is applicable only when the SPI is a controller. When hardware control is enabled, the SPI_SEL[n] pin output is asserted during the transfers, and the pin polarity between transfers is selected by the SPI_CTL.POLSEL bit. When software control is enabled, the SPI_SEL[n] pin output value is set through software control of the target select bits, and as such, the pin may either remain asserted (low) or be deasserted between transfers.	
		0	Software Target Select Control
		1	Hardware Target Select Control
5 (R/W)	CPOL	Clock Polarity. The SPI_CTL.CPOL bit selects whether the SPI uses an active-low or active-high signal for the SPI clock (SPI_CLK). This bit works with the SPI_CTL.CPHA bit to select combinations of clock phase and polarity for the SPI_CLK pin. This bit can only be changed when the SPI is disabled.	
		0	Active-high SPI CLK
		1	Active-low SPI CLK
4 (R/W)	CPHA	Clock Phase. The SPI_CTL.CPHA bit selects whether the SPI starts toggling the signal for the SPI clock (SPI_CLK) from the start of the first data bit or from the middle of the first data bit. The SPI_CTL.CPHA bit works with the SPI_CTL.CPOL bit to select combinations of clock phase and polarity for the SPI_CLK pin. This bit can only be changed when the SPI is disabled.	
		0	SPI CLK toggles from middle
		1	SPI CLK toggles from start

Table 20-18: SPI_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	ODM	Open Drain Mode. The SPI_CTL.ODM bit configures the data output pins (SPI_COTI and SPI_CITO) to behave as open drain outputs, which prevents contention and possible damage to pin drivers in multi-controller or multi-target SPI systems. When SPI_CTL.ODM is enabled and the SPI is a controller, the SPI three-states the SPI_COTI pin when the data driven out on COTI is a logic-high. The SPI does not three-state the SPI_COTI pin when the driven data is a logic-low. When SPI_CTL.ODM is enabled and the SPI is a target, the SPI three-states the SPI_CITO pin when the data driven out on SPI_CITO is a logic-high. Note that an external pull-up resistor is required on both the SPI_COTI and SPI_CITO pins when SPI_CTL.ODM is enabled.	
		0	Disable
		1	Enable
2 (R/W)	PTSE	Protected Target Select Enable. The SPI_CTL.PTSE bit enables the $\overline{\text{SPI_TS}}$ pin to provide error detection input in a multi-controller environment when the SPI is in controller mode. If some other device in the system asserts the $\overline{\text{SPI_TS}}$ pin while SPI is enabled as a controller (and SPI_CTL.PTSE is enabled), this condition causes a mode fault error.	
		0	Disable
		1	Enable
1 (R/W)	MODE	Controller/Target. The SPI_CTL.MODE bit toggles the SPI between controller mode and target mode. This bit can only be changed when the SPI is disabled.	
		0	Target
		1	Controller
0 (R/W)	EN	Enable. The SPI_CTL.EN bit enables SPI operation.	
		0	Disable SPI module
		1	Enable

Delay Register

The SPI_DLY register selects a transfer delay and the lead/lag timing between target select signals and SPI clock edge assertion/deassertion.

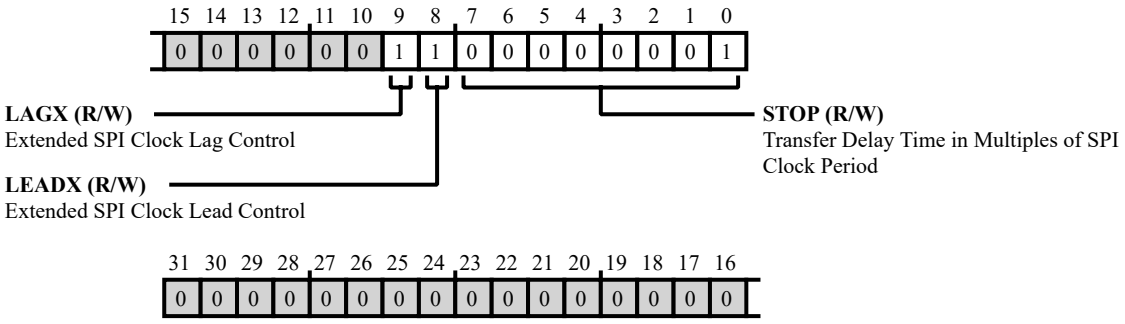

Figure 20-22: SPI_DLY Register Diagram

Table 20-19: SPI_DLY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	LAGX	Extended SPI Clock Lag Control. The SPI_DLY.LAGX bit enables insertion of a 1-SPI_CLK cycle lag (extend lag) in the timing between the target select (SPI_SEL[n]) assertion and first SPI clock edge.	
		0	Disable
		1	Enable
8 (R/W)	LEADX	Extended SPI Clock Lead Control. The SPI_DLY.LEADX bit enables insertion of a 1-SPI_CLK cycle lead (extend lead) in the timing between the target select (SPI_SEL[n]) deassertion and last SPI clock edge.	
		0	Disable
		1	Enable
7:0 (R/W)	STOP	Transfer Delay Time in Multiples of SPI Clock Period. The SPI_DLY.STOP bits select a delay (number of stop bits in multiples of SPI clock duration) at the end of each SPI transfer. The default delay is the minimum value required to comply with the SPI protocol (1-bit duration). The SPI_DLY.STOP bits can be programmed with smaller delay values, resulting in continuous operation (for example, stop bits =0).	

Masked Interrupt Condition Register

The SPI_ILAT register latches interrupts, queuing the interrupt requests for service. When a condition is indicated by a bit in the SPI_STAT register and the corresponding interrupt request is unmasked in SPI_IMSK, the SPI latches the interrupt request bit in SPI_ILAT.

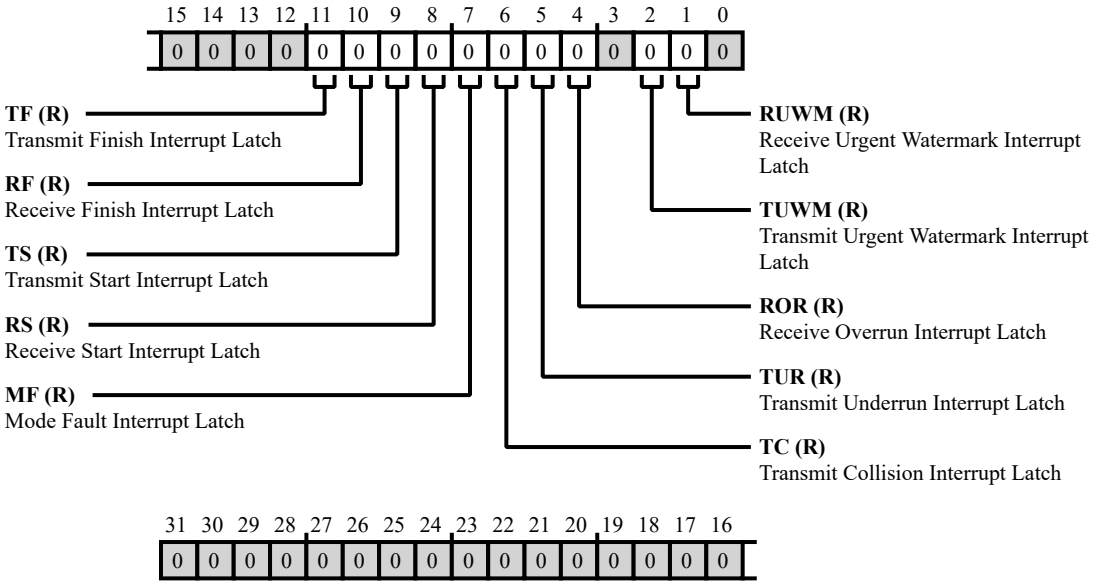

Figure 20-23: SPI_ILAT Register Diagram

Table 20-20: SPI_ILAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/NW)	TF	Transmit Finish Interrupt Latch.	
		0	No interrupt request
		1	Latched interrupt request
10 (R/NW)	RF	Receive Finish Interrupt Latch.	
		0	No interrupt request
		1	Latched interrupt request
9 (R/NW)	TS	Transmit Start Interrupt Latch.	
		0	No interrupt request
		1	Latched interrupt request
8 (R/NW)	RS	Receive Start Interrupt Latch.	
		0	No interrupt request
		1	Latched interrupt request

Table 20-20: SPI_ILAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/NW)	MF	Mode Fault Interrupt Latch.	
		0	No interrupt request
		1	Latched interrupt request
6 (R/NW)	TC	Transmit Collision Interrupt Latch.	
		0	No interrupt request
		1	Latched interrupt request
5 (R/NW)	TUR	Transmit Underrun Interrupt Latch.	
		0	No interrupt request
		1	Latched interrupt request
4 (R/NW)	ROR	Receive Overrun Interrupt Latch.	
		0	No interrupt request
		1	Latched interrupt request
2 (R/NW)	TUWM	Transmit Urgent Watermark Interrupt Latch.	
		0	No interrupt request
		1	Latched interrupt request
1 (R/NW)	RUWM	Receive Urgent Watermark Interrupt Latch.	
		0	No interrupt request
		1	Latched interrupt request

Masked Interrupt Clear Register

The SPI_ILAT_CLR register permits clearing individual mask bits in the SPI_ILAT register without affecting other bits in the register. Use write-1-to-clear on a bit in the SPI_ILAT_CLR register to clear the corresponding bit in the SPI_ILAT register.

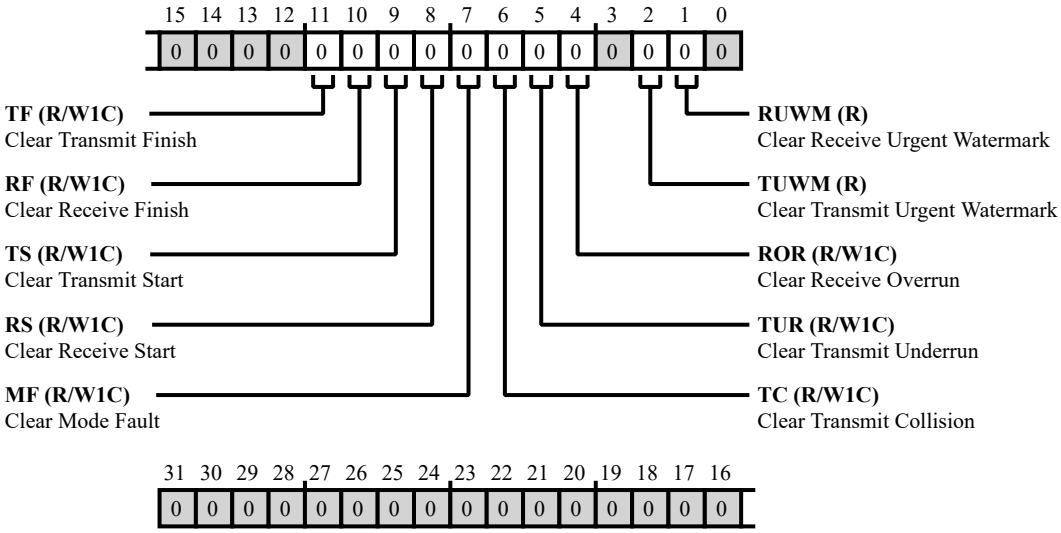

Figure 20-24: SPI_ILAT_CLR Register Diagram

Table 20-21: SPI_ILAT_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W1C)	TF	Clear Transmit Finish. The SPI_ILAT_CLR.TF bit clears the corresponding mask bit in the SPI_ILAT register.	
		0	No effect
		1	Clear mask bit
10 (R/W1C)	RF	Clear Receive Finish. The SPI_ILAT_CLR.RF bit clears the corresponding mask bit in the SPI_ILAT register.	
		0	No effect
		1	Clear mask bit
9 (R/W1C)	TS	Clear Transmit Start. The SPI_ILAT_CLR.TS bit clears the corresponding mask bit in the SPI_ILAT register.	
		0	No effect
		1	Clear mask bit

Table 20-21: SPI_ILAT_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W1C)	RS	Clear Receive Start. The SPI_ILAT_CLR.RS bit clears the corresponding mask bit in the SPI_ILAT register.	
		0	No effect
		1	Clear mask bit
7 (R/W1C)	MF	Clear Mode Fault. The SPI_ILAT_CLR.MF bit clears the corresponding mask bit in the SPI_ILAT register.	
		0	No effect
		1	Clear mask bit
6 (R/W1C)	TC	Clear Transmit Collision. The SPI_ILAT_CLR.TC bit clears the corresponding mask bit in the SPI_ILAT register.	
		0	No effect
		1	Clear mask bit
5 (R/W1C)	TUR	Clear Transmit Underrun. The SPI_ILAT_CLR.TUR bit clears the corresponding mask bit in the SPI_ILAT register.	
		0	No effect
		1	Clear mask bit
4 (R/W1C)	ROR	Clear Receive Overrun. The SPI_ILAT_CLR.ROR bit clears the corresponding mask bit in the SPI_ILAT register.	
		0	No effect
		1	Clear mask bit
2 (R/NW)	TUWM	Clear Transmit Urgent Watermark. The SPI_ILAT_CLR.TUWM bit clears the corresponding mask bit in the SPI_ILAT register.	
		0	No effect
		1	Clear mask bit

Table 20-21: SPI_ILAT_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/NW)	RUWM	Clear Receive Urgent Watermark. The `SPI_ILAT_CLR.RUWM` bit clears the corresponding mask bit in the `SPI_ILAT` register.	
		0	No effect
		1	Clear mask bit

Interrupt Mask Register

The SPI_IMSK register unmasks (enables) or masks (disables) SPI interrupt requests. When a condition is indicated by a bit in the SPI_STAT register and the corresponding interrupt request is unmasked in SPI_IMSK, the SPI latches the interrupt request bit in the SPI_ILAT register, queuing the interrupt request for service.

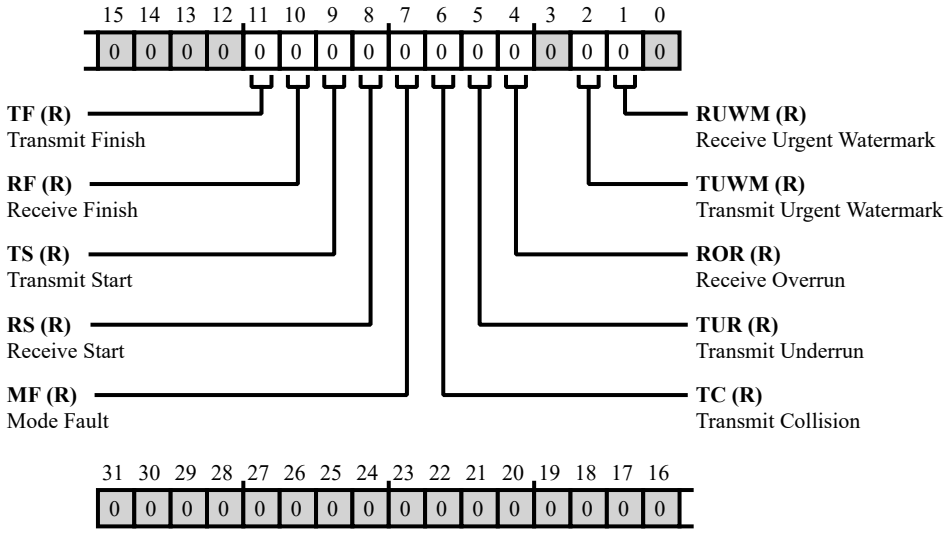

Figure 20-25: SPI_IMSK Register Diagram

Table 20-22: SPI_IMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/NW)	TF	Transmit Finish. The SPI_IMSK.TF bit unmasks (enables) or masks (disables) the TF interrupt.	
		0	Disable (mask) interrupt request
		1	Enable (unmask) interrupt request
10 (R/NW)	RF	Receive Finish. The SPI_IMSK.RF bit unmasks (enables) or masks (disables) the RF interrupt.	
		0	Disable (mask) interrupt request
		1	Enable (unmask) interrupt request
9 (R/NW)	TS	Transmit Start. The SPI_IMSK.TS bit unmasks (enables) or masks (disables) the TS interrupt.	
		0	Disable (mask) interrupt request
		1	Enable (unmask) interrupt request

Table 20-22: SPI_IMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/NW)	RS	Receive Start. The SPI_IMSK.RS bit unmasks (enables) or masks (disables) the RS interrupt.	
		0	Disable (mask) interrupt request
		1	Enable (unmask) interrupt request
7 (R/NW)	MF	Mode Fault. The SPI_IMSK.MF bit unmasks (enables) or masks (disables) the MF interrupt.	
		0	Disable (mask) interrupt request
		1	Enable (unmask) interrupt request
6 (R/NW)	TC	Transmit Collision. The SPI_IMSK.TC bit unmasks (enables) or masks (disables) the TC interrupt.	
		0	Disable (mask) interrupt request
		1	Enable (unmask) interrupt request
5 (R/NW)	TUR	Transmit Underrun. The SPI_IMSK.TUR bit unmasks (enables) or masks (disables) the TUR interrupt.	
		0	Disable (mask) interrupt request
		1	Enable (unmask) interrupt request
4 (R/NW)	ROR	Receive Overrun. The SPI_IMSK.ROR bit unmasks (enables) or masks (disables) the ROR interrupt.	
		0	Disable (mask) interrupt request
		1	Enable (unmask) interrupt request
2 (R/NW)	TUWM	Transmit Urgent Watermark. The SPI_IMSK.TUWM bit unmasks (enables) or masks (disables) the TUWM interrupt.	
		0	Disable (mask) interrupt request
		1	Enable (unmask) interrupt request
1 (R/NW)	RUWM	Receive Urgent Watermark. The SPI_IMSK.RUWM bit unmasks (enables) or masks (disables) the RUWM interrupt.	
		0	Disable (mask) interrupt request
		1	Enable (unmask) interrupt request

Interrupt Mask Clear Register

The SPI_IMSK_CLR register permits clearing individual mask bits in the SPI_IMSK register without affecting other bits in the register. Use write-1-to-clear on a bit in the SPI_IMSK_CLR register to clear the corresponding bit in the SPI_IMSK register.

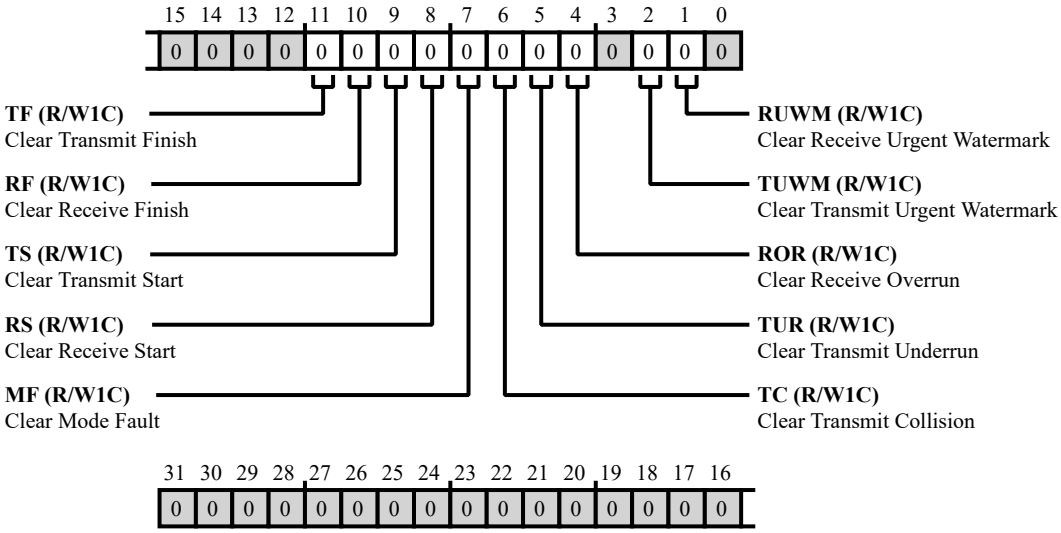

Figure 20-26: SPI_IMSK_CLR Register Diagram

Table 20-23: SPI_IMSK_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W1C)	TF	Clear Transmit Finish. The SPI_IMSK_CLR.TF bit clears the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Clear mask bit
10 (R/W1C)	RF	Clear Receive Finish. The SPI_IMSK_CLR.RF bit clears the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Clear mask bit
9 (R/W1C)	TS	Clear Transmit Start. The SPI_IMSK_CLR.TS bit clears the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Clear mask bit

Table 20-23: SPI_IMSK_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W1C)	RS	Clear Receive Start. The SPI_IMSK_CLR.RS bit clears the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Clear mask bit
7 (R/W1C)	MF	Clear Mode Fault. The SPI_IMSK_CLR.MF bit clears the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Clear mask bit
6 (R/W1C)	TC	Clear Transmit Collision. The SPI_IMSK_CLR.TC bit clears the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Clear mask bit
5 (R/W1C)	TUR	Clear Transmit Underrun. The SPI_IMSK_CLR.TUR bit clears the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Clear mask bit
4 (R/W1C)	ROR	Clear Receive Overrun. The SPI_IMSK_CLR.ROR bit clears the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Clear mask bit
2 (R/W1C)	TUWM	Clear Transmit Urgent Watermark. The SPI_IMSK_CLR.TUWM bit clears the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Clear mask bit

Table 20-23: SPI_IMSK_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W1C)	RUWM	Clear Receive Urgent Watermark. The `SPI_IMSK_CLR.RUWM` bit clears the corresponding mask bit in the `SPI_IMSK` register.	
		0	No effect
		1	Clear mask bit

Interrupt Mask Set Register

The SPI_IMSK_SET register permits setting individual mask bits in the SPI_IMSK register without affecting other bits in the register. Use write-1-to-set on a bit in the SPI_IMSK_SET register to set the corresponding bit in the SPI_IMSK register.

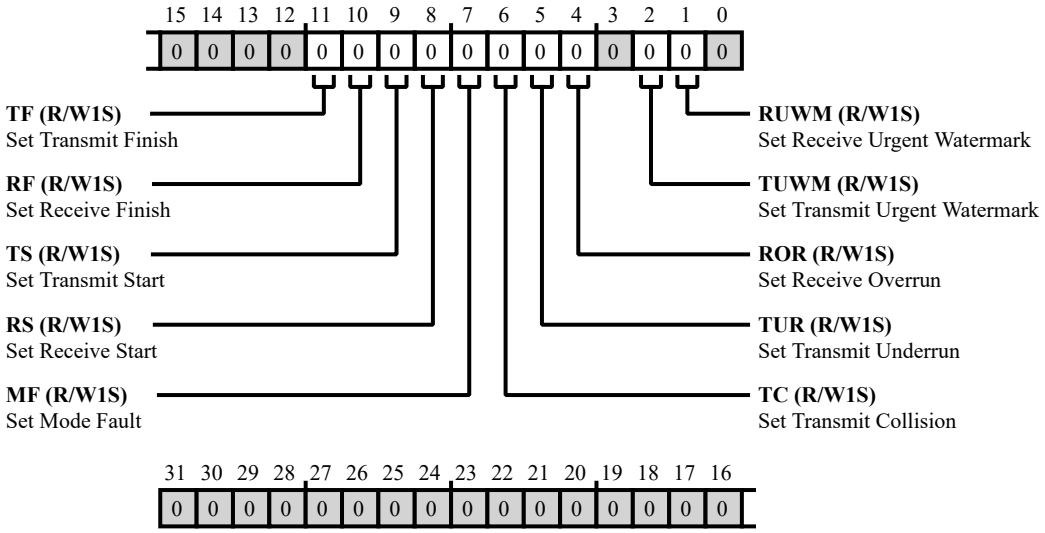

Figure 20-27: SPI_IMSK_SET Register Diagram

Table 20-24: SPI_IMSK_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W1S)	TF	Set Transmit Finish. The SPI_IMSK_SET.TF bit sets the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Set mask bit
10 (R/W1S)	RF	Set Receive Finish. The SPI_IMSK_SET.RF bit sets the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Set mask bit
9 (R/W1S)	TS	Set Transmit Start. The SPI_IMSK_SET.TS bit sets the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Set mask bit

Table 20-24: SPI_IMSK_SET Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W1S)	RS	Set Receive Start. The SPI_IMSK_SET.RS bit sets the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Set mask bit
7 (R/W1S)	MF	Set Mode Fault. The SPI_IMSK_SET.MF bit sets the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Set mask bit
6 (R/W1S)	TC	Set Transmit Collision. The SPI_IMSK_SET.TC bit sets the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Set mask bit
5 (R/W1S)	TUR	Set Transmit Underrun. The SPI_IMSK_SET.TUR bit sets the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Set mask bit
4 (R/W1S)	ROR	Set Receive Overrun. The SPI_IMSK_SET.ROR bit sets the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Set mask bit
2 (R/W1S)	TUWM	Set Transmit Urgent Watermark. The SPI_IMSK_SET.TUWM bit sets the corresponding mask bit in the SPI_IMSK register.	
		0	No effect
		1	Set mask bit

Table 20-24: SPI_IMSK_SET Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W1S)	RUWM	Set Receive Urgent Watermark. The `SPI_IMSK_SET.RUWM` bit sets the corresponding mask bit in the `SPI_IMSK` register.	
		0	No effect
		1	Set mask bit

Memory Mapped Read Header

The SPI_MMRDH register enables the use of memory-mapped mode. This mode allows direct memory-mapped read accesses of an SPI memory device and is primarily used to directly execute instructions from an SPI FLASH memory without using a low-level software driver. All overhead tasks such as transmission of the read header, pin turnaround timing and receive data sizing are handled in hardware.

The memory-mapped access mode is enabled by setting the SPI_CTL.MMSE bit. The features within the SPI_MMRDH register include a command skip mode, variable length byte addressing, and independent multi-pin support for command transmission, address transmission and data reception. In addition, the command opcode and mode bytes are fully programmable.

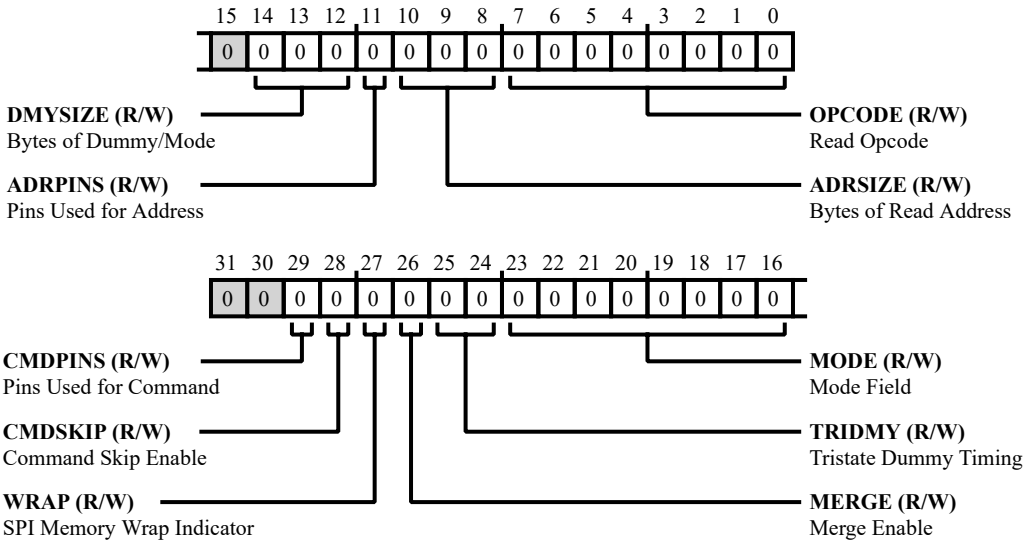

Figure 20-28: SPI_MMRDH Register Diagram

Table 20-25: SPI_MMRDH Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R/W)	CMDPINS	Pins Used for Command. The SPI_MMRDH.CMDPINS bit specifies the number of pins to be used for command transmission. This bit must be set consistent with the expectations established by the read opcode. Hardware does not interpret SPI_MMRDH.OPCODE, but rather relies on this bit to specify behavior. When cleared, it overrides the SPI_CTL.MIOM bits. When set, it uses bits specified by the SPI_CTL.MIOM bit setting.	
		0	Use Only One Pin: COTI (overrides SPI_CTL.MIOM bits)
		1	Use Pins Specified by SPI_CTL.MIOM Bits

Table 20-25: SPI_MMRDH Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
28 (R/W)	CMDSKIP	Command Skip Enable. The SPI_MMRDH.CMDSKIP bit enables command skip mode where the address is sent first and the OPCODE field is not sent (SPI_MMRDH.CMDSKIP bit =1). This mode is useful for supporting XIP (Execute-In-Place) operation where only the address is sent and the same read command is assumed. The SPI flash device must be primed with an initial read command, before the SPI_MMRDH.CMDSKIP bit is set.	
		0	OPCODE field is sent first followed by address
		1	OPCODE field is not sent; address is sent first
27 (R/W)	WRAP	SPI Memory Wrap Indicator. The SPI_MMRDH.WRAP bit must be set by software if software places a connected SPI memory device into a 8-byte, 16-byte or 32-byte wrap mode based on the ILINE and DLINE field setting of the cache configuration register address wrap mode. Software achieves this by transmitting a vendor specified command to the SPI memory device while the SPI_CTL.MMSE bit =0. If the SPI_MMRDH.WRAP bit =1, the SPI does not need to deassert the SPI target select signal and resend the read header in order to wrap to the cache line base when servicing misaligned cache fill requests. Although this improves cache fill efficiency, it requires that the SPI deassert the SPI target select pin and resend the read header whenever a DMA burst requests crosses 32 byte alignments. Setting this bit improves cache throughput but decreases DMA throughput.	
		0	SPI Memory auto increments address purely sequentially
		1	SPI Memory auto increments address but wraps within 32 Byte lines
26 (R/W)	MERGE	Merge Enable. When the SPI_MMRDH.MERGE bit is set, SPI hardware combines the two successive transfers. This increases the throughput rate when accessing a large number of sequential memory locations. For more information refer to the Merged Read Accesses section.	

Table 20-25: SPI_MMRDH Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
25:24 (R/W)	TRIDMY	Tristate Dummy Timing. The SPI_MMRDH.TRIDMY bits specify whether and when output pins are three-stated during the interval of time specified by the SPI_MMRDH.DMYSIZE bits. Output pins potentially three-stated include all pins which were used to transmit the address	
		0	Tristate outputs immediately
		1	Tristate outputs after 4 bits of dummy/mode are transmitted
		2	Tristate outputs after 8 bits of dummy/mode are transmitted
		3	Never tristate outputs (previously specified output state is held)
23:16 (R/W)	MODE	Mode Field. These bits specify up to a leading byte to be transmitted during the interval of time specified by the SPI_MMRDH.DMYSIZE bit field. This first byte, or a portion of it, is interpreted as mode bits when certain opcodes are used in conjunction with certain SPI memory devices. Mode bits are sent using the same number of pins which were used to transmit the address. Once sent, output pins will be held in their final resultant state until the conclusion of all dummy byte periods, unless three-stating the outputs is specified first by the SPI_MMRDH.TRIDMY bits.	
14:12 (R/W)	DMYSIZE	Bytes of Dummy/Mode. The SPI_MMRDH.DMYSIZE bit field specifies the number of bytes separating address transmission and read data return. Dummy bytes elapse assuming dummy bits are transmitted using the same number of pins which were used to transmit address.	
		0	0 Bytes
		1	1 Bytes
		2	2 Bytes
		3	3 Bytes
		4	4 Bytes
		5	5 Bytes
		6	6 Bytes
		7	7 Bytes

Table 20-25: SPI_MMRDH Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	ADRPINS	Pins Used for Address. The SPI_MMRDH.ADRPINS bit specifies the number of pins to be used for address transmission. This bit must be set consistent with expectations established by read opcode. Hardware does not interpret the SPI_MMRDH.OPCODE, but rather relies on this bit to specify behavior.	
		0	Use Only One Pin: COTI (overrides SPI_CTL.MIOM bits)
		1	Use Pins Specified by SPI_CTL.MIOM Bits
10:8 (R/W)	ADRSIZE	Bytes of Read Address. The SPI_MMRDH.ADRSIZE bit field defines the number of bytes used to specify the read address. The read address is sent immediately following the transmission of opcode. Unlike opcode bits, address bits may be sent using either one or multiple pins. The number of pins is selected using the SPI_MMRDH.ADRPINS bit. The address sent to a connected SPI memory device is an echo of the read address received by the SPI peripheral target port. The least significant bytes of address are sent when the entire address is not sent.	
		0	1 Byte
		1	1 Byte
		2	2 Bytes
		3	3 Bytes
		4	4 Bytes
7:0 (R/W)	OPCODE	Read Opcode. The SPI_MMRDH.OPCODE bit field specifies the initial bits transmitted in response to a read request of SPI memory. Although any opcode may be sent, values 0x03, 0x0B, 0x3B, 0x6B, 0xBB, and 0xEB are likely to be the most commonly used. SPI_MMRDH.OPCODE is sent by the SPI without interpretation; the states of these bits have no effect beyond specifying what is initially shifted across the SPI interface.	

SPI Memory Top Address

The SPI_MMTOP register specifies the top populated address of a connected SPI memory device.

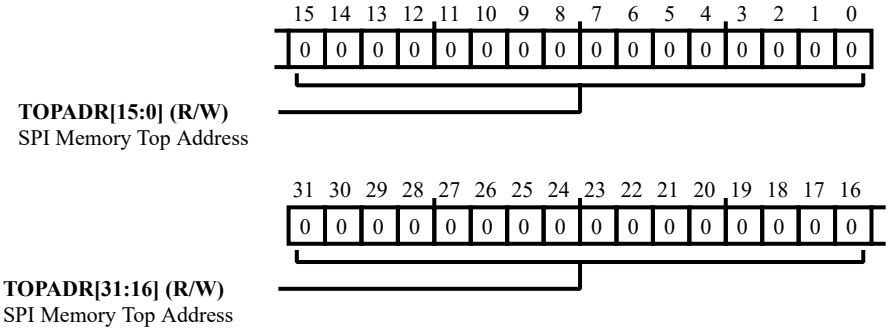

Figure 20-29: SPI_MMTOP Register Diagram

Table 20-26: SPI_MMTOP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	TOPADR	SPI Memory Top Address. The SPI_MMTOP.TOPADR bit field specifies the top populated address of a connected SPI memory device. Attempts to access SPI memory are not blocked if this address is exceeded and an error is generated as part of the read response.

Receive FIFO Data Register

The SPI_RFIFO register has an interface to the receive shift register in the SPI and has an interface to the processor data buses. The top level of the buffer is visible to programs as the 32-bit SPI_RFIFO register, but the size (number of word locations) of the receive FIFO is actually flexible with transfer word size. The size of the receive FIFO is 8 if the word size is 8-bit, or the size is 4 if the word size is 16-bit, or the size is 2 if the word size is 32-bit.

Both controllers and targets may stop or stall receive transfers based on FIFO status. When the receive FIFO is full, the SPI controller stops initiating new transfers on the SPI if SPI_RXCTL.RTI is enabled. A target may stall the SPI interface when the content of the FIFO crosses the selected watermark. If data reception continues after SPI_RFIFO is full, the data in the receive FIFO is invalid. The SPI indicates this condition with receive overrun (SPI_STAT.ROR) error. This condition is possible when SPI_RXCTL.RTI =0 and SPI_RXCTL.REN =1 for a controller, or for a target that does not exercise flow control.

Note that the receive FIFO is reset (cleared) when the SPI is disabled after being enabled.

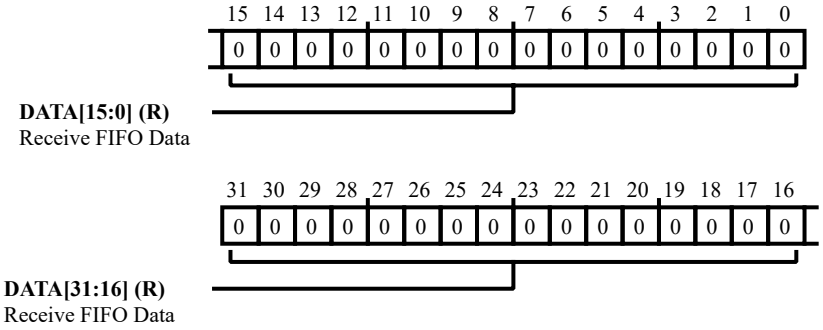

Figure 20-30: SPI_RFIFO Register Diagram

Table 20-27: SPI_RFIFO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	DATA	Receive FIFO Data. The SPI_RFIFO.DATA bit field contains the FIFO receive data.

Received Word Count Register

The SPI_RWC register holds a count of the number of words remaining to be received by the SPI. To start the decrement of the word count in SPI_RWC, enable the receive word counter (SPI_RXCTL.RWCEN =1). The SPI uses the word count to control the duration of transfers and to signal the completion of a burst of transfers with the receive finish interrupt (SPI_ILAT.RF). In DMA mode, the SPI uses the SPI_RWC register to ensure that the number of frames received during a DMA transfer is equal to the number of words programmed in the DMA channel controller. The values programmed into the SPI_RWC registers should match the word count in the DMA configuration. The SPI_RWC register maintains the number of frames to be received in a transfer. The SPI_RWC should only be changed when the counter is disabled.

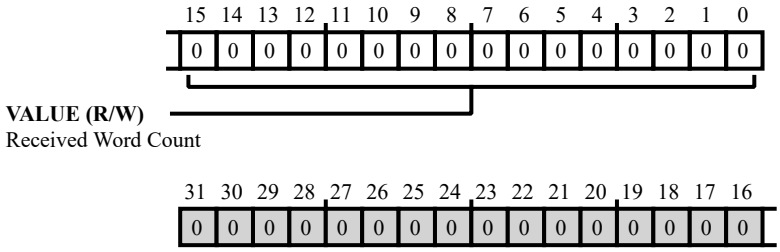

Figure 20-31: SPI_RWC Register Diagram

Table 20-28: SPI_RWC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Received Word Count. The SPI_RWC.VALUE bits hold the receive transfer word count.

Received Word Count Reload Register

The SPI_RWCR register holds the receive word count value that the SPI loads into the SPI_RWC register when the transfer count decrements to zero. To prevent the SPI from reloading the counter, use zero for the reload count value. The SPI_RWCR register should only be changed when the counter is disabled.

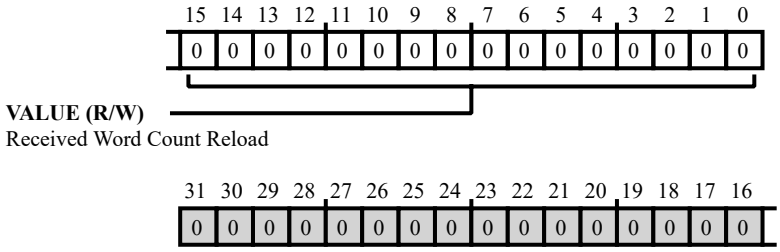

Figure 20-32: SPI_RWCR Register Diagram

Table 20-29: SPI_RWCR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Received Word Count Reload. The SPI_RWCR.VALUE bits hold the receive transfer word count reload value.

Receive Control Register

The SPI_RXCTL register enables the SPI receive channel, initiates receive transfers, and configures SPI_RFIFO buffer watermark settings.

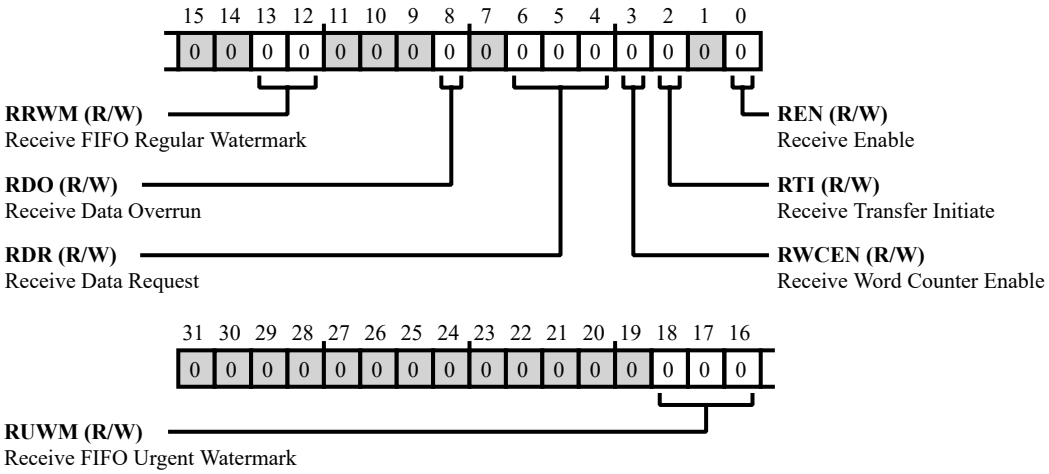

Figure 20-33: SPI_RXCTL Register Diagram

Table 20-30: SPI_RXCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
18:16 (R/W)	RUWM	Receive FIFO Urgent Watermark. The SPI_RXCTL.RUWM bits select the receive FIFO (SPI_RFIFO) watermark level for urgent data bus requests. The SPI also uses this watermark level for generation of the SPI_ILAT.RUWM interrupt. When an urgent SPI_RFIFO watermark is enabled with SPI_RXCTL.RUWM, the SPI_RXCTL.RRWM selection is used as the deassertion condition for any SPI_ILAT.RUWM interrupts that are latched.	
		0	Disabled
		1	25% full RFIFO
		2	50% full RFIFO
		3	75% full RFIFO
		4	Full RFIFO
		5	Reserved
		6	Reserved
		7	Reserved

Table 20-30: SPI_RXCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13:12 (R/W)	RRWM	Receive FIFO Regular Watermark. The SPI_RXCTL.RRWM bits select the receive FIFO (SPI_RFIFO) watermark level for regular data bus requests. When an urgent SPI_RFIFO watermark is enabled with SPI_RXCTL.RUWM, the SPI_RXCTL.RRWM selection is used as the deassertion condition for any SPI_ILAT.RUWM interrupts that are latched.	
		0	Empty RFIFO
		1	RFIFO less than 25% full
		2	RFIFO less than 50% full
		3	RFIFO less than 75% full
8 (R/W)	RDO	Receive Data Overrun. The SPI_RXCTL.RDO bit selects handling for receive data requests when the receive buffer (SPI_RFIFO) is full. If enabled and SPI_RFIFO is full, the SPI overwrites old data in the buffer with incoming data. If disabled and SPI_RFIFO is full, the SPI keeps old data in the buffer and discards incoming data.	
		0	Discard incoming data if SPI_RFIFO is full
		1	Overwrite old data if SPI_RFIFO is full
6:4 (R/W)	RDR	Receive Data Request. The SPI_RXCTL.RDR bits select receive FIFO (SPI_RFIFO) watermark conditions that direct the SPI to generate a receive data request.	
		0	Disabled
		1	Not empty RFIFO
		2	25% full RFIFO
		3	50% full RFIFO
		4	75% full RFIFO
		5	Full RFIFO
		6	Reserved
		7	Reserved
3 (R/W)	RWCEN	Receive Word Counter Enable. The SPI_RXCTL.RWCEN bit enables the decrement of the SPI_RWC register when the count is not zero and SPI_RXCTL.RTI is enabled. Enabling SPI_RXCTL.RWCEN prevents receive overrun errors from occurring. The SPI_RXCTL.RWCEN bit is valid only when the SPI is a controller.	
		0	Disable
		1	Enable

Table 20-30: SPI_RXCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	RTI	Receive Transfer Initiate. The SPI_RXCTL.RTI bit enables initiation of receive transfers if the receive FIFO (SPI_RFIFO) is not full. The bit also enables this initiation if SPI_RWC is not zero when SPI_RXCTL.RWCEN is enabled. Enabling SPI_RXCTL.RTI prevents receive overrun errors from occurring. The SPI_RXCTL.RTI bit is valid only when the SPI is a controller.	
		0	Disable
		1	Enable
0 (R/W)	REN	Receive Enable. The SPI_RXCTL.REN bit enables SPI receive channel operation.	
		0	Disable
		1	Enable

Target Select Register

The SPI_TSEL register enables the pins for output and indicates the state (high or low) of these pins when enabled.

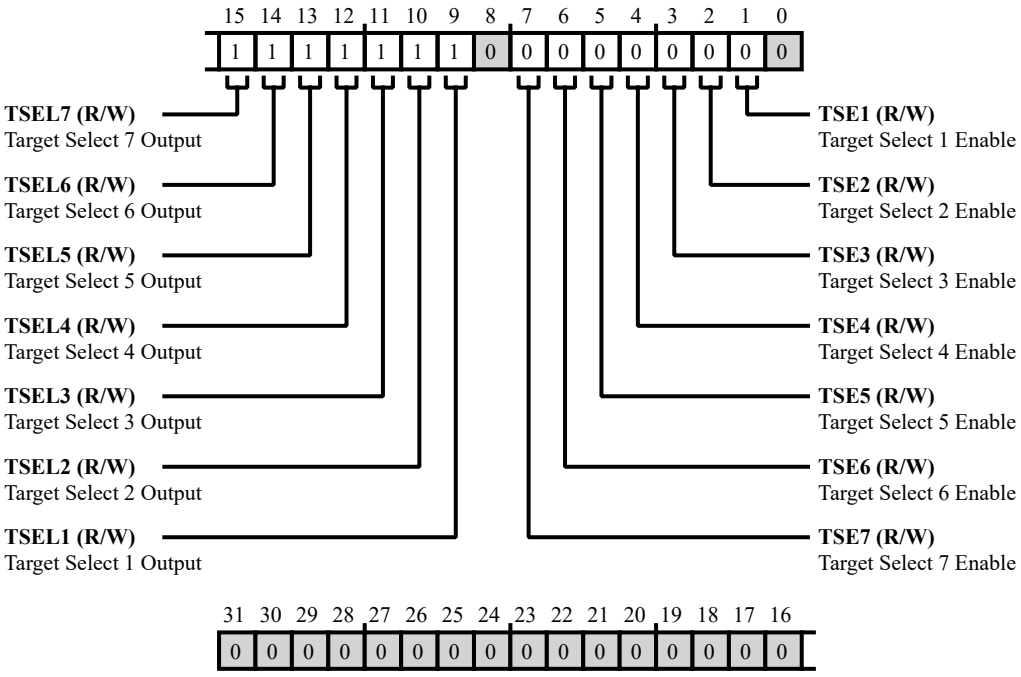

Figure 20-34: SPI_TSEL Register Diagram

Table 20-31: SPI_TSEL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	TSEL7	Target Select 7 Output. The SPI_TSEL.TSEL7 bit state indicates the value driven on the related SPI_SEL[n] pin.	
		0	Low
		1	High
14 (R/W)	TSEL6	Target Select 6 Output. The SPI_TSEL.TSEL6 bit state indicates the value driven on the related SPI_SEL[n] pin.	
		0	Low
		1	High

Table 20-31: SPI_TSEL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W)	TSEL5	Target Select 5 Output. The SPI_TSEL.TSEL5 bit state indicates the value driven on the related SPI_SEL[n] pin.	
		0	Low
		1	High
12 (R/W)	TSEL4	Target Select 4 Output. The SPI_TSEL.TSEL4 bit state indicates the value driven on the related SPI_SEL[n] pin.	
		0	Low
		1	High
11 (R/W)	TSEL3	Target Select 3 Output. The SPI_TSEL.TSEL3 bit state indicates the value driven on the related SPI_SEL[n] pin.	
		0	Low
		1	High
10 (R/W)	TSEL2	Target Select 2 Output. The SPI_TSEL.TSEL2 bit state indicates the value driven on the related SPI_SEL[n] pin.	
		0	Low
		1	High
9 (R/W)	TSEL1	Target Select 1 Output. The SPI_TSEL.TSEL1 bit state indicates the value driven on the related SPI_SEL[n] pin.	
		0	Low
		1	High
7 (R/W)	TSE7	Target Select 7 Enable. The SPI_TSEL.TSE7 bit enables the related $\overline{\text{SPI_SEL[n]}}$ pin for output. If disabled, the SPI three-states the related $\overline{\text{SPI_SEL[n]}}$ pin.	
		0	Disable
		1	Enable

Table 20-31: SPI_TSEL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W)	TSE6	Target Select 6 Enable. The SPI_TSEL.TSE6 bit enables the related $\overline{\texttt{SPI_SEL[n]}}$ pin for output. See the SPI_TSEL.TSE7 bit description for more information.	
		0	Disable
		1	Enable
5 (R/W)	TSE5	Target Select 5 Enable. The SPI_TSEL.TSE5 bit enables the related $\overline{\texttt{SPI_SEL[n]}}$ pin for output. See the SPI_TSEL.TSE7 bit description for more information.	
		0	Disable
		1	Enable
4 (R/W)	TSE4	Target Select 4 Enable. The SPI_TSEL.TSE4 bit enables the related $\overline{\texttt{SPI_SEL[n]}}$ pin for output. See the SPI_TSEL.TSE7 bit description for more information.	
		0	Disable
		1	Enable
3 (R/W)	TSE3	Target Select 3 Enable. The SPI_TSEL.TSE3 bit enables the related $\overline{\texttt{SPI_SEL[n]}}$ pin for output. See the SPI_TSEL.TSE7 bit description for more information.	
		0	Disable
		1	Enable
2 (R/W)	TSE2	Target Select 2 Enable. The SPI_TSEL.TSE2 bit enables the related $\overline{\texttt{SPI_SEL[n]}}$ pin for output. See the SPI_TSEL.TSE7 bit description for more information.	
		0	Disable
		1	Enable
1 (R/W)	TSE1	Target Select 1 Enable. The SPI_TSEL.TSE1 bit enables the related $\overline{\texttt{SPI_SEL[n]}}$ pin for output. See the SPI_TSEL.TSE7 bit description for more information.	
		0	Disable
		1	Enable

Status Register

The SPI_STAT register indicates SPI status including FIFO status, error conditions, and interrupt conditions. When an interrupt condition from this register is unmasked (enabled) by the corresponding bit in the SPI_IMSK register, the interrupt request is latched into the corresponding bit in the SPI_ILAT register.

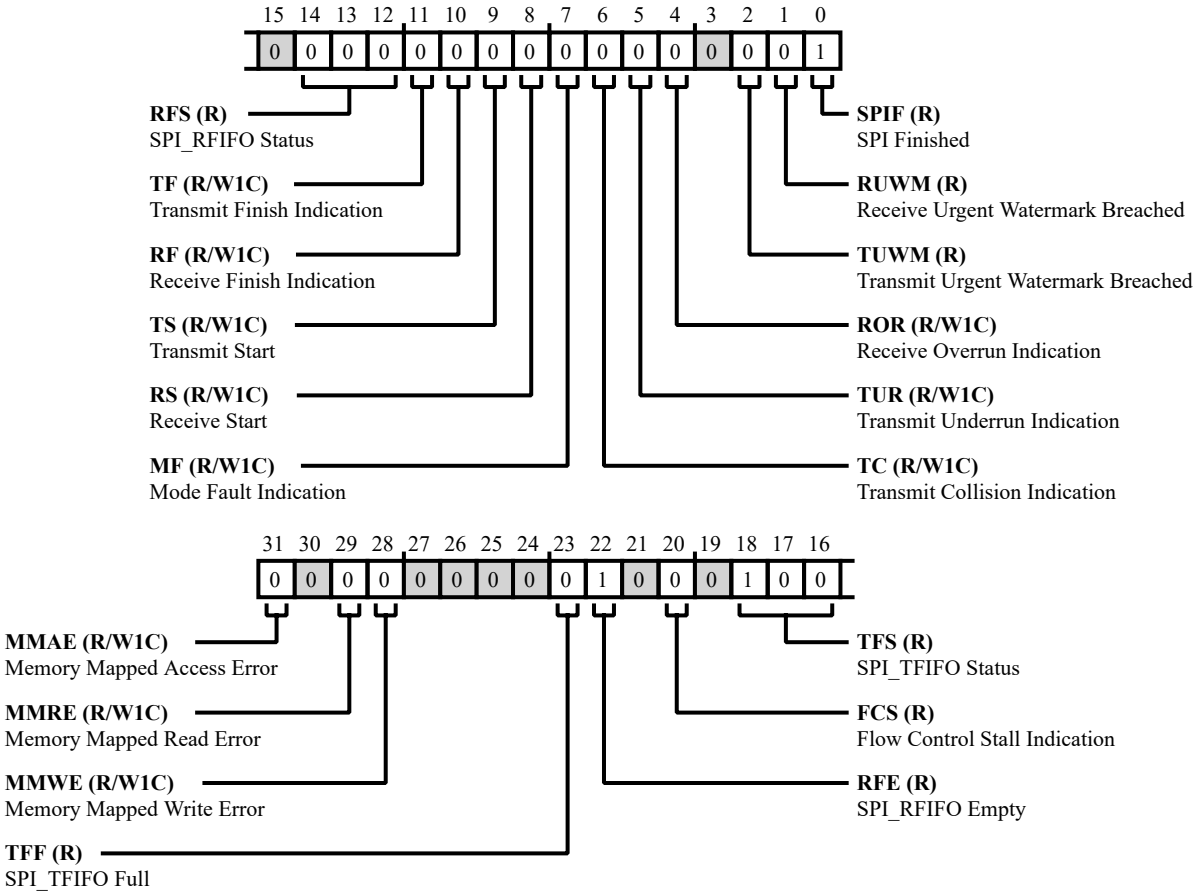

Figure 20-35: SPI_STAT Register Diagram

Table 20-32: SPI_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W1C)	MMAE	Memory Mapped Access Error. The SPI_STAT.MMAE bit =1 if an attempt is made to access either the Tx or Rx FIFO while memory-mapped access of SPI memory is enabled (see the SPI_CTL.MMSE bit). The SPI_STAT.MMAE bit =0 when a 1 is written to it. The SPI_STAT.MMAE bit is provided for software notification only. Its state has no further effect.

Table 20-32: SPI_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R/W1C)	MMRE	Memory Mapped Read Error. The SPI_STAT.MMRE bit =1 if an attempt is made to read address space reserved for memory-mapped SPI memory while memory mapping is disabled (see the SPI_CTL.MMSE bit). The SPI_STAT.MMRE bit =0 when a 1 is written to it. This bit is provided for software notification only. Its state has no further effect.	
28 (R/W1C)	MMWE	Memory Mapped Write Error. The SPI_STAT.MMWE bit =1 if an attempt is made to write address space reserved for memory-mapped SPI memory. The SPI_STAT.MMWE bit =0 when a 1 is written to it. This bit is provided for software notification only. Its state has no further effect.	
23 (R/NW)	TFF	SPI_TFIFO Full. The SPI_STAT.TFF bit indicates whether the SPI_TFIFO is full or not full.	
		0	Not full Tx FIFO
		1	Full Tx FIFO
22 (R/NW)	RFE	SPI_RFIFO Empty. The SPI_STAT.RFE bit indicates whether the SPI_RFIFO is empty or not empty.	
		0	Rx FIFO not empty
		1	Rx FIFO empty
20 (R/NW)	FCS	Flow Control Stall Indication. The SPI_STAT.FCS bit indicates whether a target has deasserted the SPI_RDY pin to stall the SPI controller while the target is unable to service the SPI controller request. This bit is valid only when the SPI is a controller (SPI_CTL.MODE =1) and flow control is enabled (SPI_CTL.FCEN =1).	
		0	No Stall (RDY pin asserted)
		1	Stall (RDY pin deasserted)
18:16 (R/NW)	TFS	SPI_TFIFO Status. The SPI_STAT.TFS bits indicate the status of the SPI_TFIFO. The SPI uses this status when evaluating transmit watermark conditions.	
		0	Full TFIFO
		1	25% empty TFIFO
		2	50% empty TFIFO
		3	75% empty TFIFO
		4	Empty TFIFO

Table 20-32: SPI_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
14:12 (R/NW)	RFS	SPI_RFIFO Status. The SPI_STAT.RFS bits indicate the status of the SPI_RFIFO. The SPI uses this status when evaluating receive watermark conditions.	
		0	Empty RFIFO
		1	25% full RFIFO
		2	50% full RFIFO
		3	75% full RFIFO
		4	Full RFIFO
11 (R/W1C)	TF	Transmit Finish Indication. The SPI_STAT.TF bit indicates that the SPI has detected the finish of a transmit burst transfer (the SPI_TWC count decrements to zero). This condition can only occur when SPI_TXCTL.TTI and SPI_TXCTL.TWCEN are enabled.	
		0	No status
		1	Transmit finish detected
10 (R/W1C)	RF	Receive Finish Indication. The SPI_STAT.RF bit indicates that the SPI has detected the finish of a receive burst transfer (the SPI_RWC count decrements to zero). This condition can only occur when SPI_RXCTL.RTI and SPI_RXCTL.RWCEN are enabled.	
		0	No status
		1	Receive finish detected
9 (R/W1C)	TS	Transmit Start. The SPI_STAT.TS bit indicates that the SPI has detected the start of a transmit burst transfer. A transmit bursts starts with the load of SPI_TWC from the SPI_TWCR. This condition can only occur when SPI_TXCTL.TTI and SPI_TXCTL.TWCEN are enabled.	
		0	No status
		1	Transmit start detected
8 (R/W1C)	RS	Receive Start. The SPI_STAT.RS bit indicates that the SPI has detected the start of a receive burst transfer. A receive bursts starts with the load of SPI_RWC from the SPI_RWCR. This condition can only occur when SPI_RXCTL.RTI and SPI_RXCTL.RWCEN are enabled.	
		0	No status
		1	Receive start detected

Table 20-32: SPI_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W1C)	MF	Mode Fault Indication. The SPI_STAT.MF bit, when SPI is a controller and SPI_CTL.PTSE is enabled, indicates that multiple controllers have asserted target select inputs.	
		0	No status
		1	Mode fault occurred
6 (R/W1C)	TC	Transmit Collision Indication. The SPI_STAT.TC bit, when SPI is a target, indicates that the load of data into the shift register has occurred too close to the first transmitting edge of the SPI clock.	
		0	No status
		1	Transmit collision occurred
5 (R/W1C)	TUR	Transmit Underrun Indication. The SPI_STAT.TUR bit, when the transmit FIFO (SPI_TFIFO) is empty, indicates that the last word in the transmit FIFO has been re-sent as transmit data. Alternately, it indicates that zero has been sent as transmit data.	
		0	No status
		1	Transmit underrun occurred
4 (R/W1C)	ROR	Receive Overrun Indication. The SPI_STAT.ROR bit, when the receive FIFO (SPI_RFIFO) is full, indicates that a word in the receive FIFO has been overwritten with incoming receive data. Alternately, it indicates that incoming receive data has been discarded.	
		0	No status
		1	Receive overrun occurred
2 (R/NW)	TUWM	Transmit Urgent Watermark Breached. The SPI_STAT.TUWM bit indicates that the transmit urgent watermark (SPI_TXCTL.TUWM) has been reached. This condition is cleared when the transmit FIFO fills enough to reach the transmit regular watermark (SPI_TXCTL.TRWM).	
		0	Tx regular watermark reached
		1	Tx urgent watermark breached
1 (R/NW)	RUWM	Receive Urgent Watermark Breached. The SPI_STAT.RUWM bit indicates that the receive urgent watermark (SPI_RXCTL.RUWM) has been reached. This condition is cleared when the receive FIFO empties enough to reach the receive regular watermark (SPI_RXCTL.RRWM).	
		0	Rx regular watermark reached
		1	Rx urgent watermark breached

Table 20-32: SPI_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/NW)	SPIF	SPI Finished. The `SPI_STAT.SPIF` bit indicates that a single word transfer is complete.	
		0	No status
		1	Completed single word transfer

Transmit FIFO Data Register

The SPI_TFIFO register has an interface to the transmit shift register in the SPI and has an interface to the processor data buses. The top level of the buffer is visible to programs as the 32-bit SPI_TFIFO register, but the size (number of word locations) of the transmit FIFO is actually flexible with transfer word size. The size of the transmit FIFO is 8 if the word size is 8-bit, or the size is 4 if the word size is 16-bit, or the size is 2 if the word size is 32-bit.

Both controllers and targets may stop or stall transmit transfers based on FIFO status. When the transmit FIFO is empty, the SPI controller stops initiating new transfers on the SPI if SPI_TXCTL.TTI is enabled. A target may stall the SPI interface when the content of the FIFO crosses the selected watermark. If data transmit requests continue after SPI_TFIFO is empty, the data sent from the transmit FIFO is invalid, and the SPI indicates this condition with transmit underrun (SPI_STAT.TUR). This condition is possible when SPI_TXCTL.TTI =0 and SPI_TXCTL.TEN =1 for a controller, or for a target that does not exercise flow control.

Note that the transmit FIFO is reset (cleared) when the SPI is disabled after being enabled.

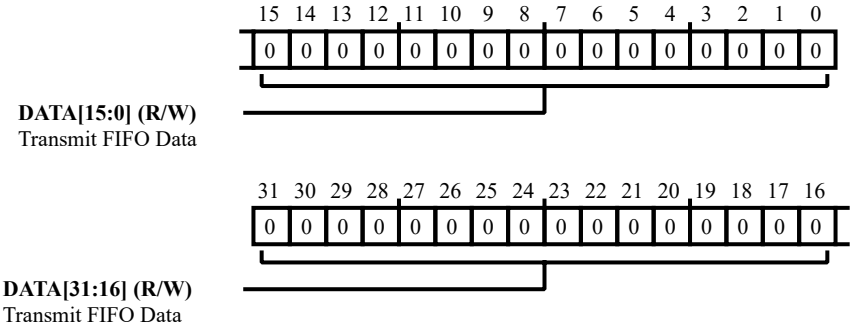

Figure 20-36: SPI_TFIFO Register Diagram

Table 20-33: SPI_TFIFO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DATA	Transmit FIFO Data. The SPI_TFIFO.DATA bit field contains the FIFO transmit data.

Transmitted Word Count Register

The SPI_TWC register holds a count of the number of words remaining to be transmitted by the SPI. To start the decrement of the word count in SPI_TWC, enable the transmit word counter (SPI_TXCTL.TWCEN =1). The SPI uses the word count to control the duration of transfers and to signal the completion of a burst of transfers with the transmit finish interrupt request. In DMA mode, the SPI uses the SPI_TWC to ensure that the number of frames transmitted during a DMA transfer is equal to the number of words programmed in the DMA channel controller. The values programmed into the SPI_TWC registers should match the word count in the DMA configuration. The SPI_TWC maintains the number of frames to be transmitted in a transfer. The SPI_TWC should only be changed when the counter is disabled.

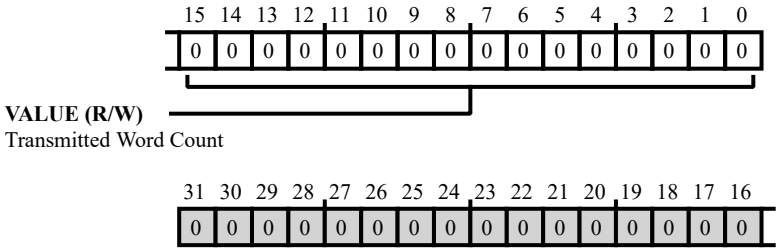

Figure 20-37: SPI_TWC Register Diagram

Table 20-34: SPI_TWC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Transmitted Word Count. The SPI_TWC.VALUE bits hold the transmit transfer word count.

Transmitted Word Count Reload Register

The SPI_TWCR register holds the transmit word count value that the SPI loads into the SPI_TWC register when the transfer count decrements to zero. To prevent the SPI from reloading the counter, use zero for the reload count value. The SPI_TWCR should only be changed when the counter is disabled.

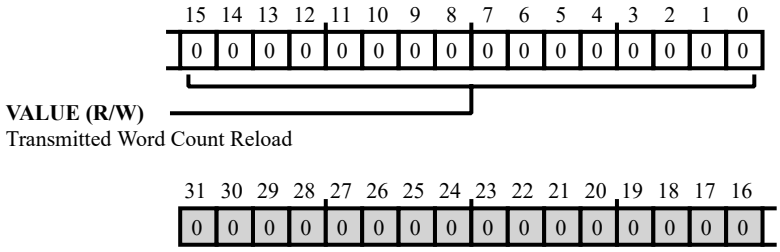

Figure 20-38: SPI_TWCR Register Diagram

Table 20-35: SPI_TWCR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Transmitted Word Count Reload. The SPI_TWCR.VALUE bits hold the transmit transfer word count reload value.

Transmit Control Register

The SPI_TXCTL register enables the SPI transmit channel, initiates transmit transfers, and configures SPI_TFIFO buffer watermark settings.

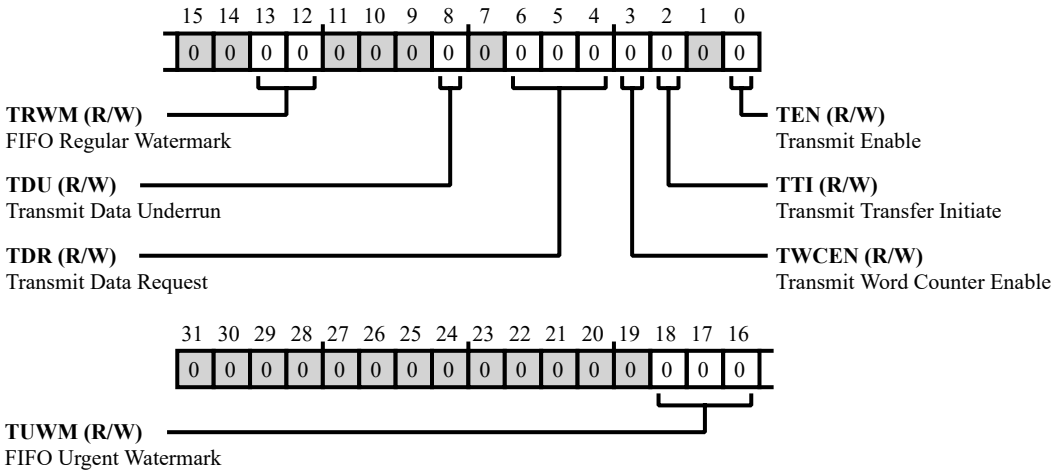

Figure 20-39: SPI_TXCTL Register Diagram

Table 20-36: SPI_TXCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
18:16 (R/W)	TUWM	FIFO Urgent Watermark. The SPI_TXCTL.TUWM bits select the transmit FIFO (SPI_TFIFO) watermark level for urgent data bus requests. The SPI also uses this watermark level for generation of the SPI_ILAT.TUWM interrupt request. When an urgent SPI_TFIFO watermark is enabled with SPI_TXCTL.TUWM, the SPI_TXCTL.TRWM selection is used as the deassertion condition for any SPI_ILAT.TUWM interrupt requests that are latched.	
		0	Disabled
		1	25% empty TFIFO
		2	50% empty TFIFO
		3	75% empty TFIFO
		4	Empty TFIFO

Table 20-36: SPI_TXCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13:12 (R/W)	TRWM	FIFO Regular Watermark. The SPI_TXCTL.TRWM bits select the transmit FIFO (SPI_TFIFO) watermark level for regular data bus requests. When an urgent SPI_TFIFO watermark is enabled with SPI_TXCTL.TUWM, the SPI_TXCTL.TRWM selection is used as the deassertion condition for any SPI_ILAT.TUWM interrupt requests that are latched.	
		0	Full TFIFO
		1	TFIFO less than 25% empty
		2	TFIFO less than 50% empty
		3	TFIFO less than 75% empty
8 (R/W)	TDU	Transmit Data Underrun. The SPI_TXCTL.TDU bit selects handling for transmit data requests when the transmit buffer (SPI_TFIFO) is empty. If enabled and SPI_TFIFO is empty, the SPI transmits zero as data. If disabled and SPI_TFIFO is empty, the SPI transmits the last word in the buffer as data.	
		0	Send last word when SPI_TFIFO is empty
		1	Send zeros when SPI_TFIFO is empty
6:4 (R/W)	TDR	Transmit Data Request. The SPI_TXCTL.TDR bits select transmit FIFO (SPI_TFIFO) watermark conditions that direct the SPI to generate a transmit status interrupt request.	
		0	Disabled
		1	Not full TFIFO
		2	25% empty TFIFO
		3	50% empty TFIFO
		4	75% empty TFIFO
		5	Empty TFIFO
3 (R/W)	TWCEN	Transmit Word Counter Enable. The SPI_TXCTL.TWCEN bit enables the decrement of the transmit word count (SPI_TWC) register when the count is not zero and SPI_TXCTL.TTI is enabled. Enabling SPI_TXCTL.TWCEN prevents transmit underrun errors from occurring. The SPI_TXCTL.TWCEN bit is valid only when the SPI is a controller.	
		0	Disable
		1	Enable

Table 20-36: SPI_TXCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	TTI	Transmit Transfer Initiate. The SPI_TXCTL.TTI bit enables initiation of transmit transfers if the transmit FIFO (SPI_TFIFO) is not empty. The bit also enables this initiation if SPI_TWC is not zero when SPI_TXCTL.TWCEN is enabled. Enabling SPI_TXCTL.TTI prevents transmit underrun errors from occurring. The SPI_TXCTL.TTI bit is valid only when the SPI is a controller.	
		0	Disable
		1	Enable
0 (R/W)	TEN	Transmit Enable. The SPI_TXCTL.TEN bit enables SPI transmit channel operation.	
		0	Disable
		1	Enable

21 Extended Serial Peripheral Interface (xSPI)

The xSPI flash controller provides access to serial flash devices that support JESD216 and JESD251 standards. The controller accesses flash devices in modes that permit efficient communication with minimal software overhead. The supported HyperBus™ protocol enables seamless communication with HyperFlash™/HyperRAM™devices. The standard SPI protocol is supported along with high performance dual, quad, and octal SPI modes, where data can be transferred on up to 8 data pins. In addition to the normal mode of operation in single transfer (STR) mode, the xSPI controller supports a dual transfer rate (DTR) mode. In DTR mode, data, address, and commands are transferred on both edges of the serial clock. With direct access mode support, any read/write to the xSPI memory-mapped space triggers a read/write to flash memory.

An integrated PHY handles the low-level timings of the data, address and control signals between the device and controller.

The xSPI controller also provides support for RWDS/DQS when sampling data. This feature improves read data capture, which, along with the PHY, enables high-speed data transfers.

xSPI Features

The xSPI controller supports the following features:

- Memory-mapped direct mode operation for performing flash data transfers
- Auto Command Mode (ACMD) to perform various memory operations with minimum software overhead
- An ACMD DMA engine that triggers transactions using descriptors fetched from the main memory. It automatically moves data between the device memory and system host memory.
- STIG mode operation to issue flash commands
- Automatic flash status polling support for flash program
- Execute in Place (XIP) support
- Device Discovery (DD) to identify the memory device
- Support for single, dual, quad, or octal modes of operation
- Support for DDR mode and DTR protocol (including octal DDR protocol)

- Data integrity features (CRC or ECC) for flash memories
- Programmable baud rate, clock phase, and polarity
- Programmable interrupt generation
- Programmable chip select control timing
- Programmable dummy cycles for read and write operations
- Support for up to 80 MHz in non-DQS mode
- Support for up to 125 MHz in DQS mode

Supported Memory Devices

The xSPI controller supports any device that is compatible with the JESD216 specification standard. In this standard, these devices are defined as profile 1 or profile 2 type devices. Traditional serial NOR flash devices tend to be compatible with the profile 1 type as defined in that standard. Devices supporting HyperBus (traditional HyperFlash and most HyperRAM or pSRAM devices) tend to be compatible with the profile 2 type. Sometimes, a pSRAM or HyperRAM device may support a profile 1 style interface; the device manufacturer selects the interface.

The supported devices include:

- *Traditional serial SPI (single/dual/quad/octal)* - Memory devices defined as profile 1 in the JEDEC JESD216 specification. The device may have been manufactured before the specification was released. Any device that specifies compliance with an xSPI profile 1, where profile 1 is described in the xSPI JEDEC JESD216 specification.
- *Traditional HyperFlash* - Memory devices defined as profile 2 in the JEDEC JESD216 specification. The device may have been manufactured before the specification was released. Any devices that specify specifies compliance with an xSPI profile 2, where profile 2 is described in the xSPI JEDEC JESD216 specification.
- *Serial RAM and HyperRAM* - Serial SRAM devices (for example, OctaRAM™/OctalRAM, HyperRAM, pSRAM) devices. These volatile RAM devices tend to be interfaced similar to profile 1 or profile 2. However, they must be occasionally self-refreshed to maintain state and may not require some elements of the sequences used to read or program traditional flash devices.
- *Serial NAND* - also referred to as SPI NAND

xSPI Functional Description

This section provides information on the function of the xSPI module.

ADSP-2184x XSPI Register List

The XSPI is an expanded SPI controller. It contains the following registers.

Table 21-1: ADSP-2184x XSPI Register List

Name	Description
XSPI_BOOT_STAT	Boot Status Register
XSPI_CMD0	Command Register 0
XSPI_CMD1	Command Register 1
XSPI_CMD2	Command Register 2
XSPI_CMD3	Command Register 3
XSPI_CMD4	Command Register 4
XSPI_CMD5	Command Register 5
XSPI_CMD_STAT	Command Status Register
XSPI_CMD_STAT_PTR	Command Status Pointer Register
XSPI_DAC_CFG	DAC Configuration Register
XSPI_DAC_REMAPADDR0	Address Remapping Register 0
XSPI_DAC_REMAPADDR1	Address Remapping Register 1
XSPI_DISCOVERY_GCTL	Device Discovery Control Register
XSPI_DMA_CTL	DMA Interface Control Register
XSPI_DMA_ERRADDR_HI	DMA Error Address High Register
XSPI_DMA_ERRADDR_LO	DMA Error Address Low Register
XSPI_ERS_SEQ_CFG0	Erase Sequence Configuration Register 0
XSPI_ERS_SEQ_CFG1	Erase Sequence Configuration Register 1
XSPI_ERS_SEQ_CFG2	Erase Sequence Configuration Register 2
XSPI_FEATURES	Controller Features Register
XSPI_GSTAT	General Controller Status Register
XSPI_INT_EN	Interrupt Enable Register
XSPI_ISTAT	Interrupt Status Register
XSPI_LONGPOL_GCTL	Long Polling Count Register
XSPI_MINICTL_DEV_ACTIVE_MAX	Device Active Maximum Clock Cycle Register
XSPI_MINICTL_CLKMODE	Clock Mode Control Register
XSPI_MINICTL_DEV_DLY	Device Delay Register
XSPI_MINICTL_HF_OFFSET	HyperFlash Offset Register
XSPI_MINICTL_JEDEC_RST_TR	JEDEC Reset Delay Register
XSPI_MINICTL_RST_PIN_CTL	Hardware Reset Control Register
XSPI_MINICTL_RST_RECOV	Reset Recovery Delay Register

Table 21-1: ADSP-2184x XSPI Register List (Continued)

Name	Description
XSPI_MINICTL_WP_CTL	Write Protect Register
XSPI_PHY_DLLOB0	PHY DLL Observable Points 0 Register
XSPI_PHY_DLLOB1	PHY DLL Observable Points 1 Register
XSPI_PHY_DLL_CTL	PHY DLL Control Register
XSPI_PHY_DLL_REQ_CTL	Bus Requester DLL Control Register
XSPI_PHY_DLL_COMP_CTL	Bus Completer DLL Control Register
XSPI_PHY_DLL_UPDT_CNT	PHY DLL Resynchronization Register
XSPI_PHY_DQS_TR	PHY DQS Timing Register
XSPI_PHY_DQ_TR	PHY DQ Timing Register

xSPI Block Diagram

The xSPI module is comprised of:

- Main command sequencer
- PHY block
- Internal transmit/receive FIFOs
- DAC/STIG controller
- Register interface

The ***xSPI Controller Block Diagram*** shows the xSPI controller functional blocks.

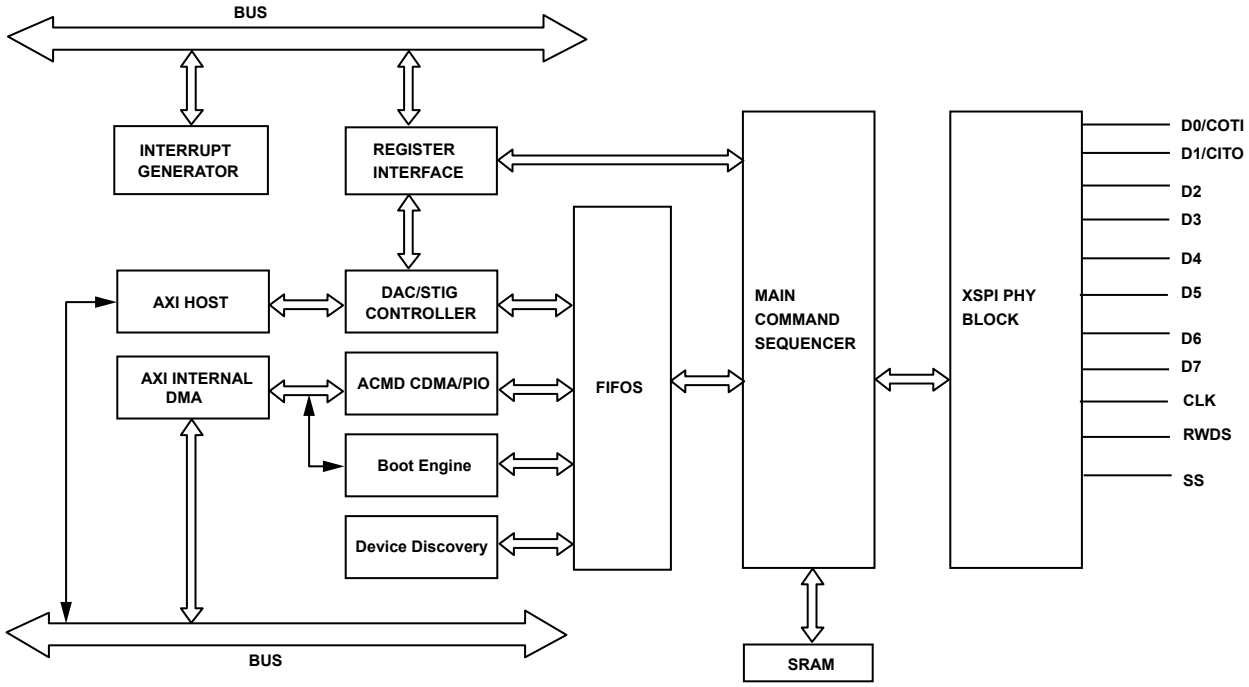

Figure 21-1: xSPI Controller Block Diagram

Architectural Concepts

There are three clock sources for xSPI controller : XSPI_CLK, SCLK0_0, SYSCLK_0. SYSCLK_0 is used to transfer data over the bus between the controller (core/DMA) and the xSPI controller. XSPI_CLK is driven on the external XSPI_CLK pin to transfer the data to/from external devices. And SCLK0_0 is used to access the xSPI controller registers to perform basic configuration of the controller and interrupt handling.

NOTE: For XSPI0, XSPI_CLK is sourced from CLKO10 (output clock of CDU) and for XSPI1, XSPI_CLK is sourced from CLKO8 (output clock of CDU). A user can select one of the options for CLKO8 and CLKO10 to source xSPI controllers. Rrefer to the CDU chapter for the clocking diagram and more details.

The xSPI controller supports independent modes/controllers for different memory devices:

- Direct mode
- STIG mode
- Auto Command Mode (ACMD, CDMA or PIO)

The bus interface provides access to controller status and configuration registers. The AXI host interface is used in direct mode, STIG mode (when necessary), and optionally in ACMD mode. The AXI internal DMA interface is only used in ACMD mode, where the internal DMA module of the xSPI controller owns and manages system transfers, and handles DMA descriptor fetches and writes and associated data buffer transfers. The DMA module used in ACMD mode implements the bus requester capability. It can automatically transfer data from/to system memory and from/to the connected xSPI device (using internal SRAM).

The boot engine and device discovery blocks in the xSPI controller use the internal DMA interface and FIFOs.

The main command sequencer holds the main sequencing logic. It is responsible for building the command structures and meeting the required device timings. It also interfaces with the PHY module and regulates data flow between the physical layer and the system interface. PHY is responsible for handling the low-level timings of the data, address, and control signals between the device and controller.

Operating Modes

There are three main usage modes for the xSPI controller: direct mode, STIG mode, and ACMD mode. These modes can perform standard read/write transactions to a device memory. However, only one mode can be active at a time.

One active work mode is selected at a time to communicate with an attached device. ACMD or direct modes are the primary operational modes. STIG mode is used as an accompanying mode to send commands or a sequences of commands to the device that may not be directly supported in ACMD or direct mode. STIG mode is a highly flexible mode that can also be used to write or read data to the device and perform other operations. However, STIG mode relies more on software to construct the necessary command structures.

ACMD mode requires that software either manage a descriptor table with high-level sequences defined within, or manage some command registers within the controller to issue these same high-level sequences. The controller can automatically translate high-level sequences (reset, erase, erase_all, program, read) into subsequences that are tied to the device type.

Direct mode, as the name suggests, directly translates read and write operations detected on the AXI host bus completer interface to equivalent low-level read and write subsequences at the device. As such, direct mode can only support read or program operations. It relies on STIG mode to perform other operations such as erase. It can also be used to directly boot from the device, when required.

Direct Mode

In direct mode, reads and writes that are issued by the processor (either by the core or MDMA controller) enter the controller using the AXI bus completer interface. The read/write operations are directly translated to read/write at the memory device. The shaded portion of the ***Direct Mode Block Diagram*** shows the flow. Direct mode allows the

processor to execute code directly, or have direct access from/to the attached memory device. This flow is sometimes referred to as eXecute-In-Place or XIP. The controller support devices operating in XIP mode (in all work modes, not just direct). However, there are steps the host must take to trigger entry to and exit from XIP mode.

See the topic Operating in Direct Mode for details on operating in direct mode, programming the mode, and usage restrictions.

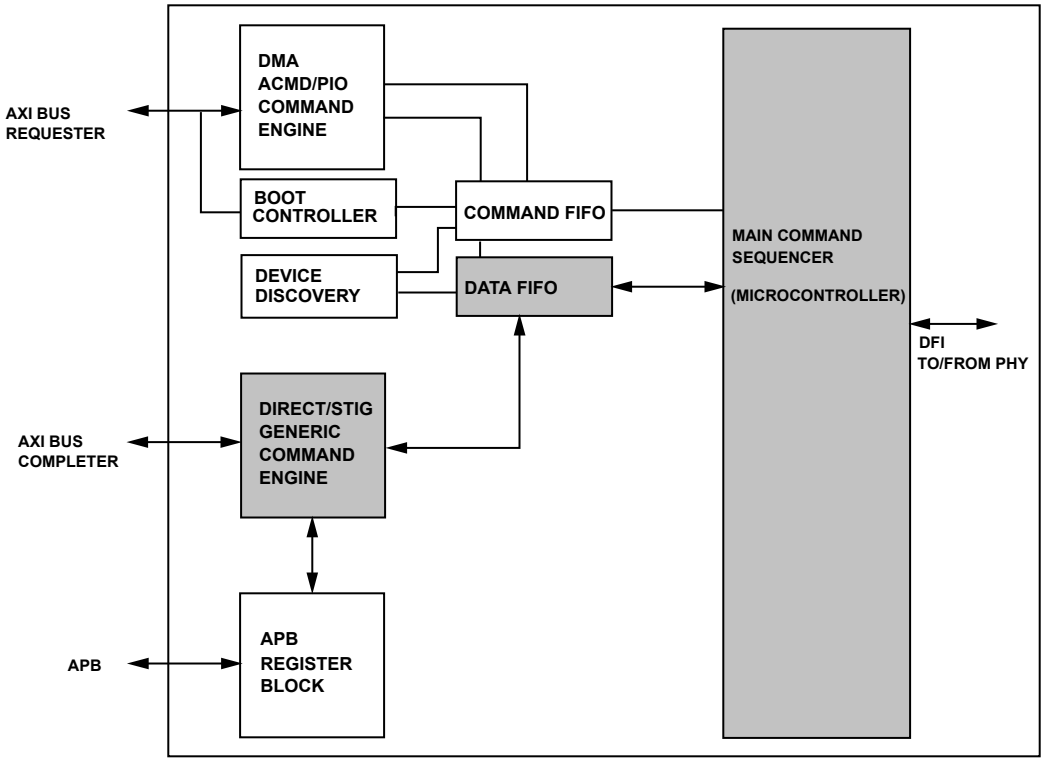

Figure 21-2: Direct Mode Block Diagram

STIG Mode

Software Triggered Instruction Generator (STIG) mode is configured and triggered using the programming interface. This mode is very flexible and configurable. In addition to performing standard reads and writes, it can also be used to access memory device registers and/or trigger functions in the memory device such as erase, read JEDEC ID, etc. STIG mode uses data paths that are similar to direct mode. However, the commands are configured and triggered through access to registers using the APB interface. Data can optionally be passed from the AXI bus completer interface, or through other registers in the APB register block. The shaded portion of the ***STIG Mode Block Diagram*** shows the operational flow.

See the topic Operating in STIG Mode for details on operating in STIG mode, programming the mode, and usage restrictions.

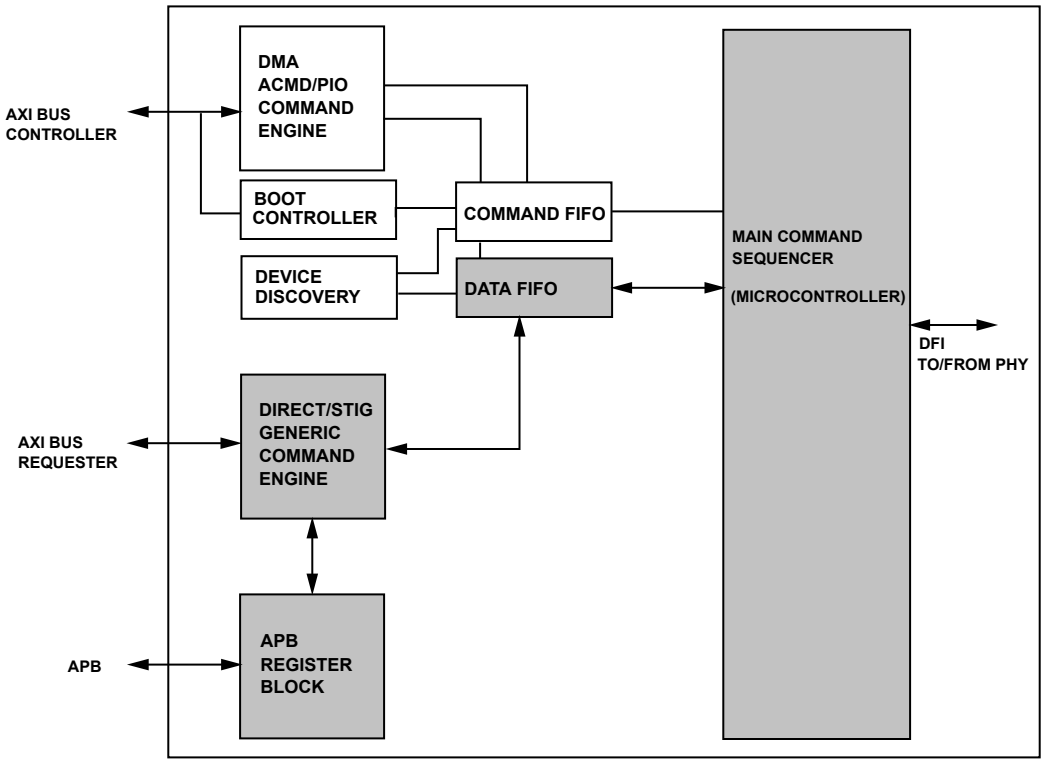

Figure 21-3: STIG Mode Block Diagram

ACMD Mode

Auto Command Mode (ACMD) mode, the user configures an advanced DMA engine capable of operating multiple parallel threads. The configuration uses controller registers and/or descriptors held in the main memory. The shaded portion of the ***ACMD Mode Block Diagram*** shows the operational flow. The ACMD DMA engine triggers transactions using the descriptors fetch from main memory to automatically move data between the device memory and system memory. ACMD mode is configured to use the AXI internal DMA bus requester interface to transfer data and to collect and process DMA descriptors.

ACMD mode can also be configured to use the AXI host interface instead. In this case, the controller signals to the processor using an interrupt or status register when it requires the host to send write data on the bus completer AXI write ports, or when it needs the processor to issue an AXI read to fetch read data.

See the topic Operating in ACMD Mode for details on operating in ACMD mode, programming the mode, and usage restrictions.

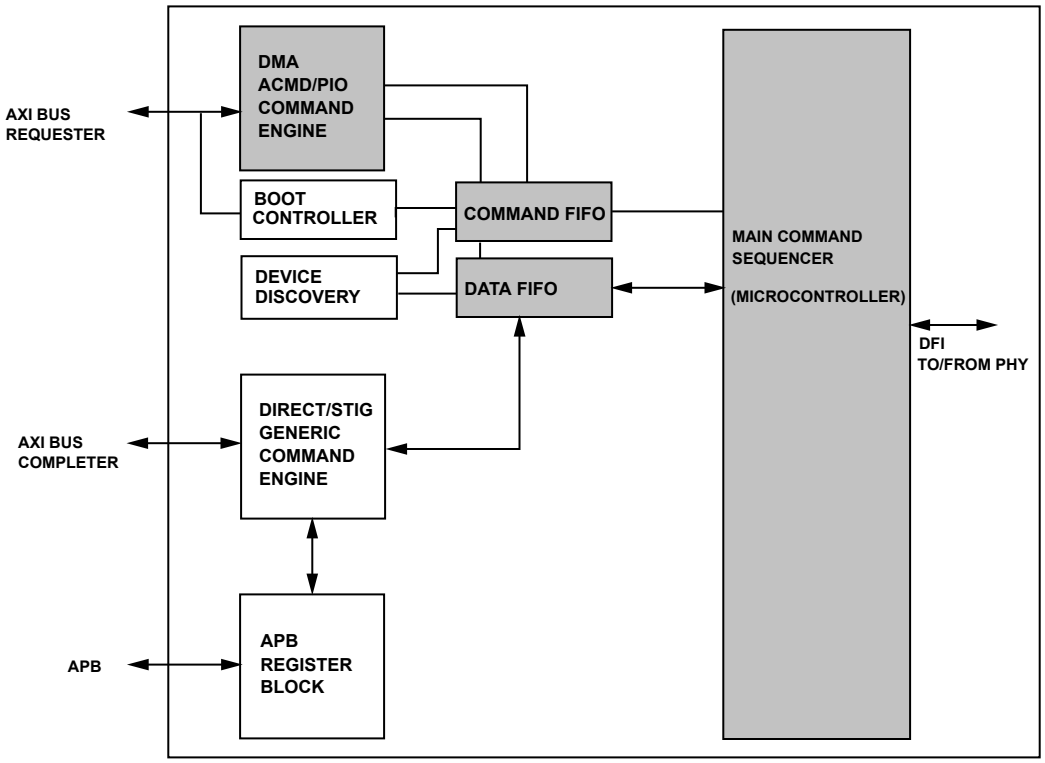

Figure 21-4: ACMD Block Diagram

Integrated Soft PHY

The xSPI PHY controller is responsible for handling the low-level timings of the data, address, and control signals between the device and controller. It provides additional logic, which operates as a bridge between formulated xSPI transactions and the timing-aware off-chip xSPI transfer to the external device. PHY has its own programmable registers. Accessing these registers occurs through the standard controller APB address space. Before the processor can communicate with the memory device, the PHY must be initialized and locked.

NOTE: In ADSP-2156x processors, the internal DMA of the xSPI controller is not supported.

See the section xSPI PHY Controller for details on how to use PHY, programming the PHY, and usage restrictions.

XIP Mode

The eXecute-In-Place (XIP) mode is also referred to as continuous mode. When the controller is in XIP mode, the processor executes code directly from the attached memory device or from where the processor has direct access to the attached memory device. The controller supports this function using the direct work mode. If executing code directly is needed, enable direct work mode.

The device uses XIP mode to improve read performance by removing the need for the controller to send the read opcode for any read operation. If the read opcode is typically sent over eight device clock cycles (SDR, serial transmission of the opcode), the read operation latency is reduced by eight cycles. This difference can significantly improve performance when executing code directly from the device. On the downside, when XIP mode is entered, the device can only perform read operations. If a different operation is required, XIP mode must be exited. Although

the controller supports XIP mode, there are steps the host must take to trigger entry to and exit from XIP mode. These steps depend on the selected work mode. See the section Entering and Exiting XIP Mode.

Configuring the Controller

To use the controller in direct, ACMD, or STIG mode, there are global configuration registers that must be configured. These are defined in the common sequence registers.

Use the following steps to configure the controller.

1. Configure the XSPI_SEQ_GCTL0 register to select the correct xSPI profile as per the memory device, to enable or disable the data swap feature, to select single or dual bytes per address, device page program size, device page read size, and other desired features.
2. Configure the XSPI_SEQ_GCTL1 register. This register is used only for SPI NAND profile to configure plane count, pages per block, extended page size, etc.
3. Configure the erase/read/program sequence. Configure the read or program sequence that the controller must send to the memory device. This sequence depends on the attached memory device. Refer to the device data sheet for details.

Some devices require a write enable sub sequence to be issued prior to a program operation (for example, to configure the write enable latch or WEL in the device). By default, it is assumed to be memory device requirement. However, the sequence can be disabled using the XSPI_WE_SEQ_CFG0.P1_EN bit. By default, the command extension of the write enable sequence is disabled. It is sent in a serial SDR format with an opcode of 0x6. If any of the parameters need changes, configure the XSPI_WE_SEQ_CFG0 register accordingly.

Some devices require the device to be polled for correctness and readiness after issuing an operation. Due to the differences between how device types interpret and respond to status requests, and different types of status requests, the controller requires several programmable registers that must be tuned to the device requirements. For direct mode, the controller can optionally check the device fail or busy status following a program or erase operation (or additionally for soft_reset/read for SPI NAND devices). For SPI NAND devices, the controller can also check the ECC status following a read page command. All of these requirements are configured using the XSPI_STAT_SEQ_CFGn registers (XSPI_STAT_SEQ_CFG0 to XSPI_STAT_SEQ_CFG10).

NOTE: When using the device discovery engine, the registers are updated automatically after power on reset. Refer to section Device Discovery for details.

The ***Global Configurations Registers*** table shows the registers used to configure the controller for various operations and types of flash devices. These registers must be initialized and configured when operating in direct or ACMD mode.

Table 21-3: Global Configurations Registers

	Profile 1 Devices	Profile 2 – HyperFlash Devices	Profile 2 – HyperRAM Devices	SPI NAND Devices

ECC Status Check	N/A	N/A	N/A	XSPI_STAT_SEQ_CFG10

Operating in Direct Mode

In direct mode, reads and writes that are issued by the processor enter the controller through the AXI bus completer interface. The read/write operations are directly translated to reads and writes at the memory device. Along with standard code execution, this mode can also be used immediately after power on reset to boot data from the attached memory device.

NOTE: This mode is different from the dedicated boot feature. The boot engine is specifically used to transfer boot code from the memory device to an area of host memory following power on reset (from which the host can then boot). There is a dedicated xSPI boot mode for the processor to support this feature. See the xSPI Controller Boot Mode topic in the Booting chapter for details.

Direct work mode is enabled by default (XSPI_WORKMODE_CTL.WORKMODE). The XSPI_WORKMODE_CTL register can only be changed when the controller is in an idle state. This state can be determined by polling the CRTL_BUSY pin of the xSPI flash controller or by polling the XSPI_GSTAT.CTL_BUSY bit. When direct mode is enabled, access to the XSPI_CMDn registers (which are only required for other work modes) are ignored and should be avoided.

Read and program/write transactions to the memory device occur only as a direct consequence of the processor applying read or write AXI transactions to the AXI bus completer interface through memory-mapped xSPI addresses.

NOTE: In direct mode, the configured page size for write or read transfers must be configured to a value wider than the selected word size of the AXI transaction (sA*SIZE). Also, the xSPI page boundaries must be aligned to the AXI transaction word size (sA*SIZE).

In addition to configuring the global registers described in Configuring the Controller, configure the direct mode specific registers such as XSPI_DAC_CFG and XSPI_DAC_REMAPADDR0/XSPI_DAC_REMAPADDR1 :

1. Write to the XSPI_DAC_CFG register to select the appropriate bank number in the attached memory device, to enable or disable AXI bus completer address remap, XIP mode, and other desired features.
2. Configure the remap address offset in the XSPI_DAC_REMAPADDR0 register.

Write Limitations

By default, the xSPI controller does not support the following functions:

- Byte writes (for example, an AXI write with an AWSIZE value of 0) to a device that is 16-bit addressed, or to an octal DDR configured device
- Issuing a write burst to an odd address to a device that is 16-bit addressed, or to an octal DDR configured device
- Using AXI write strobes to mask bytes on the write bus

These write operations can optionally be supported by setting the bit XSPI_DAC_CFG.RWDS_CAP_EN bit if the connected device supports byte masking using the DQS signal. DQS is traditionally used by a memory device to transfer a strobe with read data to help read data sampling. However, some devices also use the same signal as a byte mask for writes (in which case the limitations can be avoided).

AXI Wrapping Bursts

The following wrapping bursts restrictions are taken from the AXI standard:

- The start address must be aligned to the size of each transfer
- The length of the burst must be 2, 4, 8, or 16 transfers

Wrapping bursts are used for cache line accesses issued after a cache miss, and are, therefore, more relevant to the direct mode of operation than ACMD/STIG work modes. Internally, the xSPI controller handles AXI wrapping bursts by splitting them into separate incrementing bursts, automatically. Wrapping bursts on the AXI bus completer interface are supported even when the attached memory device does not support wrapping.

There is no restriction on using wrapping read bursts. However, there is one known scenario where wrapping write bursts received by the controller operating in direct mode through the AXI bus completer interface are not be supported. This scenario is described below:

1. The wrapping write burst restriction applies only to attached memory devices that require time to execute any program (write) operation. Flash devices, typically, operate in this manner.
2. While any program (write) operation is ongoing within the memory device, the controller has a function (which, by default, is enabled) to automatically check the status of the memory device. It does not allow any other read or write operation from the controller to proceed until the memory device has indicated that it is ready for a new operation. This function is programmable and can be disabled.
3. If the user has chosen to disable the function above (through the XSPI_STAT_SEQ_CFG1 register), the splitting of the AXI wrapping write transaction into separate write incrementing transactions results in the second incrementing write being discarded by the memory device.

Therefore, wrapping write bursts *cannot* be supported when the attached memory device requires time to process write operations and the controller function to check ready/busy status of the device has been disabled (using the XSPI_STAT_SEQ_CFG1 register). Otherwise, wrapping write bursts in direct mode are fully supported.

Entering and Exiting XIP Mode

The XSPI_DAC_CFG.XIP_EN_MB_VAL and XSPI_DAC_CFG.XIP_DIS_MB_VAL bit fields control how and when XIP mode in the device is entered or exited when using direct mode. By default, XIP mode is disabled. The ***XIP Mode Register Configurations*** table shows the registers used to configure XIP mode operations.

Most memory device use either of the one or both of the following steps to enter the XIP mode.

- Configure a specific bit in the memory configuration/status register (this step is not mandatory for all flash devices, but it which can be achieved easily using STIG mode).
- Send a read command with the correct value applied in the mode byte; the info is located immediately after the address phase of the read transaction

Set the XSPI_DAC_CFG.XIP_EN_MB_VAL bit to enter XIP mode while operating in direct mode. Follow up with a normal direct mode read transaction. As the read transaction is executed and the read sequence is sent to the device, the xSPI controller sends the value encoded in the XSPI_XIP_GCTL.XIP_EN_MB_VALUE register bit, immediately following the address phase of the transaction. Once the read transaction completes, the XSPI_XIP_GCTL.XIP_EN bit is set (=1) to indicate that both the controller and the memory device are now configured to work in XIP mode.

IMPORTANT: A direct read transfer to enable or disable XIP mode in the controller and memory device must not have more than 64B of data and must not cause crossing between pages.

To enable XIP mode during power on reset (assuming that the memory device is already configured to work in XIP mode in a non-volatile manner from reset), the XSPI_XIP_GCTL.XIP_EN bit should be set (=1). Then, each read transaction is performed in XIP mode. For example, the controller issues the read operation without sending any opcode and additionally setting the enable XIP mode bit following the address phase (when

XSPI_DAC_CFG.XIP_EN_MB_VAL = 1). The value of the XSPI_DAC_CFG.XIP_EN_MB_VAL field is sent following the address phase of the transaction.

To exit XIP mode in both the xSPI controller and the memory device, a new direct read transaction must be issued to the device with the disable XIP mode bit following address phase. Set (=1) the XSPI_DAC_CFG.XIP_DIS_MB_VAL bit to disable XIP mode. Issue a new direct read. As the read is executed and the read sequence is sent to the device, the controller sends the value encoded in the XSPI_XIP_GCTL.XIP_DIS_MB_VALUE field immediately following the address phase of the transaction. Once completed, the XSPI_XIP_GCTL.XIP_EN bit is cleared (=0) to indicate that the controller and memory device have exited XIP mode and are configured to work in normal mode.

Table 21-4: XIP Mode Register Configurations

XSPI_XIP_GCTL.XIP_EN	**XSPI_DAC_CFG.XIP_EN_MB_VAL**	**XSPI_DAC_CFG.XIP_DIS_MB_VAL**	**XSPI_READ_SEQ_CFG1.P1_MB_EN**	**Description**
0	0	0	0	Normal read mode without mode byte. (Number of dummy cycles = XSPI_READ_SEQ_CFG1.P1_MB_DMY_CNT)
0	0	1	0	Normal read mode with the additional disable mode byte following the address phase. (Number of dummy cycles = XSPI_READ_SEQ_CFG1.P1_MB_DMY_CNT)
0	0	0	1	Normal read mode with the additional disable mode byte following the address phase (number of dummy cycles = XSPI_READ_SEQ_CFG1.P1_MB_DMY_CNT)

Table 21-4: XIP Mode Register Configurations (Continued)

XSPI_XIP_GCTL.XIP_EN	XSPI_DAC_CFG.XIP_EN_MB_VAL	XSPI_DAC_CFG.XIP_DIS_MB_VAL	XSPI_READ_SEQ_CFG1.P1_MB_EN	Description
0	1	N/A	N/A	Enables XIP mode in the controller and memory device on the next read transfer – the enable mode byte is sent after the opcode and address phases. Then, XSPI_XIP_GCTL.XIP_EN =1. (Number of dummy cycles = XSPI_READ_SEQ_CFG1.P1_MB_DMY_CNT)
1	0	0	N/A	Controller reports DIR_CMD_ERR error. Mode byte must be sent when controller is configured to work in XIP mode.
1	0	1	N/A	Disables XIP mode in the controller and memory device on the next read transfer - the disable mode byte is sent after the address phase. Then, XSPI_XIP_GCTL.XIP_EN =0. (Number of dummy cycles = XSPI_READ_SEQ_CFG1.P1_MB_DMY_CNT)
1	1	N/A	N/A	Controller works in XIP mode - the enable mode byte is sent after the address phase. (Number of dummy cycles = XSPI_READ_SEQ_CFG1.P1_MB_DMY_CNT)

Table 21-4: XIP Mode Register Configurations (Continued)

XSPI_XIP_GCTL.XIP_EN	XSPI_DAC_CFG.XIP_EN_MB_VAL	XSPI_DAC_CFG.XIP_DIS_MB_VAL	XSPI_READ_SEQ_CFG1.P1_MB_EN	Description
0	0	1	1	Normal read mode with the additional disable mode byte following the address phase. (Number of dummy cycles = XSPI_READ_SEQ_CFG1.P1_MB_DMY_CNT)

Operating in ACMD Mode

The ACMD work mode relieves the host from issuing read and write commands directly. Instead, the host uses a dedicated engine to translate high-level commands into a series of low-level commands on the xSPI interface. It selects the optimal command sequence to send and to follow all transfer restrictions defined for the targeted memory device.

The auto command engine receives high-level commands either through a DMA descriptor format or directly through programmable registers. It is capable of operating multiple parallel threads that are configured using the controller registers and descriptors held in the main memory. It can operate in one of two modes – CDMA mode or PIO mode. Data transfers can be performed using either xSPI internal DMA mode or host DMA mode.

CDMA mode uses an embedded DMA to trigger various memory transactions using descriptors it fetches from main memory, automatically moving data between device memory and the host memory. In PIO work mode, dedicated controller registers are used in place of the descriptors to trigger the operation in the selected execution thread. The normal use case is to configure ACMD mode to use the internal DMA interface. The controller issues the relevant bus transactions directly to transfer data and to collect and process DMA descriptors. It is, however, possible to enable the ACMD engine to use the host DMA interface instead. In this case, the xSPI controller signals the host using an interrupt or status register when it requires the host to send write data on the host DMA write ports, or when it needs the host to issue a read command to fetch read data.

The auto command engine operates in the system (mACLK) clock domain. This mode uses system SRAM to buffer descriptor content locally; it is synchronous to mACLK.

NOTE: mACLK — This clock is SCLK0. It drives the front end of the controller. Both the AXI internal DMA and host DMA interfaces are synchronous to this clock.

The auto command engine can handle the following high-level sequences:

- Reset — sequence which allows the reset command to be sent to the selected device
- Erase — sequence to erase part of device or a whole device at once
- Program — sequence to transfer a specified amount of data from the host to the xSPI device
- Read — sequence to transfer a specified amount of data from the xSPI device to the Host

When operating in CDMA mode, the high-level sequence selection is made using a command descriptor. The DMA uses a standard structure where the head of the descriptor list is stored in APB register space. Each queued descriptor is chained together (one descriptor points to the next descriptor). For extra flexibility, up to eight descriptor chains can be managed simultaneously by the controller, and this is referred to as execution threads. Refer to section, Operating in ACMD Mode on for further details.

In PIO mode, the sequence is defined directly in specific command registers. Refer to section, Using the Auto Command in PIO Mode for further details.

NOTE: The high-level sequence the controller sends often must be broken up into multiple sub-sequences applied at the low-level xSPI interface. For example, it is common that prior to a program operation, a write enable sequence must be issued to instruct the memory device that a write operation is imminent, and, therefore, to configure the write enable latch of the device. This, obviously, depends on the attached memory type and controller configuration. The auto command engine selects the most appropriate low-level interface.

Using the Auto Command in CDMA Mode

To enable the auto command engine in CDMA mode, configure `XSPI_WORKMODE_CTL.WORKMODE` = 3. This operation can be done when the controller is in an idle state (poll the `XSPI_GSTAT.CTL_BUSY` bit). If software tries to access the `XSPI_WORKMODE_CTL` register when the controller is in the busy state, the access is ignored. To trigger the auto command engine in CDMA work mode, the `XSPI_CMD0`, `XSPI_CMD2` and `XSPI_CMD3` registers must be configured to pass the descriptor chain start address and the thread number associated with the descriptor chain. The command format for these registers are shown in the following tables.

When the ACMD mode is enabled, each write to the `XSPI_CMD0` register starts execution on a new command. Therefore, the `XSPI_CMD0` register must be written last; a write access to this register triggers the execution of the programmed operation.

Table 21-5: `XSPI_CMD0` Format for ACMD mode

`XSPI_CMD0` (offset 0x0)			
31:30	**29:27**	**26:24**	**23:0**
CDMA/PIO =00	Reserved	TRD_NUM (thread number)	Reserved

Table 21-6: `XSPI_CMD2` Format for ACMD mode

`XSPI_CMD2` **(offset 0x2) [31:0]**
Lower 32 bits of the descriptor head address

Table 21-7: `XSPI_CMD3` Format for ACMD mode

`XSPI_CMD3` (offset 0x3) [31:0]
Upper 32 bits of the descriptor head address

The host must write zero to the CDMA/PIO field of the XSPI_CMD0 register and provide the address of the head of the linked descriptor list using the XSPI_CMD3 and XSPI_CMD2 registers.

The controller issues a bus transaction to fetch the complete descriptor from main memory. The ***Command Descriptor Structure*** and ***Command Descriptor Layout*** tables present the details of the descriptor format.

Table 21-8: Command Descriptor Structure

No	63:48	47:32	31:16	15:0
0	Next pointer			
1	System memory pointer			
2	xSPI pointer			
3	Reserved			
4	Command counter		Command flags	Command type
5	Reserved		Status	

Table 21-9: Command Descriptor Layout

Field	Description
Next pointer	Next descriptor address. Address needs to follow system bus restrictions.
System memory pointer	System memory address required for data DMA commands. For read operations, this field is the address where the start of the read data is placed. For write operations, this field is the location of the start of the write data.
xSPI pointer	The field indicates the xSPI address for sequences that require addressing of the xSPI address space.
Command type	This field identifies the operation that the controller must perform. The encoding is: • 0x1000 – Erase the number of sequential sectors specified in the command counter field • 0x1001 – Full chip erase • 0x1100 – Device reset • 0x1101 – Device JEDEC reset • 0x2100 – Command to program the number of data bytes specified in the command counter field • 0x2200 – Command to read the number of data bytes specified in the command counter field • Other values are reserved
Command flags	This field contains different control flags for the operation of the command (See the ***Valid Command Flag*** table).

Table 21-9: Command Descriptor Layout (Continued)

Field	Description
Command counter	For read/program operations, the field indicates the number of data bytes to transfer minus one. For example, to transfer 1024 bytes, the value encoded is 1023. For an erase operation, this field represents the number of sectors to erase. For other operations, this field is ignored.
Status	The controller updates this field with the command status once the command operation is complete, and writes the status back to the descriptor. Refer to the Table 21-11 Descriptor Status Field table for bit descriptions.

On receipt of a complete descriptor, the controller constructs a low-level command or a series of low-level commands.

NOTE: If XIP mode is enabled in the controller (that is, `XSPI_XIP_GCTL.XIP_EN` = 1, which is supported by some devices to improve read performance), the connected device can only be read. Therefore, any other command will fail. As such, invoking the CDMA descriptor with a non-read command type results in the controller ignoring it and raising a DSC_ERROR fail status.

The ***Valid Command Flag*** table describes the allowed values in the command flags field of the descriptor.

Table 21-10: Valid Command Flag

Bits	Name	Description
15:11	Reserved	Reserved
10	DMA_SEL	This bit indicates which DMA interface is used to transfer data for read or program operations. If the selected command does not require a data transfer, this bit is ignored. 0: Selects the host DMA interface 1 : Selects the internal DMA interface Refer to section,Selecting the DMA Interface in ACMD mode for details on how to configure this bit.
9	CONT	Set (=1) the bit to indicate that another valid descriptor after this has been queued and is ready for the controller to fetch and process. Clear (=0) the bit when this descriptor is last in the descriptor chain.
8	INT	Set (=1) the bit to instruct the controller to issue an interrupt after the completion of descriptor processing. The triggered interrupt is identified in the

Table 21-10: Valid Command Flag (Continued)

Bits	Name	Description
		XSPI_TRD_COMP_ISTAT register. The bit of the interrupt status register that is set (=1) maps to the thread of the descriptor (as indicated originally in the descriptor by the TRD[n] field).
7	MB_XIP_DIS	When XIP mode is enabled in the controller and the attached memory device, setting this bit (=1) indicates to the controller that it must send mode bits to disable and exit XIP mode. When set, the controller sends mode bits as specified in the XSPI_XIP_GCTL.XIP_DIS_MB_VALUE field. Additionally, the XSPI_XIP_GCTL.XIP_EN_MB_VALUE bit is cleared to disable XIP mode in the controller. This bit is valid only for read commands. If XSPI_READ_SEQ_CFG1.P1_MB_EN =1 and XSPI_XIP_GCTL.XIP_EN = 0 the controller ignores the value of this field and it is treated as set (=1) (for example, mode bits are sent regardless of the value of this field).
6	MB_XIP_EN	This bit triggers entry to XIP mode. Setting this bit indicates to the controller that it must send mode bits to the device to enable XIP mode. The mode bits that are sent depend on the XSPI_XIP_GCTL.XIP_EN_MB_VALUE field. Additionally, the XSPI_XIP_GCTL.XIP_EN bit is set to enable XIP mode in the controller. This bit is valid only for read commands.

Table 21-10: Valid Command Flag (Continued)

Bits	Name	Description
5	xSPI_PTR_CONT	If this bit is set, the xSPI pointer field of current descriptor is ignored, and command engine uses the existing xSPI pointer value. Essentially, setting this bit allows the host to continue a data transfer from the address on the flash interface where a previously completed descriptor finished. This feature can only be triggered if a previous descriptor in the chain had this bit cleared and the xSPI pointer was initialized. It must also only be used for a command of the same type (for example, a series of read descriptors or series of write descriptors). For SPI NAND devices, a transfer is always continued from the beginning of the next page even if the current page was not filled completely (column address = 0, row address incremented).
4	SYS_PTR_CONT	If this bit is set (=1), the system memory pointer field of the current descriptor is ignored. The command engine uses the existing memory pointer value. This bit allows the data transfer to continue on the host interface where the previously completed descriptor finished. This feature can only be triggered if a previous descriptor in the chain had this bit cleared and the system memory pointer was initialized. It must also only be used for commands of the same type (for example, a series of read descriptors or series of write descriptors).
3	Reserved	Reserved
2:0	BANK	The field indicates the device number (bank/CS) that is selected for sequence execution.

NOTE: If the INT bit is not set in the current descriptor and the following descriptor chain is dropped from execution due to an error, the controller does not set the TRD[n] interrupt flag in the `XSPI_TRD_COMP_ISTAT` register. The error condition is, however, always reported by setting the TRD[n] bit in the `XSPI_TRD_ERR_ISTAT` register. The bit can be used to detect that the descriptor chain execution was interrupted due to an error. The n in the field names represent the thread number for which the error or complete condition occurred.

Opon completion of a command, the controller writes back the status into the descriptor status field. This field value is ignored during descriptor read operation. The status word is described in the ***Descriptor Status Field*** table.

Table 21-11: Descriptor Status Field

Bits	Name	Description
31:24	Reserved	Reserved
23:16	ECC_STAT	Value of the ECC status returned by the SPI NAND device. The value of this field applies to last read operation. It is updated only when fail checking is enabled.
15	COMPLETE	When set, the bit denotes that the controller has updated status information and the operation is complete. This bit is set even when the operation ended as a failure. This bit should be in a cleared state while descriptor is constructed.
14	FAIL	When set, the bit denotes that the operation failed to complete successfully.
13:6	Reserved	Reserved
5	ECC_CORR_ERROR	The bit indicates that an ECC correctable error was detected during page read. This bit is valid only for SPI NAND devices when `XSPI_STAT_SEQ_CFG10.ECC_FAIL_EN=1`.
4	DEVICE_ERROR	The bit indicates that a device error was detected during a read status operation for erase/program/read.
3	DQS_ERROR	This bit is set when an incorrect number of DQS pulses were detected during a direct mode read or status check. Essentially, this status is passed from the soft PHY and could mean: The PHY is configured badly such that it expects DQS strobes but never received them, or, The value (`XSPI_PHY_GATE_LPBK_CTL.RD_DEL_SEL` field) is incorrect and has caused data corruption and pointer misalignment in the PHY. To resolve this issue, the PHY must be reset to clear the DQS_OVF and DQS_UR flags and reset the read data pointers.

Table 21-11: Descriptor Status Field (Continued)

Bits	Name	Description
2	CRC_ERROR	When set, the bit indicates that the controller detected a CRC error.
1	BUS_ERROR	When set, the bit indicates that the controller got an error response on the system DMA interface.
0	DSC_ERROR	This bit indicates that an invalid descriptor sequence has been detected.

The auto command engine accept new commands only when the thread selected is in am idle state. The host software should check the thread status before it queues any new commands. The threads status is available in the XSPI_TRD_STAT register. Commands sent to a busy thread are ignored and XSPI_ISTAT.CMD_IGNORED = 1.

Using the Auto Command in PIO Mode

In PIO work mode, dedicated command registers are used to trigger operation in a selected execution thread of the auto command engine. In this mode it is only possible to trigger a single command in each of the execution threads. This mode is useful when host software wants to trigger a single operation. In this case it is much simpler and faster to program a few controller registers than prepare a descriptor list in system memory. Functionality of this work mode is similar to the CDMA work mode for cases where the descriptors chain contains only a single descriptor. The auto command engine executes the programmed command and returns a status word separately for each execution thread. Status words are mapped into controller status registers, where it remains valid until a new command is triggered on this thread.

Depending on the selected operation, the number of XSPI_CMD* required to be programmed. The registers described as unused for given operation do not need to be set. XSPI_CMD1 to XSPI_CMD5registers retain the contents from previous writes meaning that if the current register configuration matches what is needed for the next operation, it can be left unchanged. The only exception is the XSPI_CMD0 register. This register must always be written on each operation. Write access to this register triggers operation execution. Host software needs to initialize all required command registers before it writes to command register 0.

- The reset and chip erase sequences only requires XSPI_CMD0 to be written to. XSPI_CMD1 through XSPI_CMD5 registers are unused.
- The sector erase sequence requires XSPI_CMD0, XSPI_CMD1, XSPI_CMD4 and XSPI_CMD5 to be written, XSPI_CMD2 and XSPI_CMD3 are unused.
- The program and read sequences require all XSPI_CMD* registers to be written.

The XSPI_CMD0 - XSPI_CMD5 tables below show the layout for the available high-level sequences that may be triggered in PIO mode. The operation is always triggered when XSPI_CMD0 is written to, so configure XSPI_CMD1-XSPI_CMD5 registers first.

Table 21-12: XSPI_CMD0 Layout for PIO Sequences

Bits	Name	Description
31:30	CDMA/PIO	Set (=1) for PIO work mode.
29:27	-	Reserved
26:24	TRD_NUM	This field selects the destination thread number for command. Software can select any available thread. Commands can be issued in parallel to all threads.
23	-	Reserved
22:20	BANK/CS	Selects device targeted by the sequence
19	DMA_SEL	This bit selects which DMA interface should be used for transferring data. It is only relevant for commands that transfer data (for example, read or program operations). Clear (=0) to use the host DMA interface. Set (=1) to use the internal DMA interface.
18	INT	If this bit is set, an interrupt is issued after the operation has finished. The triggered interrupt is indicated in the XSPI_TRD_COMP_ISTAT register, where interrupt bit is selected by the thread number in the TRD[n] field.
17	MB_XIP_DIS	When XIP mode is enabled in the controller and the attached memory device, setting this bit indicates to the controller that it must send mode bits to disable and exit XIP mode. When set, the controller sends mode bits as specified in the XSPI_XIP_GCTL.XIP_DIS_MB_VALUE field . Additionally, the XSPI_XIP_GCTL.XIP_EN_MB_VALUE bit is cleared to disable XIP mode in the controller. This bit is valid only for read operations. If XSPI_READ_SEQ_CFG1.P1_MB_EN= 1 and XSPI_XIP_GCTL.XIP_EN_MB_VALUE = 0 the controller ignores the value of this field. It is treated as set (= 1) (for example, mode bits are sent regardless of the value of this field).

Table 21-12: XSPI_CMD0 Layout for PIO Sequences (Continued)

Bits	Name	Description
16	MB_XIP_EN	This bit triggers entry to XIP mode. Setting this bit indicates to the controller that it must send mode bits to the device to enable XIP mode. The mode bits sent depends on the XSPI_XIP_GCTL.XIP_EN_MB_VALUE field. Additionally, the XSPI_XIP_GCTL.XIP_EN_MB_VALUE bit is set to enable XIP mode in the con- troller. This bit is valid only for read operations.
15:0	CMD_TYPE	This field identifies the kind of operation that is executed by the con- troller. It is con- figured as follows: 0x1100 : Reset sequence (soft reset) 0x1101 : Reset sequence (JEDEC reset) 0x1000 : Sector erase sequence 0x1001 : Chip erase sequence 0x2100 : Program sequence 0x2200 : Read sequence

The XSPI_CMD1 register is required for all operations other than reset and chip erase. It holds the lower half of the memory device starting address where the operation takes place.

Table 21-13: XSPI_CMD1 Layout for PIO Sequences

Bits	Name	Description
31:0	xSPIAddress (Lower)	This field contains the lower half of the starting address of the operation in the xSPI device.

The XSPI_CMD2 is only required for read and program operations. It holds the lower half of the host side address where the operation fetches data for writes, or places data for reads.

Table 21-14: XSPI_CMD2 Layout for PIO Sequences

Bits	Name	Description
31:0	SYS_ADDR_PTR_L	Host memory address required for DMA transfers. It is lower half of the address.

The XSPI_CMD3 is only required for read and program operations. It holds the upper half of the host side address where the operation should fetch data for writes, or place data for reads.

Table 21-15: XSPI_CMD3 Layout for PIO Sequences

Bits	Name	Description
31:0	SYS_ADDR_PTR_H	Host memory address required for DMA transfers. It is upper half of the address.

The XSPI_CMD4 is required for sector erase operations as well as read and program operations. For sector erase, it holds the number of sectors that must be erased. For read/program operations, it holds the number of data bytes that should be transferred.

Table 21-16: XSPI_CMD4 Layout for PIO SECTOR ERASE Sequences

Bits	Name	Description
31:0	SECT_CNT	Sector counter. Determines how many sectors shouldbe erased. Number of sectors is decoded as a value of this field plus 1 (that is, to erase 1 sector this field should have value 0, and so on).

Table 21-17: XSPI_CMD4 Layout for PIO READ/PROGRAM Sequences

Bits	Name	Description
31:0	DATA_CNT	Data counter. Determines how many data bytes should be transferred minus 1. For example, if 1024 bytes should be transferred, the value to be programmed should be 1023.

The XSPI_CMD5 is required for all operations other than reset and chip erase. It holds the upper half of the memory device starting address where the operation should take place.

Table 21-18: XSPI_CMD5 Layout for PIO Sequences

Bits	Name	Description
31:0	xSPI Address (Upper)	This field contains additional address space for the xSPI address. It is utilized for SPI NAND devices to hold both the row and column address as a single xSPI address. For sector erase operations, bits that belong to column address must be cleared (=0).

Status Checking

The host can check the operating status of each active thread. After the thread ID is written to the XSPI_CMD_STAT_PTR register, the status can be read from the XSPI_CMD_STAT register. The COMPLETE bit is cleared when a new operation is triggered, and all other fields within the XSPI_CMD_STAT register should at this point be ignored. When the selected operation is complete, the controller sets the COMPLETE bit and all other register fields reflects the status of that operation.

The ***Status Checking*** table describes the status fields.

Table 21-19: Status Checking

Bits	Name	Description
31:24	Reserved	Reserved
23:16	ECC_STAT	Value of the ECC status returned by the SPI NAND device. Value of this field applies to last read operation and is updated only when fail checking is enabled.
15	COMPLETE	When set, denotes that the controller has updated status information and the operation is complete. This bit shall be set even if the operation ended as a failure.
14	FAIL	When set, denotes that operation failed to complete successfully.
13:6	Reserved	Reserved
5	ECC_CORR_ERROR	ECC correctable error was detected during page read. This field is valid only for SPI NAND devices when the `XSPI_STAT_SEQ_CFG10.ECC_FAIL_EN` =1.
4	DEVICE_ERROR	Device error was detected during read status operation for erase/program/read operation.
3	DQS_ERROR	Incorrect DQS pulses number was detected during the data read operation. This is information from the PHY that either the DQS strobe did not appear during read (for example, device is not connected to the controller) or RD_DEL_SEL signal value is incorrect (`XSPI_PHY_GATE_LPBK_CTL.RD_DEL_SEL`) and data read from the flash device are corrupted and read FIFO pointers in the PHY are misaligned. The $\overline{\text{DLL_RST}}$ signals to clear DQS_OVF and DQS_UR flags in the PHY and clear all PHY read data pointers. One of these is required by the PHY before continuing to work after the DQS_ERROR signal assertion.
2	CRC_ERROR	When set, it indicates that the controller detected a CRC error.

Table 21-19: Status Checking (Continued)

Bits	Name	Description
1	BUS_ERROR	When set, it indicates that the controller got an error response on the system DMA interface.
0	CMD_ERROR	This bit indicates that an invalid command sequence has been detected.

Selecting the DMA Interface

ACMD mode can be configured to use an internal DMA interface to have the controller issue the relevant bus transactions to transfer data and to collect and process DMA descriptors. This mode requires the least amount of software overhead. It is, however, also possible to enable the ACMD engine to use the host DMA interface instead.

- To use the ACMD in CDMA mode with data transfers passing via the host DMA interface, follow the process as described in the section, Using the Auto Command in CDMA Mode, clearing the DMA_SEL bit in the command flags.
- To use the ACMD in CDMA mode with data transfers passing via the internal DMA interface, follow the process as described in the section, Using the Auto Command in CDMA Mode, setting the DMA_SEL bit in the command flags.
- To use the ACMD in PIO mode with data transfers passing via the host DMA interface, follow the process as described in the section, Using the Auto Command in PIO Mode, clearing the DMA_SEL bit of the `XSPI_CMD0` register.
- To use the ACMD in PIO mode with data transfers passing via the internal DMA interface, follow the process as described in the section, Using the Auto Command in PIO Mode, setting the DMA_SEL bit of the `XSPI_CMD0` register.

When transfers using the bus completer interface are enabled, the following sequence also needs to be followed by the external host to transfer the required data:

1. Poll the `XSPI_ISTAT.SDMA_TRIGG` bit. Or, if an interrupt is preferable, unmask the interrupt associated with SDMA_TRIGG by setting the `XSPI_INT_EN.SDMA_TRIGG_EN` bit. When the bit is asserted, the host can proceed.
2. The external host reads the `XSPI_SDMA_SIZ` register, the `XSPI_SDMA_TRD_STAT` register and the `XSPI_SDMA_ADDR0`/`XSPI_SDMA_ADDR1` registers. The `XSPI_SDMA_SIZ` register reports the size of the data transfer that must be transferred. The `XSPI_SDMA_TRD_STAT` register reports the thread ID of the operation that triggered SDMA data transfer and also reports the data transfer direction. The `XSPI_SDMA_ADDR0`/`XSPI_SDMA_ADDR1` registers indicate the address (awaddr/araddr) the external host must use on the write or read transaction when it issues it.
3. Before starting data transmission, the external host must clear the `XSPI_ISTAT.SDMA_TRIGG` register by writing 1.

4. Host can now transfer data. For program operations, it is expected that the host will issue one or more write requests with a total size matching the data transfer indicated in step 2. For read operations, it is expected that the host will issue one or more read requests with a total size matching the data transfer indicated in step 2. The address issued by the host should match that being reported in the XSPI_SDMA_ADDR0/ XSPI_SDMA_ADDR1 registers.

If the host ignores any of the requirements and starts the data transfer when the host DMA is not ready, theXSPI_ISTAT.SDMA_ERR flag is set. If the XSPI_INT_EN.SDMA_ERR_EN bit is set, an interrupt is also triggered. When the XSPI_DMA_CTL.SDMA_ERR_RSP bit is set, an error response is returned; if it is cleared, the OK response is returned.

If the host sends an unsupported transaction to a bus completer interface, the host DMA ignores this access and the XSPI_ISTAT.SDMA_ERR flag is set. If an error response is detected on the system bus during host DMA transfer, the fail and bus error bits are set in the last operation status. The last operation status can check in:

- The XSPI_CMD_STAT register. After selecting thread in which command was executed (for ACMD PIO work mode). Thread is selected by value of the XSPI_CMD_STAT_PTR register. This method is valid for the ACMD PIO and STIG work modes.
- The status field of the command descriptor. This method is valid for the CDMA work mode.

Performing transactions in wrong direction (that is, the host issuing a write transaction to the bus completer port in case of sending read operation command to an xSPI device) is forbidden and causes the XSPI_ISTAT.SDMA_ERR flag to be set. If the XSPI_INT_EN.SDMA_ERR_EN bit is set, an interrupt is also triggered.

Rules and Limitations

The host must follow the following rules when using ACMD mode:

- For SPI NAND devices, the initial column address must be specified within the range of the page size.
- For profile 2 or profile 1, octal DDR devices, the number of bytes to be transferred must be even.
- For profile 2 or profile 1, octal DDR devices, the start address of the transfer in the xSPI device must be even.
- For profile 1 and octal DDR devices, the command extension must be enabled.
- For DATA_PER_ADDR (when the device is 16-bit addressed), the start address must be even and the number of bytes to transfer must be even.
- If XIP mode is enabled, only read operations are permitted.
- Only the supported command types as illustrated in this section should be attempted.

Violating any of the above rules results in the controller returning the DSC_ERROR/CMD_ERROR status.

NOTE: DSC_ERROR and CMD_ERROR status bits are only intended to ease debug and integration and should never be triggered for correct controller operation. Using the controller outside of the descriptor and command rules may lead to undefined behavior.

In automatic work modes, the controller writes/reads data consecutively from the specified address. If a page boundary is crossed, the transaction continues from the beginning of the next page.

Operating in STIG Mode

The Software-Triggered Instruction Generator (STIG) mode allows software to define the low-level commands and sequences sent to the memory device. Relative to direct or ACMD mode, it is more flexible because software can control the low-level characteristics of each operation carried out on the device. STIG mode is normally used with the direct or ACMD modes of operation.

To enable the STIG work mode, the `XSPI_WORKMODE_CTL.WORKMODE` field must be set (= 1) . This can be done only when the controller is in an idle state. The ***STIG Mode Registers*** table shows the registers used to configure STIG mode operations.

Table 21-20: STIG Mode Registers

Bits	Name	Description
31:0	`XSPI_CMD0`	A write to this register triggers the STIG operation and has no other purpose. Reading this register is ignored.
31:0	`XSPI_CMD1`	Holds bits [31:0] of the STIG instruction
31:0	`XSPI_CMD2`	Holds bits [63:32] of the STIG instruction
31:0	`XSPI_CMD3`	Holds bits [95:64] of the STIG instruction
31:0	`XSPI_CMD4`	Holds bits [127:96] of the STIG instruction

Instruction Variants

The main instruction variants for STIG mode include the generic command instruction, legacy HyperFlash or profile 2 instructions, and legacy SPI xSPI profile 1 or SPI NAND instructions. The following tables show the structure of the STIG command instruction (`XSPI_CMDn`) for each variant.

Table 21-21: STIG Command Instruction - Legacy SPI, xSPI Profile 1 or SPI NAND

Name	Bits	Description
Reserved	127:126	N/A
t_{CMS}/t_{CEM} Enable (`XSPI_SEQ_GCTL0.TCMS_EN`)	125	Setting this bit enables the feature that automatically forces the controller to pause activity to the memory device to allow it to perform a periodic refresh operation. Some volatile memory devices require this functionality (for example, HyperRAM). This functionality is referred to as t_{CMS} timing. When set, the controller pauses activity as specified in the `XSPI_MINICTL_DEV_ACTIVE_MAX` register.

Table 21-21: STIG Command Instruction - Legacy SPI, xSPI Profile 1 or SPI NAND (Continued)

Name	Bits	Description
Instruction Termination (INSTR_LINK)	124	This bit is only relevant when the instruction type field of the instruction = 0, 32, 36 or 96. See the section Instruction Type Variants for details on instruction type configuration. The field assigned to this bit indicates whether the instruction is to be terminated (CS is deactivated after the instruction finishes) or the instruction is glued with the next instruction (providing it is ready to be fetched from the command FIFO). 0 – Current sequence is terminated and not glued with another instruction of the same type 1 – Current sequence is glued with the next STIG instruction
Reserved	123:119	N/A
CRC Variant (CRC_VARIANT)	118	Determines when the CRC is calculated on an outbound command. When cleared (=0), calculate for the address bytes only. When set (=1), calculate for all bytes in the sequence.
CRC Enable (CRC_EN)	117	Set to enable dynamic CRC calculation and output the value on xSPI flash interface in the transfer modes as specified by ADDR_EDGE_MODE and ADDR_NO_OF_IOS. If the octal DDR (8D) variant is configured, the calculated CRC byte is maintained for a full flash clock cycle.
XIP Enable (XIP_EN)	116	Setting this bit instructs the controller to block the sending of the opcode, which is needed when the device is operating in XIP mode 0 – Opcode transfer phase is sent 1 – Opcode transfer phase is not sent (XIP enabled)
Address Shift (ADDR_SHIFT)	115	When the ADDR_EDGE_MODE and ADDR_NO_OF_IOS configuration determines the octal DDR variant, two bytes are required to be sent in a single flash clock cycle. Therefore, the host must configure an even number of bytes in the quoted case. However, there are specific exceptions such as the Adesto octal DTR SFDP command which requires a {A2,A1,A0,do not care} flash interface address alignment rather than a common {A3,A2,A1,A0} alignment. The ADDR_SHIFT bit shifts the address byte chain by one byte towards the left and fills the least-significant byte with zeroes (when an octal DDR address structure is required).
Reserved	114:111	N/A
Bank Number (BANK_NUM)	110:108	This field informs the controller on which memory device the sequences should be executed. This information directly maps to the chip select (CS) pin.

Table 21-21: STIG Command Instruction - Legacy SPI, xSPI Profile 1 or SPI NAND (Continued)

Name	Bits	Description
Opcode Edge Mode (OPCODE_EDGE_MODE)	107	This bit selects SDR or DDR operation at the memory device 0 – SDR 1 – DDR
Reserved	106	N/A
Opcode IO Mode (OPCODE_NO_OF_IOS)	105:104	Determines number of active IOs for opcode phase of the instruction 0 – Single 1 – Dual 2 – Quad 3 – Octal
Reserved	103:101	N/A
Opcode Extension Enable (OPCODE_EXT_EN)	100	Enables dual byte opcode for the instruction 0 – Only CMD[87:80] is transmitted in the opcode phase of the instruction. 1 – CMD[87:80] followed by CMD_EXT[79:72] is transmitted in the opcode phase of the instruction. If the OPCODE_EDGE_MODE and OPCODE_NO_OF_IOS configuration determines the octal DDR variant, two bytes are required to be sent in a single flash clock cycle. The host must also set OPCODE_EXT_EN =1. Failure to do this results in an error being reported.
Address Edge Mode (ADDR_EDGE_MODE)	99	Determines edge mode for the address phase of the instruction. 0 – SDR 1 – DDR
Reserved	98	N/A
Address IO Mode (ADDR_NO_OF_IOS)	97:96	Determines the number of active IOs for the address phase of the instruction 0 – Single 1 – Dual 2 – Quad 3 – Octal
Reserved	95	N/A

Table 21-21: STIG Command Instruction - Legacy SPI, xSPI Profile 1 or SPI NAND (Continued)

Name	Bits	Description
Address Number of bytes (ADDR_NO_OF_BYTES)	94:92	Determines the number of address bytes to be sent in the instruction. Up to six address bytes can be sent in one sequence. A value of 7 encoded here is not permitted. A value of 0 encoded implies that no address bytes are sent (for example, address phase is disabled). If ADDR_EDGE_MODE and ADDR_NO_OF_IOS configuration determines the octal DDR variant, two bytes are required to be sent in a single flash clock cycle. The host must configure an even number of address. If the host configures ADDR_NO_OF_BYTES = 1 or 3 or 5, the controller generates an error.
Reserved	91:90	N/A
Number of data bytes (DATA_NO_OF_BYTES) or Number of mode bytes (MODE_NO_OF_BYTES)	89:88	For cases where the number of data (or mode) bytes is ≤ 2, this field allows that data to be included within this instruction, directly avoiding the need to glue a separate data sequence instruction. If there are more than two data bytes required to be transferred, the instruction must be glued with a data sequence. Note that if up to two data (or mode) bytes are transferred directly from this instruction, the format in which they are presented to the device depends on the ADDR_EDGE_MODE and ADDR_NO_OF_IOS configuration. If the host needs the data to be sent in a different format, this field must be cleared (=0). Instead, transfer the data using a glued data sequence instruction, or generic instruction where the format of those data bytes can be individually configured. 0 – zero data/mode bytes are sent to device (data phase disabled) 1 – One byte is transferred to the device 2 – Two bytes are transferred to the device 3 – N/A If ADDR_EDGE_MODE and ADDR_NO_OF_IOS configuration determines the octal DDR variant, two bytes are required to be sent in a single flash clock cycle. The host must configure an even number of bytes. Failure to do this results in an error being reported.
CMD	87:80	Opcode mnemonic
CMD_EXT	79:72	Opcode extension mnemonic
ADDR5	71:64	Byte 5 of the address phase
ADDR4	63:56	Byte 4 of the address phase

Table 21-21: STIG Command Instruction - Legacy SPI, xSPI Profile 1 or SPI NAND (Continued)

Name	Bits	Description
ADDR3	55:48	Byte 3 of the address phase
ADDR2	47:40	Byte 2 of the address phase
ADDR1	39:32	Byte 1 of the address phase
ADDR0	31:24	Byte 0 of the address phase
DATA1/MODE1	23:16	Byte 1 of the data/mode phase
DATA0/MODE0	15:8	Byte 0 of the data/mode phase
Reserved	7	N/A
Instruction Type	6:0	This field defines the type (index) of the instruction. A description of each value and its corresponding instruction can be found in the section, Instruction Type Variants.

Table 21-22: STIG Instruction - Legacy HyperFlash or xSPI Profile 2

Name	Bits	Description
Reserved	127:126	N/A
t_{CMS}/t_{CEM} Enable (TCMS_EN)	125	Setting this bit enables the feature that automatically forces the controller to pause activity to the memory device to allow it to perform a periodic refresh operation. Some volatile memory devices require this functionality (for example, HyperRAM) and is referred to as t_{CMS} timing. When set, the controller pauses activity as specified in the XSPI_MINICTL_DEV_ACTIVE_MAX register.
Instruction Termination (INSTR_LINK)	124	This bit is only relevant when the instruction_type field of the instruction = 0, 32, 36 or 96. Refer to the Instruction Type Variants section for details on instruction type configuration. The field assigned to this bit indicates whether the instruction is to be terminated (CS is to be deactivated after the instruction finishes) or the instruction is to be glued with the next instruction providing it is ready to be fetched from the command FIFO. 0 – Current sequence is terminated and not glued with another instruction of the same type 1 – Current sequence is glued with the next STIG instruction
Reserved	123:119	N/A
CRC Variant (CRC_VARIANT)	118	When the CRC is calculated on the outbound command, this bit indicates when cleared (=0) to calculate for the address bytes only, or when set (=1) to calculate for all bytes in the sequence.

Table 21-22: STIG Instruction - Legacy HyperFlash or xSPI Profile 2 (Continued)

Name	Bits	Description
CRC Enable (CRC_EN)	117	Set to enable dynamic CRC calculation and output this value on xSPI flash interface in the transfer modes specified by ADDR_EDGE_MODE and ADDR_NO_OF_IOS configuration. If an octal DDR (8D) variant is configured, the calculated CRC byte is maintained for full flash clock cycle.
XIP Enable (XIP_EN)	116	Setting this bit instructs the controller to block the sending of the opcode, which is needed when the device is operating in XIP mode. 0 – Opcode transfer phase is sent 1 – Opcode transfer phase is not sent (XIP enabled)
Address Shift (ADDR_SHIFT)	115	If ADDR_EDGE_MODE and ADDR_NO_OF_IOS configuration determine the octal DDR variant, two bytes are required to be sent in a single flash clock cycle. The host must configure an even number of bytes in the quoted case. However, there are specific exceptions. For example, the Ades-to octal DTR SFDP command requires a {A2,A1,A0,do not care} flash interface address alignment rather than the common {A3,A2,A1,A0} alignment. The ADDR_SHIFT bit shifts the address byte chain by one byte towards the left and fills the least-significant byte with zeroes providing the octal DDR address is required.
Reserved	114:111	N/A
Bank Number (BANK_NUM)	110:108	This field informs the controller on which memory device the sequence should be executed. This information directly maps to the chip select (CS) pin.
Opcode Edge Mode (OPCODE_EDGE_MODE)	107	This bit selects SDR or DDR operation at the memory device 0 – SDR 1 – DDR
Reserved	106	NA
Opcode IO Mode (OPCODE_NO_OF_IOS)	105:104	Indicates the number of active IOs for opcode phase of the instruction 0 – Single 1 – Dual 2 – Quad 3 – Octal
Reserved	103:101	N/A

Table 21-22: STIG Instruction - Legacy HyperFlash or xSPI Profile 2 (Continued)

Name	Bits	Description
Opcode Extension Enable (OPCODE_EXT_EN)	100	Enables dual byte opcode for the instruction 0 – Only CMD[87:80] is transmitted in the opcode phase of the instruction 1 – CMD[87:80] followed by CMD_EXT[79:72] is transmitted in the opcode phase of the instruction If OPCODE_EDGE_MODE and OPCODE_NO_OF_IOS configuration determines the octal DDR variant, two bytes are required to be sent in a single flash clock cycle. It is therefore required that the host also sets OPCODE_EXT_EN. Failure to do this results in an error being reported.
Address Edge Mode (ADDR_EDGE_MODE)	99	Determines edge mode for address phase of the instruction 0 – SDR 1 – DDR
Reserved	98	N/A
Address IO Mode (ADDR_NO_OF_IOS)	97:96	Determines number of active IOs for the address phase of the instruction 0 – Single 1 – Dual 2 – Quad 3 – Octal
Reserved	95	N/A
Address Number of bytes (ADDR_NO_OF_BYTES)	94:92	Determines number of address bytes to be sent in the instruction. Up to 6 address bytes can be sent in one sequence. A value of 7 encoded here is not permitted. A value of 0 encoded implies that no address bytes is sent (for example, the address phase is disabled). If ADDR_EDGE_MODE and ADDR_NO_OF_IOS configuration determines the octal DDR variant, two bytes are required to be sent in a single flash clock cycle. It is, therefore, required for the host to configure an even number of address. If the host configures ADDR_NO_OF_BYTES = 1, 3 or 5, the controller generates an error.
Reserved	91:90	N/A

Table 21-22: STIG Instruction - Legacy HyperFlash or xSPI Profile 2 (Continued)

Name	Bits	Description
Number of data bytes (DATA_NO_OF_BYTES) or Number of mode bytes (MODE_NO_OF_BYTES)	89:88	For cases where the number of data (or mode) bytes is ≤ 2, this field allows that data be included within this instruction, directly avoiding the need to glue a separate data sequence instruction. If there are more than two data bytes required to be transferred, the instruction must be glued with a data sequence. Note that if up to two data (or mode) bytes are transferred directly from this instruction, the format in which they are presented to the device depends on the ADDR_EDGE_MODE and ADDR_NO_OF_IOS configuration. If the host needs the data to be sent in a different format, the field must be cleared (=0) . Instead, transfer the data using a glued data sequence instruction, or generic instruction, where the format of the data bytes can be individually configured. 0 – Zero data/mode bytes are sent to device (data phase disabled) 1 – One byte is transferred to the device 2 – Two bytes are transferred to the device 3 – N/A If ADDR_EDGE_MODE and ADDR_NO_OF_IOS configuration determines the octal DDR variant, two bytes are required to be sent in a single flash clock cycle. The host must configure an even number of bytes. Failure to do this results in an error being reported.
CMD	87:80	Opcode mnemonic
CMD_EXT	79:72	Opcode extension mnemonic
ADDR5	71:64	Byte 5 of the address phase
ADDR4	63:56	Byte 4 of the address phase
ADDR3	55:48	Byte 3 of the address phase
ADDR2	47:40	Byte 2 of the address phase
ADDR1	39:32	Byte 1 of the address phase
ADDR0	31:24	Byte 0 of the address phase
DATA1/MODE1	23:16	Byte 1 of the data/mode phase
DATA0/MODE0	15:8	Byte 0 of the data/mode phase
Reserved	7	N/A
Instruction Type	6:0	This field defines the type (index) of the instruction. A description of each value and its corresponding instruction can be found in the section, Instruction Type Variants.

Table 21-23: Generic Command STIG Instruction

Name	Bits	Description
Reserved	127:125	N/A
Instruction Termination (INSTR_LINK)	124	This bit is only relevant when the instruction_type field of the instruction=0, 32, 36 or 96. Refer to section Instruction Type Variants for details on the instruction type setting. The field assigned to this bit indicates whether the instruction is to be terminated (CS must be deactivated after the instruction finishes) or glued with the next instruction (providing it is ready to be fetched from the command FIFO). 0 – Current sequence is terminated and not glued with another instruction of the same type 1 – Current sequence is glued with the next STIG instruction
Reserved	123:118	N/A
CRC Enable (CRC_EN)	117	Set to enable dynamic CRC calculation and output this value on the xSPI flash interface. The transfer modes are specified by ADDR_EDGE_MODE and ADDR_NO_OF_IOS configuration. If the octal DDR (8D) variant is configured, the calculated CRC byte is maintained for a full flash clock cycle.
Reserved	116:111	N/A
Bank Number (BANK_NUM)	110:108	This field informs the controller on which memory device the sequence should be executed. This information directly maps to the chip select (CS) pin.
Edge Mode (EDGE_MODE)	107	This bit selects SDR or DDR operation at the memory device. 0 – SDR 1 – DDR
Reserved	106	N/A
IO Mode (NO_OF_IOS)	105:104	Determines number of active IOs for the instruction 0 – Single 1 – Dual 2 – Quad 3 – Octal
Reserved	103:92	N/A

Table 21-23: Generic Command STIG Instruction (Continued)

Name	Bits	Description
Number of bytes (NO_OF_BYTES)	91:88	Determines the number of bytes to be sent in the instruction At least one byte must be sent, but no more than 10 bytes in one sequence. If EDGE_MODE and NO_OF_IOS configuration determines the octal DDR variant, two bytes must be sent in a single flash clock cycle. The host must configure an even number of bytes in the quoted case (allowable NO_OF_BYTES = 0 or 2 or 4 or 6 or 8 or 10). If the host configures NO_OF_BYTES = 1 or 3 or 5 or 7 or 9, the controller does not accept the transfer request and generates an error.
BYTE9	87:80	The 10th byte sent when NO_OF_BYTES = 10
BYTE8	79:72	The 9th byte sent when NO_OF_BYTES ≥9
BYTE7	71:64	The 8th byte sent when NO_OF_BYTES ≥8
BYTE6	63:56	The 7th byte sent when NO_OF_BYTES ≥7
BYTE5	55:48	The 6th byte sent when NO_OF_BYTES ≥6
BYTE4	47:40	The 5th byte sent when NO_OF_BYTES ≥5
BYTE3	39:32	The 4th byte sent when NO_OF_BYTES ≥4
BYTE2	31:24	The 3rd byte sent when NO_OF_BYTES ≥3
BYTE1	23:16	The 2nd byte sent when NO_OF_BYTES ≥2
BYTE0	15:8	The 1st byte sent
Reserved	7	N/A
Instruction Type	6:0	This field defines the type (index) of the instruction. A description of each value and its corresponding instruction can be found in the section Instruction Type Variants.

Glued Data Instruction

The ***Data Instruction Structure*** table outlines the structure of the main data instruction variant that the host issues as the final glued instruction of a sequence of instructions. This variant cannot be used by itself and must be glued to one of the other variants. It is typically used to define how data is transferred in accordance with the details specified in the other three main command variants. As such, this variant must never be the first instruction issued by the host; it is always the last instruction.

Table 21-24: Data Instruction Structure

Name	Bits	Description
Reserved	127:123	N/A

Table 21-24: Data Instruction Structure (Continued)

Name	Bits	Description
CRC Chunk Size (CRC_CHUNK_SIZE)	122:120	This field presents the size of the CRC chunk as configured in the memory device. It is the number of bytes after which the CRC byte is placed onto the bus. 1 – N/A 2 – 8B chunk size 3 – 16B chunk size 4 – 32B chunk size 5 – 64B chunk size 6 – 128B chunk size 7 – 256B chunk size 8 – 512B chunk size
CRC Read Status Inversion Enable (CRC_INV)	119	This bit controls whether the controller requests one more status slice to check its data integrity. The expectation is that the redundant data chunk will be inverted (as applicable for Macronix MX25 octal devices). If redundant, data from flash is not inverted. A CRC error is generated. This bit must only be set when CRC_EN = 1, DATA_EDGE_MODE = 1 (DDR), DATA_NO_OF_IOS = 3 (octal) and DATA_NO_OF_BYTES = 2 because this set of parameters matches the implementation of Macronix MX25 octal devices. If CRC_INV = 1, the CRC_CHUNK_SIZE configuration is ignored because these two sequence parameters are mutually exclusive.
CRC Output Enable (CRC_OE)	118	This bit specifies whether the CDC is an output on both clock edges, with the CRC being inverted on the second clock edge. 0 – Inverted CRC is not output 1 – Inverted CRC is output
CRC Enable (CRC_EN)	117	This bit is set to enable dynamic CRC calculation and output this value on the xSPI flash interface. The transfer modes are specified by ADDR_EDGE_MODE and ADDR_NO_OF_IOS configurations. If an octal DDR (8D) variant is configured, the calculated CRC byte is maintained for a full flash clock cycle.

Table 21-24: Data Instruction Structure (Continued)

Name	Bits	Description
CRC Unaligned Chunk Enable (CRC_UAL_CHUNK_EN)	116	Setting this bit instructs the controller to take into consideration the command address in determining where the CRC bytes are expected to be returned from the memory device. This bit can be set (=1) only when the sequence (DATA_SEQ) is glued with the READ_PROFILE_1 sequence. It must be cleared (=0), otherwise. For example, if the original flash address is 0x4 and CRC_CHUNK_SIZE is 16B, the first CRC from the device is expected to occur after 12 bytes (CRC_CHUNK_SIZE - (device address)). Only even addresses are supported (when CRC_UAL_CHUNK_EN = 1) as required by Macronix MX25 octal devices.
CRC Unaligned Chunk Check (CRC_UAL_CHUNK_CHK)	115	Set this bit to have the controller check the correctness of a CRC unaligned chunk from a flash device. It can be set (=1) only when CRC_UAL_CHUNK_EN = 1. It must be cleared (=0), otherwise. Because Macronix MX25 octal devices do not guarantee the correctness of CRC calculated for unaligned chunk, the controller provides control of this check. When configured, DATA_NO_OF_BYTES accommodates many CRC chunks; the CRC correctness is checked for all chunk-aligned CRC slices regardless of the CRC_UAL_CHUNK_CHK value.
Reserved	114:113	N/A
Data Swap	112	When set (=1), this bit swaps the order of bytes transferred in a single octal DDR clock cycle. When DATA_EDGE_MODE and DATA_NO_OF_IOS do not reflect the octal DDR mode, this bit should be cleared (=0).
Reserved	111	N/A
Bank Number (BANK_NUM)	110:108	This field informs the controller on which memory device the sequence should be executed. This value directly maps to the chip select (CS) pin.
Data Edge Mode (DATA_EDGE_MODE)	107	This bit selects SDR or DDR operation at the memory device 0 – SDR 1 – DDR
Reserved	106	N/A

Table 21-24: Data Instruction Structure (Continued)

Name	Bits	Description
Data IO Mode (DATA_NO_OF_IOS)	105:104	Determines number of active IOs for all data bytes of the instruction Data bytes associated with the instruction are taken from an internal data FIFO (for write operations) and put into the internal data FIFO (for read operations) 0 – Single 1 – Dual 2 – Quad 3 – Octal
Reserved	103:101	N/A
Transfer Direction (DIR)	100	Determines the direction of the data stream 0 – Read from memory device 1 – Write to memory device
Reserved	99:93	N/A
Data Size per Flash Address Location (DATA_PER_ADDR)	92	Indicates how many bytes of data are assigned to a single flash memory address. The controller uses this information to internally calculate consecutive addresses of all data bytes in a sequence. The address incrementation step is assumed to be 1. 0 – The memory device is byte addressable 1 – The memory device is two byte addressable
Reserved	91:90	N/A
Number of dummy (latency) cycles (NO_OF_DUMMY)	89:84	Indicates the number of dummy cycles before the data phase Note that the definition of latency cycles for legacy HyperFlash, and xSPI profile 2 devices overlaps with the address transfer phase by one clock cycle. The number of required latency cycles is one less than programmed. If an external board delay incurs a few more clock cycle long additional latency (for read commands), compensation is handled by the PHY module.
HyperFlash Read Crossing Boundary Enable (HF_READ_BOUND_EN)	83	The controller uses this bit to calculate a read transaction crossing a page boundary phase in which data is not valid (based on the number of dummy cycles (NO_OF_DUMMY) and the start address of the associated instruction). During the latency period, the device does not generate DQS.
Reserved	82:80	N/A

Table 21-24: Data Instruction Structure (Continued)

Name	Bits	Description
Number of data bytes (DATA_NO_OF_BYTES)	79:48	Indicates the number of data bytes to be sent in the instruction. All data bytes are taken from the data FIFO of the controller (for write operations) and put into the data FIFO (for read operations). When DATA_EDGE_MODE and DATA_NO_OF_IOS configuration indicates the octal DDR variant, two bytes are required to be sent in a single flash clock cycle. Therefore, the host must configure an even number of data bytes. Failure to do this causes the controller to generate an error.
Reserved	47:25	N/A
Status Data Source (STATUS_SOURCE)	24	The bit is valid only when DIR = 0 (read transaction) and there are ≤2 bytes to be read. When there are >2 bytes to be read, this bit should be zero. This bit determines how the host eventually receives the data. If there are ≤ 2 bytes to be read, the host can choose to have the two bytes reported in the STIG status register at offset 0x44. Otherwise, the read data must be fetched using the bus completer AXI interface. 0 – Read data is sent to the AXI bus completer interface 1 – Read data is sent to the STIG status register at offset 0x44
Reserved	23:7	N/A
Instruction Type	6:0	This value is always fixed at 127 for the glued data instruction.

Instruction Type Variants

The *Typical Device Operations* table shows typical operations and the associated value in the instruction type field that the host can carry out on the device using instruction variant 1. The table also outlines whether an instruction supports instruction gluing.

NOTE: If a data instruction is glued to the back of one of the instructions, the data instruction must have an instruction type field configured to 128.

Table 21-25: Typical Device Operations - Variant 1

Operation	Instruction Type	Assumed Instruction Gluing
Read	1	Yes – Glue with data instruction
Read In XIP	1	Yes – Glue with data instruction
Write	0	Yes, if data length is greater than two bytes
Set WEL	0	No
Clear WEL	0	No

Table 21-25: Typical Device Operations - Variant 1 (Continued)

Operation	Instruction Type	Assumed Instruction Gluing
SPI_NAND Read ID	32	Yes – Glue with data or variant instruction

The *Typical Device Operations* table shows typical operations and the associated value in the instruction type field that the host can carry out on the device using instruction variant 2. The table outlines some of the instruction fields that must be forced to a fixed value to carry out the operation, and whether an instruction supports instruction gluing.

The variant should be used when trying to formulate a generic or custom command sequence that is not a known protocol-specific instruction. For this instruction, select an instruction type field of 96. This instruction is permitted to be glued with another variant 3 instruction or with a data sequence instruction.

Table 21-26: Typical Device Operations - Variant 2

Operation	Instruction Type	Assumed Instruction Gluing
Write/Read for HyperRAM Devices	32	Yes – Glue with data or variant instruction
WREN 1	33	No
WREN 2	34	No
Profile 2 Read	35	Yes – Glue with data instruction
Profile 2 Program	36	Yes, if the data length is greater than two bytes. Can glue with data or another variant

Reset/ASO Exit	53	No
Enter Default Protocol Mode	54	No
Read SFDP	55	Yes – Glue with data instruction

Switching Work Modes

STIG work mode provides an interface to execute low-level transactions on the xSPI flash interface. It is expected to be used in conjunction with ACMD or direct work mode. Therefore, switching into and out of STIG mode can become a common requirement. The host software must enter and exit STIG mode when the target xSPI flash device is in the idle state.

Before the host switches to STIG mode, it must wait for all operations that address the same xSPI flash device to be finished. Before the host exits STIG mode, it must check whether the device is in an idle state. Waiting for the last STIG command to complete execution may not be enough for cases where the command caused the xSPI device go into a busy state. In such cases, the host can poll the status register of the device. It can issue STIG instructions to execute read status commands and continue to do this until the memory device has reached an idle state. Once the device is in the idle state, the host can exit STIG mode.

Programming STIG Mode

Complete the following steps to program STIG mode.

1. Wait for xSPI flash controller to be in the idle state, then, poll the `XSPI_GSTAT.CTL_BUSY` bit.
2. Configure the `XSPI_WORKMODE_CTL` field to 2'b01 to enable STIG work mode.
3. Configure the command registers (`XSPI_CMD1` to `XSPI_CMD4`) .
4. Enable the STIG DONE interrupt when completion of the requested STIG transaction must raise external interrupt or sdma_trigg for the AXI bus completer interface transactions. Set the `XSPI_INT_EN.STIG_DONE_EN`, `XSPI_INT_EN.SDMA_TRIGG_EN`, and `XSPI_INT_EN.GINT_EN` bits to enable these interrupts.
5. Start the STIG operation by writing to the `XSPI_CMD0` register. Set `XSPI_GSTAT.GCMD_ENG_MC_BUSY` = 1.
6. Based on the instruction type field, the host must select one of the following:
   - Gluing with a data sequence, proceed to the next step.
   - For other instructions without the gluing condition, skip to step 9.
   - Otherwise, return to configuring the command register step.
7. When the instruction that contains the data sequence command indicates a read direction, and the number of data to be read is one or two bytes and the STATUS_SOURCE field in the instruction =1, then skip to step 9.

In all other cases, proceed to the next step.

8. The host transfers data through the AXI host interface of the controller to complete the STIG operation. In this step, XSPI_GSTAT.GCMD_ENG_MC_BUSY =1.
   a. Poll the XSPI_ISTAT.SDMA_TRIGG bit, or alternatively wait for the interrupt if the SDMA_TRIGG interrupt was unmasked. When XSPI_ISTAT.SDMA_TRIGG =1, proceed.
   b. Read the XSPI_SDMA_SIZ and XSPI_SDMA_TRD_STAT registers to determine the number of bytes to transfer, the thread ID and transfer direction.
   c. Clear the XSPI_ISTAT.SDMA_TRIGG flag.
   d. The external host can now transfer data. For program operations, it is expected that the external host will issue one or more AXI write requests with a total size matching the data transfer indicated in step b. For read operations, it is expected that the external host will issue one or more AXI read requests with a total size matching the data transfer indicated in step b. The external host should issue an address that matches the one reported in the XSPI_SDMA_ADDR0 and XSPI_SDMA_ADDR1 registers.
   e. If the host ignores any of the requirements described above and starts the data transfer when the host DMA is not ready, the XSPI_ISTAT.SDMA_ERR flag is set. If XSPI_INT_EN.SDMA_ERR_EN = 1, an interrupt is also triggered. When XSPI_DMA_CTL.SDMA_ERR_RSP =1, an error response is returned. When XSPI_DMA_CTL.SDMA_ERR_RSP =0, an OK response is returned.
   f. If the host sends an unsupported transaction to the bus completer interface, the bus completer DMA ignores the access and the SDMA_ERR flag in the XSPI_ISTAT register is set. If an AXI error response is detected on the system bus during host DMA transfer, the fail and bus error bits are set in the last operation status. The last operation status can be checked in the XSPI_CMD_STAT register.
   g. Performing transactions in wrong direction (that is, a write transaction to host DMA port in case of sending read operation command to xSPI device) is forbidden and causes the XSPI_ISTAT.SDMA_ERR flag to be set.When XSPI_INT_EN.SDMA_ERR_EN = 1, an interrupt is also triggered. When XSPI_DMA_CTL.SDMA_ERR_RSP =1, an error response is returned. When XSPI_DMA_CTL.SDMA_ERR_RSP =0, an OK response is returned.
9. Wait for the STIG transaction completion status. Poll the COMPLETE bit in the XSPI_CMD_STAT register or view the status through the external interrupt from the STIG_DONE (when correctly enabled by the host). In this step, XSPI_GSTAT.GCMD_ENG_BUSY =1.
10. Check the STIG status by reading the XSPI_CMD_STAT register. In this step, the generic command engine busy flags are programmed to a low value.
11. If another STIG operation must be executed, go to step 3. Otherwise, if the work mode must be changed, wait for the controller idle state by polling the XSPI_GSTAT.CTL_BUSY bit.

STIG Mode Status

The host can check the latest STIG operation status by reading the XSPI_CMD_STAT register.

After every new operation is triggered, the COMPLETE bit is cleared and other bits in the status register are not valid. When the operation completes, the COMPLETE bit is set and other bits in the status register become valid.

Table 21-27: STIG Mode XSPI_CMD_STAT Bit Descriptions

Name	Bits	Description
DATA_FROM_DEV	31:16	This field holds one or two bytes read from memory device. Fields of the DATA_SEQ instruction must be configured as follow: DATA_NO_OF_BYTES = 1 – one byte, or 2 – two bytes STATUS_SOURCE = 1. In other cases, data from the flash device is available on the bus completer data interface.
COMPLETE	15	When set, it denotes that the controller has updated status information and the operation is complete. This bit is set even when the operation ended as a failure.
FAIL	14	When set, it denotes that the operation failed to complete successfully.
Reserved	13:4	N/A
DQS_ERROR	3	The bit indicates that an incorrect DQS pulses number was detected during the data read operation. This is information from the PHY that either the DQS strobe did not appear during read (for example, the device is not connected to the controller) or the RD_DEL_SEL signal value is incorrect (field in the XSPI_PHY_GATE_LPBK_CTL) and data read from flash device are corrupted and read FIFO pointers in the PHY are misaligned. The DLL RESET or RESET signals clear the underrun/overflow flags in the PHY and clear all PHY read data pointers. One of these flags is required by the PHY before continuing to work after a DQS_ERROR assertion.
CRC_ERROR	2	This bit indicates that a CRC error has been received
BUS_ERROR	1	When set, it indicates that the controller received an error response on the system DMA interface.
CMD_ERROR	0	This bit indicates that an invalid command sequence has been detected.

STIG Limitations

STIG mode has the following limitations:

- The HOLD# functionality (alternative function of DQ3 pin of some legacy SPI devices) is not supported in STIG mode. Since STIG mode is fully software controlled, the HOLD# function is not particularly useful. Transfer management can instead be handled by higher-level layers (system layers) throttling when STIG transfers are triggered.
- The xSPI flash controller does not support wrap data flash transfer commands (all data to/from device are considered linear).
- The maximum number of bytes that can be read when using a generic STIG instruction type is limited to 64 bytes. Similarly, a maximum of 64 bytes can be read for all legacy HyperFlash and xSPI profile 2 instructions other than the READ_PROFILE_2 and READ_SFDP_P2.
- If XIP mode is used, the read operation that is used to either enter or exit XIP mode should not attempt to transfer more than 64B.

Sequencing STIG Operation

Internally, the STIG instructions are held in the main data FIFO. Based on the instruction type, glued instructions are sent and buffered in a second-level internal cache FIFO. This cache FIFO can accommodate up to 16 glued sequences (if more glued sequences are requested, an incorrect sequence error is generated). The instructions are processed together when the INSTR_LINK field = 0 of the last instruction in the instruction chain.

Internally, the controller translates the instructions and breaks them down into the correct sequence required by the memory device based on the type of the command. The general structure of xSPI frame is shown in the ***STIG Frame Structure*** diagram.

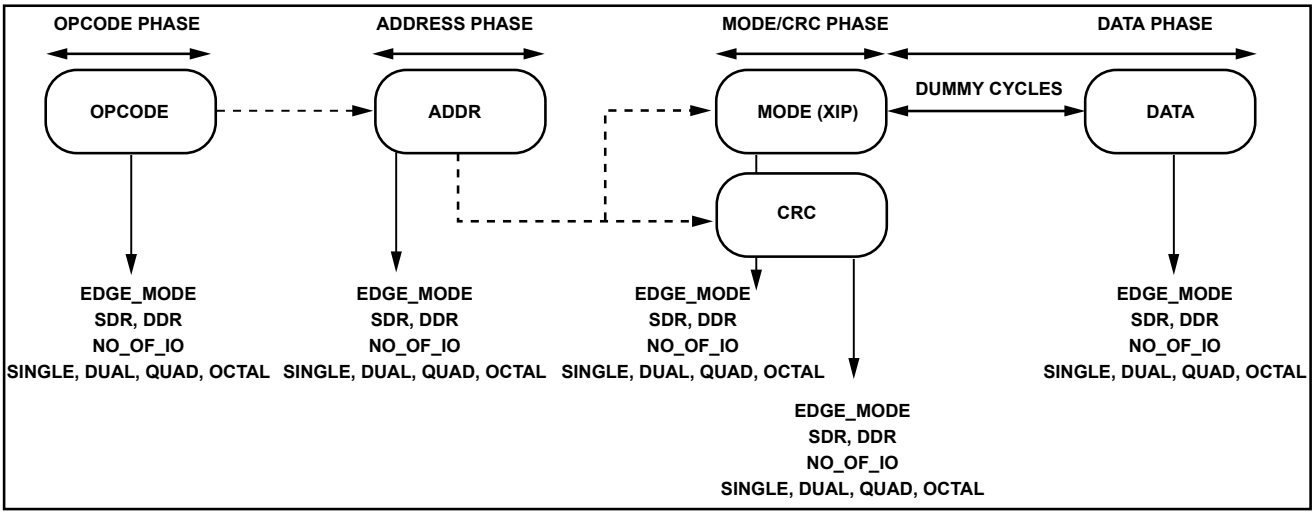

Figure 21-5: STIG Frame Structure

The blocks correspond to xSPI transfer phases. Depending on the individual command layout , some phases may be dropped; however, the order is always maintained.(Refer to JESD216 or a particular xSPI device specification). The EDGE_MODE and NO_Of_IOS can also differ in between phases. Per JESD216, only incremental increases over the number of IOs used or number of clock edges used is permitted. For example, the (opcode=1S, addr=8D, data=8D) transfer variant may be supported by current devices, but, a variant like (opcode=1S, addr=8D, data=4S)

is not. JESD216 does not allow for transfers with a number of active IO lines that differs from one another more than once. Also, note that if any of the phases are configured to be 8D and the associated NO_OF_BYTES corresponds to an odd value, the controller generates an error and does not accept the instruction. The 8D variant always requires an even number of bytes. The flexible command sequence structure of the controller allows any configuration of EDGE_MODE and NO_OF_IOS that provides a future proven solution for new variants of future revisions of JESD216.

Event Handling

The controller reports errors slightly differently depending on the selected work mode:

- For STIG or ACMD PIO work modes, the status is reported using the `XSPI_CMD_STAT` register at offset 0x44.
- For ACMD CDMA work mode, the status is reported using the status field of descriptor associated with a specified thread and the `XSPI_CMD_STAT` register.
- For direct work mode - the DIR_* bits in the `XSPI_ISTAT` register reflect the status.

The ***Error Descriptions*** table identifies the errors that can occur.

Table 21-28: Error Descriptions

Error	Description
DQS Error	This type of error is reported when the attached PHY detects a DQS underrun/overflow situation. When the DQS error is detected then data stream transferred from the xSPI flash memory can be corrupted. The host should assert DLL_RST_N or RST_N to clear DQS underrun/overflow flags in the PHY and clear all PHY read data pointers.
System Bus Error	For ACMD or STIG work modes, for the AXI bus completer interface, this error is reported when: 1. The host attempts to access the bus completer interface before it is permitted (refer to the required steps in STIG and ACMD sections of this document). 2. The host issues an unsupported burst type. The controller only supports incremental (non-wrapping) bursts. For the AXI bus requester interface (not applicable for STIG or direct mode) the error may occur when an AXI error response is returned on RRESP or BRESP.

Table 21-28: Error Descriptions (Continued)

Error	Description
CMD Error	STIG mode: This error occurs when the specific STIG sequence as defined in this document is not followed properly. To rectify, review the sequence carefully and repeat. Direct mode: In this mode, the DIR_CMD_ERR interrupt is triggered when the host has issued an AXI transaction that cannot be executed by the controller for one of the following reasons. • The command extension is not enabled when the opcode phase reflects octal DDR mode. • The number of address bytes is not even when the address phase reflects octal DDR mode. • The address value is not even when the address phase reflects octal DDR mode. • The number of data bytes is not even when the data phase reflects octal DDR mode, unless RWDS byte masking functionality is enabled through the direct access configuration register (only available for direct work modes). • The number of bytes for the status checking sequence is not even when data phase reflects octal DDR mode. • Device and controller are configured to work in XIP mode but, the write access was made from the host. • Device and controller are configured to work in XIP mode but, the sending of mode byte (enable/disable) is disabled. • The DATA_PER_ADDR parameter is set and transfer address or transfer size is not even, unless RWDS byte masking functionality is enabled through the direct access configuration register (only available for direct work modes). • Word size (sAWSIZE or sARSIZE) is greater than the selected page size in profile 1 or profile 2 - HF. ACMD mode: Conditions which cause the CMD_ERROR being triggered are described in the section, Rules and Limitations.
CRC Error	When CRC checking is enabled, this error is reported when the controller has detected a CRC error.
Device Error	A device error is reported when the attached memory device returned fail after checking the status of the last erase/program/read operation. It is applicable only for ACMD and direct work modes. The status of a read operation is only checked for SPI NAND devi-

Table 21-28: Error Descriptions (Continued)

Error	Description
	ces. Detecting an error in this case means that the device returned an uncorrectable ECC error.
ECC Error	An ECC correctable error is reported when the attached memory device returns a correctable error during a read operation and when the XSPI_STAT_SEQ_CFG10.ECC_FAIL_EN field is set in the register.

Device Discovery

Device discovery (DD) is used to identify the memory device and pre-configure controller registers to the required state automatically following power on reset. Automated device discovery is implemented in the controller using the SFDP as defined in JEDEC standard JESD216. The SFDP standard provides a consistent method of describing the functional and feature capabilities of serial flash devices in a standard set of parameter tables. The SFDP must be implemented in the attached memory device for discovery to be successful.

Device discovery can be triggered in two ways — automatically, following power on reset (by default, this always occurs, unless the controller input discovery_inhibit is set (=1), or manually using the discovery control XSPI_DISCOVERY_GCTL register.

Discovery Modes

Device discovery can automatically identify the memory device at power on reset and initialize many of the controller registers. However, the user can alternatively choose to trigger device discovery manually. There are three modes of operation for device discovery: full automatic, preconfigured SFDP, and preconfigured non-SFDP.

Full Automatic Mode Detection - In this default mode, the controller must first determine how to communicate with an unknown device. Per JESD216, if the memory device supports device discovery, it must also support the read SFDP command. The controller, therefore, attempts to communicate by sending read SFDP commands in different transfer formats. Each time it waits for an indication that the device has interpreted the command successfully. When a valid SFDP header is recognized, the controller knows which transfer format has been successful. It proceeds automatically to fetch and decode the SFDP database residing within the device. As the database is fetched from the device, the controller updates the controller registers accordingly.

To trigger device discovery using this mode as part of power on reset initialization, ensure inputs XSPI_DISCOVERY_GCTL.INHIBIT = 0 and XSPI_DISCOVERY_GCTL.NUM_LINES = 0.

To trigger device discovery using this mode from the registers, write the following values to the XSPI_DISCOVERY_GCTL register.

- XSPI_DISCOVERY_GCTL.REQ_TYP = 0
- XSPI_DISCOVERY_GCTL.NUM_LINES = 0
- XSPI_DISCOVERY_GCTL.REQ = 1

When operating in full automatic mode detection, the initial querying of the memory device to identify the correct transfer mode is performed as part of the controller's initialization process. Once completed, the XSPI_DISCOVERY_GCTL register (at 0x260) is automatically updated.

Preconfigured SFDP mode - If the user already knows what memory device the controller is connected to and that SFDP is supported, the controller does not need to query the device with different transfer formats of the read SFDP command. Device discovery is triggered as in full automatic detection mode, but it bypasses the initial sequence to identify the required transfer mode. This can speed up the device identification process.

To trigger device discovery using this mode as part of power on reset initialization, ensure inputs XSPI_DISCOVERY_GCTL.INHIBIT = 0 and XSPI_DISCOVERY_GCTL.NUM_LINES !=0. To trigger device discovery using this mode from registers, write the following values to the XSPI_DISCOVERY_GCTL register:

- XSPI_DISCOVERY_GCTL.REQ_TYP = 0
- XSPI_DISCOVERY_GCTL.NUM_LINES != 0 (choose the value suited to the attached device, refer to the XSPI_DISCOVERY_GCTL register definition for details)
- XSPI_DISCOVERY_GCTL.REQ = 1

Preconfigured non-SFDP mode - In this mode, the controller does not attempt to fetch the SFDP database from the memory device. This alternative configuration method allows the controller to operate with a pre-known memory device. It is optional, and the user can alternatively program each controller register manually.

To trigger device discovery using this mode as part of power on reset initialization, ensure inputs XSPI_DISCOVERY_GCTL.INHIBIT = 1 and XSPI_DISCOVERY_GCTL.NUM_LINES !=0. To trigger device discovery using this mode from the registers, write the following values to the XSPI_DISCOVERY_GCTL register:

- XSPI_DISCOVERY_GCTL.REQ_TYP = 1
- XSPI_DISCOVERY_GCTL.NUM_LINES != 0 (choose the value suited to the attached device, refer to the XSPI_DISCOVERY_GCTL register definition for details)
- XSPI_DISCOVERY_GCTL.REQ = 1

Discovery Flow

The ***Discovery Flow Diagram*** shows the operations and decisions that are part of the device discovery process.If device discovery is inhibited, or no valid SFDP header or parameter page header is recognized during the flow, the SFDP database/parameter page cannot be obtained from the device and all controller registers retain the reset values.

The host must not trigger any operation while device discovery is in progress. The discovery process completion is marked by the controller setting the XSPI_DISCOVERY_GCTL.PASS bit. When full automatic mode is in use, discovery is complete when either the INIT_COMP pin is high, or XSPI_GSTAT.INIT_PASS =1.

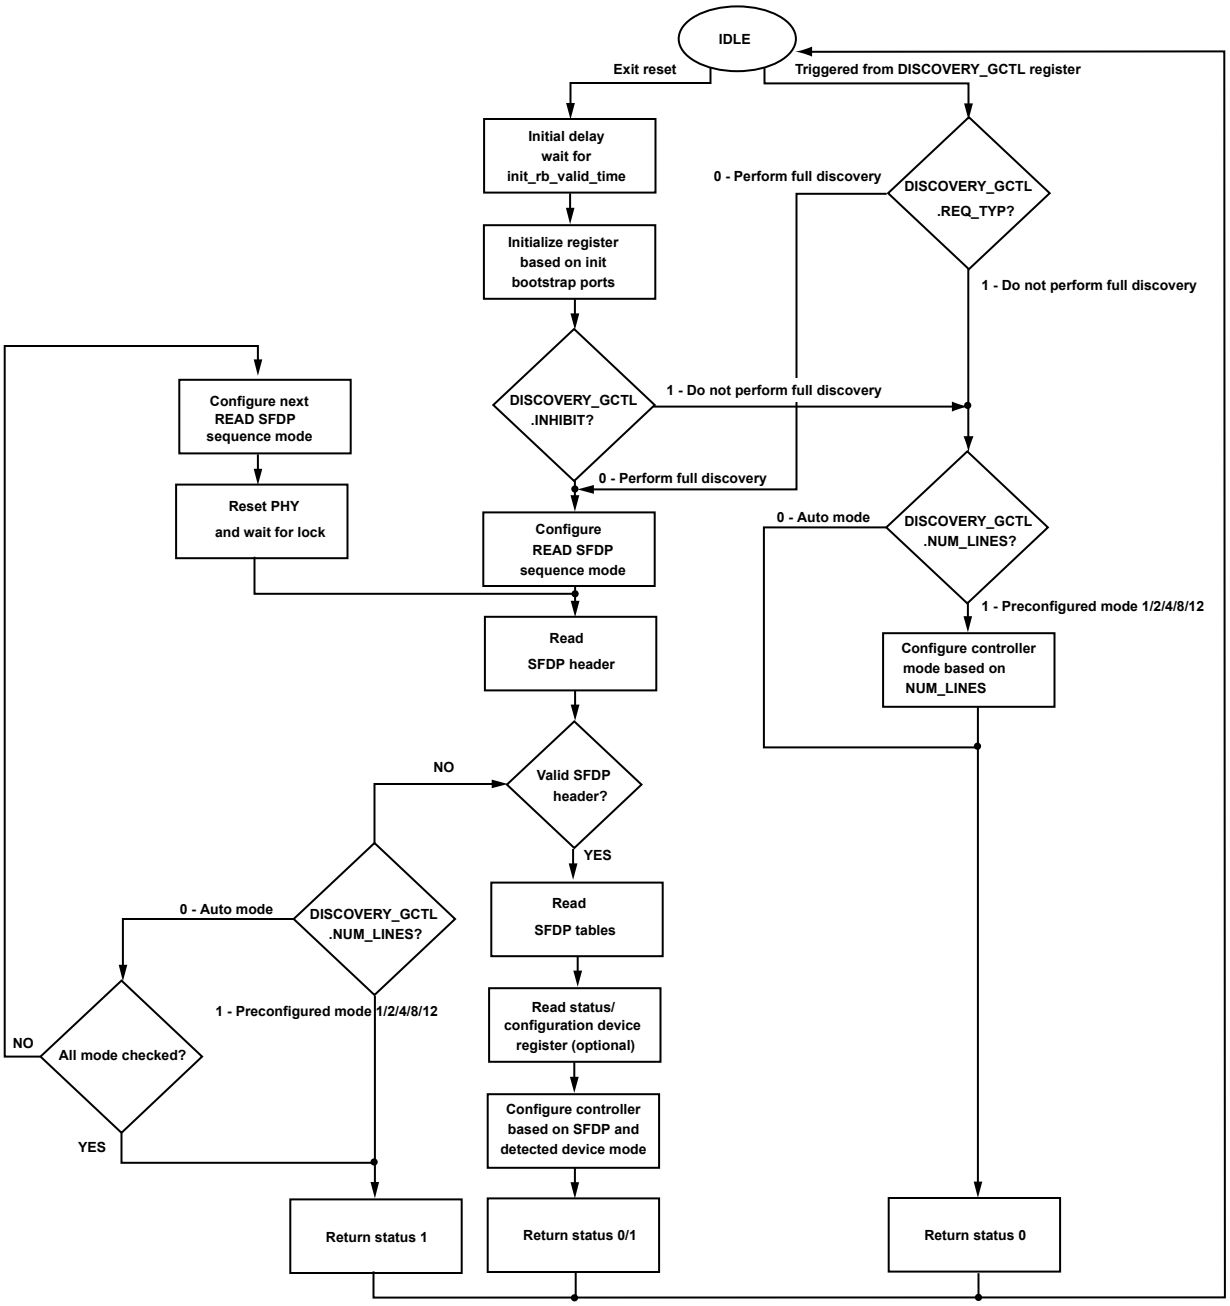

Figure 21-6: Device Discovery Flow

SFDP Command Structure

When full automatic mode detection is active, the controller must determine how to communicate with the device. It communicates by repeatedly sending read SFDP commands in different transfer formats. This mode is selected when `XSPI_DISCOVERY_GCTL.NUM_LINES` signals is configured to 4'd0. The algorithm that the controller executes differs from the suggested algorithm presented in the JESD216 specification document. The algorithm starts with single mode, goes through dual, quad, and octal modes, and finishes with the read SFDP command (compliant with legacy HyperFlash and xSPI profile 2.0).

The read SFDP commands are sent in the following order. If the device does not successfully interpret any of these steps, the device discovery is deemed to have failed.

1. 1S-1S-1S — opcode, address and data phases used for reading SFDP database are sent on one line in SDR mode. Command uses three address bytes and eight dummy clock cycles.
2. 1D-1D-1D — opcode, address and data phases used for reading SFDP database are sent on one line in DDR mode. Command uses three address bytes and eight dummy clock cycles.
3. 2S-2S-2S — opcode, address and data phases used for reading SFDP database are sent on two lines in SDR mode. Command uses three address bytes and eight dummy clock cycles.
4. 2D-2D-2D — opcode, address and data phases used for reading SFDP database are sent on two lines in DDR mode. Command uses three address bytes and eight dummy clock cycles.
5. 4S-4S-4S — opcode, address and data phases used for reading SFDP database are sent on four lines in SDR mode. Command uses three address bytes and eight dummy clock cycles.
6. 4D-4D-4D (Quad DDR* - presented as 4S-4D-4D in JESD216 specification) — opcode, address, and data phases used for reading SFDP database are sent on four lines. The opcode phase is sent in DDR mode with enabled command extension value. Address and data phases are sent in DDR mode. Command uses 3 address bytes and eight dummy clock cycles.
7. 4D-4D-4D (Quad DDR) — opcode, address and data phases used for reading SFDP database are sent on four lines in DDR mode. Command uses three address bytes and eight dummy clock cycles.
8. 8S-8S-8S — opcode, address and data phases used for reading SFDP database are sent on eight lines in SDR mode. Command uses three address bytes and eight dummy clock cycles.
9. 8S-8S-8S — opcode, address and data phases used for reading SFDP database are sent on eight lines in SDR mode. Command uses four address bytes and 20 dummy clock cycles. The opcode is sent twice and the second one is logical negation of the first one.
10. 8D-8D-8D — opcode, address and data phases used for reading SFDP database are sent on eight lines in DDR mode. Command uses four address bytes and 8 dummy clock cycles. The opcode extension is repetition of the opcode.
11. 8D-8D-8D — opcode, address and data phases used for reading SFDP database are sent on eight lines in DDR mode. Command sends the address over two clock cycles (meaning four bytes are send as this is octal DDR), but only three address bytes are valid. The opcode extension is repetition of the opcode.
12. 8D-8D-8D — opcode, address and data phases used for reading SFDP database are sent on eight lines in DDR mode. Command uses four address bytes and 20 dummy clock cycles. The opcode extension is logical negation of the opcode.
13. 8D-8D-8D — read SFDP command for legacy HyperFlash and xSPI profile 2.0 memory devices with 15 latency clock cycles. When preconfigured mode is selected, the above step is not required.

To use preconfigured mode in device discovery, configure the parameters of the read SFDP (READ_SFDP) instructions using `XSPI_DISCOVERY_GCTL` register fields shown in the following table.

Table 21-29: Read SFDP Command Variations - XSPI_DISCOVERY_GCTL Register

							XSPI_SEQ_GCTL1.PLANE_CNT parameter value.
14	N/A	N/A	0/1	0/1	N/A	1	Read parameter page command in 1-1-1 mode for legacy SPI NAND device (at PoR command is not send to device). CMD_TYP field/port is used to set XSPI_SEQ_GCTL1.PLANE_CNT parameter value.

SPI NAND Workflow

When connected to an SPI NAND memory device, the device discovery executes the following commands to read the parameter page database from the flash device:

1. Wait for MISCREG_XSPI_CTL1.RB_VLD_TM- this step is done only when device discovery is enabled at PoR. The RB_VALID_TIME is taken from the MISCREG_XSPI_CTL1 32-bit controller input.
2. Send 8'hFF reset command if MISCREG_XSPI_CTL0.EXTP_VL bootstrap port is 0, otherwise the reset command is not sent - this step is done only when device discovery is enabled at PoR.
3. Wait for the device ready state by reading the OIP bit in the flash device (get feature command 8'h0F with one address byte 8'hC0) - this step is done only when device discovery is enabled at PoR and if MISCREG_XSPI_CTL0.EXTP_VL - bootstrap port is 1'b0.
4. Read configuration register (get feature command 8'h0F with one address byte 8'hB0).
5. Configure bit 6th in the configuration register to enter parameter page read mode (configure feature command 8'h1F with one address byte 8'hB0).
6. Send read page 13h command with the block address of 24'h0001.
7. Wait for device ready state by reading the OIP bit in the flash device (get feature command 8'h0F with one address byte 8'hC0).
8. Send the read from cache 8'h0B command with the page address of 16'd0 and eight dummy clock cycles to fetch the parameter page signature.

9. Send the read from cache 8'h0B command with the page address of 16'd80 and eight dummy clock cycles to fetch the page size, page size extension and block size.
10. Restore the value in the configuration register read in step 3 (configure feature command 8'h1F with one address byte 8'hB0).
11. If a valid parameter page header was received, then configure the controller to SPI NAND mode.
12. Return status.

Discovery Status

When device discovery is performed as part of controller initialization, the status can be interpreted by looking at the INIT_FAIL controller output as follows.

NOTE: In the *Discovery Status Parameters* table, the controller's parameters related to CRC are updated to the values from the bootstrap ports (discovery_crc_*) except where invalid values of `XSPI_DISCOVERY_GCTL.NUM_LINES` are configured, or where the controller failed to detect the device accurately.

Table 21-30: Discovery Status Parameters

`XSPI_DISCOVERY_GCTL.INHIBIT`	**`XSPI_DISCOVERY_GCTL.NUM_LINES`**[3:0]	**Description** **(INIT_FAIL status is valid when INIT_PASS = 1)**
1	0	INIT_FAIL = 2'b00 – Device discovery is disabled Note that the PHY registers are still updated separately – see the section xSPI PHY Controller.
1	1, 2, 4, 8 or 12	INIT_FAIL = 2'b00 – The SFDP database was not read. The controller was, however, configured to the selected mode.
1	14	INIT_FAIL = 2'b00 – The SFDP database was not read. The controller was, however, configured to SPI NAND mode.
1	3, 5, 6, 7, 9, 10, 11, 13 or 15	INIT_FAIL = 2'b00 – The SFDP database was not read. Invalid configuration of `XSPI_DISCOVERY_GCTL.NUM_LINES`. The controller registers remain unchanged.
0	0	INIT_FAIL = 2'b00 – Device discovery enabled and detected an xSPI profile 1 device or profile 2 device during auto-detection mode. INIT_FAIL = 2'b10 – Device discovery enabled and detected a legacy SPI device during auto-detection mode INIT_FAIL = 2'b01 – Device discovery enabled but did not detect a device during auto-detection mode.

Table 21-30: Discovery Status Parameters (Continued)

XSPI_DISCOVERY_GCTL.INHIBIT	**XSPI_DISCOVERY_GCTL.NUM_LINES**[3:0]	**Description** **(INIT_FAIL status is valid when INIT_PASS = 1)**
0	1, 2, 4, 8 or 12	INIT_FAIL = 2'b00 – Device discovery enabled and detected an xSPI profile 1 device or profile 2 device during preconfigured detection mode. INIT_FAIL = 2'b10 – Device discovery enabled and detected a legacy SPI device during pre-configured detection mode. INIT_FAIL = 2'b01 – Device discovery enabled but did not detect a device during preconfigured-detection mode.
0	14	INIT_FAIL = 2'b00 – Device discovery enabled and detected a legacy SPI NAND device during pre-configured detection mode. INIT_FAIL = 2'b01 – Device discovery enabled but did not detect a legacy SPI NAND device during preconfigureddetection mode.
0	3, 5, 6, 7, 9, 10, 11, 13 or 15	INIT_FAIL = 2'b01 – Invalid configuration on XSPI_DISCOVERY_GCTL.NUM_LINES. The controller registers remain unchanged.

When device discovery is triggered from the registers, the same status can be interpreted using the XSPI_DISCOVERY_GCTL.FAIL field of the discovery control register.

XSPI_DISCOVERY_GCTL.INHIBIT	**XSPI_DISCOVERY_GCTL.NUM_LINES**[3:0]	**Description** **(XSPI_DISCOVERY_GCTL.FAIL** **status is valid when XSPI_DISCOVERY_GCTL.PASS** **= 1)**
0	0	XSPI_DISCOVERY_GCTL.FAIL = 2'b00 – Device discovery enabled and detected an xSPI profile 1 device or profile 2 device during auto-detection mode. XSPI_DISCOVERY_GCTL.FAIL = 2'b10 – Device discovery enabled and detected a legacy SPI device during auto-detection mode. XSPI_DISCOVERY_GCTL.FAIL = 2'b01 – Device discovery enabled but did not detect a device during auto-detection mode.

XSPI_DISCOVERY_GCTL.INHIBIT	XSPI_DISCOVERY_GCTL.NUM_LINES[3:0]	Description (XSPI_DISCOVERY_GCTL.FAIL status is valid when XSPI_DISCOVERY_GCTL.PASS = 1)
0	1, 2, 4, 8 or 12	XSPI_DISCOVERY_GCTL.FAIL = 2'b00 – Device discovery enabled and detected an xSPI profile 1 device or profile 2 device during preconfigured detection mode. XSPI_DISCOVERY_GCTL.FAIL = 2'b10 – Device discovery enabled and detected a legacy SPI device during pre-configured detection mode. XSPI_DISCOVERY_GCTL.FAIL = 2'b01 – Device discovery enabled but did not detect device during preconfigured detection mode. Presents how to configure device discovery module in preconfigured detection mode.
0	14	XSPI_DISCOVERY_GCTL.FAIL = 2'b00 – Device discovery enabled and detected a legacy SPI NAND device during pre-configured detection mode. XSPI_DISCOVERY_GCTL.FAIL = 2'b01 – Device discovery enabled but did not detect a legacy SPI NAND device during preconfigured detection mode.
0	3, 5, 6, 7, 9, 10, 11, 13 or 15	XSPI_DISCOVERY_GCTL.FAIL = 2'b01 – Invalid configuration of XSPI_DISCOVERY_GCTL.NUM_LINES. The controller registers remain unchanged.
1	1, 2, 4, 8 or 12	XSPI_DISCOVERY_GCTL.FAIL = 2'b00 – The SFDP database was not read. The controller is configured to the selected mode.
1	14	XSPI_DISCOVERY_GCTL.FAIL = 2'b00 – The SFDP database was not read. The controller is configured to SPI NAND mode.

Discovery Restrictions

As defined in the JESD216 standard, flash devices can implement various parameter tables. But, only the JEDEC basic flash parameter table is mandatory. The following restrictions apply to xSPI profile 1 and profile 2 memory devices with a SFDP revision number is greater than or equal to 16'h0107:

- For xSPI profile 1 memory devices that are configured to any mode other than single, the SFDP database must implement the SCCR (status, control and configuration register) map for the xSPI memory devices parameter table. This implementation allows the controller to update its registers accurately. If the device does not implement the map fully, some of the sequence-related registers of the controller can get commonly used values instead.

- For xSPI profile 2 memory device, the SFDP database must implement the SCCR map for xSPI profile 2 memory devices parameter table. This implementation allows the controller to update its registers accurately. If the device does not implement the map fully, some of the sequence-related registers of the controller can get commonly used values instead.

Discovery Limitations

Note the following device discovery limitations:

- The device discovery module must not be used to detect a device that is configured to operate in XIP mode.
- The device discovery module must not be used to detect the HyperRAM device. Only profile 1, profile 2 - HF and SPI NAND devices are supported for device discovery.

Legacy Devices

When the number of dummy clock cycles for a read command (READ_SEQ_PL_DUMMY_CNT) parameter cannot be read from the device status/configuration register, the controller configures a default value for single, dual, quad modes or 16/20 for octal modes. The device discovery module ends with a 2'b10 status, but, with the wrong number of dummy clock cycles. In a similar way, if the number of dummy clock cycles for a status checking command (READ_SEQ_PL_DEV_RDY_DUMMY_CNT) cannot be read from the from the SFDP database, the device discovery module configures a default value. See the section Controller Reconfiguration.

Device Specific Configuration

Macronix MX25 octal devices - To configure the controller to STR-OPI mode without trying to read SFDP database, device discovery must be run in not full discovery pre-configuration mode:

- `XSPI_DISCOVERY_GCTL.INHIBIT` = 1 or `XSPI_DISCOVERY_GCTL.REQ_TYP` = 1
- `XSPI_DISCOVERY_GCTL.NUM_LINES` = 8
- `XSPI_DISCOVERY_GCTL.ABNUM` = 1
- `XSPI_DISCOVERY_GCTL.DMY_CNT`= 1
- `XSPI_DISCOVERY_GCTL.CMD_TYP` = 0
- `XSPI_DISCOVERY_GCTL.OE_EN` = 1
- `XSPI_DISCOVERY_GCTL.OE_VAL` = 1.

To configure the controller to DTR-OPI mode without trying to read SFDP database, device discovery must be run in not full discovery pre-configuration mode:

- `XSPI_DISCOVERY_GCTL.INHIBIT` = 1 or `XSPI_DISCOVERY_GCTL.REQ_TYP`= 1
- `XSPI_DISCOVERY_GCTL.NUM_LINES` = 8
- `XSPI_DISCOVERY_GCTL.ABNUM` = 1
- `XSPI_DISCOVERY_GCTL.DMY_CNT` = 1

- XSPI_DISCOVERY_GCTL.CMD_TYP = 1
- XSPI_DISCOVERY_GCTL.OE_EN = 0 or 1
- XSPI_DISCOVERY_GCTL.OE_VAL = 1

Controller Reconfiguration

When device discovery completes successfully, the controller automatically updates various registers in the controller. The registers depend on the type of memory device attached. For profile 1 or SPI NAND devices, the registers used to define how the command (opcode), address, and data are transferred between the controller and device. The *Device Discovery Parameter* tables show the parameters in the device sequence registers that require updates.

Table 21-31: Device Discovery Parameters - Profile 1 or SPI NAND devices

Detected/Selected Mode	Command Phase (*cmd_ios, *cmd_edge, *cmd_ext_en, *cmd_ext_val)	Address Phase (*addr_ios, *addr_edge,*addr_cnt)	Data Phase (*data_ios, *data_edge)
Single SDR	0,0, 0, I	0*,0, 3(4)**	0*,0
Single DDR	0,1, 0, I	0*,1, 3(4)**	0*,1
Dual SDR	1,0, 0, I	1,0, 3(4)**	1,0
Dual	1,1, 0, I	1,1, 3(4)**	1,1
Quad SDR	2,0, 0, I	2,0, 3(4)**	2,0
Quad DDR	2,1, 0, I	2,1, 3(4)**	2,1
Quad DDR	2,1, 1, N	2,1, 3(4)**	2,1
Octal SDR without command extension	3,0, 0, I	3,0, 3(4)**	3,0
Octal SDR with command extension repeated	3,0, 1, R	3,0, 3(4)**	3,0
Octal SDR with command extension inverted	3, 0, 1, I	3, 0, 3(4)**	3, 0
Octal DDR with command extension repeated	3, 1, 1, R	3, 1, 4**	3, 1
Octal DDR with command extension inverted	3, 1, 1, I	3, 1, 4**	3, 1
SPI NAND	0, 0, 0, R	0, 0, 2	0, 0

NOTE: • * = single SDR/DDR mode, the number of IOs for address and data phases (for read and program commands) can, in many devices, be reprogrammed higher than what is shown in the table; but, the lower value is chosen as a result of device discovery.

- ** = the number of address bytes for read/program/erase sector commands is configured to four when:
  - the device operates with four address bytes, or
  - when SFDP indicates support for four address byte commands, or
  - when octal DDR mode is detected (in which case only an even number of address bytes can be transferred during the address phase).
  - In all other cases, the device discovery module configures the number of address bytes based on the number of address bytes that is used to detect the device.
- R = the command extension is repeated
- I = the command extension is inverted
- N = command value consists of the first half of the opcode (bits[7:4]) repeated twice, and command extension value consists of second half of the opcode (bits[3:0]) repeated twice. For example, if the attached memory requires 0x12 opcode for a program page operation, then PROG_SEQ_PL_CMD_VAL is configured to 8'h11 and PROG_SEQ_PL_CMD_EXT_VAL is configured to 8'h22. This mode is presented as 4S-4D-4D in the JESD216 specification.

Common Sequence Register Updates

For profile 1, profile 2 (HF) or SPI NAND devices, the ***Device Discovery Parameters*** table shows the common sequence parameters in the `XSPI_SEQ_GCTL0` and `XSPI_SEQ_GCTL1` registers. The registers are updated after discovery.

Table 21-32: Device Discovery Parameters - Profile 1, Profile 2(HF) or SPI NAND devices

Parameter Name	Full Discovery Process	Not Full Discovery Process
TYP	• 0 when a legacy SPI or xSPI profile 1 device is detected • 1 when a legacy HyperFlash or xSPI profile 2 device is detected • 3 when a legacy SPI NAND device is detected.	• 0 for legacy SPI or xSPI profile 1 configuration • 1 for legacy HyperFlash or xSPI profile 2 configuration • 3 for SPI NAND configuration
DATA_PER_ADDR	• 0 when legacy SPI, xSPI profile 1 and SPI NAND devices are detected • 1 when a legacy HyperFlash or xSPI profile 2 device is detected	• 0 for legacy SPI, xSPI profile 1, or SPI NAND configuration • 1 for legacy HyperFlash or xSPI profile 2 configuration

Table 21-32: Device Discovery Parameters - Profile 1, Profile 2(HF) or SPI NAND devices (Continued)

Parameter Name	Full Discovery Process	Not Full Discovery Process
PSIZ_PGM	Value is read from the SFDP database or parameter page	4'd8 for legacy SPI or xSPI profile 1 configuration 4'd9 for legacy HyperFlash or xSPI profile 2 configuration 4'd11 for SPI NAND configuration if `XSPI_DISCOVERY_GCTL.ABNUM` bootstrap port/register field is 1'b0. Otherwise, 4'd12.
PSIZ_RD	For SPI NAND devices, the value is read from the parameter page. Otherwise, 4'd15 value is configured.	4'd15 for profile 1 and profile 2 - HF 4'd11 for SPI NAND configuration if `XSPI_DISCOVERY_GCTL.ABNUM` bootstrap port/register field is 1'b0. Otherwise, 4'd12.
DATA_SWAP	1 when the SFDP header is swapped in octal DDR mode. Otherwise, 0.	1 for legacy SPI or xSPI profile 1 when octal DDR mode is configured, number of address bytes is 4, and number of dummy cycles is 20 1 for legacy HyperFlash or xSPI profile 2 configuration. Otherwise, 0.
CRC_EN	Parameter is updated from bootstrap port signal DISCOVERY_SEQ_CRC_EN after controller initialization process only	Parameter is updated from bootstrap port signal DISCOVERY_SEQ_CRC_EN after controller initialization process only
CRC_VAR	Parameter is updated from bootstrap port signal DISCOVERY_SEQ_CRC_VARIANT after controller initialization process only	Parameter is updated from bootstrap port signal DISCOVERY_SEQ_CRC_VARIANT after controller initialization process only
CRC_OE	Parameter is updated from bootstrap port signal DISCOVERY_SEQ_CRC_CHUNK after controller initialization process only	Parameter is updated from bootstrap port signal DISCOVERY_SEQ_CRC_OE after controller initialization process only
CHUNK_SIZ	Parameter is updated from bootstrap port signal DISCOVERY_SEQ_CRC_CHUNK_SIZE after controller initialization process only	Parameter is updated from bootstrap port signal DISCOVERY_SEQ_CRC_CHUNK_SIZE after controller initialization process only
UAL_CHUNK_EN	Parameter is updated from bootstrap port signal DISCOVERY_SEQ_CRC_UAL_CHUNK_EN after controller initialization process only	Parameter is updated from bootstrap port signal DISCOVERY_SEQ_CRC_UAL_CHUNK_EN after controller initialization process only
UAL_CHUNK_CHK	Parameter is updated from bootstrap port signal DISCOVERY_SEQ_CRC_UAL_CHUNK_CHK after controller initialization process only	Parameter is updated from bootstrap port signal DISCOVERY_SEQ_CRC_UAL_CHUNK_CHK after controller initialization process only

Table 21-32: Device Discovery Parameters - Profile 1, Profile 2(HF) or SPI NAND devices (Continued)

Parameter Name	Full Discovery Process	Not Full Discovery Process
PSIZ_EXT	For SPI NAND devices, the value is read from the parameter page	64 value is configured if XSPI_DISCOVERY_GCTL.DMY_CNT = 1'b0. Otherwise, 128.
PCA_SIZ	For SPI NAND devices when page size equals 4KB, 1'b1 value is set. Otherwise, 1'b0 value is configured.	Value is configured to the value of XSPI_DISCOVERY_GCTL.ABNUM field/ bootstrap port
PLANE_CNT	Value is configured to the value of XSPI_DISCOVERY_GCTL.CMD_TYP register field/bootstrap port	Value is configured to the value of XSPI_DISCOVERY_GCTL.CMD_TYP register field/bootstrap port
PPER_BLOCK	Value is read from the parameter page	6 (64 pages per block) value is configured
TCMS_EN	1'd0 value is configured	1'd0 value is configured

Reset Sequence Parameters for Profile 1 Devices

For profile 1 devices, the reset sequence registers are used when a reset command is issued to the memory device. The parameters are identified in the XSPI_RST_SEQ_CFG0 and XSPI_RST_SEQ_CFG1 registers. The registers are updated as shown in the ***Reset Sequence Parameters - Profile 1 Devices*** table.

Table 21-33: Reset Sequence Parameters - Profile 1 Devices

Parameter Name	Full Discovery Process	Not Full Discovery Process
XSPI_RST_SEQ_CFG0.CMD0_EN	0 when the device supports the soft reset command - 0xF0	Always 1
XSPI_RST_SEQ_CFG0.CMD0_EN	Always 8'h66 command is configured	Always 8'h66 command is configured
XSPI_RST_SEQ_CFG0.CMD1_VALUE	When the device supports soft reset command, 8'hF0. Otherwise, 8'h99 command is configured.	Always 8'h99 command is configured
XSPI_RST_SEQ_CFG1.P1_DAT_VALUE	Always 8'hD0 value is configured	Always 8'hD0 value is configured
XSPI_RST_SEQ_CFG0.DAT_EN	Always 0	Always 0
XSPI_ERS_SEQ_CFG0.CMD_VALUE	Read from the SFDP database	8'h20 command when XSPI_DISCOVERY_GCTL.ABNUM = 0, 8'h21 command when XSPI_DISCOVERY_GCTL.ABNUM = 1
XSPI_ERS_SEQ_CFG1.P1_SECT_SIZ_VALUE	Read from the SFDP database	Always 4'd12 (4kB)
XSPI_ERS_SEQ_CFG2.ERSA_P1_CMD_VALUE	Always 8'hC7 command is configured	Always 8'hC7 command is configured

Erase Sequence Register Updates

For profile 1 devices, the erase sequence registers are used when an erase_sector or erase_all command is issued to the memory device. The parameters are identified in the XSPI_ERS_SEQ_CFG0, XSPI_ERS_SEQ_CFG1, and XSPI_ERS_SEQ_CFG2 registers. The registers are updated as shown in the ***Erase_Sector / Erase_All Sequence Parameters*** table.

Table 21-34: Erase_Sector / Erase_All Sequence Parameters - Profile 1 Devices

Parameter Name	Full Discovery Process	Not Full Discovery Process
XSPI_ERS_SEQ_CFG0.CMD_VALUE	8'hD8 command is configured	8'hD8 command is configured
XSPI_ERS_SEQ_CFG1.P1_SECT_SIZ_VALUE	Calculated as follow: 2^N, where N=column address size + pages row address size	5'd18 value is configured
XSPI_ERS_SEQ_CFG2.ERSA_P1_CMD_VALUE	Always 8'hC7 command is configured	Always 8'hC7 command is configured

For SPI NAND devices, the erase sequence registers are used when an erase_sector command is issued to the memory device. The parameters are identified in the XSPI_ERS_SEQ_CFG0 and XSPI_ERS_SEQ_CFG1 registers. The registers are updated as shown in the ***Erase_Sector Sequence Parameters*** table.

Table 21-35: Erase_Sector Sequence Parameters - SPI NAND Devices

Parameter Name	Full Discovery Process	Not Full Discovery Process
XSPI_ERS_SEQ_CFG0.CMD_VALUE	8'hD8 command is configured	8'hD8 command is configured
XSPI_ERS_SEQ_CFG1.P1_SECT_SIZ_VALUE	Calculated as follow: 2^N, where N = column address size + pages row address size	5'd18 value is configured
XSPI_ERS_SEQ_CFG2.ERSA_P1_CMD_VALUE	Always 8'hC7 command is configured	Always 8'hC7 command is configured

Write Enable Sequence Register Updates

For profile 1 or SPI NAND devices, the write enable sequence parameters are identified in the XSPI_WE_SEQ_CFG0 register. The registers are used when the controller needs to prepare the device for a program operation. The ***Write Enable Sequence Parameters*** table shows the parameters for full and not full discovery.

Table 21-36: Write Enable Sequence Parameters - Profile 1 and SPI NAND devices

Parameter Name	Full Discovery Process	Not Full Discovery Process
XSPI_WE_SEQ_CFG0.P1_CMD_VALUE	Always 8'h06 command is configured	Always 8'h06 command is configured
XSPI_WE_SEQ_CFG0.P1_EN	Always1'b1 value is set	Always1'b1 value is set

Program Sequence Register Updates

For profile 1, profile 2 HyperFlash, or SPI NAND devices, the program sequence parameters are identified in the XSPI_PROG_SEQ_CFG0, XSPI_PROG_SEQ_CFG1, and XSPI_PROG_SEQ_CFG2 registers. The registers

used when the controller needs to perform a program (write) operation. The parameters are shown in the ***Program Sequence Parameters*** tables.

Table 21-37: Program Sequence Parameters - Profile 1

Detected/Selected Mode	Parameter Name	Full Discovery Process	Not Full Discovery Process
Single	XSPI_PROG_SEQ_CFG0.P1_CMD_VALUE	8'h8E command is configured (1-8-8 with 4 address bytes) when the SFDP database indicates support for this command by device 8'h84 command is configured (1-1-8 with 4 ad-dress bytes) when SFDP database indicates support for this command by device 8'h3E command is configured (1-4-4 with 4 address bytes) when SFDP database indicates indicates support for command by device 8'h34 command is configured (1-1-4 with 4 address bytes) when SFDP database indicates indicates support for this command by device 8'h12 command is configured (1-1-1 with 4 address bytes) when SFDP database indicates indicates support for this command by device Otherwise, 8'h02 command is configured (1-1-1 with 3 or 4 address bytes)	8'h02 command is configured when XSPI_DISCOVERY_GCTL.ABNUM = 0 8'h12 command is configured when XSPI_DISCOVERY_GCTL.ABNUM = 1
Single		6'd0 value is configured	6'd0 value is configured
Dual, Quad, Octal	XSPI_PROG_SEQ_CFG0.P1_CMD_VALUE	8'h12 command is configured when the SFDP database indicates support for this command by device Otherwise, 8'h02 command is configured	8'h02 command is configured when XSPI_DISCOVERY_GCTL.ABNUM = 0 8'h12 command is configured when XSPI_DISCOVERY_GCTL.ABNUM = 1
Dual, Quad, Octal	XSPI_PROG_SEQ_CFG0.P1_DMY_CNT	6'd0 value is configured	6'd0 value is configured

Table 21-38: Program Sequence Parameters - Profile 2 HF Devices

Parameter Name	Full Discovery Process	Not Full Discovery Process
XSPI_PROG_SEQ_CFG2.P2_MSK_CMD_MOD	Always 0 is configured	Always 0 is configured
XSPI_PROG_SEQ_CFG2.P2_BURST_TYP	Always 1 (linear burst) is set	Always 1 (linear burst) is set
XSPI_PROG_SEQ_CFG2.P2_TARGET	Always 0 (memory space) is configured	Always 0 (memory space) is configured

Table 21-38: Program Sequence Parameters - Profile 2 HF Devices (Continued)

Parameter Name	Full Discovery Process	Not Full Discovery Process
XSPI_PROG_SEQ_CFG2.P2_LATENCY_CNT	Parameter is not updated after discovery procedure since it is related with profile 2 - HR which is not supported by the device discovery module	Parameter is not updated after discovery procedure since it is related with profile 2 - HR which is not supported by the device discovery module

Table 21-39: Program Sequence Parameters - SPI NAND Devices

Parameter Name	Parameter Value
XSPI_PROG_SEQ_CFG0.P1_CMD_VALUE	8'h02 command is configured

Read Sequence Register Updates

For profile 1, profile HyperFlash, or SPI NAND devices, read sequence registers are identified in XSPI_READ_SEQ_CFG0, XSPI_READ_SEQ_CFG1 and XSPI_READ_SEQ_CFG2 registers. The registers used when the controller needs to perform a read operation. The parameters are shown in the ***Read Sequence Parameters*** table.

Table 21-40: Read Sequence Parameters - Profile 1 Devices

Detected / Selected Mode	Parameter Name	Full Discovery Process	Not Full Discovery Process
Single	P1_CMD_VALUE	When the SFDP database indicates supporting the command by device: 8'hCC command is configured (1-8-8 with 4 address bytes) 8'h7C command is configured (1-1-8 with 4 address bytes) 8'hEC command is configured (1-4-4 with 4 address bytes) 8'h6C command is configured (1-1-4 with 4 address bytes) 8'hBC command is configured (1-2-2 with 4 address bytes) 8'h3C command is configured (1-1-2 with 4 address bytes) 8'h0C command is configured (1-1-1 with 4 address bytes) Read command value for 1-8-8 mode with 3 or 4 address bytes is read from SFDP database and configured Read command value for 1-1-8 mode with 3 or 4 address bytes is read from SFDP database and configured Read command value for 1-4-4 mode with 3 or 4 address bytes is read from SFDP database and configured Read command value for 1-1-4 mode with 3 or 4 address bytes is read from SFDP database and configured Read command value for 1-2-2 mode with 3 or 4 address bytes is read from SFDP database and configured Read command value for 1-1-2 mode with 3 or 4 address bytes is read from SFDP database and configured Otherwise, 8'h0B command value (1-1-1 with 3 or 4 address bytes)	8'h03 command is configured when `XSPI_DISCOVERY_GCTL.ABNUM` = 0 and `XSPI_DISCOVERY_GCTL.DMY_CNT` = 0 8'h13 command is configured when `XSPI_DISCOVERY_GCTL.ABNUM` = 1 and `XSPI_DISCOVERY_GCTL.DMY_CNT` = 0 8'h0B command is configured when `XSPI_DISCOVERY_GCTL.ABNUM` = 0 and `XSPI_DISCOVERY_GCTL.DMY_CNT` = 1 8'h0C command is configured when `XSPI_DISCOVERY_GCTL.ABNUM` = 1 and `XSPI_DISCOVERY_GCTL.DMY_CNT` = 1
Single	P1_DMY_CNT	Number of dummy clock cycles is read from the SFDP database. For 8'0B and 8'h0C read commands 8 number of dummy cycles are set.	0 dummy clock cycles are configured when `XSPI_DISCOVERY_GCTL.DMY_CNT` = 0, 8 dummy clock cycles are configured when `XSPI_DISCOVERY_GCTL.DMY_CNT` = 1.

Table 21-40: Read Sequence Parameters - Profile 1 Devices (Continued)

Detected / Selected Mode	Parameter Name	Full Discovery Process	Not Full Discovery Process
Dual	P1_CMD_VALUE	Read command is read from the SFDP database.	8'h0B command is configured when XSPI_DISCOVERY_GCTL.ABNUM = 0 8'h0C command is configured when XSPI_DISCOVERY_GCTL.ABNUM = 1
Dual	P1_DMY_CNT	If possible, number of dummy clock cycles is read from the memory configuration/status register. Otherwise, the number of dummy clock cycles is read from the SFDP database.	8 dummy clock cycles are configured when XSPI_DISCOVERY_GCTL.DMY_CNT = 0 10 dummy clock cycles are configured when XSPI_DISCOVERY_GCTL.DMY_CNT = 1
Quad	P1_CMD_VALUE	Read command is read from the SFDP database.	8'h0B command is configured when XSPI_DISCOVERY_GCTL.ABNUM= 0, 8'h0C command is configured when XSPI_DISCOVERY_GCTL.ABNUM = 1.
Quad	P1_DMY_CNT	If possible, the number of dummy clock cycles is read from the memory configuration/status register. Otherwise, the number of dummy clock cycles is read from the SFDP database.	8 dummy clock cycles are configured when XSPI_DISCOVERY_GCTL.DMY_CNT = 0
Octal	P1_CMD_VALUE	8'h0C command is sconfigured when the SFDP database indicates supporting this command by device. Otherwise, 8'h0B command is configured	8'hEC command is configured when XSPI_DISCOVERY_GCTL.ABNUM= 1 XSPI_DISCOVERY_GCTL.DMY_CNT = 1, XSPI_DISCOVERY_GCTL.CMD_TYP[0] = 0 and XSPI_DISCOVERY_GCTL.OE_EN = 1 8'h EE command is configured when XSPI_DISCOVERY_GCTL.ABNUM = 1, XSPI_DISCOVERY_GCTL.DMY_CNT = 1 XSPI_DISCOVERY_GCTL.CMD_TYP[0] =1 8'h 0B command is configured when XSPI_DISCOVERY_GCTL.ABNUM = 0 8'h0C command is configured when XSPI_DISCOVERY_GCTL.ABNUM= 1

Table 21-40: Read Sequence Parameters - Profile 1 Devices (Continued)

Detected / Selected Mode	Parameter Name	Full Discovery Process	Not Full Discovery Process
Octal	P1_DMY_CNT	If possible, number of dummy clock cycles is read from the memory configuration/status register. Otherwise, 16 dummy clock cycles are configured when 8 dummy clock cycles have been used for device detection, or, 20 dummy clock cycles are configured when 20 dummy clock cycles have been used for device detection	16 dummy clock cycles are configured when `XSPI_DISCOVERY_GCTL.DMY_CNT` = 0 20 dummy clock cycles is configured when `XSPI_DISCOVERY_GCTL.DMY_CNT` = 1

Table 21-41: Read Sequence Parameters - Profile 1 Devices (mode byte)

Parameter Name	Full Discovery Process	Not Full Discovery Process
`XSPI_READ_SEQ_CFG1.P1_MB_DMY_CNT`	If possible, (number of clock cycles to send the mode byte (mb_factor) is not greater than `XSPI_READ_SEQ_CFG1.P1_MB_DMY_CNT`), the value equals the P1_MB_DMY_CNT - mb_factor. Otherwise, 0 is configured. mb_factor = 2*(3 — P1_ADDR_IOS— P1_ADDR_EDGE)	Value is computed in the same way as for full discovery process
`XSPI_READ_SEQ_CFG1.P1_MB_EN`	If the basic flash parameter table indicates support for mode byte for the selected read command, then 1. Otherwise, 0.	Always 1'b0
`XSPI_XIP_GCTL.XIP_DIS_MB_VALUE`	Always 8'hFF value	Always 8'hFF value

*When the address phase is in octal DDR mode, then mb_factor = 1.

Table 21-42: Read Sequence Parameters - Profile 2 HF Devices

Parameter Name	Full Discovery Process	Not Full Discovery Process
`XSPI_READ_SEQ_CFG2.P2_LATENCY_CNT`	If possible, the number of latency clock cycles is read from the device status/configuration register. Otherwise, the number of latency clock cycles is configured to the number that is used to read the SFDP database.	Number of latency clock cycles is configured to number that is used to read the SFDP database

Table 21-42: Read Sequence Parameters - Profile 2 HF Devices (Continued)

Parameter Name	Full Discovery Process	Not Full Discovery Process
XSPI_READ_SEQ_CFG2.P2_HF_BOUND_EN	Value is equal to the XSPI_DISCOVERY_GCTL.ABNUM for preconfigured mode, or, 1 for auto-detection mode	Value is equal to the XSPI_DISCOVERY_GCTL.ABNUM
XSPI_READ_SEQ_CFG2.P2_MSK_CMD_MOD	Always 0 is configured	Always 0 is configured
XSPI_READ_SEQ_CFG2.P2_BURST_TYP	Always 1 (linear burst) is configured	Always 1 (linear burst) is configured
XSPI_READ_SEQ_CFG2.P2_TARGET	Always 0 (memory space) is configured	Always 0 (memory space) is configured

Table 21-43: Read Sequence Parameters - SPI NAND Devices

Parameter Name	Parameter Value
XSPI_READ_SEQ_CFG0.P1_CMD_VALUE	8'h0B command is configured
XSPI_READ_SEQ_CFG0.P1_DMY_CNT	8 dummy clock cycles are configured

Table 21-44: Read Sequence Parameters for SPI-NAND Devices (mode byte)

Parameter Name	Parameter Value
XSPI_READ_SEQ_CFG1.P1_MB_EN	0
XSPI_READ_SEQ_CFG1.P1_MB_DMY_CNT	0 dummy clock cycles are configured
XSPI_XIP_GCTL.XIP_DIS_MB_VALUE	Always 8'hFF value
XSPI_READ_SEQ_CFG1.P1_CACHE_RANDOM_READ_EN	0

Status Sequence Register Updates

For profile 1, profile HyperFlash, or NAND devices, the status sequence registers are identified in the XSPI_STAT_SEQ _CFG register. The registers are used when the controller needs to check the status of the memory device. The parameters are shown in the ***Status Sequence Parameters*** table.

Table 21-45: Status Sequence Parameters - Profile 1 Devices

Parameter Name	Full Discovery Process	Not Full Discovery Process
XSPI_ERS_SEQ_CFG0.ADDR_CNT	When possible, the number of address bytes is read from the SFDP database. Otherwise, 2 address bytes are configured for octal DDR mode and 1 address byte is configured.	Four address bytes are configured when XSPI_DISCOVERY_GCTL.ABNUM= 1 and XSPI_DISCOVERY_GCTL.DMY_CNT=1
XSPI_STAT_SEQ_CFG1.P1_ERS_FAIL_ADDR_EN	Address phase is enabled when the SFDP database indicates a requirement of an address phase	Address phase is always disabled

Table 21-45: Status Sequence Parameters - Profile 1 Devices (Continued)

Parameter Name	Full Discovery Process	Not Full Discovery Process
	for reading the erase error bit. Otherwise, the address phase is disabled.	
XSPI_STAT_SEQ_CFG1.P1_ERS_FAIL_DMY_CNT	Number of dummy clock cycles is read from the SFDP database.	8 dummy clock cycles are configured for octal modes. Otherwise, 1 dummy clock cycle is configured when the data phase is in DDR mode and 0 for other cases.
XSPI_STAT_SEQ_CFG2.P1_ERS_FAIL_CMD_VALUE	Command is read from the SFDP database when it indicates support for an erase error bit. Otherwise, the 8'h05 command is configured.	8'h05 command is configured
XSPI_STAT_SEQ_CFG1.P1_PROG_FAIL_ADDR_EN	Address phase is enabled when the SFDP database indicates the requirement of an address phase for reading the program error bit. Otherwise, the address phase is disabled.	Address phase is always disabled
XSPI_STAT_SEQ_CFG1.P1_PROG_FAIL_DMY_CNT	Number of dummy clock cycles is read from the SFDP database	8 dummy clock cycles are configured for octal modes. Otherwise, 1 dummy clock cycle is configured when the data phase is in DDR mode and 0 for other cases.
XSPI_STAT_SEQ_CFG2.P1_PROG_FAIL_CMD_VALUE	Command is read from the SFDP database when it indicates support of the program error bit. Otherwise, the 8'h05 command is configured.	8'h05 command is configured
XSPI_STAT_SEQ_CFG1.P1_DEV_RDY_ADDR_EN	Address phase is enabled when the SFDP database indicates the requirement of an address phase for reading the RDY/ BUSY bit. Otherwise, the address phase is disabled.	Address phase is enabled when XSPI_DISCOVERY_GCTL.ABNUM = 1,XSPI_DISCOVERY_GCTL.DMY_CNT =1, XSPI_DISCOVERY_GCTL.CMD_TYP[0] = 0, and XSPI_DISCOVERY_GCTL.OE_EN = 1
XSPI_STAT_SEQ_CFG1.P1_ERS_FAIL_ADDR_EN	Address phase is enabled when the SFDP database indicates the requirement of an address phase for reading the erase error bit. Otherwise, the address phase is disabled.	Address phase is always disabled
XSPI_STAT_SEQ_CFG1.P1_ERS_FAIL_DMY_CNT	Number of dummy clock cycles is read from the SFDP database	8 dummy clock cycles are configured for octal modes. Otherwise, 1 dummy clock cycle is configured when the data phase is in DDR mode and 0 for other cases.
XSPI_STAT_SEQ_CFG2.P1_ERS_FAIL_CMD_VALUE	Command is read from the SFDP database when it indicates support for the erase error bit. Otherwise, the 8'h05 command is configured.	8'h05 command is configured
XSPI_STAT_SEQ_CFG1.P1_PROG_FAIL_ADDR_EN	Address phase is enabled when the SFDP database indicates the requirement of an address phase for reading the program error bit. Otherwise, the address phase is disabled.	Address phase is always disabled

Table 21-45: Status Sequence Parameters - Profile 1 Devices (Continued)

Parameter Name	Full Discovery Process	Not Full Discovery Process
XSPI_STAT_SEQ_CFG1.P1_PROG_FAIL_DMY_CNT	Number of dummy clock cycles is read from the SFDP database	8 dummy clock cycles are configured for octal modes. Otherwise, 1 dummy clock cycle is configured when the data phase is in DDR mode and 0 for other cases.
XSPI_STAT_SEQ_CFG2.P1_PROG_FAIL_CMD_VALUE	Command is read from the SFDP database when it indicates support for the program error bit. Otherwise, the 8'h05 command is configured.	8'h05 command is configured
XSPI_STAT_SEQ_CFG1.P1_DEV_RDY_ADDR_EN	Address phase is enabled when the SFDP database indicates the requirement of an address phase for reading the RDY/ BUSY bit. Otherwise, the address phase is disabled.	Address phase is enabled when XSPI_DISCOVERY_GCTL.ABNUM= 1, XSPI_DISCOVERY_GCTL.DMY_CNT = 1, XSPI_DISCOVERY_GCTL.CMD_TYP = 0 and XSPI_DISCOVERY_GCTL.OE_EN = 1 or when XSPI_DISCOVERY_GCTL.ABNUM= 1, XSPI_DISCOVERY_GCTL.DMY_CNT=1 and XSPI_DISCOVERY_GCTL.CMD_TYP[0] = 1 Otherwise, the address phase is disabled.
XSPI_STAT_SEQ_CFG1.P1_DEV_RDY_DMY_CNT	Number of dummy clock cycles is read from the SFDP database.	4 dummy clock cycles are set if XSPI_DISCOVERY_GCTL.ABNUM= 1, XSPI_DISCOVERY_GCTL.DMY_CNT= 1, XSPI_DISCOVERY_GCTL.CMD_TYP = 0 and XSPI_DISCOVERY_GCTL.OE_EN is 1 or if XSPI_DISCOVERY_GCTL.ABNUM= 1, XSPI_DISCOVERY_GCTL.DMY_CNT= 1 and XSPI_DISCOVERY_GCTL.CMD_TYP[0] = 1 else 8 dummy clock cycles are configured for other octal modes Otherwise, 1 dummy clock cycles is configured when data phase in DDR mode and 0 in other all other modes
XSPI_STAT_SEQ_CFG2.P1_DEV_RDY_CMD_VALUE	Command is read from the SFDP database when it supports the RDY/BUSY bit. Otherwise, the 8'h05 command is configured.	8'h05 command is configured

Table 21-46: Status Sequence Parameters - Profile 2 HF Devices

Parameter Name	Parameter Value	Not Full Discovery Process
XSPI_STAT_SEQ_CFG4.P2_LATENCY_CNT	When possible, the number of latency clock cycles is read from the device status/configuration register. Otherwise, the number of latency clock cycles is configured to a number that is used to read the SFDP database.	Number of latency clock cycles is configured to a number that is used to read the SFDP database
XSPI_STAT_SEQ_CFG4.P2_MSK_CMD_MOD	Always 0	Always 0

Table 21-47: Status Sequence Parameters

Parameter Name	Parameter Value	Not Full Discovery Process
XSPI_STAT_SEQ_CFG5.PROG_FAIL_EN	1 when the SFDP database indicates support for the program error bit. Otherwise, 0.	Always 0
XSPI_STAT_SEQ_CFG5.PROG_FAIL_SIZ	1 when the data phase reflects octal DDR mode. Otherwise, 0.	1 when the data phase reflects octal DDR mode. Otherwise, 0.
XSPI_STAT_SEQ_CFG5.PROG_FAIL_VALUE	Value is read from the SFDP database when it indicates support for the program error bit. Otherwise, 0.	Always 0
XSPI_STAT_SEQ_CFG5.PROG_FAIL_IDX	Value is read from the SFDP database when it indicates support for the program error bit. Otherwise, 0.	Always 0
XSPI_STAT_SEQ_CFG8.PROG_FAIL_ADDR_VALUE	Value is read from the SFDP database when it indicates support for the program error bit. Otherwise, 0x00000000 address is configured.	Always 0x00000000 address is configured.
XSPI_STAT_SEQ_CFG5.ERS_FAIL_EN	1 when the SFDP database indicates support for the program error bit. Otherwise, 0.	Always 0
XSPI_STAT_SEQ_CFG5.ERS_FAIL_SIZ	1 when the data phase reflects octal DDR mode. Otherwise, 0.	1 when the data phase reflects octal DDR mode. Otherwise, 0.
XSPI_STAT_SEQ_CFG5.ERS_FAIL_VALUE	Value is read from the SFDP database when it indicates support for the erase error bit. Otherwise, 0.	Always 0
XSPI_STAT_SEQ_CFG5.ERS_FAIL_IDX	Value is read from the SFDP database when it indicates support for the erase error bit. Otherwise, 0.	Always 0
XSPI_STAT_SEQ_CFG9.ERS_FAIL_ADDR_VALUE	Value is read from the SFDP database if it indicatesupport for the erase error bit, Otherwise, 0x00000000 address is configured.	Always 0x00000000 address is configured
XSPI_STAT_SEQ_CFG5.DEV_RDY_EN	Always 1	Always 1

Table 21-47: Status Sequence Parameters (Continued)

Parameter Name	Parameter Value	Not Full Discovery Process
XSPI_STAT_SEQ_CFG5.DEV_RDY_SIZ	1 when the data phase reflects octal DDR mode. Otherwise, 0.	1 when the data phase reflects octal DDR mode. Otherwise, 0.
XSPI_STAT_SEQ_CFG5.DEV_RDY_VALUE	Value is read from the SFDP database if it indicates support for the RDY/BUSY bit, Otherwise, 0 for legacy SPI and xSPI profile 1 or 1 for legacy HyperFlash and xSPI profile 2.	0 for legacy SPI and xSPI profile 1 1 for legacy HyperFlash and xSPI profile 2
XSPI_STAT_SEQ_CFG5.DEV_RDY_IDX	Value is read from the SFDP database if it indicates support for the RDY/BUSY bit, Otherwise, 0 for legacy SPI and xSPI profile 1 or 7 for legacy HyperFlash and xSPI profile 2.	0 for legacy SPI and xSPI profile 1 7 for legacy HyperFlash and xSPI profile 2
XSPI_STAT_SEQ_CFG7.DEV_RDY_ADDR_VALUE	Value is read from the SFDP database if it indicates support for the RDY/BUSY bit, Otherwise, 0x00000000 address is configured.	Always 0x00000000 address is configured.

The following status sequence parameters are updated in the XSPI_STAT_SEQ_CFGn registers for SPI NAND devices following device discovery.

Table 21-48: Status Sequence Parameters for SPI NAND Devices

Parameter Name	Parameter Value
XSPI_ERS_SEQ_CFG0.ADDR_CNT	0 (one address byte)
XSPI_STAT_SEQ_CFG1.P1_ERS_FAIL_ADDR_EN	1
XSPI_STAT_SEQ_CFG1.P1_ERS_FAIL_DMY_CNT	0 dummy clock cycles are configured
XSPI_STAT_SEQ_CFG2.P1_ERS_FAIL_CMD_VALUE	8'h0F command is configured
XSPI_STAT_SEQ_CFG1.P1_PROG_FAIL_ADDR_EN	1
XSPI_STAT_SEQ_CFG1.P1_PROG_FAIL_DMY_CNTT	0 dummy clock cycles are configured
XSPI_STAT_SEQ_CFG2.P1_PROG_FAIL_CMD_VALUE	8'h0F command is configured
XSPI_STAT_SEQ_CFG1.P1_DEV_RDY_ADDR_EN	1
XSPI_STAT_SEQ_CFG1.P1_DEV_RDY_DMY_CNT	0 dummy clock cycles are configured
XSPI_STAT_SEQ_CFG2.P1_DEV_RDY_CMD_VALUE	8'h0F command is configured
XSPI_STAT_SEQ_CFG5.PROG_FAIL_SIZ	0
XSPI_STAT_SEQ_CFG5.PROG_FAIL_VALUE	1
XSPI_STAT_SEQ_CFG5.ERS_FAIL_IDX	3
XSPI_STAT_SEQ_CFG8.PROG_FAIL_ADDR_VALUE	32'h00000C0 value is configured

Table 21-48: Status Sequence Parameters for SPI NAND Devices (Continued)

Parameter Name	Parameter Value
XSPI_STAT_SEQ_CFG5.ERS_FAIL_EN	1
XSPI_STAT_SEQ_CFG5.ERS_FAIL_SIZ	0
XSPI_STAT_SEQ_CFG5.ERS_FAIL_VALUE	1
XSPI_STAT_SEQ_CFG5.ERS_FAIL_IDX	2.
XSPI_STAT_SEQ_CFG9.ERS_FAIL_ADDR_VALUE	32'h00000C0 value is configured
XSPI_STAT_SEQ_CFG5.DEV_RDY_EN	1
XSPI_STAT_SEQ_CFG5.DEV_RDY_SIZ	0
XSPI_STAT_SEQ_CFG5.DEV_RDY_VALUE	0
XSPI_STAT_SEQ_CFG5.DEV_RDY_IDX	0
XSPI_STAT_SEQ_CFG7.DEV_RDY_ADDR_VALUE	32'h00000C0 value is configured
XSPI_STAT_SEQ_CFG10.CRDY_VALUE	0
XSPI_STAT_SEQ_CFG10.CRDY_IDX	7
XSPI_STAT_SEQ_CFG10.ECC_FAIL_EN	0
XSPI_STAT_SEQ_CFG10.ECC_FAIL_VALUE	0
XSPI_STAT_SEQ_CFG10.ECC_FAIL_MSK	0

Boot Engine

xSPI controller provides an option to boot directly from the attached memory device using direct mode following controller reset. Alternatively, the controller can use a dedicated boot engine to transfer the boot code from the memory device to an area of host memory. The boot engine automatically triggers a page read command and probes the status of the transfer.

The boot engine assumes that the boot image is stored in the xSPI device connected to bank 0. The boot image is stored in the xSPI memory. It is composed of a configuration record and main data. The configuration record contains the following information:

- Main data size — the overall data size that need to be transferred during boot process
- Host address — the address on the host side where the boot image is transferred
- Image offset — the address inside the xSPI device from where the boot image is transferred
- SPI NAND page size — For NAND devices, this provides the SPI NAND device page size that is used to determine number of read iterations

After the boot process completes, the boot engine module writes the boot operation status. Only a single boot image copy is stored in the xSPI memory. This kind of memory is less prone to errors. So, no additional copies are required.

The figure shows the boot engine module functional diagram.

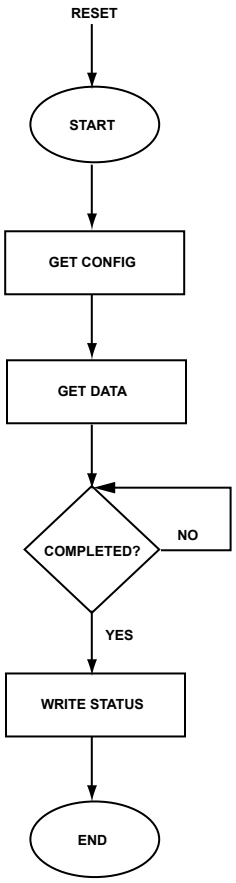

Figure 21-7: Boot Engine Flow

Configuring the Boot Engine

The boot engine is enabled by writing 1 to `MISCREG_XSPI_CTL0.BT_EN` field before doing a controller reset. Once reset is done, the controller fetches a 256-bit configuration record stored in the memory device. This record should have been previously stored in the memory device from address 0x0. The Boot Engine Configuration Record Layout figure provides the details of the required layout of the configuration record.

- Main data size — exists at memory device address 0x00. The lower 32 bits contain the size of the boot record information, the higher 32 bits are reserved.
- Image offset — exists at memory device address 0x08. The lower 48 bits contain the starting address of the boot image within the memory device. The higher 16 bits are reserved.
- Host address — exists at memory device address 0x10. The whole 64 bits contain the host address indicating where the boot image is copied.
- SPI NAND page size — exists at memory device address 0x18. It provides SPI NAND device page size which is used to determine the number of read iterations. Information is stored in the first 16 bits. The upper 48 bits are reserved.

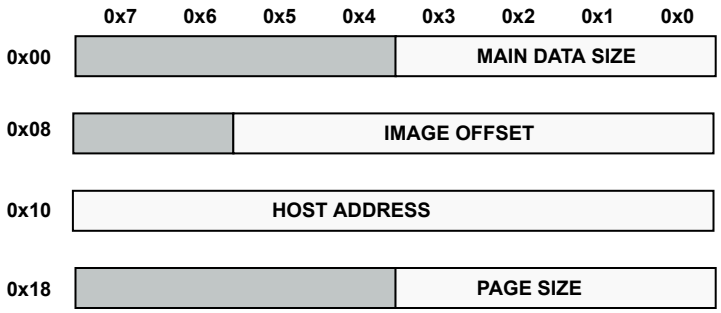

Figure 21-8: Boot Engine Configuration Record Layout

The register fields table shows the bits used by the boot engine to select valid commands and manage data transfer between the xSPI device and host memory. Register content is established by the device discovery process or register field reset vectors. The boot engine assumes that the information in these control registers are valid when boot process is triggered.

The following configuration register fields are used in the boot process:

Table 21-49: Registers for Boot

Register	Bit
XSPI_SEQ_GCTL0	- XSPI_SEQ_GCTL0.TYP - XSPI_SEQ_GCTL0.DAT_SWAP - XSPI_SEQ_GCTL0.UAL_CHUNK_CHK - XSPI_SEQ_GCTL0.UAL_CHUNK_EN - XSPI_SEQ_GCTL0.CHUNK_SIZ - XSPI_SEQ_GCTL0.CRC_OE - XSPI_SEQ_GCTL0.CRC_VAR - XSPI_SEQ_GCTL0.CRC_EN - XSPI_SEQ_GCTL0.DAT_PER_ADDR
XSPI_XIP_GCTL	- XSPI_XIP_GCTL.XIP_DIS_MB_VALUE
XSPI_READ_SEQ_CFG0	- XSPI_READ_SEQ_CFG0.P1_DMY_CNT - XSPI_READ_SEQ_CFG0.P1_DAT_EDGE - XSPI_READ_SEQ_CFG0.P1_DAT_IOS - XSPI_READ_SEQ_CFG0.P1_ADDR_EDGE - XSPI_READ_SEQ_CFG0.P1_ADDR_IOS - XSPI_READ_SEQ_CFG0.P1_ADDR_CNT - XSPI_READ_SEQ_CFG0.P1_CMD_EDGE - XSPI_READ_SEQ_CFG0.P1_CMD_IOS - XSPI_READ_SEQ_CFG0.P1_CMD_VALUE

Table 21-49: Registers for Boot (Continued)

Register	Bit
XSPI_READ_SEQ_CFG1	- XSPI_READ_SEQ_CFG1.P1_CMD_EXT_EN - XSPI_READ_SEQ_CFG1.P1_CMD_EXT_VALUE - XSPI_READ_SEQ_CFG1.P1_MB_EN - XSPI_READ_SEQ_CFG1.P1_MB_DMY_CNT
XSPI_READ_SEQ_CFG2	- XSPI_READ_SEQ_CFG2.P2_LATENCY_CNT - XSPI_READ_SEQ_CFG2.P2_HF_BOUND_EN - XSPI_READ_SEQ_CFG2.P2_MSK_CMD_MOD - XSPI_READ_SEQ_CFG2.P2_BURST_TYP - XSPI_READ_SEQ_CFG2.P2_TARGET
XSPI_STAT_SEQ_CFG0 (only for SPI NAND device)	- XSPI_STAT_SEQ_CFG0.P1_DAT_EDGE - XSPI_STAT_SEQ_CFG0.P1_DAT_IOS - XSPI_STAT_SEQ_CFG0.P1_CMD_EXT_EN - XSPI_STAT_SEQ_CFG0.P1_CMD_EDGE - XSPI_STAT_SEQ_CFG0.P1_CMD_IOS - XSPI_STAT_SEQ_CFG0.P1_ADDR_EDGE - XSPI_STAT_SEQ_CFG0.P1_ADDR_IOS - XSPI_STAT_SEQ_CFG0.P1_ADDR_CNT
XSPI_STAT_SEQ_CFG1(only for SPI NAND device)	- XSPI_STAT_SEQ_CFG1.P1_DEV_RDY_ADDR_EN - XSPI_STAT_SEQ_CFG1.P1_DEV_RDY_DMY_CNT
XSPI_STAT_SEQ_CFG2 (only for SPI NAND device)	- XSPI_STAT_SEQ_CFG2.P1_DEV_RDY_CMD_VALUE
XSPI_STAT_SEQ_CFG3 (only for SPI NAND device)	- XSPI_STAT_SEQ_CFG3.P1_DEV_RDY_CMD_EXT_VALUE
XSPI_STAT_SEQ_CFG5 (only for SPI NAND device)	- XSPI_STAT_SEQ_CFG5.DEV_RDY_SIZ - XSPI_STAT_SEQ_CFG5.DEV_RDY_VALUE - XSPI_STAT_SEQ_CFG5.DEV_RDY_IDX
XSPI_STAT_SEQ_CFG7 (only for SPI NAND device)	- XSPI_STAT_SEQ_CFG7.DEV_RDY_ADDR_VALUE

xSPI PHY Controller

The PHY handles the low-level timings of the data, address, and control signals between the device and controller. The PHY has its own programmable register group.

PHY Initialization

Before the host can communicate with the memory device, software must initialize the PHY and lock it. The soft PHY contains three synthesizable delay lines (DLLs) that are built from 256 delay elements. The first delay line is the controller delay line and it measures how many delay elements are needed to match the XSPI_CLK clock

period. The other two delay lines are targets, one for the transmission TX outbound path and the other for the reception RX inbound path.

The TX target delay line can use the controller delay line measurements to influence how much delay to add to transmitted data based on a percentage of the clock period. This improves the eye diagram (a common indicator of the quality of signals in high-speed digital transmissions) of the memory device. Similarly, the RX target delay line can shift the read sampling clock as a percentage of the clock period to find the ideal sampling point for the inbound read data. Before this can happen however, the controller delay line must be configured and this is done immediately after power on reset (PoR). This is PHY locking, a fully internal PHY function that attempts to lock the bus requestor delay line. Until the PHY is locked, there can be no access to or from the memory device.

When choosing to disable the controller delay line (that is, saturation mode), the target delay line cannot be programmed based on a percentage of the clock period and instead must be manually configured. This is suitable for when operating the PHY at slower data rates, when the controller delay line does not have enough delay elements to measure the complete clock period. Running at these slower rates does not require fine tuning of the target delay lines (when running at SDR) and manual configured is acceptable.

NOTE: PHY locking should not be confused with PHY training. PHY training is a software application (not part of the controller deliverables) that can be implemented to help tune the PHY to find the pbest sampling point and allow the highest possible `XSPI_CLK` frequency. The controller does not implement PHY training.

To lock the controller delay line and have the general PHY ready to transfer data, some of the PHY registers must be programmed with appropriate values that are dependent on the `XSPI_CLK` frequency. The PHY runs at the same frequency as the attached memory device clock and uses system parameters such as board skew, pad delays, and so forth. Failure to program suitable values can result in the PHY inability to lock and unable to properly wake up.

Initial PHY Registers to Configure

The PHY registers that must be initially configured before attempting to lock the PHY are described in the following sections:

- XSPI_PHY_DLL_CTL Register
- XSPI_PHY_DQ_TR Register
- XSPI_PHY_DQS_TR Register
- XSPI_PHY_GATE_LPBK_CTL Register
- XSPI_PHY_DLL_REQ_CTL Register
- XSPI_PHY_DLL_COMP_CTL Register

XSPI_PHY_DLL_CTL Register

This register generally controls how the PHY target delay lines are routinely updated to compensate for drift caused by dynamic factors such as temperature or open-circuit voltage (OCV). It also contains register settings that are dependent on the attached memory device and operating mode.

The XSPI_PHY_DLL_CTL.SDR_EDGE_ACT[21:21] bit controls on which clock edge the PHY controller transmits write data. It is only required for SDR operation and when the PHY controller defaults to propagating write data on the clock rising edge. Generally keep at the default state of zero, unless the memory device (in SDR operation) is unable to sample the data.

The XSPI_PHY_DLL_CTL.DQS_LST_DAT_DRP_EN[20:20] bit must only be set to one, when all of the following conditions are met:

- The attached memory device issues read data on the negative clock edge.
- The memory device supports DQS (transfer two data words per clock cycle) and the PHY has been set up to sample read data using that DQS signal. The DQS that the memory device sends contains one extra edge than normal and the PHY must compensate for the added edge.

XSPI_PHY_DQ_TR Register

This register controls the timing of the main data (DQ) bus as it switches from the PHY to the memory device. Adjustments can be made to control when the attached DQ pads switch direction (that is, to add delay when the output enable switches from input to output and from output to input). There is also an option to define additional latency on the data bus itself, in units of one-half clock cycle.

NOTE: The XSPI_PHY_DQ_TR.DAT_OE_END field (which defaults to 0x2 and controls when the output enable switches from output to input) must always be configured to a minimum value of 0x1. This register does not influence the locking procedure.

XSPI_PHY_DQS_TR Register

This register determines the read data sampling method used by the PHY. See PHY Read Sampling Method Selection for more details.

CAUTION: This register must be updated to reflect the read data sampling method to successfully read any data from the device.

XSPI_PHY_GATE_LPBK_CTL Register

This register controls the gate for read data sampling to occur and enables the loopback BIST test modes within the PHY. There are fields that must be set up prior to locking. When the register fields are not mentioned in this section, the field can be left in its default state.

- XSPI_PHY_GATE_LPBK_CTL.GATE_CFG – Use when the PHY is not using DQS from the device to sample read data. (Determined by the read data sampling method described in PHY Read Sampling Method Selection.) PHY uses information from the controller to determine which cycle the read data should be returning from the device, and when it should be sampling the DQ bus. When the round-trip delay of the entire read operation (based on WRITE CLK PAD delay + PCB trace to device + PCB trace from device + DQ PAD delay) exceeds one clock cycle, then the PHY must also delay the cycle in which it samples that data.

  When DQS from the device is not used to sample read data, the XSPI_PHY_GATE_LPBK_CTL.GATE_CFG field = floor (round-trip delay in ns / clock period in ns)

- XSPI_PHY_GATE_LPBK_CTL.RD_DEL_SEL = ceiling (round-trip delay in ns / clock period in ns) + 2

XSPI_PHY_DLL_REQ_CTL Register

CAUTION: With a small value, the initial lock time is longer. Values less than 0x04 may cause no lock by the delay line.

Use these register fields to configure and direct the controller delay line, prior to the PHY locking.

- XSPI_PHY_DLL_REQ_CTL.DLL_BYPASS_MODE – When set (=1) (default), it disables the controller delay line and the PHY always locks immediately. This forces saturation mode . When the user wants the PHY to operate in saturation mode, this field should be set and the PHY requires no further effort to lock.
- XSPI_PHY_DLL_REQ_CTL.PHASE_DT_SEL – This defaults to zero, but Analog Devices recommends it be configured to 0x2.
- XSPI_PHY_DLL_REQ_CTL.DLL_START_PT – The controller delay line can take some time to measure the clock period and then signal that the lock was achieved. It must start from a fixed number of delay elements and either add or remove delay elements until it finds the appropriate delay matching the clock period. Configuring this field can speed up the locking time. This field should be configured such that it is not greater than 7/8^{ths} of the clock period (use the worst-case element delay).

Example: When the clock frequency is 200 MHz (5 ns cycle time) and a worst-case element delay of 80 ps, this field equals [5 * (7/8) / .080 = 54] elements. When the locking time is not a concern, a small value such as 0x04 can be used instead to ensure that the delay line does not lock on a harmonic.

XSPI_PHY_DLL_COMP_CTL Register

This register controls the TX and RX target delay lines. When the PHY is operating in saturation mode, the number of delay elements can be manually programmed for both delay lines. Otherwise, each delay line can be precisely delayed by steps (1/256th of the clock period). The XSPI_PHY_DLL_COMP_CTL register does not need to be updated to initially lock the PHY, but it must be given appropriate values for the memory device to be able to sample the data sent by the PHY, and for the PHY to sample the data sent by the device.

On the transmit side, the DQ line can be delayed using the TX target delay line. On the receive side, the sampling clock (which depends on the chosen read data sampling method described in PHY Read Sampling Method Selection) is delayed by the RX target delay line. Choose initial values for these fields—setup times, skew between DQS and the data, board delays, and so forth—all affect where the eye diagram begins.

Initial values for the RX target delay line can be calculated using the steps found in the following section. The delivered script automatically calculates the required values, but these are for additional guidance.

IMPORTANT: Performing a full training sequence is the only way to calculate the most optimum delay value to find the center of the eye diagram.

Initial Value Selection for XSPI_PHY_DLL_COMP_CTL Register

1. Express the quarter_cycle_period in picoseconds. For example, when the clock period is 10 ns, configure this field equal to 2500 ps.

2. For the `delay_of_each_element` variable, calculate the expected delay through each implemented PHY delay element in ps. The delay elements within the PHY are made up of two NAND2 gates as selected in the hand instantiated cells. For example, when the delay through each NAND2 is 12 ps, the delay element = 24 ps.
3. Determine the `max_dqs_dq_skew` (in ns) maximum skew between the DQS strobe and the DQ data obtained from the memory device datasheet `tdqsq` value.
4. The `max_dqs_dq_skew_perclk` skew as a percentage of the clock equals `(max_dqs_dq_skew)` divided by the clock period.
5. The `rx_setup time` in ns is the time the device takes to drive the read data following the edge of the clock. This time is specified in the memory device datasheet. Note there are specific times for SDR and for each edge to valid data in DDR. Pick the largest value (worst case).
6. Calculate the `rx_setup_gt_half` value when `rx_setup` is greater than one-half the clock cycle. Determine the difference between these two values in nanoseconds. Formula: `rx_setup_gt_half` = rx_setup – (clock_period / 2).
7. Calculate the `rx_setup_gt_full` value when `rx_setup+4` is greater than a clock cycle. Determine the difference between these two values in nanoseconds. Formula: `rx_setup_gt_full` = rx_setup + 4 – clock_period.
8. Calculate the `tx_setup_de` value. Let `tx_setup` be the setup time in ps, that the target memory device requires before it samples write data. This is often referred to as `tDVCH` in the device data sheet. Divide the `tx_setup` time by the delay of each element to get the number of delay elements needed to cover the set up.
9. Calculate the `tx_skew_margin_de` value for the TX skew margin. Let `quarter_cycle_de` be the quarter_cycle_period variable divided by the delay of each element to get the number of delay elements needed to cover the ¼ of the clock period. Divide again by five to get the number of delay elements needed to cover 1/20th of the clock period. This value is chosen for the TX skew margin.

Value Selection for RX Target Delay Lines

Use the ***RX Target Delay Line Parameters*** table to configure initial values for the RX target delay line.

Table 21-50: RX Target Delay Line Parameters

Parameters	Initial Value to Store in RX Delay Line Field
Saturation Mode = 1 Using DQS from device	`ceiling`((max_dqs_dq_skew*1000) / delay_of_each_element) + 1
Saturation Mode = 1 Using Internal or External Loopback DQS `rx_setup` ≤ half clock period	1

Table 21-50: RX Target Delay Line Parameters (Continued)

Parameters	Initial Value to Store in RX Delay Line Field
Saturation Mode = 1 Using Internal or External Loopback DQS rx_setup > half clock period rx_setup + 4 ≤ clock period	Setup time is quite large relative to the clock period. Need to delay initial sample point accordingly. `ceiling`((rx_setup_gt_half*1000) / delay_of_each_element) + 1
Saturation Mode = 1 Using Internal or External Loopback DQS rx_setup + 4 > clock period	Setup time is very large relative to the clock period. For SDR modes, Analog Devices recommends setting `SDR_EDGE_ACT` to force the capture edge to be negative. `ceiling`((rx_setup_gt_full*1000) / delay_of_each_element) + 1
Saturation Mode = 0 Using DQS from device `max_dqs_dq_skew_perclk` > 1	255
Saturation Mode = 0 Using DQS from device `max_dqs_dq_skew_perclk` ≤ 1	`max_dqs_dq_skew_perclk` * 256 + 0.01*256
Saturation Mode = 0 Using Internal or External Loopback DQS rx_setup ≤ half clock period	0
Saturation Mode = 0 Using Internal or External Loopback DQS rx_setup > half clock period rx_setup + 4 ≤ clock period	`ceiling`(256*(rx_setup_gt_half/clk_period)) + 25; Adding 25 extra elements to guarantee minimal skew.
Saturation Mode = 0 Using Internal or External Loopback `rx_setup` + 4 > clock period	`ceiling`(256*(rx_setup_gt_full/clk_period)) + 25; Adding 25 extra elements to guarantee minimal skew.

CAUTION: The maximum value that can be programmed for the controller delay line is 255. When any calculation exceeds 255, configure the value to 255.

Value Selection for TX Target Delay Lines

Use the ***TX Target Delay Line Parameters*** table to configure initial values for the TX target delay line.

Table 21-51: TX Target Delay Line Parameters

Parameters	Initial Value to Store in TX Delay Line Field
Saturation Mode = 1 flash setup is greater than quarter of cycle - skew margin (tx_setup_de > (quarter_cycle_de – tx_skew_margin_de))	0x5
Saturation Mode = 1 flash setup is less than or equal to quarter of cycle - skew margin (tx_setup_de ≤ (quarter_cycle_de – tx_skew_margin_de))	Set to 25% That is, 25% ceiling(quarter_cycle_de)
Saturation Mode = 0 flash setup is greater than quarter of a cycle (tx_setup_de > quarter_cycle_de)	0x15
Saturation Mode = 0 flash setup is less than or equal to quarter of cycle (tx_setup_de = quarter_cycle_de)	0x33

CAUTION: The maximum value that can be programmed for the controller delay line is 255. When any calculation exceeds 255, configure the value to 255.

PHY Re-initialization

Once the host is operational, it can update the PHY registers and trigger a re-initialization or locking procedure using bits 24 and 25 of the `XSPI_PHY_DLL_CTL` register. A re-initialization must be performed whenever the PHY registers are modified or when the user has changed the `XSPI_CLK` frequency.

Resynchronization of Target Delay Lines

While the PHY is running, the target delay lines can still occasionally require resynchronization as a result of temperature changes, OCV, and how much that change alters the delay through the delay elements. The frequency at which this resync needs to happen depends on how much change those dynamic factors can make on the delay through the delay line and whether that change is sufficient that the sampling point is no longer within the valid data window.

There is no need to resync when the `DLL_LOCK_VALUE` has not changed or has only changed by a small amount. Analog Devices recommends that software monitors the `XSPI_PHY_DLLOB0.DLL_LOCK_VALUE` field and triggers a resync when the `XSPI_PHY_DLLOB0.DLL_LOCK_VALUE` has changed by a significant amount since the last resync (for example, 10%). Alternatively, a user can choose to resync periodically, often enough to mitigate these changes in delay, but which does not impact overall performance.

During a resynchronization, the memory device cannot be accessed. For automatic recurring delay line resynchronizations, configure the `XSPI_PHY_DLL_UPDT_CNT.RESYNC_CNT` field to a value other than 0x0. The value defines the time interval between each resync in `xspi_clk cycles`.

CAUTION: The memory interface must be idle during resync operation.

When a resync happens while the controller is communicating with the memory device, the resync is automatically withheld until the memory operation completes. Similarly, when a resync is already in progress, the controller withholds any normal operation triggered by the host until that resync completes. The `XSPI_PHY_DLL_CTL.RESYNC_IDLE_CNT` field defines the wait time after a resync operation completes when normal traffic can resume.

PHY Read Sampling Method Selection

To use the PHY, decide which read sampling mechanism to use. Essentially, there are two options the user can select from when using the PHY:

- DQS Mode for PHY Read Sampling
- Non-DQS Mode (Loopback) for PHY Read Sampling

DQS Mode for PHY Read Sampling

The highest device clock frequencies and, therefore, performance is achieved when the memory device drives DQS. DQS is an independent signal that is driven parallel to the read data and acts as a source synchronous clock from the device to the PHY. The PHY takes the DQS from the device, passes it through the receive delay line (for programmable incremental delay steps) and uses the resulting signal as a strobe to sample incoming read data. To support this option, the memory device being targeted must support DQS. Additionally, a physical hardware DQS pin connection must be provided. Ensure that bit 20 of the `XSPI_PHY_DQS_TR` register is cleared (=0).

Non-DQS Mode (Loopback) for PHY Read Sampling

The memory device sometimes does not supply DQS or lacks DQS hardware support on board. The alternative option is to mimic the data sampling strobe, referred to as the DQS loopback options of the PHY. Generally, this mode is referred as on-DQS (loopback) mode.

Non-DQS Loopback Mode With a Pad

Internal loopback through the `pad_mem_rebar_t pad`. This still requires the integrator to implement the `pad_mem_rebar_t pad`, although it is not bonded out to a pin. This option can be chosen when dynamic factors like OCV are not important (perhaps because the operating frequency is slower or only SDR operation is needed). This loopback function is performed within the pad and includes pad delays. Depending on the chosen pads, pad delays can be significant, so including these in the loopback path can be important. To support this option, the user must implement the `pad_mem_rebar_t pad`, but it is not connected to anything on the board. Bits 20 and 21 of the`XSPI_PHY_DQS_TR` register must be set (=1). Bit 22 of the `XSPI_PHY_DQS_TR` register must be cleared (=0).

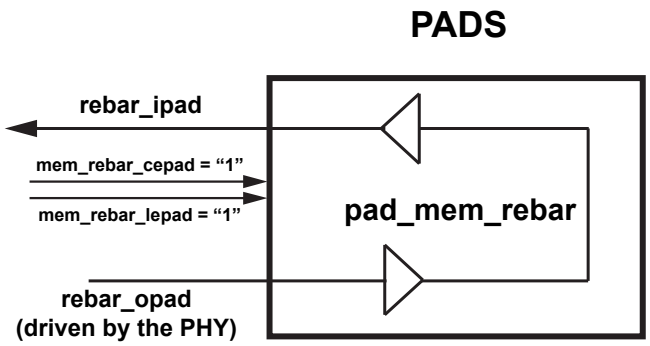

Figure 21-9: Logic Diagram for Non-DQS (Loopback) Mode With Pad

Memory Device Data Integrity

Some memory devices support advanced data integrity checking functions (for example, Macronix MX25). The controller is compatible with the following device capabilities.

ECC Data Integrity

Some memory devices have built-in Error Checking and Correcting (ECC). During a page program operation, the device automatically creates the ECC. During a read operation, the device checks and when necessary, automatically corrects errors. These devices can output an ECC status signal (ECS#) to signal the ECC correction status. The status is optionally passed to the controller using the `XSPI_DFI_GP_OPEN_DRAIN` input, which can be visible with the interrupt status register.

CRC Parity Check

Some memory devices have built-in cyclic redundancy check (CRC) capabilities. For write operations, the controller must send the CRC code to the device for checking. For read operations, the device must send the CRC code and the code must be validated using the controller.

The controller can generate the CRC on the address and calculate it with an exclusive-OR of the address bytes. This is sent to the device immediately after the address bytes. The controller can also generate a CRC on a chunk (programmable number of bytes ranging from 8 bytes through 512 bytes) of the write data. A CRC code is inserted into the outbound data stream immediately following that data chunk. Configuring the controller to use CRC depends on the active work mode. The CRC on the data bytes is calculated by exclusively-ORing the data bytes within a chunk.

CRC Using Direct or ACMD Mode

CRC is enabled using the `XSPI_SEQ_GCTL0`[8:8] bit. It can be configured to always assume that a CRC code is immediately present after the address bytes, or when it is to be inserted into the data stream after a chunk of bytes (independent of whether the stream is sending address bytes or data bytes). This operation is controlled using bit nine of the same register. Some devices require that the CRC be sent first with the CRC value and then repeated with an inverted value. Enable this option using the `XSPI_SEQ_GCTL0`[10:10] bit. Control the chunk size (number of bytes protected by the CRC) with the `XSPI_SEQ_GCTL0`[14:12] field. When the first CRC code

protects the address and is part of the data bytes, bit 16 should be set (=1). When checking that the first CRC code for read data is required, then bit 17 must also be set.

CRC Using STIG Mode

The parameters defined in the XSPI_SEQ_GCTL0 register apply also for the direct and ACMD modes available directly in the glued data STIG instruction described in the Glued Data Instruction section. Enable the CRC using the XSPI_SEQ_GCTL0.CRC_EN field. Control the chunk size (number of bytes protected by the CRC) using the XSPI_SEQ_GCTL0.CHUNK_SIZ field. When the first CRC code protects the address and part of the data bytes, the XSPI_SEQ_GCTL0.UAL_CHUNK_EN field must be cleared (=0). When needing to check the first CRC code for read data, theXSPI_SEQ_GCTL0.UAL_CHUNK_CHK bit must be set (=1).

Miscellaneous Low-level Configurations

The following configurations are supported using the ACMD, direct, and STIG modes.

Write Protection

Some devices that operate in single or dual mode support the use of a write protect signal using the DQ2 pin. The controller can support this feature by using the XSPI_MINICTL_WP_CTL register. See the XSPI_MINICTL_WP_CTL register description for configuration details.

Device Reset

When operating in single or dual mode, some devices have a dedicated #RESET pin or support the hardware reset using the DQ3 pin. The controller supports the driving of reset on any bank (chip select) with the XSPI_MINICTL_WP_CTL register.

SPI Clock CPOL and CPHA Configuration

When operating in Single Data Rate (SDR), the transfers to and from the SPI memory device can operate in SPI mode 0 (polarity CPOL=0, phase CPHA=0, neither checked) or SPI mode 3 (CPOL=1, CPHA=1, both checked). It is unlikely this default configuration needs changing, but the option is available using the XSPI_MINICTL_CLKMODE register.

JEDEC Reset Delay Settings

When issuing a JEDEC reset instruction to the memory device, the Joint Electron Device Engineering Council Solid State Technology Association (JEDEC) standard requires the controller to adhere to the t_{CSL} and t_{CSH} timing parameters. When non-default settings are required, a user programs the XSPI_MINICTL_JEDEC_RST_TR register with specific values.

Device Delay Settings

The XSPI_MINICTL_DEV_DLY register can provide minimum delays between transactions at the memory device interface.

Reset Recovery Delay Settings

Following a hardware reset, the user can force a minimum time delay using the XSPI_MINICTL_RST_RECOV register, before the chip select moves to an active state.

t_{CMS} Timing Pause Refresh Settings

Some volatile memory devices can require a periodic refresh (for example, HyperRAM). This refresh action is referred to as t_{CMS} timing. Use the XSPI_MINICTL_DEV_ACTIVE_MAX register and the XSPI_SEQ_GCTL0.TCMS_EN bit for the controller to configure a maximum time that the chip select remains in an active state to perform a periodic refresh operation. The controller automatically breaks up larger transactions. This action is transparant to the host interface.

Legacy HyperFlash or Profile 2 Address Settings

By default, the host address must be rearranged to form the Command/Address (CA) structure for many legacy HyperFlash and profile 2 devices. Typically, the CA field has a reserved section; some bits of the host address must be shifted. The XSPI_MINICTL_HF_OFFSET register provides the user a method to configure the mapping of these reserved bits.

Multiple Device Connections to Controller

The xSPI controller can connect to a maximum of eight memory devices using the chip select (CS). Throughout this hardware reference, each device connected to an individual chip select is referred to as a bank. Mixed device types are permitted, but, cannot be used simultaneously. For example, when bank zero is connected to a quad SPI NOR flash device and bank one is connected to a HyperBus style device, then some reconfiguration of the xSPI register space is required when the host switches between accessing these devices.

SPI NAND Device Operation Settings

For SPI NAND devices, the memory device address contains both row and column addresses. The ***SPI NAND Device Memory Address*** figure shows the field layout. The boundary between the row and column addresses can be configured using the XSPI_SEQ_GCTL1.PCA_SIZ field. When the selected sequences require a number of bits aligned to 8 (for example, when a sequence requires 16 bits and contains 4 dummy bits before the 12 bits of the column address), the added dummy bits are internally cleared (=0).

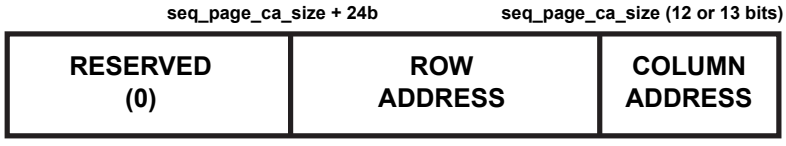

Figure 21-10: SPI NAND Device Memory Address

The SPI NAND devices require a specific page layout. The host software must program the controller to adhere to this field layout. It especially important not to overwrite the reserved areas as bad block data.

ADSP-2184x XSPI Register Descriptions

Expanded Serial Peripheral Interface (XSPI) contains the following registers.

Table 21-52: ADSP-2184x XSPI Register List

Name	Description
XSPI_BOOT_STAT	Boot Status Register
XSPI_CMD0	Command Register 0
XSPI_CMD1	Command Register 1
XSPI_CMD2	Command Register 2
XSPI_CMD3	Command Register 3
XSPI_CMD4	Command Register 4
XSPI_CMD5	Command Register 5
XSPI_CMD_STAT	Command Status Register
XSPI_CMD_STAT_PTR	Command Status Pointer Register
XSPI_DAC_CFG	DAC Configuration Register
XSPI_DAC_REMAPADDR0	Address Remapping Register 0
XSPI_DAC_REMAPADDR1	Address Remapping Register 1
XSPI_DISCOVERY_GCTL	Device Discovery Control Register
XSPI_DMA_CTL	DMA Interface Control Register
XSPI_DMA_ERRADDR_HI	DMA Error Address High Register
XSPI_DMA_ERRADDR_LO	DMA Error Address Low Register
XSPI_ERS_SEQ_CFG0	Erase Sequence Configuration Register 0
XSPI_ERS_SEQ_CFG1	Erase Sequence Configuration Register 1
XSPI_ERS_SEQ_CFG2	Erase Sequence Configuration Register 2
XSPI_FEATURES	Controller Features Register
XSPI_GSTAT	General Controller Status Register
XSPI_INT_EN	Interrupt Enable Register
XSPI_ISTAT	Interrupt Status Register
XSPI_LONGPOL_GCTL	Long Polling Count Register
XSPI_MINICTL_DEV_ACTIVE_MAX	Device Active Maximum Clock Cycle Register
XSPI_MINICTL_CLKMODE	Clock Mode Control Register
XSPI_MINICTL_DEV_DLY	Device Delay Register
XSPI_MINICTL_HF_OFFSET	HyperFlash Offset Register
XSPI_MINICTL_JEDEC_RST_TR	JEDEC Reset Delay Register

Table 21-52: ADSP-2184x XSPI Register List (Continued)

Name	Description
XSPI_MINICTL_RST_PIN_CTL	Hardware Reset Control Register
XSPI_MINICTL_RST_RECOV	Reset Recovery Delay Register
XSPI_MINICTL_WP_CTL	Write Protect Register
XSPI_PHY_DLLOB0	PHY DLL Observable Points 0 Register
XSPI_PHY_DLLOB1	PHY DLL Observable Points 1 Register
XSPI_PHY_DLL_CTL	PHY DLL Control Register
XSPI_PHY_DLL_REQ_CTL	Bus Requester DLL Control Register
XSPI_PHY_DLL_COMP_CTL	Bus Completer DLL Control Register
XSPI_PHY_DLL_UPDT_CNT	PHY DLL Resynchronization Register
XSPI_PHY_DQS_TR	PHY DQS Timing Register
XSPI_PHY_DQ_TR	PHY DQ Timing Register
XSPI_PHY_FEATURES	PHY Features Register
XSPI_PHY_GATE_LPBK_CTL	PHY Gate Loopback Control Register
XSPI_PHY_GCTL	PHY Global Control Register
XSPI_PHY_GPIO_CTL0	PHY GPIO Control Register 0
XSPI_PHY_GPIO_CTL1	PHY GPIO Control Register 1
XSPI_PHY_GPIO_STAT0	PHY GPIO Status Register 0
XSPI_PHY_GPIO_STAT1	PHY GPIO Status Register 1
XSPI_PHY_GTSEL	PHY Global Termination Control Register
XSPI_PHY_IE_TR	PHY DQS Input Enable Timing Register
XSPI_PHY_OB0	PHY Observable Points Register
XSPI_PHY_REVID	PHY Revision ID Register
XSPI_PHY_STATIC_TGL	PHY Static Aging Register
XSPI_PHY_WR_DESKEW_PAD_CTL0	PHY Deskew Write Register
XSPI_PROG_SEQ_CFG0	Program Sequence Configuration Register 0
XSPI_PROG_SEQ_CFG1	Program Sequence Configuration Register 1
XSPI_PROG_SEQ_CFG2	Program Sequence Configuration Register 2
XSPI_READ_SEQ_CFG0	Read Sequence Configuration Register 0
XSPI_READ_SEQ_CFG1	Read Sequence Configuration Register 1
XSPI_READ_SEQ_CFG2	Read Sequence Configuration Register 2
XSPI_REVID	Revision ID Register

Table 21-52: ADSP-2184x XSPI Register List (Continued)

Name	Description
XSPI_RST_SEQ_CFG0	Reset Sequence Configuration Register 0
XSPI_RST_SEQ_CFG1	Reset Sequence Configuration Register 1
XSPI_SDMA_ADDR0	Host DMA Buffer Address Register 0
XSPI_SDMA_ADDR1	Host DMA Buffer Address Register 1
XSPI_SDMA_SIZ	Host DMA Block Size Register
XSPI_SDMA_TRD_STAT	Host DMA Thread Status Register
XSPI_SEQ_GCTL0	Sequence Configuration Register 0
XSPI_SEQ_GCTL1	Sequence Configuration Register 1
XSPI_SHORTPOL_GCTL	Short Polling Count Register
XSPI_STAT_SEQ_CFG0	Status Checking Sequence Configuration Register 0
XSPI_STAT_SEQ_CFG1	Status Checking Sequence Configuration Register 1
XSPI_STAT_SEQ_CFG10	Status Checking Sequence Configuration Register 10
XSPI_STAT_SEQ_CFG2	Status Checking Sequence Configuration Register 2
XSPI_STAT_SEQ_CFG3	Status Checking Sequence Configuration Register 3
XSPI_STAT_SEQ_CFG4	Status Checking Sequence Configuration Register 4
XSPI_STAT_SEQ_CFG5	Status Checking Sequence Configuration Register 5
XSPI_STAT_SEQ_CFG7	Status Checking Sequence Configuration Register 7
XSPI_STAT_SEQ_CFG8	Status Checking Sequence Configuration Register 8
XSPI_STAT_SEQ_CFG9	Status Checking Sequence Configuration Register 9
XSPI_TRD_COMP_ISTAT	Auto Command Engine Interrupt Status Thread Register
XSPI_TRD_ERR_INT_EN	Thread Error Interrupt Enable Register
XSPI_TRD_ERR_ISTAT	Thread Error Interrupt Status Register
XSPI_TRD_STAT	Auto Command Engine Thread Status Register
XSPI_WE_SEQ_CFG0	WEL Sequence Configuration Register
XSPI_WORKMODE_CTL	Device Control Register
XSPI_XIP_GCTL	XIP Configuration Register

Boot Status Register

The XSPI_BOOT_STAT register provides the status of the most recent boot operation, triggered by the automated boot controller.

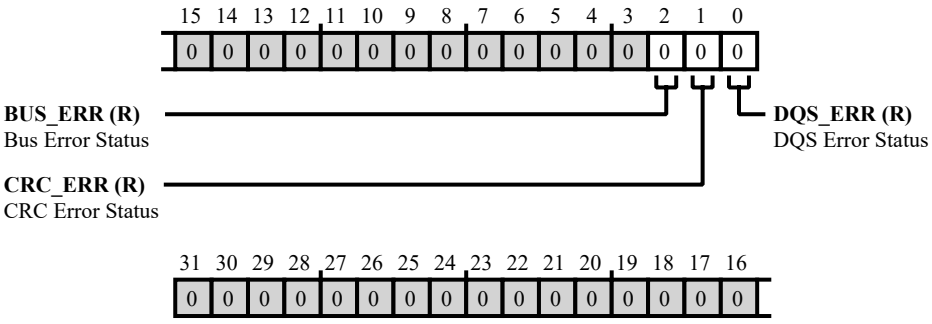

Figure 21-11: XSPI_BOOT_STAT Register Diagram

Table 21-53: XSPI_BOOT_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/NW)	BUS_ERR	Bus Error Status. The XSPI_BOOT_STAT.BUS_ERR field describes bus status during the boot process. When set, the boot process failed due to the bus interface receiving an error response from the target.	
		0	No Error Detected
		1	Error Detected
1 (R/NW)	CRC_ERR	CRC Error Status. The XSPI_BOOT_STAT.CRC_ERR field describes CRC status during the boot process. When set, the boot process failed due to the CRC error on the xSPI interface.	
		0	No Error Detected
		1	Error Detected
0 (R/NW)	DQS_ERR	DQS Error Status. The XSPI_BOOT_STAT.DQS_ERR bit field describes the DQS status during the boot process. When set, the boot process failed due to the DQS error on the xSPI interface.	
		0	No Error Detected
		1	Error Detected

Command Register 0

Writing data to the XSPI_CMD0 register initiates a new transaction of the xSPI flash controller in CDMA/PIO and STIG work mode.

Encoding of the register depends on the selected work mode.

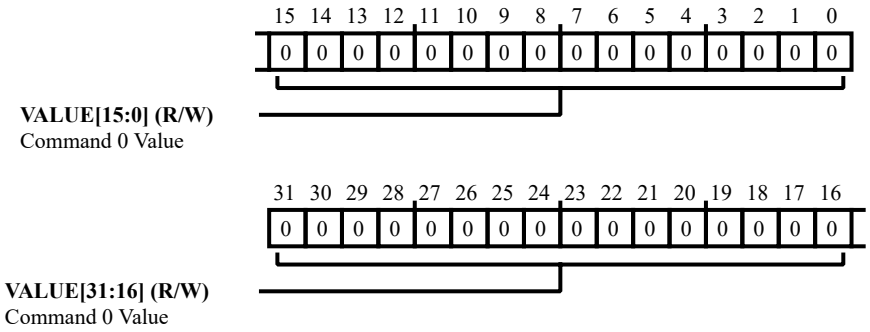

Figure 21-12: XSPI_CMD0 Register Diagram

Table 21-54: XSPI_CMD0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Command 0 Value. Command 0 register field.

Command Register 1

The XSPI_CMD1 register is only used in CDMA/PIO and STIG work mode. Field encoding of the register depends on the selected work mode.

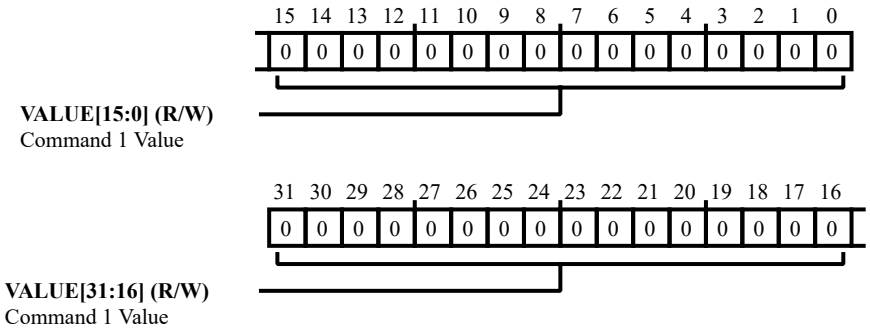

Figure 21-13: XSPI_CMD1 Register Diagram

Table 21-55: XSPI_CMD1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Command 1 Value. Command 1 register field.

Command Register 2

The XSPI_CMD2 register is only used in CDMA/PIO and STIG work mode. Field encoding of the register depends on the selected work mode.

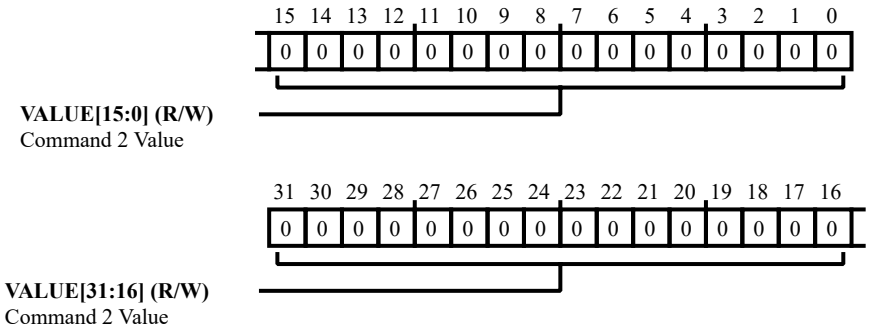

Figure 21-14: XSPI_CMD2 Register Diagram

Table 21-56: XSPI_CMD2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Command 2 Value. Command 2 register field.

Command Register 3

The XSPI_CMD3 register is only used in CDMA/PIO and STIG work mode; the definition changes depending on the work mode.

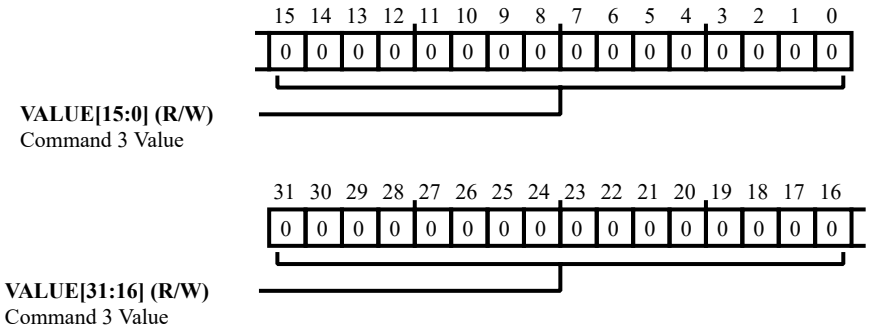

Figure 21-15: XSPI_CMD3 Register Diagram

Table 21-57: XSPI_CMD3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Command 3 Value. Command 3 register field.

Command Register 4

The XSPI_CMD4 register is only used in CDMA/PIO and STIG work mode; the definition changes depending on the work mode.

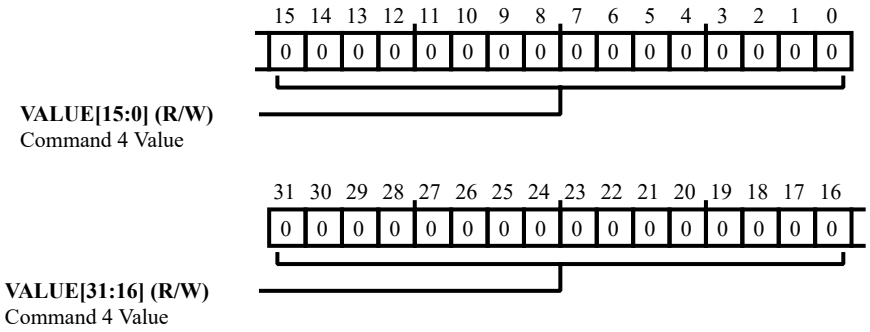

Figure 21-16: XSPI_CMD4 Register Diagram

Table 21-58: XSPI_CMD4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Command 4 Value. Command 4 register field.

Command Register 5

The XSPI_CMD5 register is only used in CDMA/PIO and STIG work mode; the definition changes depending on the work mode.

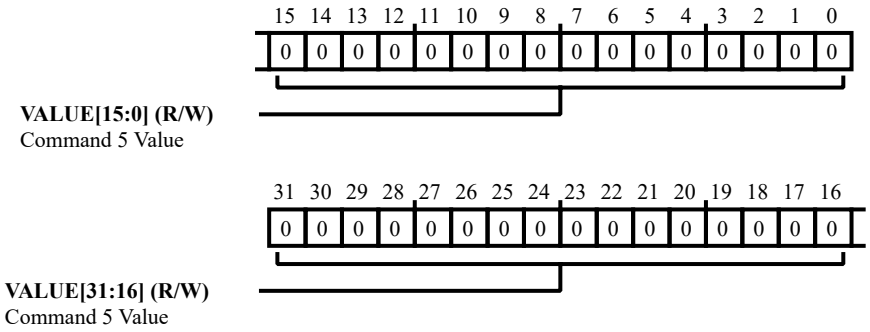

Figure 21-17: XSPI_CMD5 Register Diagram

Table 21-59: XSPI_CMD5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Command 5 Value. Command 5 register field.

Command Status Register

The XSPI_CMD_STAT register reports the command status for the selected thread in ACMD and STIG work mode, when an xSPI flash transaction has completed.

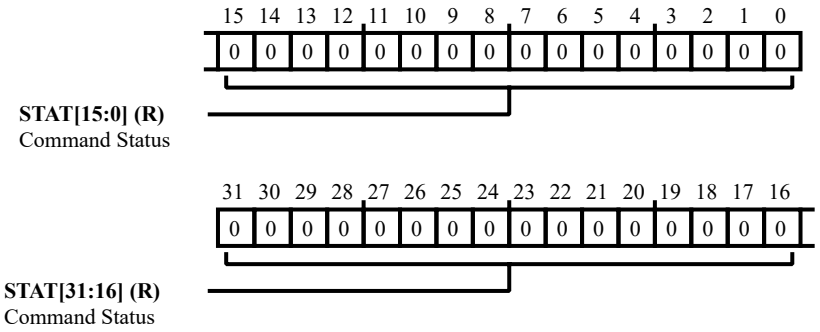

Figure 21-18: XSPI_CMD_STAT Register Diagram

Table 21-60: XSPI_CMD_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	STAT	Command Status. When operating in ACMD mode, the XSPI_CMD_STAT.STAT bit field reports the descriptor status associated with the selected thread (the thread to which this status belongs is selected via the XSPI_CMD_STAT_PTR register). When operating in STIG mode, this register reports the STIG completion status. Refer to section "STIG Mode Status" for a full bitwise definition.

Command Status Pointer Register

The XSPI_CMD_STAT_PTR register selects the thread that is used for outputting the command status in the XSPI_CMD_STAT register.

This register is relevant for ACMD mode only.

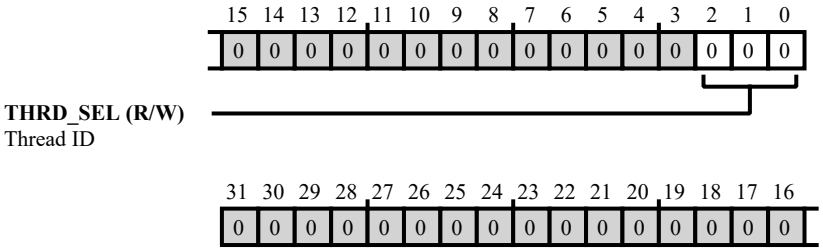

Figure 21-19: XSPI_CMD_STAT_PTR Register Diagram

Table 21-61: XSPI_CMD_STAT_PTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
2:0 (R/W)	THRD_SEL	Thread ID. The XSPI_CMD_STAT_PTR.THRD_SEL bit field indicates the thread ID status; the status is available in the XSPI_CMD_STAT register.

DAC Configuration Register

The XSPI_DAC_CFG register holds specific configuration information required while operating in direct work mode.

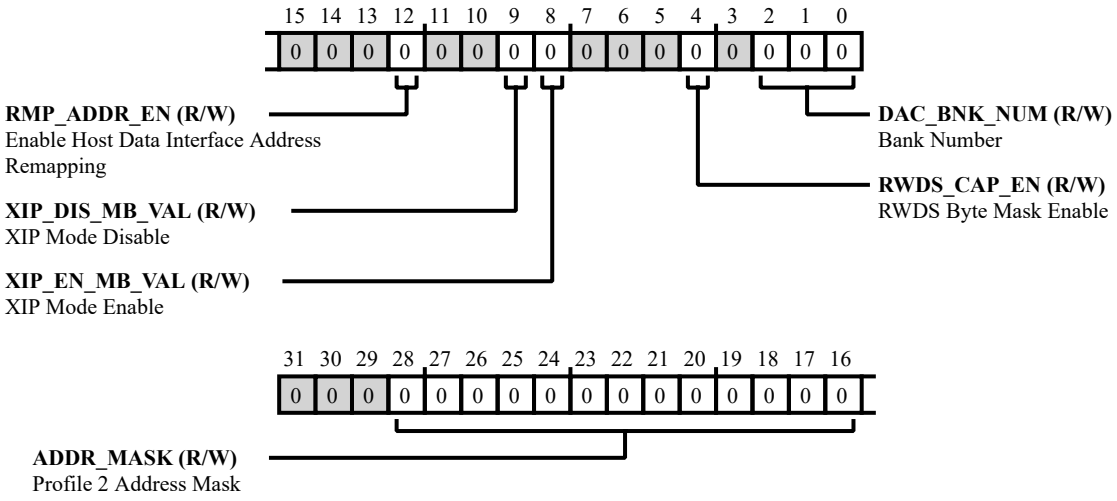

Figure 21-20: XSPI_DAC_CFG Register Diagram

Table 21-62: XSPI_DAC_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
28:16 (R/W)	ADDR_MASK	Profile 2 Address Mask. The XSPI_DAC_CFG.ADDR_MASK bit field enables masking bits [44:32] of the system address for read/write transfers for profile 2.
12 (R/W)	RMP_ADDR_EN	Enable Host Data Interface Address Remapping. When the XSPI_DAC_CFG.RMP_ADDR_EN bit is set (=1), the incoming AXI host address is adapted and sent to the flash device as (address - N), where N is the value stored in the remap address register (XSPI_DAC_REMAPADDRn).
9 (R/W)	XIP_DIS_MB_VAL	XIP Mode Disable. The XSPI_DAC_CFG.XIP_DIS_MB_VAL bit is used to trigger exit from XIP mode within the device. When XSPI_DAC_CFG.XIP_DIS_MB_VAL is set (=1), the controller sends mode bits specified in the XSPI_XIP_GCTL. XIP_DIS_MB_VALUE on the next read transaction. This disables XIP work mode for both the device and controller.
8 (R/W)	XIP_EN_MB_VAL	XIP Mode Enable. The XSPI_DAC_CFG.XIP_EN_MB_VAL bit is used to trigger entry to XIP mode within the device. When XSPI_DAC_CFG.XIP_EN_MB_VAL is set (=1), the controller sends mode bits as specified in XSPI_XIP_GCTL. XIP_EN_MB_VAL on the next read transaction. This switches both device and controller into XIP work mode.

Table 21-62: XSPI_DAC_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
4 (R/W)	RWDS_CAP_EN	RWDS Byte Mask Enable. When enabled, the controller supports byte masking in the connected device by automatically translating the incoming AXI host interface write strobes as needed. If the connected device does not support RWDS byte masking, the `XSPI_DAC_CFG.RWDS_CAP_EN` bit must be cleared. Note that when the `XSPI_DAC_CFG.RWDS_CAP_EN` bit is cleared, the controller assumes all bytes on the AXI write channel have an equivalent AXI write strobe set to 1. Also note that when this bit is cleared, the user cannot send byte writes to an octal DDR device or to a device that is 16-bit addressed.
2:0 (R/W)	DAC_BNK_NUM	Bank Number. The `XSPI_DAC_CFG.DAC_BNK_NUM` bit field indicates the bank (the attached memory device) targeted by the controller while operating in direct mode.

Address Remapping Register 0

When XSPI_DAC_CFG.RMP_ADDR_EN =1, the incoming AXI host interface address is adapted and sent to the flash device as (address - N), where N[31:0] is the value stored in this register.

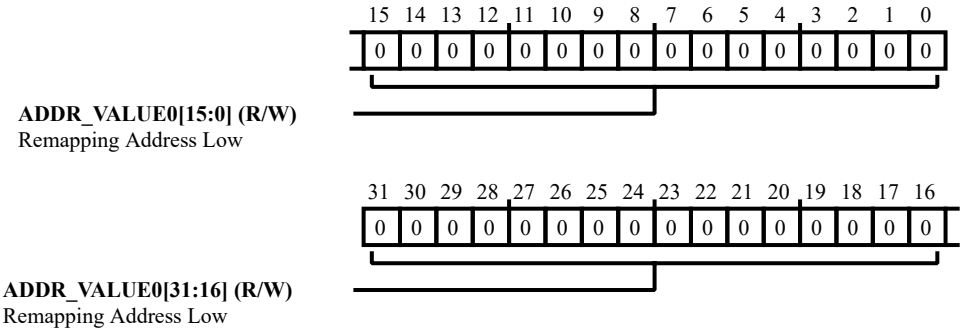

Figure 21-21: XSPI_DAC_REMAPADDR0 Register Diagram

Table 21-63: XSPI_DAC_REMAPADDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	ADDR_VALUE0	Remapping Address Low. The `XSPI_DAC_REMAPADDR0.ADDR_VALUE0` bit field indicates the remapping of the incoming address on the AXI host interface to a different address used by the flash device. The value of this register must be aligned to 8 bytes.

Address Remapping Register 1

When XSPI_DAC_CFG.RMP_ADDR_EN =1, the incoming host interface address is adapted and sent to the flash device as (address - N), where N[63:32] is the value stored in this register.

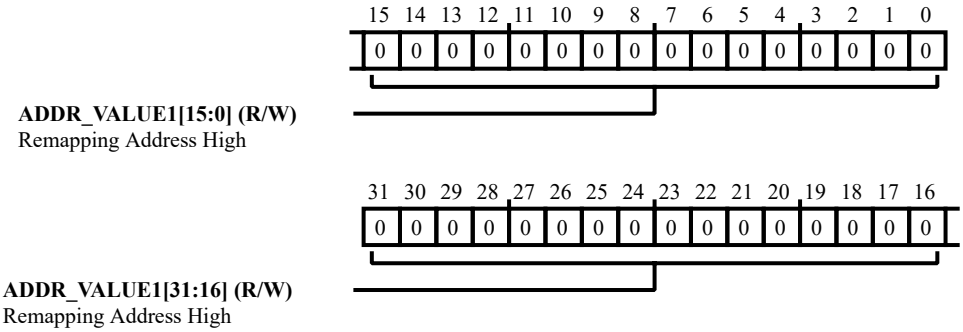

Figure 21-22: XSPI_DAC_REMAPADDR1 Register Diagram

Table 21-64: XSPI_DAC_REMAPADDR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	ADDR_VALUE1	Remapping Address High. The `XSPI_DAC_REMAPADDR1.ADDR_VALUE1` bit field indicates the remapping of the incoming address on the host interface to a different address used by the flash device.

Device Discovery Control Register

The XSPI_DISCOVERY_GCTL register controls device discovery.

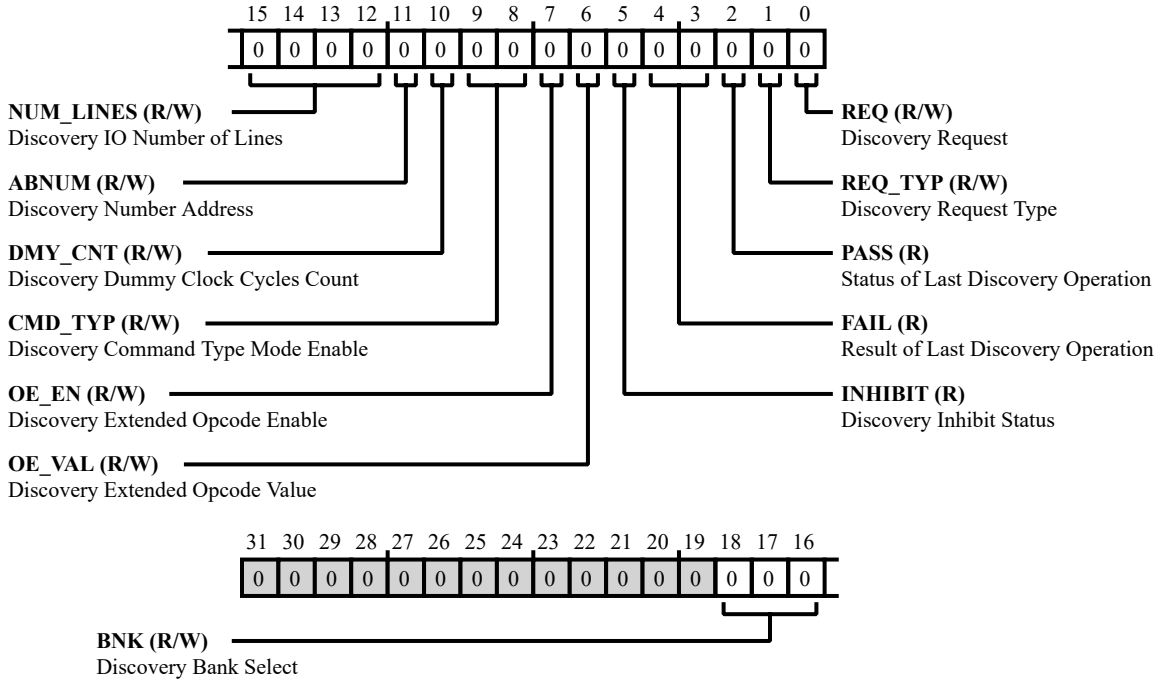

Figure 21-23: XSPI_DISCOVERY_GCTL Register Diagram

Table 21-65: XSPI_DISCOVERY_GCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
18:16 (R/W)	BNK	Discovery Bank Select. The XSPI_DISCOVERY_GCTL.BNK bit field indicates the discovery bank. Writing a value of 0x0-0x7 selects a bank. This field is updated after the initialization process.	
15:12 (R/W)	NUM_LINES	Discovery IO Number of Lines. This is a 4-bit value used in discovery mode. Writing a value to the XSPI_DISCOVERY_GCTL.NUM_LINES bit field selects number of xSPI I/Os used by device discovery. This field is updated after the initialization process.	
		0	Auto
		1	1 line
		2	2 lines
		3	Reserved
		4	4 lines

Table 21-65: XSPI_DISCOVERY_GCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		5	Reserved
		6	Reserved
		7	Reserved
		8	8 lines
		9	Reserved
		10	Reserved
		11	Reserved
		12	8 lines for legacy HyperFlash and xSPI profile
		13	Reserved
		14	1 line for legacy SPI NAND
		15	Reserved
11 (R/W)	ABNUM	Discovery Number Address. The `XSPI_DISCOVERY_GCTL.ABNUM` bit enables discovery 4-bit addressing. This field is updated after the initialization process.	
		0	3-bit addressing
		1	4-bit addressing
10 (R/W)	DMY_CNT	Discovery Dummy Clock Cycles Count. The `XSPI_DISCOVERY_GCTL.DMY_CNT` bit indicates the discovery number of dummy clock cycles. This bit is updated after the initialization process.	
		0	8 dummy clock cycles
		1	20 dummy clock cycles
9:8 (R/W)	CMD_TYP	Discovery Command Type Mode Enable. The `XSPI_DISCOVERY_GCTL.CMD_TYP` bit selects the discovery command type mode. This field is updated after the initialization process.	
		0	SDR mode enabled
		1	DDR mode enabled
		2	DTR mode enabled (quad mode only)
		3	Reserved

Table 21-65: XSPI_DISCOVERY_GCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/W)	OE_EN	Discovery Extended Opcode Enable. The `XSPI_DISCOVERY_GCTL.OE_EN` bit enables the discovery extended opcode. This field is updated after the initialization process.	
		0	Disable
		1	Enable
6 (R/W)	OE_VAL	Discovery Extended Opcode Value. The `XSPI_DISCOVERY_GCTL.OE_VAL` bit field indicates the discovery extended opcode value. This field is updated after the initialization process.	
		0	Extended opcode is 8'hA5
		1	Extended opcode is 8'h5A
5 (R/NW)	INHIBIT	Discovery Inhibit Status. The `XSPI_DISCOVERY_GCTL.INHIBIT` bit indicates whether device discovery is inhibited at power on.	
		0	Discovery allow
		1	Discovery inhibit
4:3 (R/NW)	FAIL	Result of Last Discovery Operation. The `XSPI_DISCOVERY_GCTL.FAIL` bit field indicates the result of the last discovery operation. Valid when PASS = 1.	
		0	xSPI or SPI NAND device detected
		1	Fail
		2	Legacy SPI device detected
		3	N/A
2 (R/NW)	PASS	Status of Last Discovery Operation. The `XSPI_DISCOVERY_GCTL.PASS` bit indicates the status of the last discovery operation. `XSPI_DISCOVERY_GCTL.PASS` =1 when the device discovery operation has finished. The result can be read from the FAIL field.	
1 (R/W)	REQ_TYP	Discovery Request Type. The `XSPI_DISCOVERY_GCTL.REQ_TYP` bit indicates the discovery request type.	
		0	Full discovery. Perform full discovery process (try to detect device)
		1	Selected mode. Configure registers only to selected mode (not full discovery process)

Table 21-65: XSPI_DISCOVERY_GCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W)	REQ	Discovery Request. Writing 1 to the `XSPI_DISCOVERY_GCTL.REQ` bit triggers the device discovery operation. The `XSPI_DISCOVERY_GCTL.REQ` bit is cleared by hardware when the device discovery operation completes.

DMA Interface Control Register

The XSPI_DMA_CTL register is a common register for both the host and internal DMA interface.

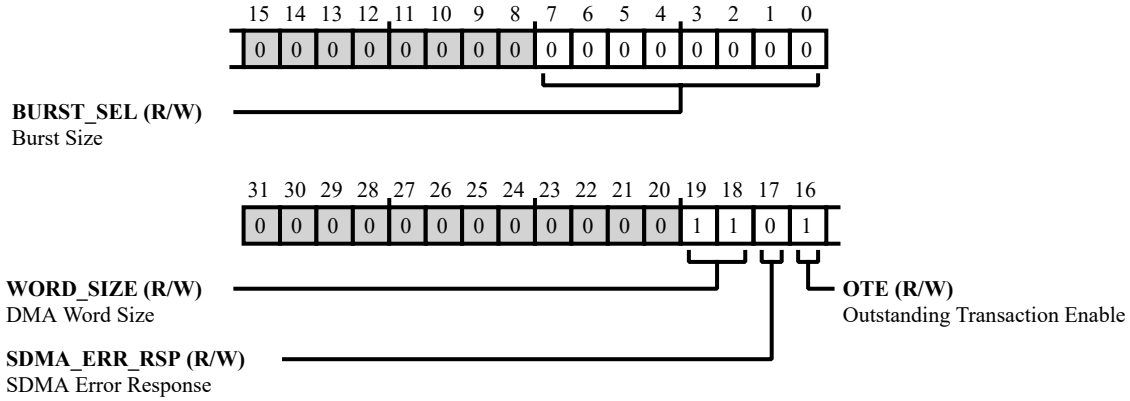

Figure 21-24: XSPI_DMA_CTL Register Diagram

Table 21-66: XSPI_DMA_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
19:18 (R/W)	WORD_SIZE	DMA Word Size. The XSPI_DMA_CTL.WORD_SIZE bit field indicates the AXI transaction size used by the internal DMA interface to transfer data.	
		0	Byte
		1	16-bit word
		2	32-bit word
		3	64-bit word
17 (R/W)	SDMA_ERR_RSP	SDMA Error Response. AXI error responses can only occur in ACMD or STIG work modes. When XSPI_DMA_CTL.SDMA_ERR_RSP is set (=1), an AXI error response is returned if one of the following is true. 1. The host attempts to access the target interface before it is permitted (refer to the required steps in STIG and ACMD sections of this document). 2. The host issues an unsupported burst type. The controller only supports incremental bursts (non-wrapping) bursts currently. When XSPI_DMA_CTL.SDMA_ERR_RSP is cleared (=0), an OK response is returned.	
16 (R/W)	OTE	Outstanding Transaction Enable. The XSPI_DMA_CTL.OTE bit enables an outstanding transaction. This only applies to the internal DMA interface. The AXI host interface ignores this bit and accepts all incoming transactions.	

Table 21-66: XSPI_DMA_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	BURST_SEL	Burst Size. The `XSPI_DMA_CTL.BURST_SEL` bit field indicates the maximum AXI burst size used by the internal DMA interface. The maximum burst size can be calculated as `XSPI_DMA_CTL.BURST_SEL`+1. Note that this field must be changed only when controller is in an idle state.

DMA Error Address High Register

Internal DMA interface error address [63:32]. The XSPI_DMA_ERRADDR_HI register holds the upper 32 bits of the address of the AXI request on the system bus requester data interface that caused the CDMA_TERR or DDMA_TERR bits in the XSPI_ISTAT register to be set. This register is overwritten when further error responses are detected.

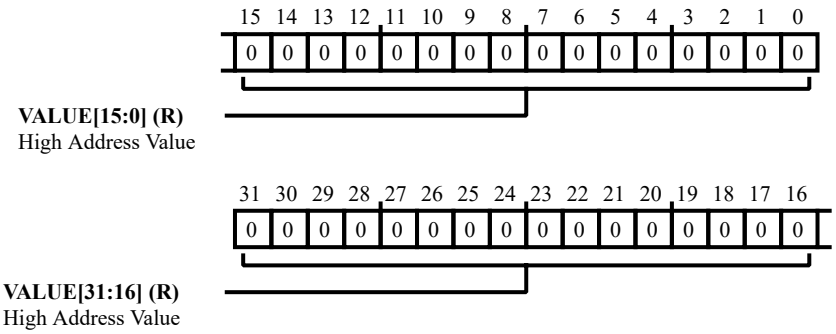

Figure 21-25: XSPI_DMA_ERRADDR_HI Register Diagram

Table 21-67: XSPI_DMA_ERRADDR_HI Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	High Address Value. The XSPI_DMA_ERRADDR_HI.VALUE bit field indicates the address of the first request on the internal DMA interface that returned an error response.

DMA Error Address Low Register

Internal DMA interface error address [31:0]. The XSPI_DMA_ERRADDR_LO register holds the lower 32 bits of the address of the AXI request on the system bus requester data interface that caused the CDMA_TERR or DDMA_TERR bits in the XSPI_ISTAT register to be set. The XSPI_DMA_ERRADDR_LO register is overwritten when further error responses are detected.

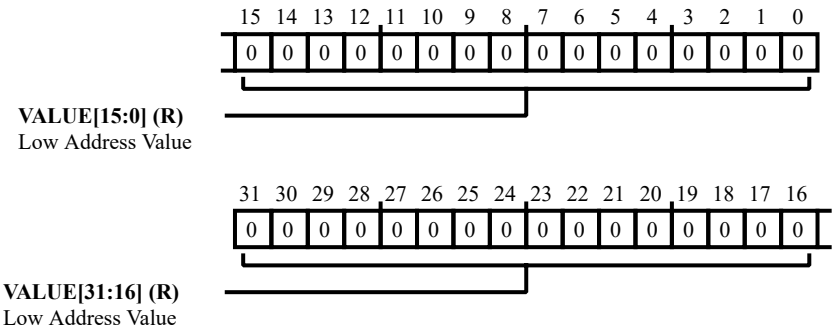

Figure 21-26: XSPI_DMA_ERRADDR_LO Register Diagram

Table 21-68: XSPI_DMA_ERRADDR_LO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Low Address Value. The XSPI_DMA_ERRADDR_LO.VALUE bit field indicates the address of the first request on the internal DMA interface that returned an error response.

Erase Sequence Configuration Register 0

The XSPI_ERS_SEQ_CFG0 register configures the erase_sector sequence for profile 1 and SPI NAND in ACMD work mode.

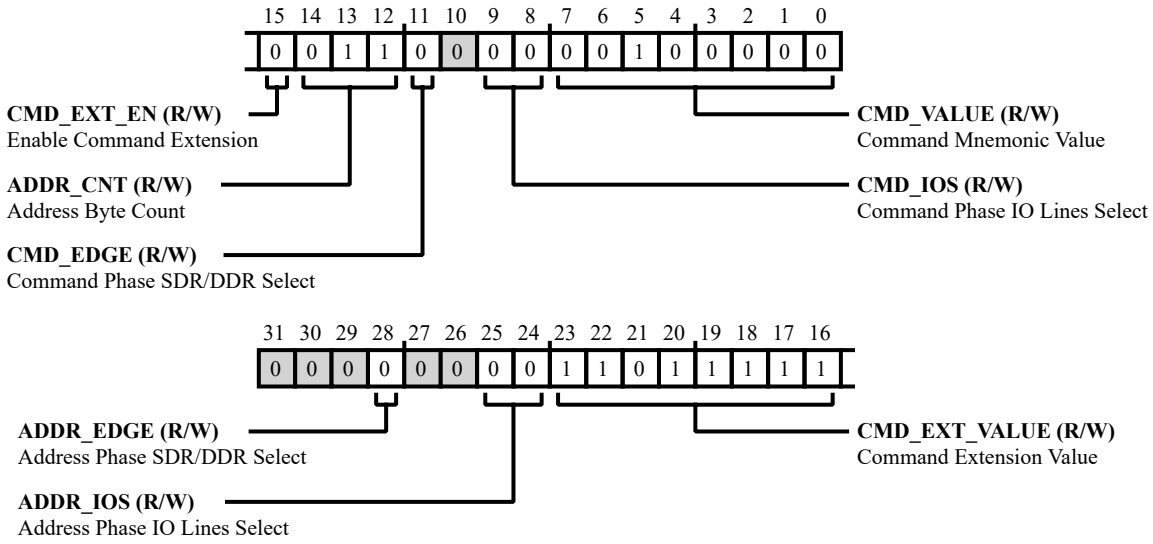

Figure 21-27: XSPI_ERS_SEQ_CFG0 Register Diagram

Table 21-69: XSPI_ERS_SEQ_CFG0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
28 (R/W)	ADDR_EDGE	Address Phase SDR/DDR Select. The XSPI_ERS_SEQ_CFG0.ADDR_EDGE bit selects between SDR/DDR mode for the address phase.	
25:24 (R/W)	ADDR_IOS	Address Phase IO Lines Select. The XSPI_ERS_SEQ_CFG0.ADDR_IOS bit field indicates the number of data lines used to send the address phase.	
		0	One data line used (for example, serial)
		1	Two data lines used
		2	Four data lines used
		3	Eight data lines used
23:16 (R/W)	CMD_EXT_VALUE	Command Extension Value. The XSPI_ERS_SEQ_CFG0.CMD_EXT_VALUE bit field indicates the command extension value, when enabled.	
15 (R/W)	CMD_EXT_EN	Enable Command Extension. The XSPI_ERS_SEQ_CFG0.CMD_EXT_EN bit enables command extension.	

Table 21-69: XSPI_ERS_SEQ_CFG0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
14:12 (R/W)	ADDR_CNT	Address Byte Count. The `XSPI_ERS_SEQ_CFG0.ADDR_CNT` bit field indicates the number of address bytes.	
11 (R/W)	CMD_EDGE	Command Phase SDR/DDR Select. The `XSPI_ERS_SEQ_CFG0.CMD_EDGE` bit field selects between SDR/DDR mode for the command phase.	
9:8 (R/W)	CMD_IOS	Command Phase IO Lines Select. The `XSPI_ERS_SEQ_CFG0.CMD_IOS` bit field indicates the number of data lines used to send the command phase.	
		0	One data line used (for example, serial)
		1	Two data lines used
		2	Four data lines used
		3	Eight data lines used
7:0 (R/W)	CMD_VALUE	Command Mnemonic Value. The `XSPI_ERS_SEQ_CFG0.CMD_VALUE` bit field indicates the command mnemonic value.	

Erase Sequence Configuration Register 1

The XSPI_ERS_SEQ_CFG1 register configures the erase_sector sequence for profile 1 and SPI NAND in ACMD work mode.

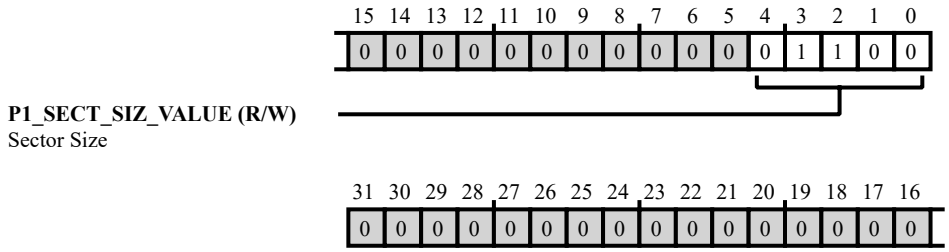

Figure 21-28: XSPI_ERS_SEQ_CFG1 Register Diagram

Table 21-70: XSPI_ERS_SEQ_CFG1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
4:0 (R/W)	P1_SECT_SIZ_VALUE	Sector Size. The XSPI_ERS_SEQ_CFG1.P1_SECT_SIZ_VALUE bit field indicates the sector size. Value encoded as $2^{erss_seq_p1_sect_size}$: 8'h00 - 1B 8'h01 - 2B 8'h02 - 4B ... 8'h0f - 32kB 8'h10 - 64kB ... 8'h1f - (2^{31})B

Erase Sequence Configuration Register 2

The XSPI_ERS_SEQ_CFG2 register configures the erase_all sequence for profile 1 in ACMD work mode.

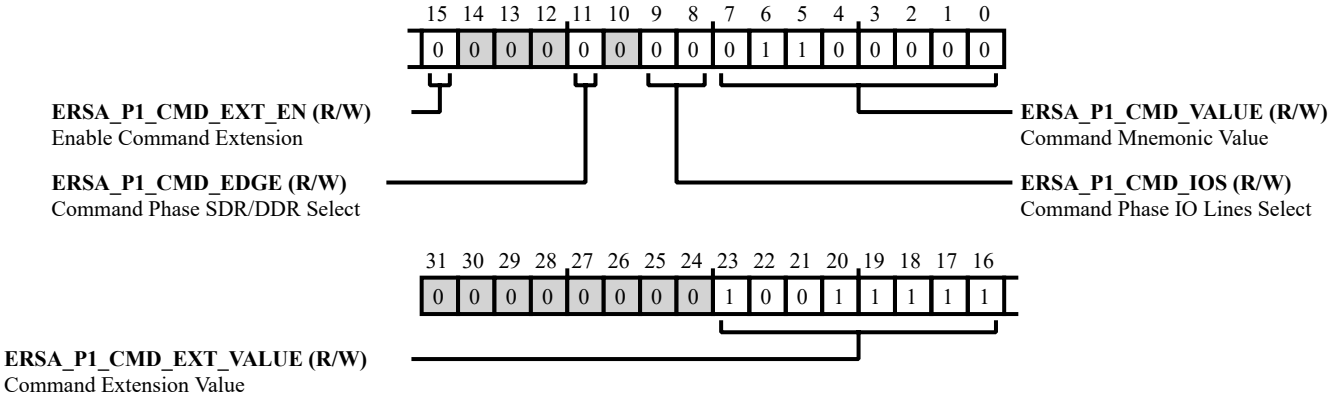

Figure 21-29: XSPI_ERS_SEQ_CFG2 Register Diagram

Table 21-71: XSPI_ERS_SEQ_CFG2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
23:16 (R/W)	ERSA_P1_CMD_EXT_VALUE	Command Extension Value. The XSPI_ERS_SEQ_CFG2.ERSA_P1_CMD_EXT_VALUE bit field indicates the command extension value.	
15 (R/W)	ERSA_P1_CMD_EXT_EN	Enable Command Extension. The XSPI_ERS_SEQ_CFG2.ERSA_P1_CMD_EXT_EN bit field enables the command extension.	
11 (R/W)	ERSA_P1_CMD_EDGE	Command Phase SDR/DDR Select. The XSPI_ERS_SEQ_CFG2.ERSA_P1_CMD_EDGE bit selects between SDR/DDR mode for the command phase.	
9:8 (R/W)	ERSA_P1_CMD_IOS	Command Phase IO Lines Select. The XSPI_ERS_SEQ_CFG2.ERSA_P1_CMD_IOS bit field indicates the number of data lines used to send the command phase.	
		0	One data line used (for example, serial)
		1	Two data lines used
		2	Four data lines used
		3	Eight data lines used
7:0 (R/W)	ERSA_P1_CMD_VALUE	Command Mnemonic Value. The XSPI_ERS_SEQ_CFG2.ERSA_P1_CMD_VALUE bit field indicates the command mnemonic value.	

Controller Features Register

The XSPI_FEATURES register shows the available hardware features of the controller.

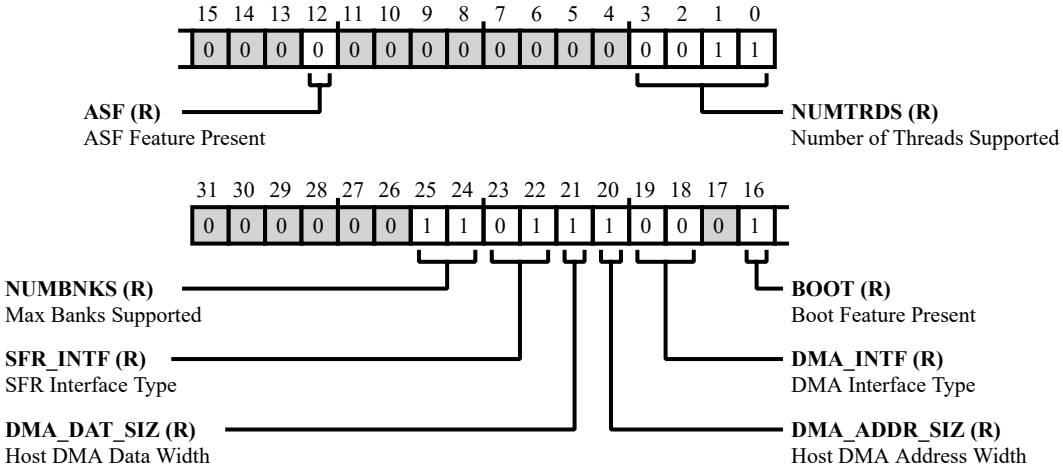

Figure 21-30: XSPI_FEATURES Register Diagram

Table 21-72: XSPI_FEATURES Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
25:24 (R/NW)	NUMBNKS	Max Banks Supported. The XSPI_FEATURES.NUMBNKS bit field indicates the maximum number of banks supported by hardware.	
		0	One bank
		1	Two banks
		2	Four banks
		3	Eight banks
23:22 (R/NW)	SFR_INTF	SFR Interface Type. The XSPI_FEATURES.SFR_INTF bit field indicates the SFR interface type 1-APB, other values reserved.	
21 (R/NW)	DMA_DAT_SIZ	Host DMA Data Width. The XSPI_FEATURES.DMA_DAT_SIZ bit indicates the host DMA data width.	
		0	32 bit
		1	64 bit

Table 21-72: XSPI_FEATURES Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
20 (R/NW)	DMA_ADDR_SIZ	Host DMA Address Width. The `XSPI_FEATURES.DMA_ADDR_SIZ` bit indicates the host DMA address width.	
		0	32 bit
		1	64 bit
19:18 (R/NW)	DMA_INTF	DMA Interface Type. The `XSPI_FEATURES.DMA_INTF` bit field indicates the DMA interface type (0-AXI4 other values reserved).	
16 (R/NW)	BOOT	Boot Feature Present. The `XSPI_FEATURES.BOOT` bit indicates whether the boot feature is present.	
12 (R/NW)	ASF	ASF Feature Present. The `XSPI_FEATURES.ASF` bit indicates whether the ASF feature is present.	
3:0 (R/NW)	NUMTRDS	Number of Threads Supported. The `XSPI_FEATURES.NUMTRDS` bit field indicates the number of threads available in the controller.	
		0	One thread
		1	Two threads
		2	Four threads
		3	Eight threads
		4-15	Reserved

General Controller Status Register

The XSPI_GSTAT register indicates the status of the controller.

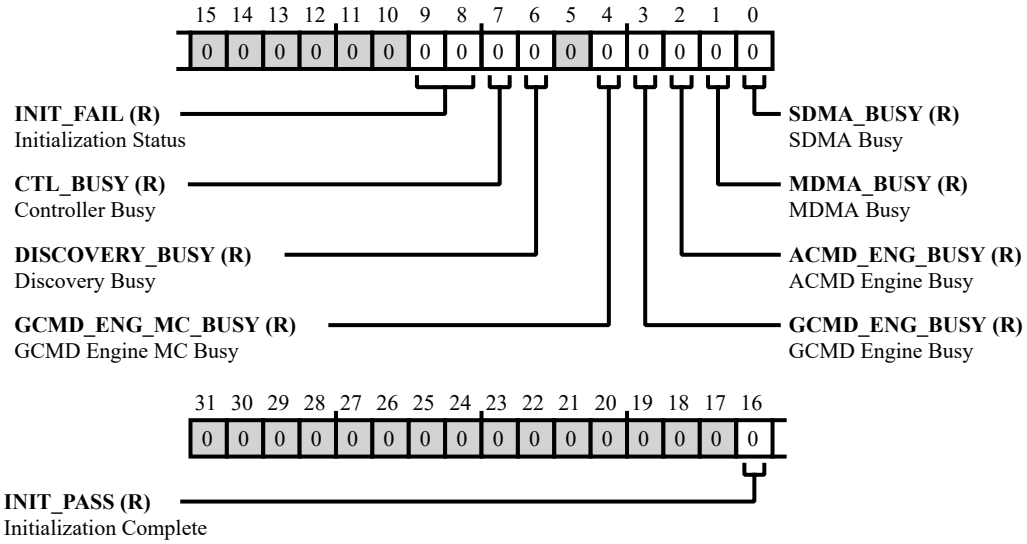

Figure 21-31: XSPI_GSTAT Register Diagram

Table 21-73: XSPI_GSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/NW)	INIT_PASS	Initialization Complete. When XSPI_GSTAT.INIT_PASS is set (=1), the xSPI controller has completed its reset and initialization process.	
9:8 (R/NW)	INIT_FAIL	Initialization Status. The XSPI_GSTAT.INIT_FAIL bit field indicates the initialization process status.	
		0	xSPI device detected
		1	Initialization has failed
		2	Legacy SPI device detected
		3	N/A
7 (R/NW)	CTL_BUSY	Controller Busy. The XSPI_GSTAT.CTL_BUSY bit indicates whether controller is in the busy state. Note that this bit is also routed to the controller interface via the CTRL_BUSY pin.	
		0	Idle
		1	Busy

Table 21-73: XSPI_GSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
6 (R/NW)	DISCOVERY_BUSY	Discovery Busy. When `XSPI_GSTAT.DISCOVERY_BUSY` is set (=1), device discovery is in progress. When device discovery is inhibited, this bit is also set during the PHY initialization procedure.
4 (R/NW)	GCMD_ENG_MC_BUSY	GCMD Engine MC Busy. The bit `XSPI_GSTAT.GCMD_ENG_MC_BUSY` is relevant for STIG mode only. This bit indicates when the controller is waiting for next/last instruction in a glued instruction chain or it is executing a requested sequence on the xSPI interface.
3 (R/NW)	GCMD_ENG_BUSY	GCMD Engine Busy. When operating in direct work mode, the `XSPI_GSTAT.GCMD_ENG_BUSY` is set (=1), when the direct CMD generator is busy. Note that no new requests on the host interface are accepted while `XSPI_GSTAT.GCMD_ENG_BUSY` is set. When operating in STIG work mode, the `XSPI_GSTAT.GCMD_ENG_BUSY` is set while the STIG engine is busy.
2 (R/NW)	ACMD_ENG_BUSY	ACMD Engine Busy. When `XSPI_GSTAT.ACMD_ENG_BUSY` is set (=1), the auto command engine is busy (ACMD mode only).
1 (R/NW)	MDMA_BUSY	MDMA Busy. When `XSPI_GSTAT.MDMA_BUSY` is set (=1), the internal DMA interface is busy.
0 (R/NW)	SDMA_BUSY	SDMA Busy. When `XSPI_GSTAT.SDMA_BUSY` is set (=1), the host interface is busy.

Interrupt Enable Register

If the selected bit of the XSPI_INT_EN register is set (=1), the rising edge of the corresponding bit in the XSPI_ISTAT register triggers an interrupt.

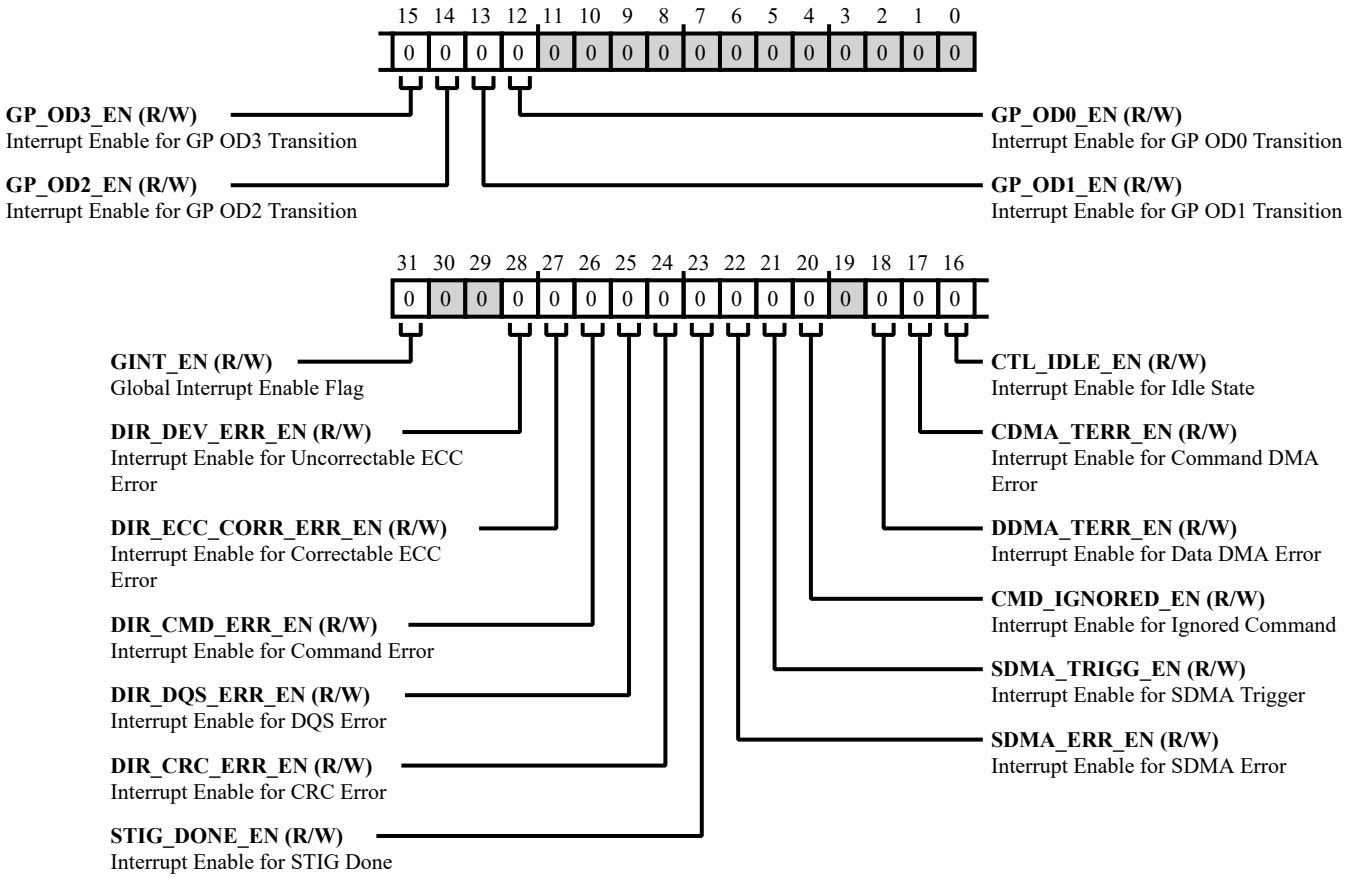

Figure 21-32: XSPI_INT_EN Register Diagram

Table 21-74: XSPI_INT_EN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	GINT_EN	Global Interrupt Enable Flag. The XSPI_INT_EN.GINT_EN bit enables a global interrupt flag.
28 (R/W)	DIR_DEV_ERR_EN	Interrupt Enable for Uncorrectable ECC Error. The XSPI_INT_EN.DIR_DEV_ERR_EN bit enables an interrupt when an uncorrectable ECC or program fail error occurred in direct work mode.
27 (R/W)	DIR_ECC_CORR_ERR_EN	Interrupt Enable for Correctable ECC Error. The XSPI_INT_EN.DIR_ECC_CORR_ERR_EN bit enables an interrupt when a correctable ECC error occurred in direct work mode.

Table 21-74: XSPI_INT_EN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
26 (R/W)	DIR_CMD_ERR_EN	Interrupt Enable for Command Error. The `XSPI_INT_EN.DIR_CMD_ERR_EN` bit enables an interrupt when an invalid command sequence has been detected in direct work mode.
25 (R/W)	DIR_DQS_ERR_EN	Interrupt Enable for DQS Error. The `XSPI_INT_EN.DIR_DQS_ERR_EN` bit enables an interrupt when the controller returns a DQS error after a read or status checking command in direct work mode.
24 (R/W)	DIR_CRC_ERR_EN	Interrupt Enable for CRC Error. The `XSPI_INT_EN.DIR_CRC_ERR_EN` bit enables an interrupt when the controller returns a CRC error after a read or status checking command in direct work mode.
23 (R/W)	STIG_DONE_EN	Interrupt Enable for STIG Done. The `XSPI_INT_EN.STIG_DONE_EN` bit enables an interrupt when an instruction in a glued chain is complete.
22 (R/W)	SDMA_ERR_EN	Interrupt Enable for SDMA Error. The `XSPI_INT_EN.SDMA_ERR_EN` bit enables an interrupt when an illegal access to the host DMA interface is detected.
21 (R/W)	SDMA_TRIGG_EN	Interrupt Enable for SDMA Trigger. The `XSPI_INT_EN.SDMA_TRIGG_EN` bit enables an interrupt when the trigger condition for the host DMA is met.
20 (R/W)	CMD_IGNORED_EN	Interrupt Enable for Ignored Command. The `XSPI_INT_EN.CMD_IGNORED_EN` bit enables an interrupt for detection of an ignored command.
18 (R/W)	DDMA_TERR_EN	Interrupt Enable for Data DMA Error. The `XSPI_INT_EN.DDMA_TERR_EN` bit enables an interrupt for detecting a data internal DMA error.
17 (R/W)	CDMA_TERR_EN	Interrupt Enable for Command DMA Error. The `XSPI_INT_EN.CDMA_TERR_EN` bit enables an interrupt for detecting an auto CMD engine target error.
16 (R/W)	CTL_IDLE_EN	Interrupt Enable for Idle State. The `XSPI_INT_EN.CTL_IDLE_EN` bit enables an interrupt for detecting that the controller has returned to the idle state.
15 (R/W)	GP_OD3_EN	Interrupt Enable for GP OD3 Transition. The `XSPI_INT_EN.GP_OD3_EN` bit enables an interrupt for detecting the high-to-low or low-to-high transition on the XSPI_DFI_GP_OPEN_DRAIN[3] input pin.

Table 21-74: XSPI_INT_EN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/W)	GP_OD2_EN	Interrupt Enable for GP OD2 Transition. The `XSPI_INT_EN.GP_OD2_EN` bit enables an interrupt for detecting the high-to-low or low-to-high transition on the XSPI_DFI_GP_OPEN_DRAIN[2] input pin.
13 (R/W)	GP_OD1_EN	Interrupt Enable for GP OD1 Transition. The `XSPI_INT_EN.GP_OD1_EN` bit enables an interrupt for detecting the high-to-low or low-to-high transition on the XSPI_DFI_GP_OPEN_DRAIN[1] input pin.
12 (R/W)	GP_OD0_EN	Interrupt Enable for GP OD0 Transition. The `XSPI_INT_EN.GP_OD0_EN` bit enables an interrupt for detecting the high-to-low or low-to-high transition on the XSPI_DFI_GP_OPEN_DRAIN[0] input pin.

Interrupt Status Register

The XSPI_ISTAT register contains information about functional areas requiring servicing. Many of the bits serve as an indicator to further read and service various status registers. After servicing the interrupt source associated with a bit, the user must clear that interrupt source bit by writing a 1 to it.

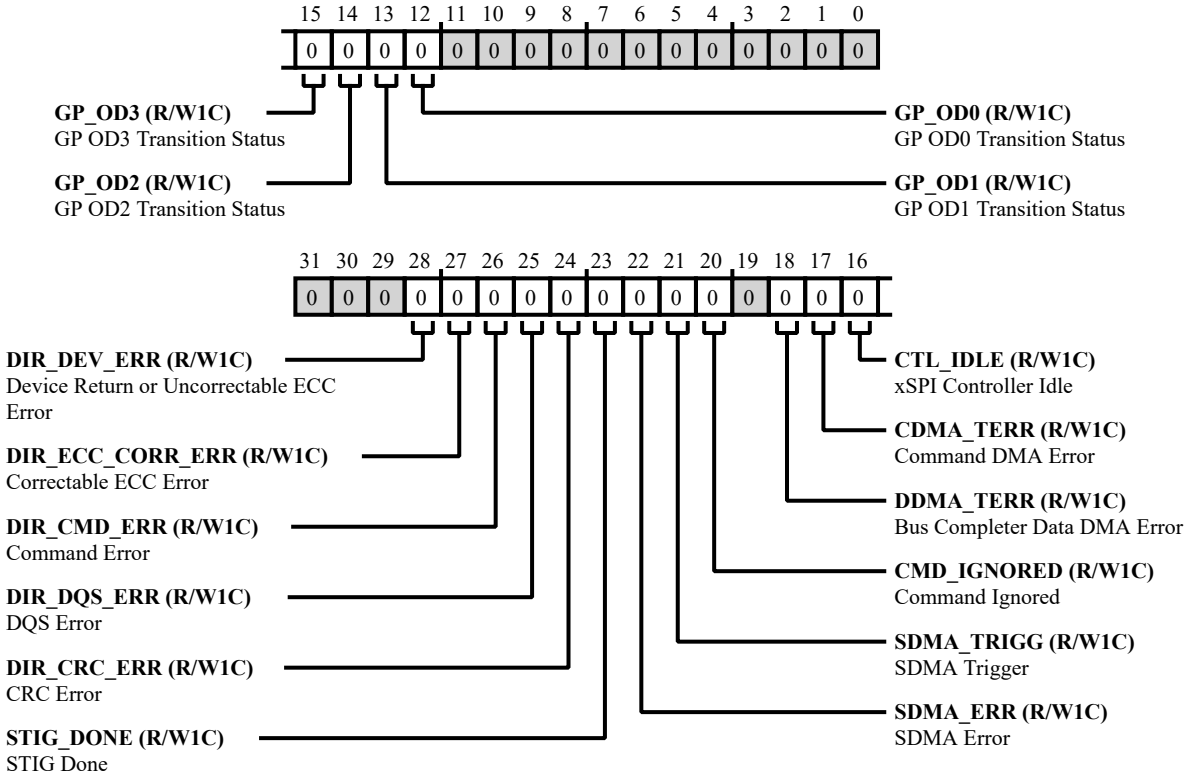

Figure 21-33: XSPI_ISTAT Register Diagram

Table 21-75: XSPI_ISTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
28 (R/W1C)	DIR_DEV_ERR	Device Return or Uncorrectable ECC Error. The XSPI_ISTAT.DIR_DEV_ERR bit is set (=1) when a program operation in direct mode failed. That is, the device returned the program fail bit when the status was checked. This bit is also set when an uncorrectable ECC error occurs in direct mode.
27 (R/W1C)	DIR_ECC_CORR_ERR	Correctable ECC Error. The XSPI_ISTAT.DIR_ECC_CORR_ERR bit is set (=1) when a correctable ECC error occurs in direct mode.

Table 21-75: XSPI_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
26 (R/W1C)	DIR_CMD_ERR	Command Error. The XSPI_ISTAT.DIR_CMD_ERR bit is set (=1) when the host has attempted to do something that is unsupported or incorrect. For example, the host has triggered a write when the device is operating in XIP mode. The full list of error conditions is described in the Event Handling section.
25 (R/W1C)	DIR_DQS_ERR	DQS Error. The XSPI_ISTAT.DIR_DQS_ERR bit is set (=1) when an incorrect number of DQS pulses were detected during a direct mode read or status check. The status is passed from the soft PHY and could mean that the PHY is configured badly such that it expects DQS strobes but never received them or that the XSPI_PHY_GATE_LPBK_CTL .RD_DEL_SEL value is incorrect and has caused data corruption and pointer misalignment in the PHY. To resolve this issue, the PHY must be reset to clear the XSPI_PHY_OB0.DQS_UR and XSPI_PHY_OB0.DQS_OV flags and reset the read data pointers.
24 (R/W1C)	DIR_CRC_ERR	CRC Error. The XSPI_ISTAT.DIR_CRC_ERR bit is set (=1) when CRC checking is enabled and a CRC error after a read or status checking command in direct work mode has been detected.
23 (R/W1C)	STIG_DONE	STIG Done. The XSPI_ISTAT.STIG_DONE bit is set (=1) when the last instruction in a glued chain has completed.
22 (R/W1C)	SDMA_ERR	SDMA Error. The XSPI_ISTAT.SDMA_ERR bit is set (=1) when an illegal access to the target DMA interface is detected.
21 (R/W1C)	SDMA_TRIGG	SDMA Trigger. The XSPI_ISTAT.SDMA_TRIGG bit indicates when the trigger condition for the target DMA is met. It is relevant to STIG and ACMD mode only and used to instruct the host when an access on the host interface is to be performed. For details, see the Operating in ACMD or STIG mode section.
20 (R/W1C)	CMD_IGNORED	Command Ignored. In ACMD work mode, the controller detected that a command that was sent by the host was to an already busy thread and ignored it. In STIG work mode, the controller detected that a command was sent when the STIG engine was already busy and ignored it.
18 (R/W1C)	DDMA_TERR	Bus Completer Data DMA Error. ACMD mode only. The XSPI_ISTAT.DDMA_TERR bit is set (=1) when a system bus error was detected on the internal DMA interface during data reads or writes.

Table 21-75: XSPI_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
17 (R/W1C)	CDMA_TERR	Command DMA Error. Command DMA target error. ACMD mode only. The `XSPI_ISTAT.CDMA_TERR` bit is set (=1) when a system bus error was detected on the internal DMA interface during descriptor reads or writes.
16 (R/W1C)	CTL_IDLE	xSPI Controller Idle. This is general status. The `XSPI_ISTAT.CTL_IDLE` bit indicates that the xSPI controller has returned to an idle state.
15 (R/W1C)	GP_OD3	GP OD3 Transition Status. The `XSPI_ISTAT.GP_OD3` bit indicates a high-to-low or low-to-high transition was detected on the XSPI_DFI_GP_OPEN_DRAIN[3] input pin.
14 (R/W1C)	GP_OD2	GP OD2 Transition Status. The `XSPI_ISTAT.GP_OD2` bit indicates a high-to-low or low-to-high transition detected on the XSPI_DFI_GP_OPEN_DRAIN[2] input pin.
13 (R/W1C)	GP_OD1	GP OD1 Transition Status. The `XSPI_ISTAT.GP_OD1` bit indicates a high-to-low or low-to-high transition detected on the XSPI_DFI_GP_OPEN_DRAIN[1] input pin.
12 (R/W1C)	GP_OD0	GP OD0 Transition Status. The `XSPI_ISTAT.GP_OD0` bit indicates a high-to-low or low-to-high transition detected on the XSPI_DFI_GP_OPEN_DRAIN[0] input pin.

Long Polling Count Register

The XSPI_LONGPOL_GCTL register contains the wait count value for long polling.

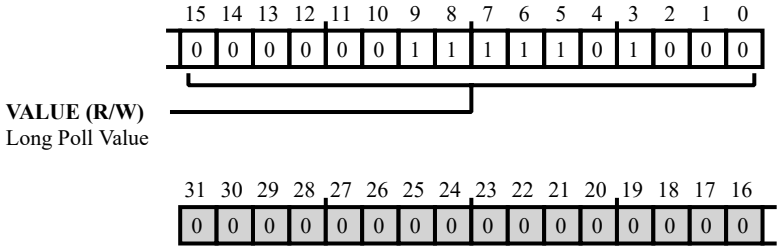

Figure 21-34: XSPI_LONGPOL_GCTL Register Diagram

Table 21-76: XSPI_LONGPOL_GCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Long Poll Value. The XSPI_LONGPOL_GCTL.VALUE bit field indicates the number of system clock cycles after an erase/write operation has been issued before the controller starts to check device status (ready/busy and fail/pass). First status checking polling happens after at least this many number of system clock cycles. The next status checking will happen every XSPI_SHORTPOLL_GCTL.VALUE cycles. The long polling value should be significantly larger the short polling value.

Device Active Maximum Clock Cycle Register

The XSPI_MINICTL_DEV_ACTIVE_MAX register is used to introduce a maximum number of xSPI clock cycles through which the CS number is kept active (low) on the memory interface. It is sometimes referred to as tCMS or tCEM timing. It is generally only relevant for RAM devices that must be periodically refreshed. The refresh is typically handled internal to the device. But, to fit this refresh operation along with normal controller requests, the controller my need to limit its access time. The user can program this register to force the controller to obey that requirement.

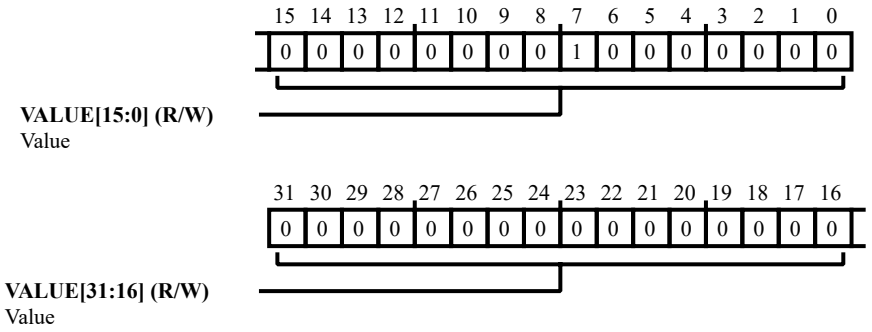

Figure 21-35: XSPI_MINICTL_DEV_ACTIVE_MAX Register Diagram

Table 21-77: XSPI_MINICTL_DEV_ACTIVE_MAX Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Value. The XSPI_MINICTL_DEV_ACTIVE_MAX.VALUE bit field is only valid when XSPI_SEQ_GTL0.TCMS_EN is set (=1). When using the STIG work mode, this is also only valid when the TCMS_EN bit of the STIG instruction is set. The XSPI_MINICTL_DEV_ACTIVE_MAX.VALUE bit field must only be enabled while working with RAM devices that require timing constraint for chip select low pulse width (the most common name is tCMS or tCEM in device specification).

Clock Mode Control Register

The XSPI_MINICTL_CLKMODE register defines the CPOL/CPHA settings for legacy SPI mode (defaulting to mode 0).

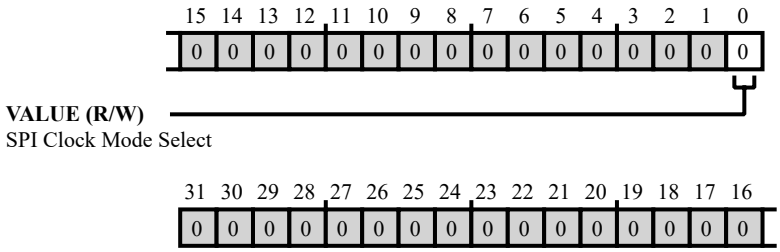

Figure 21-36: XSPI_MINICTL_CLKMODE Register Diagram

Table 21-78: XSPI_MINICTL_CLKMODE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W)	VALUE	SPI Clock Mode Select. The XSPI_MINICTL_CLKMODE.VALUE bit indicates the SPI clock mode. For DDR transfers, this bit must be cleared (=0) to meet DDR flash timings. For SDR transfers, allowable values are as follows: 0 - SPI mode 0 (clock is low when SPI bus is in idle) 1 - SPI mode 3 (clock is high when SPI bus is in idle)

Device Delay Register

The XSPI_MINICTL_DEV_DLY register is used to introduce relative device selection delays with respect to generated xSPI flash interface.

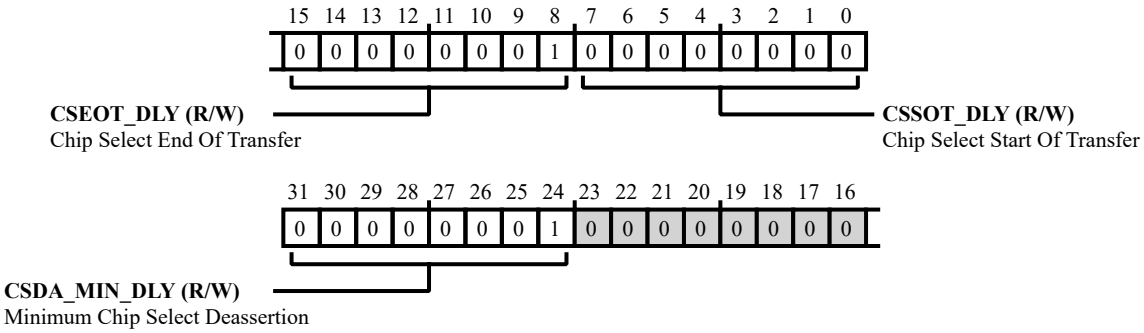

Figure 21-37: XSPI_MINICTL_DEV_DLY Register Diagram

Table 21-79: XSPI_MINICTL_DEV_DLY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	CSDA_MIN_DLY	Minimum Chip Select Deassertion. The XSPI_MINICTL_DEV_DLY.CSDA_MIN_DLY bit field indicates the Minimum Chip Select (CSDA_MIN) deassertion timing.
15:8 (R/W)	CSEOT_DLY	Chip Select End Of Transfer. The XSPI_MINICTL_DEV_DLY.CSEOT_DLY bit field indicates the Chip Select End Of Transfer (CSEOT). It improves the CS deassertion device timing to the last active clock edge.
7:0 (R/W)	CSSOT_DLY	Chip Select Start Of Transfer. The XSPI_MINICTL_DEV_DLY.CSSOT_DLY bit field indicates the Chip Select Start Of Transfer (CSSOT). It improves the CS deassertion device timing to the first active clock edge.

HyperFlash Offset Register

The XSPI_MINICTL_HF_OFFSET register is only applicable for legacy HyperFlash or xSPI profile 2 devices and can be used to configure the reserved area of the Command/Address (CA) field.

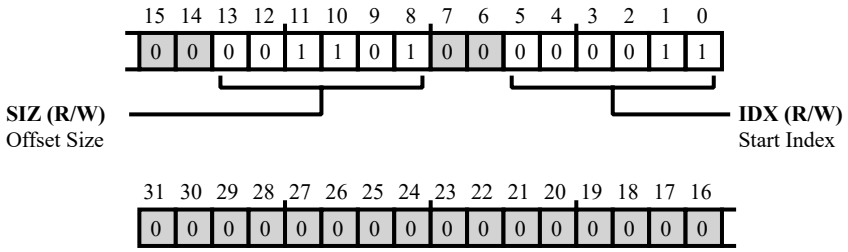

Figure 21-38: XSPI_MINICTL_HF_OFFSET Register Diagram

Table 21-80: XSPI_MINICTL_HF_OFFSET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
13:8 (R/W)	SIZ	Offset Size. The XSPI_MINICTL_HF_OFFSET.SIZ bit field indicates the offset size of the reserved area in the command format.
5:0 (R/W)	IDX	Start Index. The XSPI_MINICTL_HF_OFFSET.IDX bit field indicates the starting index of the reserved area in the command format.

JEDEC Reset Delay Register

The XSPI_MINICTL_JEDEC_RST_TR register is used to introduce relative device selection delays applicable for JEDEC reset instruction.

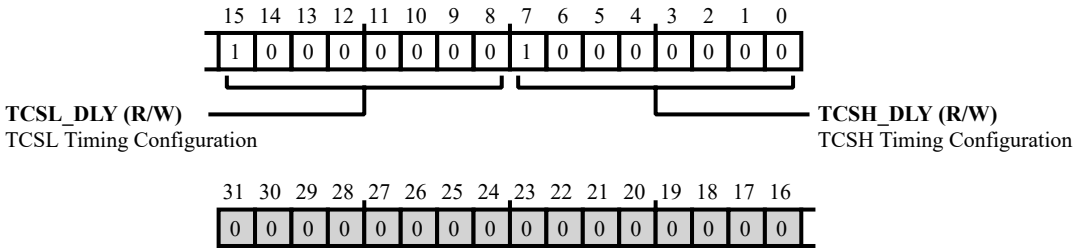

Figure 21-39: XSPI_MINICTL_JEDEC_RST_TR Register Diagram

Table 21-81: XSPI_MINICTL_JEDEC_RST_TR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W)	TCSL_DLY	TCSL Timing Configuration. The XSPI_MINICTL_JEDEC_RST_TR.TCSL_DLY bit field indicates how many xSPI clock cycles constitute tCSL timing of JEDEC reset instruction.
7:0 (R/W)	TCSH_DLY	TCSH Timing Configuration. The XSPI_MINICTL_JEDEC_RST_TR.TCSH_DLY bit field indicates how many xSPI clock cycles constitute tCSH timing of JEDEC reset instruction.

Hardware Reset Control Register

The XSPI_MINICTL_RST_PIN_CTL register configures the software controlled hardware reset.

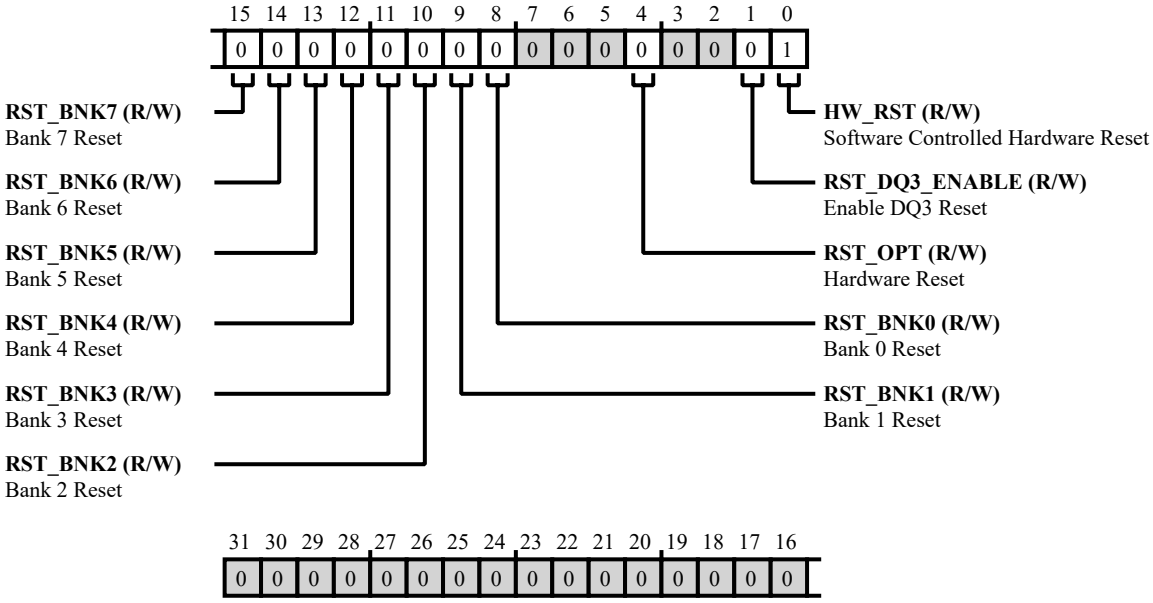

Figure 21-40: XSPI_MINICTL_RST_PIN_CTL Register Diagram

Table 21-82: XSPI_MINICTL_RST_PIN_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	RST_BNK7	Bank 7 Reset. The XSPI_MINICTL_RST_PIN_CTL.RST_BNK7 bit activates software controlled hardware reset signal on bank 7 (such as a device connected to chip select bit 7). It is applicable only for devices that support the RESET pin.	
		0	Disable
		1	Enable
14 (R/W)	RST_BNK6	Bank 6 Reset. The XSPI_MINICTL_RST_PIN_CTL.RST_BNK6 bit activates software controlled hardware reset signal on bank 6 (such as a device connected to chip select bit 6). It is applicable only for devices that support the RESET pin.	
		0	Disable
		1	Enable

Table 21-82: XSPI_MINICTL_RST_PIN_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W)	RST_BNK5	Bank 5 Reset. The `XSPI_MINICTL_RST_PIN_CTL.RST_BNK5` bit activates software controlled hardware reset signal on bank 5 (such as a device connected to chip select bit 5). It is applicable only for devices that support the RESET pin.	
		0	Disable
		1	Enable
12 (R/W)	RST_BNK4	Bank 4 Reset. The `XSPI_MINICTL_RST_PIN_CTL.RST_BNK4` bit activates software controlled hardware reset signal on bank 0 (such as a device connected to chip select bit 4). It is applicable only for devices that support the RESET pin.	
		0	Disable
		1	Enable
11 (R/W)	RST_BNK3	Bank 3 Reset. The `XSPI_MINICTL_RST_PIN_CTL.RST_BNK3` bit activates software controlled hardware reset signal on bank 3 (such as a device connected to chip select bit 3). It is applicable only for devices that support the RESET pin.	
		0	Disable
		1	Enable
10 (R/W)	RST_BNK2	Bank 2 Reset. The `XSPI_MINICTL_RST_PIN_CTL.RST_BNK2` bit activates software controlled hardware reset signal on bank 2 (such as a device connected to chip select bit 2). It is applicable only for devices that support the RESET pin.	
		0	Disable
		1	Enable
9 (R/W)	RST_BNK1	Bank 1 Reset. The `XSPI_MINICTL_RST_PIN_CTL.RST_BNK1` bit activates software controlled hardware reset signal on bank 1 (such as a device connected to chip select bit 1). It is applicable only for devices that support the RESET pin.	
		0	Disable
		1	Enable

Table 21-82: XSPI_MINICTL_RST_PIN_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	RST_BNK0	Bank 0 Reset. The `XSPI_MINICTL_RST_PIN_CTL.RST_BNK0` bit activates the software controlled hardware reset signal on bank 0 (such as a device connected to chip select bit 0). It is applicable only for devices that support the RESET pin.	
		0	Disable
		1	Enable
4 (R/W)	RST_OPT	Hardware Reset. The `XSPI_MINICTL_RST_PIN_CTL.RST_OPT` bit indicates the hardware reset option.	
		0	RESET pin. Device RESET# pin is used for toggling device hardware reset functionality.
		1	DQ3 pin. Device DQ3 pin is used for toggling device hardware reset functionality.
1 (R/W)	RST_DQ3_ENABLE	Enable DQ3 Reset. The `XSPI_MINICTL_RST_PIN_CTL.RST_DQ3_ENABLE` bit enables passing RESET to the DQ3 port of the device (by switching direction of DQ3 pad).	
0 (R/W)	HW_RST	Software Controlled Hardware Reset. The value of this field is directly routed to the DQ3 or RESET# output signal (depending on XSPI_MINICTRL_RST_PIN_CTL. RST_OPT). The value can be changed only when xSPI flash interface is in an idle state. The value of the software controlled hardware reset signal is overwritten when DQ3 is a valid transaction pin. The controller does not check the device hardware reset setup/hold timings - this must be ensured by the host. The host is also responsible for triggering a suitable reset method by selecting the corresponding bank number and reset method (as defined in this register). The controller does not drive RESET value during read data phase of any active transfer (as transfer direction switches in this transfer part).	

Reset Recovery Delay Register

The XSPI_MINICTL_RST_RECOV register is used to introduce relative reset recovery delay with respect to generated xSPI flash interface.

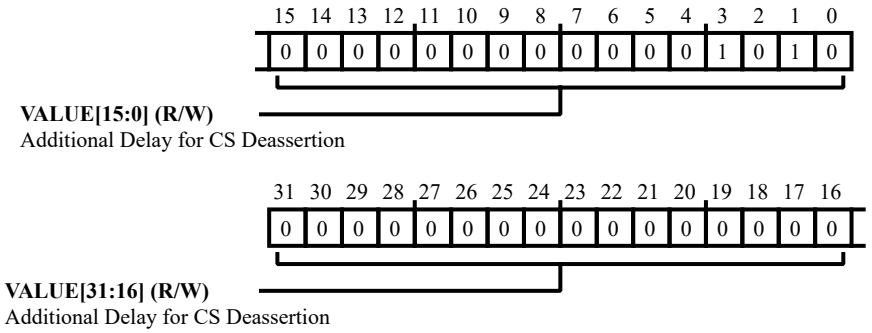

Figure 21-41: XSPI_MINICTL_RST_RECOV Register Diagram

Table 21-83: XSPI_MINICTL_RST_RECOV Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Additional Delay for CS Deassertion. The XSPI_MINICTL_RST_RECOV.VALUE bit field defines the additional delay for CS deassertion to accommodate device reset recovery timing.

Write Protect Register

The XSPI_MINICTL_WP_CTL register controls write protection.

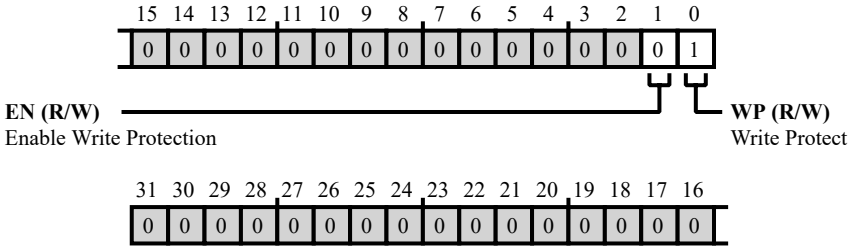

Figure 21-42: XSPI_MINICTL_WP_CTL Register Diagram

Table 21-84: XSPI_MINICTL_WP_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
1 (R/W)	EN	Enable Write Protection. The XSPI_MINICTL_WP_CTL.EN bit enables passing the write protect signal to the device (by switching direction of DQ2 pad).
0 (R/W)	WP	Write Protect. The XSPI_MINICTL_WP_CTL.WP bit indicates the write protect signal for all devices. Value of this register is directly routed to the DQ2 output signal. The value can be changed only when xSPI flash interface is in an idle state. Value of the write protection signal is overwritten in case DQ2 is a valid transaction pin. The controller does not check the write protect setup/hold timings - this must be ensured by the host. The controller does not drive the write protect value during the read data phase of any active transfer. Write protection on DQ2 functionality is only supported by flash devices and when the controller is configured in single and dual SPI modes.

PHY DLL Observable Points 0 Register

The XSPI_PHY_DLLOB0 register holds observable points in the PHY.

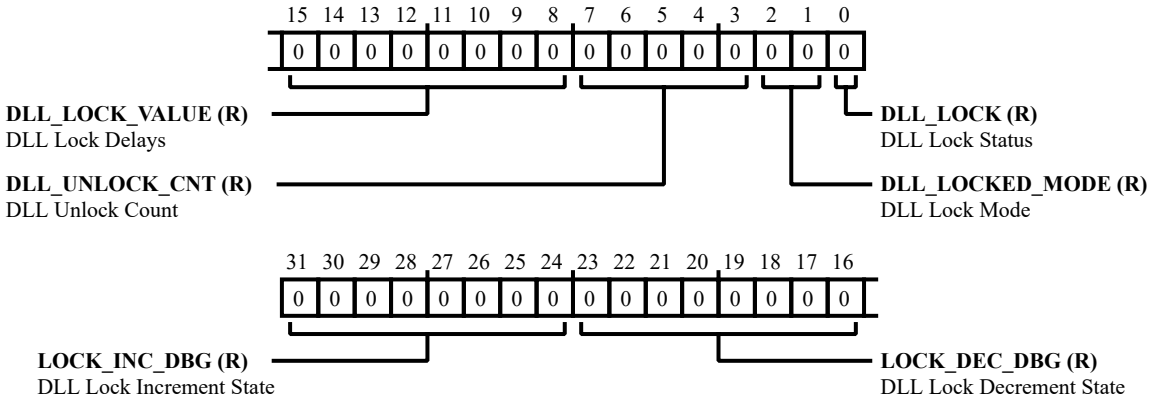

Figure 21-43: XSPI_PHY_DLLOB0 Register Diagram

Table 21-85: XSPI_PHY_DLLOB0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/NW)	LOCK_INC_DBG	DLL Lock Increment State. The XSPI_PHY_DLLOB0.LOCK_INC_DBG bit field holds the state of the cumulative DLL_LOCK_INC register when the DLL_UNLOCK_CNT field (bits [7:3]) of this parameter was triggered to increment or was last saturated at a value of 0x1f.
23:16 (R/NW)	LOCK_DEC_DBG	DLL Lock Decrement State. The XSPI_PHY_DLLOB0.LOCK_DEC_DBG bit field holds the state of the cumulative DLL_LOCK_DEC register when the DLL_UNLOCK_CNT field (bits [7:3]) of this parameter was triggered to decrement or was last saturated at a value of 0x1f.
15:8 (R/NW)	DLL_LOCK_VALUE	DLL Lock Delays. The XSPI_PHY_DLLOB0.DLL_LOCK_VALUE bit field indicates the number of delay elements that the DLL has determined for lock in either full clock or half clock mode. In full clock mode, this value equals the number of delay elements in one cycle. In half clock mode, this value equals the number of delay elements in one half clock cycle. In saturation mode, this value equals the maximum number of delay elements. The slaves use this value to configure their delays for the clock write and read DQS signals. This value is valid only when locking mechanism is done.
7:3 (R/NW)	DLL_UNLOCK_CNT	DLL Unlock Count. The XSPI_PHY_DLLOB0.DLL_UNLOCK_CNT bit field indicates the number of times that the bus requester DLL consecutive increment or decrement value programmed in the DLL_LOCK_NUM field (bits [18:16]) of the XSPI_PHY_DLL_REQ_CTL register has been triggered. The DLL_UNLOCK_CNT saturates at a value of 0x1f. Asserting the XSPI_PHY_DLL_CTL.DLL_RST resets this counter to 0.

Table 21-85: XSPI_PHY_DLLOB0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2:1 (R/NW)	DLL_LOCKED_MODE	DLL Lock Mode. The `XSPI_PHY_DLLOB0.DLL_LOCKED_MODE` bit field indicates the mode in which the DLL has achieved the lock.	
		0	Full Clock Mode. The bus requester delay line was long enough to lock on one full clock cycle of delay. In this mode, the DLL_LOCK_VALUE field (bits [15:8]) of this parameter indicates the number of delays in full clock cycles.
		1	Reserved
		2	Half Clock Mode. The bus requester delay line was not long enough to lock one full cycle of delay but could lock on a half-cycle of delay. In this mode, the DLL_LOCK_VALUE field (bits [15:8]) of this parameter indicates the number of delays in one half clock cycles.
		3	Saturation Mode. The bus requester delay line was not long enough to lock on a full or a half-clock cycle. In this mode, the encoder value is fixed at the maximum delay line setting and the bus requester DLL will be disabled. The bus completer delay lines continue to use the fractional delays based upon the fixed saturation value of the delay line.
0 (R/NW)	DLL_LOCK	DLL Lock Status. The `XSPI_PHY_DLLOB0.DLL_LOCK` bit indicates the status of the DLL locking when the DLL lock logic is found (not inc AND not dec) OR (an inc then dec) OR (a dec then inc). When `XSPI_PHY_DLL_REQ_CTL.DLL_START_PT` is configured to be smaller than half a clock period, the first found (a dec then inc) is not the DLL locking point , but DLL_LOCK is asserted. 0 - DLL has not locked 1 - DLL is locked	
		0	Not Locked
		1	Locked

PHY DLL Observable Points 1 Register

The XSPI_PHY_DLLOB1 register holds observable points in the PHY.

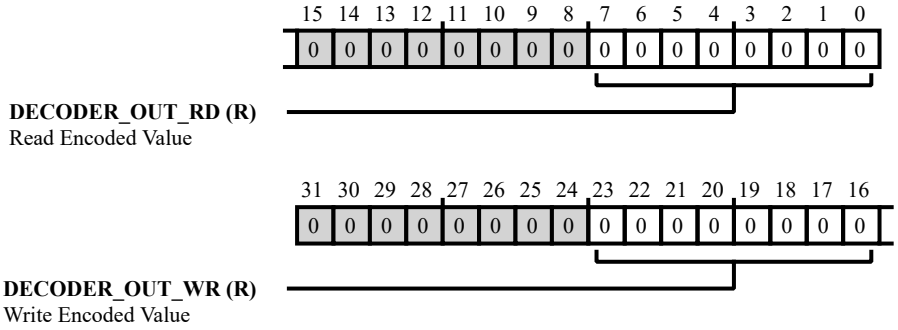

Figure 21-44: XSPI_PHY_DLLOB1 Register Diagram

Table 21-86: XSPI_PHY_DLLOB1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:16 (R/NW)	DECODER_OUT_WR	Write Encoded Value. The XSPI_PHY_DLLOB1.DECODER_OUT_WR bit field holds the encoded value for the clock write delay line for this slice.
7:0 (R/NW)	DECODER_OUT_RD	Read Encoded Value. The XSPI_PHY_DLLOB1.DECODER_OUT_RD bit field holds the encoded value for the read delay line for this slice.

PHY DLL Control Register

The XSPI_PHY_DLL_CTL register configures the resynchronization of the bus completer DLL of the PHY. When the PHY is used with the xSPI controller, this register is automatically updated by device discovery during initialization.

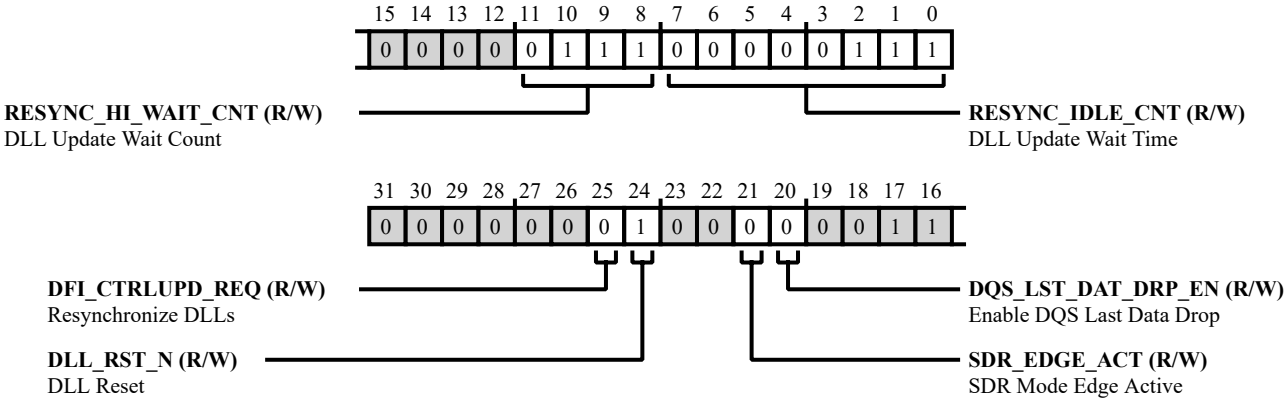

Figure 21-45: XSPI_PHY_DLL_CTL Register Diagram

Table 21-87: XSPI_PHY_DLL_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
25 (R/W)	DFI_CTRLUPD_REQ	Resynchronize DLLs. The XSPI_PHY_DLL_CTL.DFI_CTRLUPD_REQ bit signals to resynchronize the DLLs and read and write FIFO pointers. To send the update request to the PHY, the host must first set this bit (=1), then, wait until the bit is cleared (=0). Do not use this signal when automatic resynchronization is enabled (XSPI_PHY_DLL_UPDT_CNT is not zero).
24 (R/W)	DLL_RST_N	DLL Reset. The XSPI_PHY_DLL_CTL.DLL_RST_N bit resets the DLLs of the PHY and starts searching for lock again.
21 (R/W)	SDR_EDGE_ACT	SDR Mode Edge Active. The XSPI_PHY_DLL_CTL.SDR_EDGE_ACT bit indicates how the PHY samples data on the edges of the sampling clock. In SDR mode, only one sample is needed. When XSPI_PHY_DLL_CTL.SDR_EDGE_ACT is cleared (=0), the controller propagates data from the positive edge of the PHY sampling clock. When XSPI_PHY_DLL_CTL.SDR_EDGE_ACT is set (=1), the controller propagates data from the negative edge of PHY sampling clock. In DDR mode, this bit must be cleared.

Table 21-87: XSPI_PHY_DLL_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
20 (R/W)	DQS_LST_DAT_DRP_EN	Enable DQS Last Data Drop. XSPI_PHY_DLL_CTL.DQS_LST_DAT_DRP_EN is set (=1) when the flash device issues data on the negative edge of the flash clock and returns them with DQS, and the PHY is configured to sample data in DQS mode. In this case, the number of DQS edges equals to number of requested data + 1. When XSPI_PHY_DLL_CTL.DQS_LST_DAT_DRP_EN is set, the controller internally requests this redundant data at the end of the transfer cleaning up the PHY FIFO.
17 (R/W)	EXTENDED_WR_MODE	. This PHY register field is not applicable for xSPI flash Controller.
16 (R/W)	EXTENDED_RD_MODE	. This PHY register field is not applicable for xSPI flash controller.
11:8 (R/W)	RESYNC_HI_WAIT_CNT	DLL Update Wait Count. The XSPI_PHY_DLL_CTL.RESYNC_HI_WAIT_CNT bit field defines the number of xSPI clock cycles for which the DLL update request (XSPI_PHY_DLL_CTL.DFI_CTRLUPD_REQ) must be asserted to resynchronize the DLLs and read and write FIFO pointers.
7:0 (R/W)	RESYNC_IDLE_CNT	DLL Update Wait Time. The XSPI_PHY_DLL_CTL.RESYNC_IDLE_CNT bit field defines the wait time (in terms of xSPI clock cycles) between the deassertion of the DLL update request (XSPI_PHY_DLL_CTL.DFI_CTRLUPD_REQ) and resuming traffic to the PHY.

Bus Requester DLL Control Register

The XSPI_PHY_DLL_REQ_CTL register controls the bus requester DLL logic.

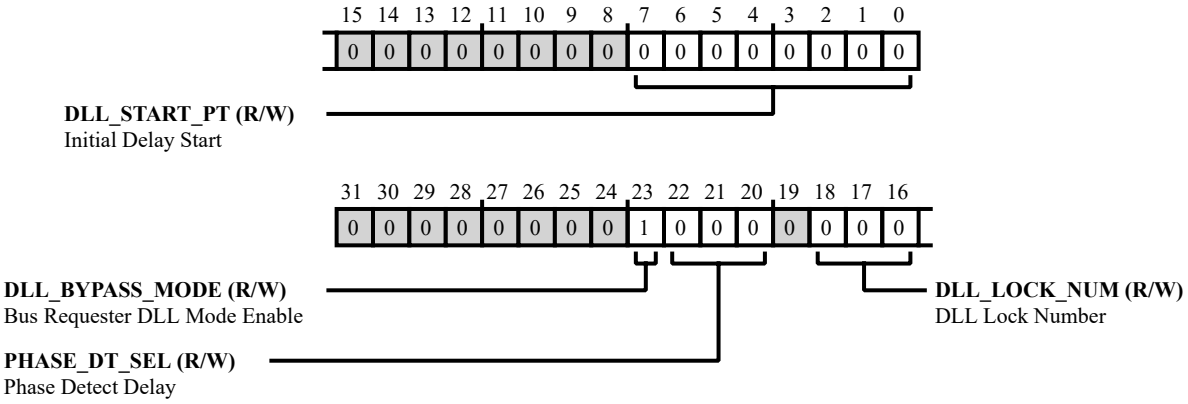

Figure 21-46: XSPI_PHY_DLL_REQ_CTL Register Diagram

Table 21-88: XSPI_PHY_DLL_REQ_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
23 (R/W)	DLL_BYPASS_MODE	Bus Requester DLL Mode Enable. The XSPI_PHY_DLL_REQ_CTL.DLL_BYPASS_MODE bit enables DLL bypass mode control. It controls the bypass mode of the bus requester and bus completer DLLs. The XSPI_PHY_DLL_REQ_CTL.DLL_BYPASS_MODE bit is intended to be used only for debug.	
		0	Normal Operational Mode. DLL functioning in normal mode where the bus completer delay line settings are used as fractional delay of the bus requester delay line encoder reading of the number of delays in one cycle.
		1	Bypass Mode On. Delays are defined in the XSPI_PHY_DLL_COMP_CTL register. The bus requester DLL is disabled with only 1 delay element in its delay line. The bus completer delay lines decode delays in absolute delay elements rather than as fractional delays. The XSPI_PHY_DLLOB0. DLL_LOCK is forced high.
22:20 (R/W)	PHASE_DT_SEL	Phase Detect Delay. The XSPI_PHY_DLL_REQ_CTL.PHASE_DT_SEL bit field indicates the number of delay elements to be inserted between the phase detect flip-flops. Defaults to 0x0, although the recommended value is 2 elements. But, if a lock condition is not detected, the user should increase the number of delay elements.	
		0	One Delay Element
		1	Two Delay Elements

Table 21-88: XSPI_PHY_DLL_REQ_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		2	Three Delay Elements
		3	Four Delay Elements
		4	Five Delay Elements
		5	Six Delay Elements
		6	Seven Delay Elements
		7	Eight Delay Elements
18:16 (R/W)	DLL_LOCK_NUM	DLL Lock Number. The `XSPI_PHY_DLL_REQ_CTL.DLL_LOCK_NUM` bit field holds the number of consecutive increment or decrement indications that trigger an unlock condition and increment the XSPI_PHY_DLLOB0.DLL_UNLOCK_CNT field and either the XSPI_PHY_DLLOB0.LOCK_DEC_DBG or XSPI_PHY_DLLOB0.LOCK_DEC_DBG fields.	
7:0 (R/W)	DLL_START_PT	Initial Delay Start. The `XSPI_PHY_DLL_REQ_CTL.DLL_START_PT` bit field indicates the initial delay value for the DLL. This value is also used as the increment value if the initial value is less than a half-clock cycle. This field must be set such that it is not greater than 7/8ths of a clock period given the worst case element delay. For example, if the frequency is 200MHz (5ns cycle time) with a worst case element 80ps delay, this field must be configured to = 5 * (7/8) / .080 = 54 elements. This calculation helps determine the start point which achieves the fastest lock. However, a small value such as 0x04 may be used instead to ensure that the DLL does not lock on a harmonic. Note that with a small value like this, the initial lock time is longer. Value smaller than 0x04 may cause no lock by DLL.	

Bus Completer DLL Control Register

The XSPI_PHY_DLL_COMP_CTL register controls the bus completer DLL.

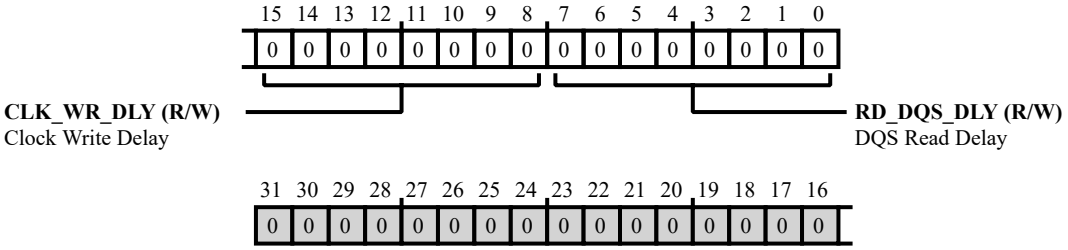

Figure 21-47: XSPI_PHY_DLL_COMP_CTL Register Diagram

Table 21-89: XSPI_PHY_DLL_COMP_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W)	CLK_WR_DLY	Clock Write Delay. The XSPI_PHY_DLL_COMP_CTL.CLK_WR_DLY bit field controls the clock write delay line which adjusts the write DQ bit timing in 1/256th steps of the clock period in normal DLL locked mode. In bypass mode, this field directly programs the number of delay elements.
7:0 (R/W)	RD_DQS_DLY	DQS Read Delay. The XSPI_PHY_DLL_COMP_CTL.RD_DQS_DLY bit field controls the read DQS delay which adjusts the timing in 1/256th of the clock period when in normal DLL locked mode. In bypass mode, this field directly programs the number of delay elements.

PHY DLL Resynchronization Register

The XSPI_PHY_DLL_UPDT_CNT register configures the resynchronization of the bus completer DLL of the PHY.

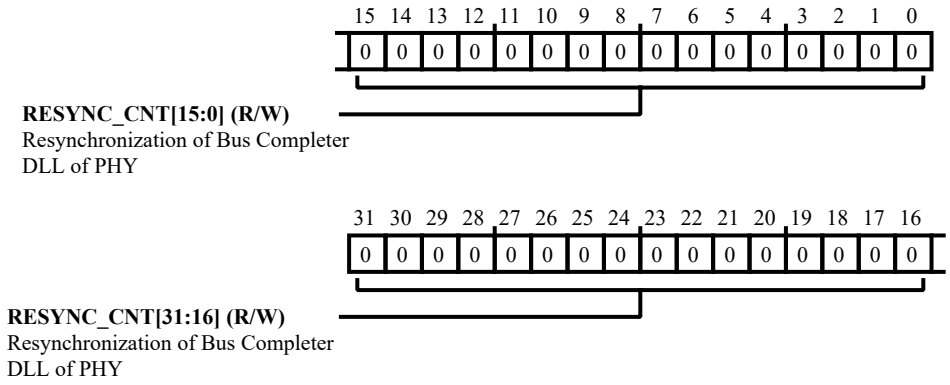

Figure 21-48: XSPI_PHY_DLL_UPDT_CNT Register Diagram

Table 21-90: XSPI_PHY_DLL_UPDT_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	RESYNC_CNT	Resynchronization of Bus Completer DLL of PHY. The XSPI_PHY_DLL_UPDT_CNT.RESYNC_CNT bit field defines the time interval (in terms of xSPI clock) to send an update (XSPI_PHY_DLL_CTL.DFI_CTRLUPD_REQ=1) to the PHY to re-synchronize the bus completer DLL values with that of the bus requester DLL and to also re-synchronize the read and write FIFO pointers in the read path. If the value in this field is zero, the controller will not further DLL update requests to the PHY. DFI_CTRLUPD_REQ signal can be controlled directly by the host using XSPI_PHY_DLL_CTL.DFI_CTRLUPD_REQ. Note: While this feature is enabled, access to the PHY registers shall not be performed.

PHY DQS Timing Register

The XSPI_PHY_DQS_TR register controls the DQS related timing.

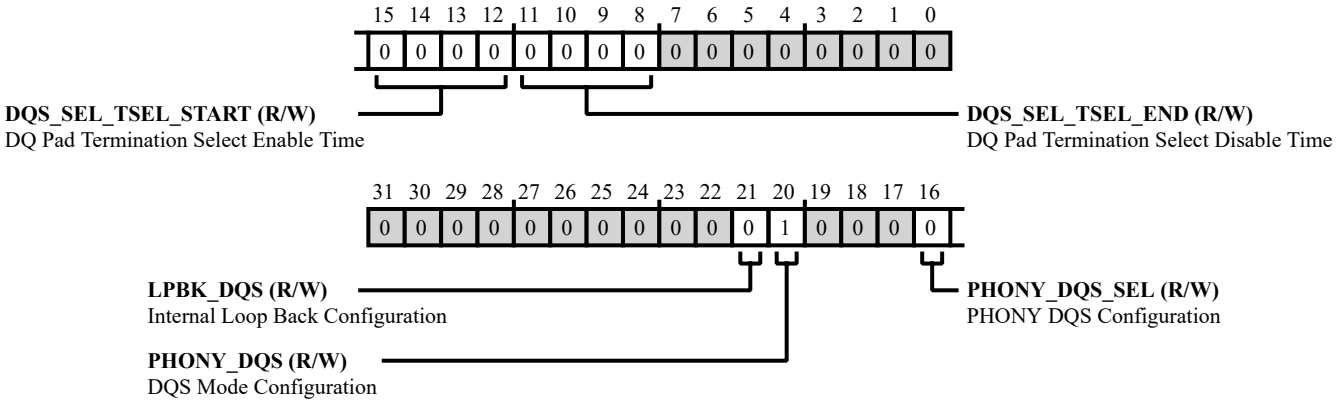

Figure 21-49: XSPI_PHY_DQS_TR Register Diagram

Table 21-91: XSPI_PHY_DQS_TR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
21 (R/W)	LPBK_DQS	Internal Loop Back Configuration. The XSPI_PHY_DQS_TR.LPBK_DQS bit is used in conjunction with bits 22 and 20 to control how read data is sampled by the PHY. The XSPI_PHY_DQS_TR.LPBK_DQS bit is only valid when bit 20 is set (=1), meaning it is only relevant when read data is not being sampled by DQS from the memory device. If bit 20 is cleared (=0), the XSPI_PHY_DQS_TR.LPBK_DQS bit should also be cleared. When using the PHY with the xSPI controller, this bit must be set to the same value as bit 20.This bit selects which internal source is used by the PHY to sample the read data. This is internally generated and is passed out of the PHY via rebar_opad If bit 22 of this register is '0', then it will be internally looped back within the rebar pad. If bit 22 of this register is '1', the rebar_opad will be passed through the rebar pad and it will be the responsibility of the integrator to loop that back to the PHY into the lpbk_dqs pin. 0 - Use phony DQS for data capture 1 - Use lpbk_dqs for data capture. [/list].

Table 21-91: XSPI_PHY_DQS_TR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
20 (R/W)	PHONY_DQS	DQS Mode Configuration. The `XSPI_PHY_DQS_TR.PHONY_DQS` bit is used in conjunction with bits 22 and 21 to control how read data is sampled by the PHY. The `XSPI_PHY_DQS_TR.PHONY_DQS` bit selects whether the read data sent by the memory device is sampled by DQS supplied by the memory device, or by a signal locally generated within the PHY.	
		0	Use DQS from device
		1	Use internally generated DQS
16 (R/W)	PHONY_DQS_SEL	PHONY DQS Configuration. When `XSPI_PHY_DQS_TR.PHONY_DQS_SEL` is cleared (=0), the PHONY_DQS is synchronous with rising edge of the CLK_PHY before sending to the entry flops. When `XSPI_PHY_DQS_TR.PHONY_DQS_SEL` is set (=1), the PHONY_DQS signal is synchronous with the falling edge of CLK_PHY before sending to the entry flops.	
15:12 (R/W)	DQS_SEL_TSEL_START	DQ Pad Termination Select Enable Time. The `XSPI_PHY_DQS_TR.DQS_SEL_TSEL_START` bit field defines the DQ pad dynamic termination select enable time. Larger values add greater delay to when tsel turns on. Each bit changes the output enable time by a 1/2 cycle resolution.	
11:8 (R/W)	DQS_SEL_TSEL_END	DQ Pad Termination Select Disable Time. The `XSPI_PHY_DQS_TR.DQS_SEL_TSEL_END` bit field defines the DQ pad dynamic termination select disable time. Larger values increase the delay to when tsel turns off. Each bit changes the output enable time by a 1/2 cycle resolution.	

PHY DQ Timing Register

The XSPI_PHY_DQ_TR register controls the DQ related timing.

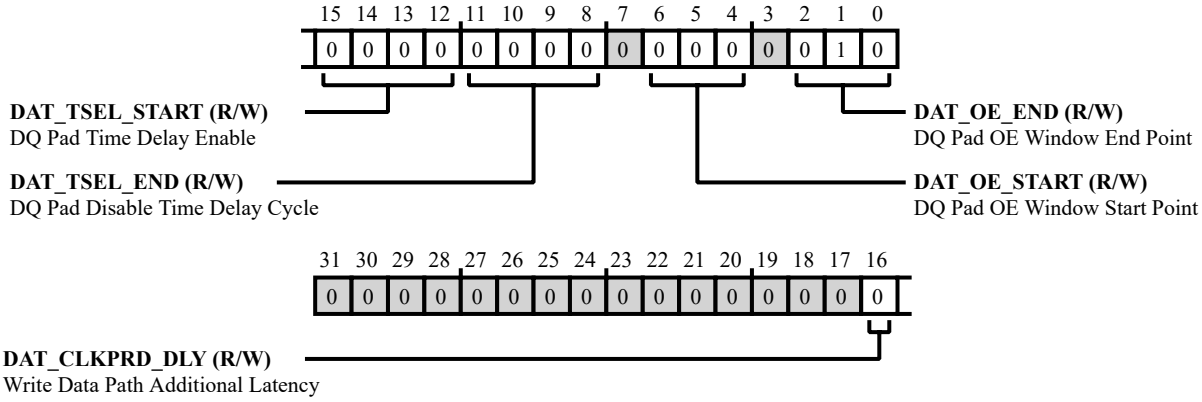

Figure 21-50: XSPI_PHY_DQ_TR Register Diagram

Table 21-92: XSPI_PHY_DQ_TR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
16 (R/W)	DAT_CLKPRD_DLY	Write Data Path Additional Latency. The XSPI_PHY_DQ_TR.DAT_CLKPRD_DLY bit field defines additional latency on the write data path. It also adds a clock cycle delay for the data OE path which is equivalent of adding 2 to DAT_OE_END and DAT_OE_START.
15:12 (R/W)	DAT_TSEL_START	DQ Pad Time Delay Enable. The XSPI_PHY_DQ_TR.DAT_TSEL_START bit field defines the DQ pad dynamic termination select enable time. Larger values add greater delay to when tsel turns on. Each bit changes the output enable time by a 1/2 cycle resolution.
11:8 (R/W)	DAT_TSEL_END	DQ Pad Disable Time Delay Cycle. The XSPI_PHY_DQ_TR.DAT_TSEL_END bit field defines the DQ pad dynamic termination select disable time. Larger values increase the delay to when tsel turns off. Each bit changes the output enable time by a 1/2 cycle resolution.
6:4 (R/W)	DAT_OE_START	DQ Pad OE Window Start Point. The XSPI_PHY_DQ_TR.DAT_OE_START bit field adjusts the starting point of the DQ pad output enable window. Lower numbers pull the rising edge earlier in time and larger numbers cause the rising edge to be delayed. Each bit changes the output enable time by a 1/2 cycle resolution.
2:0 (R/W)	DAT_OE_END	DQ Pad OE Window End Point. The XSPI_PHY_DQ_TR.DAT_OE_END bit field adjusts the ending point of the DQ pad output enable window. Lower numbers pull the falling edge earlier in time and larger numbers cause the falling edge to be delayed. Each bit changes the output enable time by a 1/2 cycle resolution.

PHY Features Register

The XSPI_PHY_FEATURES register shows the available hardware features.

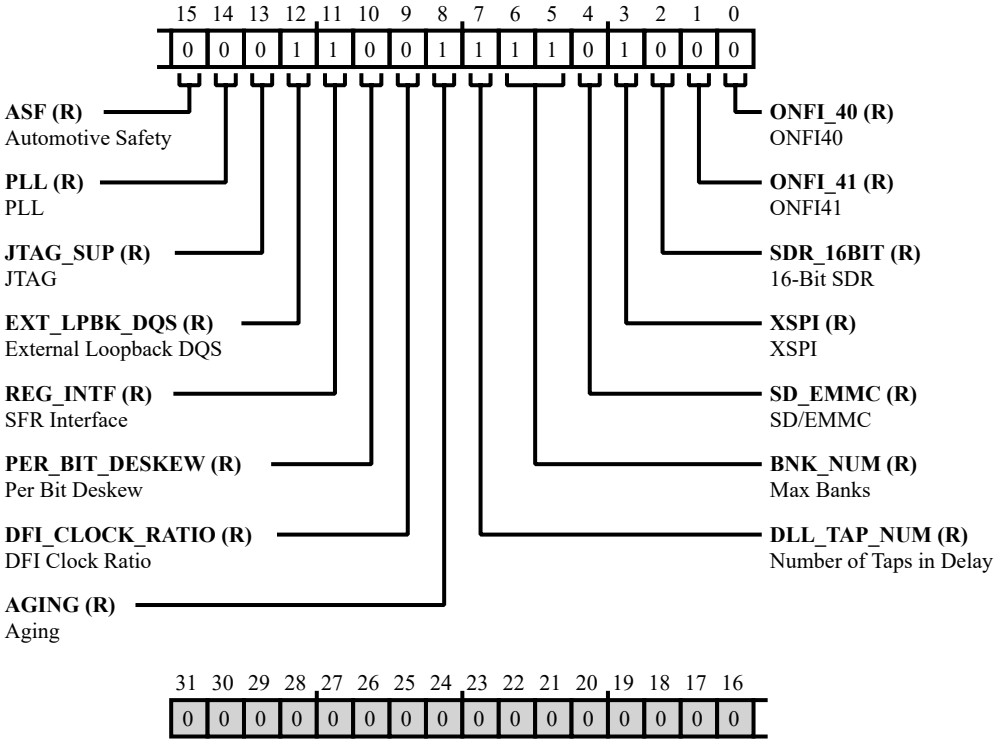

Figure 21-51: XSPI_PHY_FEATURES Register Diagram

Table 21-93: XSPI_PHY_FEATURES Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/NW)	ASF	Automotive Safety. The XSPI_PHY_FEATURES.ASF bit indicates support for an automotive safety feature.
14 (R/NW)	PLL	PLL. The XSPI_PHY_FEATURES.PLL bit indicates support for PLL.
13 (R/NW)	JTAG_SUP	JTAG. The XSPI_PHY_FEATURES.JTAG_SUP bit indicates support for JTAG multiplexing.
12 (R/NW)	EXT_LPBK_DQS	External Loopback DQS. The XSPI_PHY_FEATURES.EXT_LPBK_DQS bit indicates support for an external LPBK_DQS IO pad.

Table 21-93: XSPI_PHY_FEATURES Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/NW)	REG_INTF	SFR Interface. The `XSPI_PHY_FEATURES.REG_INTF` bit indicates the SFR interface type. This is an encoded value.	
		0	DFI
		1	APB
10 (R/NW)	PER_BIT_DESKEW	Per Bit Deskew. The `XSPI_PHY_FEATURES.PER_BIT_DESKEW` bit indicates support for per-bit deskew.	
9 (R/NW)	DFI_CLOCK_RATIO	DFI Clock Ratio. The `XSPI_PHY_FEATURES.DFI_CLOCK_RATIO` bit indicates support for a clock ratio on the DFI interface. This is an encoded value.	
		0	1:1
		1	1:2
8 (R/NW)	AGING	Aging. The `XSPI_PHY_FEATURES.AGING` bit indicates support for aging in delay lines.	
7 (R/NW)	DLL_TAP_NUM	Number of Taps in Delay. The `XSPI_PHY_FEATURES.DLL_TAP_NUM` bit indicates the number of taps in the delay line.	
		0	128
		1	256
6:5 (R/NW)	BNK_NUM	Max Banks. The `XSPI_PHY_FEATURES.BNK_NUM` bit field indicates the maximum number of banks supported by hardware. This is an encoded value.	
		0	One bank
		1	Two banks
		2	Four banks
		3	Eight banks
4 (R/NW)	SD_EMMC	SD/EMMC. The `XSPI_PHY_FEATURES.SD_EMMC` bit indicates support for SD/eMMC.	
3 (R/NW)	XSPI	XSPI. The `XSPI_PHY_FEATURES.XSPI` bit indicates support for xSPI.	

Table 21-93: XSPI_PHY_FEATURES Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
2 (R/NW)	SDR_16BIT	16-Bit SDR. The `XSPI_PHY_FEATURES.SDR_16BIT` bit indicates support for 16-bit in ONFI SDR work mode.
1 (R/NW)	ONFI_41	ONFI41. The `XSPI_PHY_FEATURES.ONFI_41` bit indicates support for ONFI4.1 - NAND flash.
0 (R/NW)	ONFI_40	ONFI40. The `XSPI_PHY_FEATURES.ONFI_40` bit indicates support for ONFI4.0 - NAND flash.

PHY Gate Loopback Control Register

The XSPI_PHY_GATE_LPBK_CTL register controls the gate and loopback control related timing.

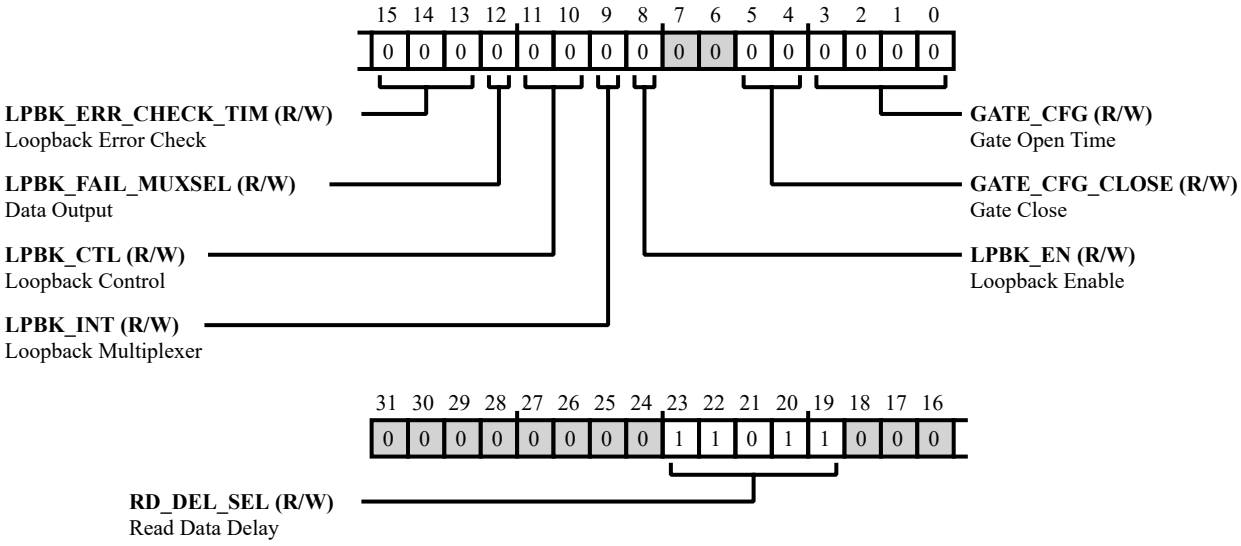

Figure 21-52: XSPI_PHY_GATE_LPBK_CTL Register Diagram

Table 21-94: XSPI_PHY_GATE_LPBK_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
23:19 (R/W)	RD_DEL_SEL	Read Data Delay. The XSPI_PHY_GATE_LPBK_CTL.RD_DEL_SEL bit defines the read data delay. It indicates the number of cycles to delay the dfi_rddata_en signal prior to enabling the read FIFO. After this delay, the read pointers begin incrementing the read FIFO. If sync_method is set (=1) the value of this field must take into account the synchronization time of the pointers in the entry FIFO (adding three clock cycles should be sufficient).	
15:13 (R/W)	LPBK_ERR_CHECK_TIM	Loopback Error Check. The XSPI_PHY_GATE_LPBK_CTL.LPBK_ERR_CHECK_TIM bit field indicates the cycle delay between the LFSR and loopback error check logic to ensure that the LFSR sourced data and data being looped back arrive at the same clock cycle for comparison. This value is related to the XSPI_PHY_GATE_LPBK_CTL .RD_DEL_SEL field, and is equal to 7 - RD_DEL_SEL.	
12 (R/W)	LPBK_FAIL_MUXSEL	Data Output. The XSPI_PHY_GATE_LPBK_CTL.LPBK_FAIL_MUXSEL bit selects the data output type for XSPI_PHY_OB0.LPBK_DQ_DAT.	
		0	Return the expected data
		1	Return the actual data

Table 21-94: XSPI_PHY_GATE_LPBK_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11:10 (R/W)	LPBK_CTL	Loopback Control. The `XSPI_PHY_GATE_LPBK_CTL.LPBK_CTL` bit field indicates the loopback control.	
		0	Normal operation mode
		1	Loopback start. Enable loopback write mode.
		2	Loopback stop. Stop loopback to check error register.
		3	Clear. Clear loopback registers.
9 (R/W)	LPBK_INT	Loopback Multiplexer. The `XSPI_PHY_GATE_LPBK_CTL.LPBK_INT` bit controls the loopback read multiplexer.	
		0	External loopback
		1	Internal loopback
8 (R/W)	LPBK_EN	Loopback Enable. The `XSPI_PHY_GATE_LPBK_CTL.LPBK_EN` bit controls the internal write multiplexer.	
		0	Normal operation
		1	Enable loopback
5:4 (R/W)	GATE_CFG_CLOSE	Gate Close. The `XSPI_PHY_GATE_LPBK_CTL.GATE_CFG_CLOSE` bit field allows extending the closing of the DQS gate. Recommended value is zero. rebar_dfi - Read enable output signal. It is an internal signal between the xSPI PHY and xSPI controller. dfi_cebar - Peripheral select output (CS) signal. It is an internal signal between the xSPI PHY and xSPI controller.	
3:0 (R/W)	GATE_CFG	Gate Open Time. Coarse adjust of gate open time. The `XSPI_PHY_GATE_LPBK_CTL.GATE_CFG` bit field is the number of cycles to delay the dfi_rddata_en signal prior to opening the gate in full cycle increments. Decreasing this value pulls the gate earlier in time. This field must be programmed such that the gate signal lands in the valid DQS gate window.	

PHY Global Control Register

The XSPI_PHY_GCTL register handles the global control settings for the PHY.

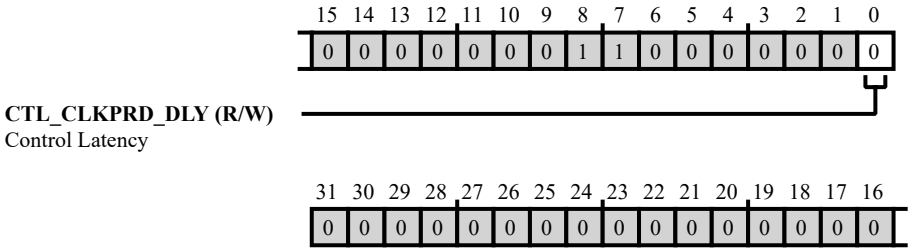

Figure 21-53: XSPI_PHY_GCTL Register Diagram

Table 21-95: XSPI_PHY_GCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W)	CTL_CLKPRD_DLY	Control Latency. The XSPI_PHY_GCTL.CTL_CLKPRD_DLY bit indicates an additional latency on the control signals WE/RE/CE/WP.

PHY GPIO Control Register 0

The XSPI_PHY_GPIO_CTL0 register is a general purpose register. The [31:0] vector is brought to the PHY I/Os. These pins can be used to control any static settings that may be required for the connected I/O pads.

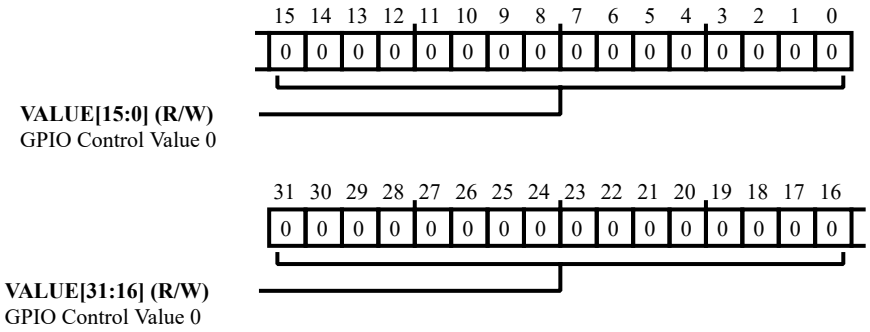

Figure 21-54: XSPI_PHY_GPIO_CTL0 Register Diagram

Table 21-96: XSPI_PHY_GPIO_CTL0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	GPIO Control Value 0. The [31:0] vector is brought to the PHY I/Os. The XSPI_PHY_GPIO_CTL0.VALUE bit field can used to control any static settings that may be required for the connected IO pads.

PHY GPIO Control Register 1

The XSPI_PHY_GPIO_CTL1 register is a general purpose register. The [31:0] vector is brought to the PHY I/Os. These pins can be used to control any static settings that may be required for the connected I/O pads.

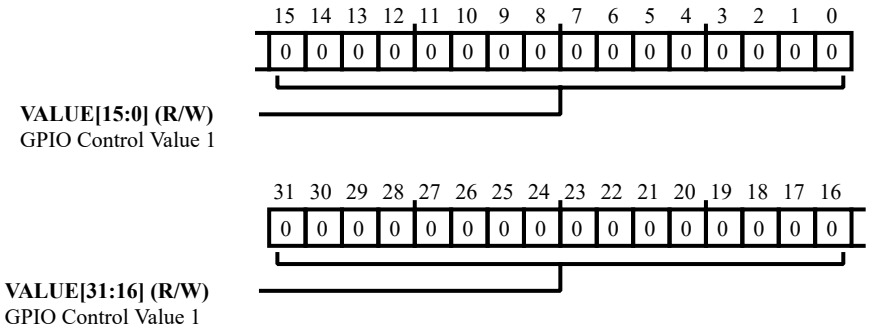

Figure 21-55: XSPI_PHY_GPIO_CTL1 Register Diagram

Table 21-97: XSPI_PHY_GPIO_CTL1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	GPIO Control Value 1. The [31:0] vector is brought to the PHY I/Os. The XSPI_PHY_GPIO_CTL1.VALUE bit field can used to control any static settings that may be required for the connected IO pads.

PHY GPIO Status Register 0

The XSPI_PHY_GPIO_STAT0 register is a general purpose register. A [31:0] vector is brought from the PHY I/Os to this register. This can be used as a status register.

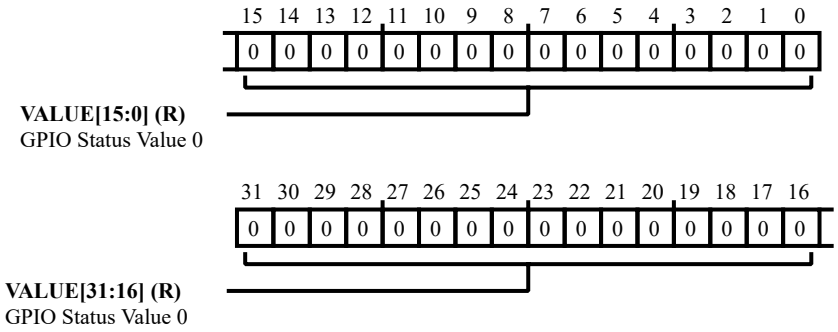

Figure 21-56: XSPI_PHY_GPIO_STAT0 Register Diagram

Table 21-98: XSPI_PHY_GPIO_STAT0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	GPIO Status Value 0. A [31:0] vector is brought from the PHY IOs to this register. The XSPI_PHY_GPIO_STAT0.VALUE bit field can used as a status register.

PHY GPIO Status Register 1

The XSPI_PHY_GPIO_STAT1 register is a general purpose register. A [31:0] vector is brought from the PHY I/Os to this register. This can be used as a status register.

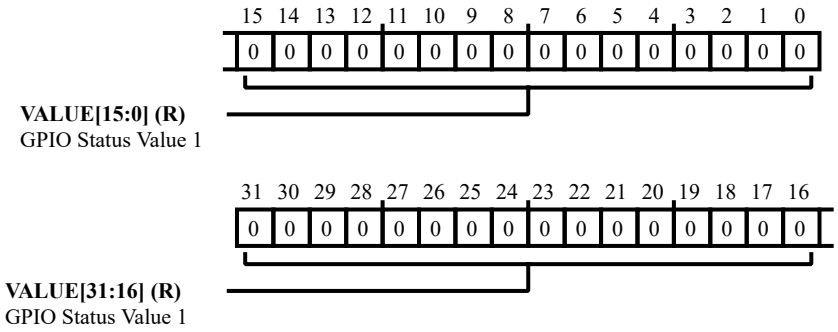

Figure 21-57: XSPI_PHY_GPIO_STAT1 Register Diagram

Table 21-99: XSPI_PHY_GPIO_STAT1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	GPIO Status Value 1. A [31:0] vector is brought from the PHY I/Os to this register. The XSPI_PHY_GPIO_STAT1.VALUE bit field can be used as a status register.

PHY Global Termination Control Register

The XSPI_PHY_GTSEL register handles the global control settings for the termination selects for reads.

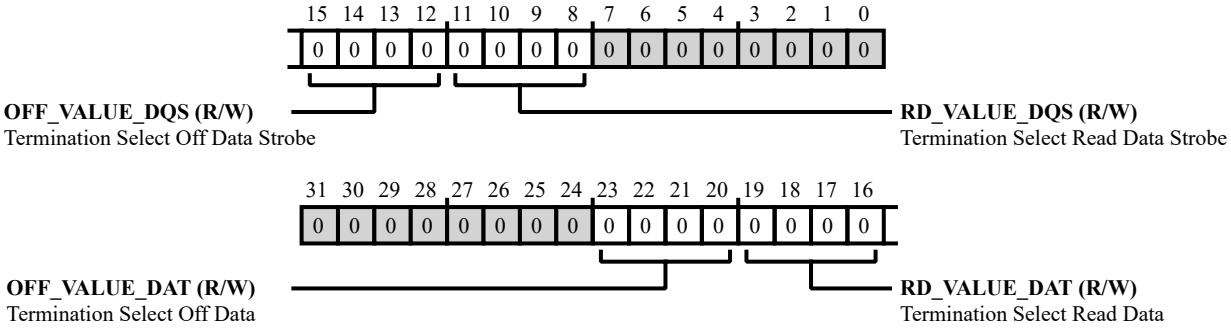

Figure 21-58: XSPI_PHY_GTSEL Register Diagram

Table 21-100: XSPI_PHY_GTSEL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:20 (R/W)	OFF_VALUE_DAT	Termination Select Off Data. The XSPI_PHY_GTSEL.OFF_VALUE_DAT bit field indicates the termination select off value for the data.
19:16 (R/W)	RD_VALUE_DAT	Termination Select Read Data. The XSPI_PHY_GTSEL.RD_VALUE_DAT bit field indicates the termination select read value for the data.
15:12 (R/W)	OFF_VALUE_DQS	Termination Select Off Data Strobe. The XSPI_PHY_GTSEL.OFF_VALUE_DQS bit field indicates the termination select off value for the data strobe.
11:8 (R/W)	RD_VALUE_DQS	Termination Select Read Data Strobe. The XSPI_PHY_GTSEL.RD_VALUE_DQS bit field indicates the termination select read value for the data strobe.

PHY DQS Input Enable Timing Register

The XSPI_PHY_IE_TR register controls the DQS related timing.

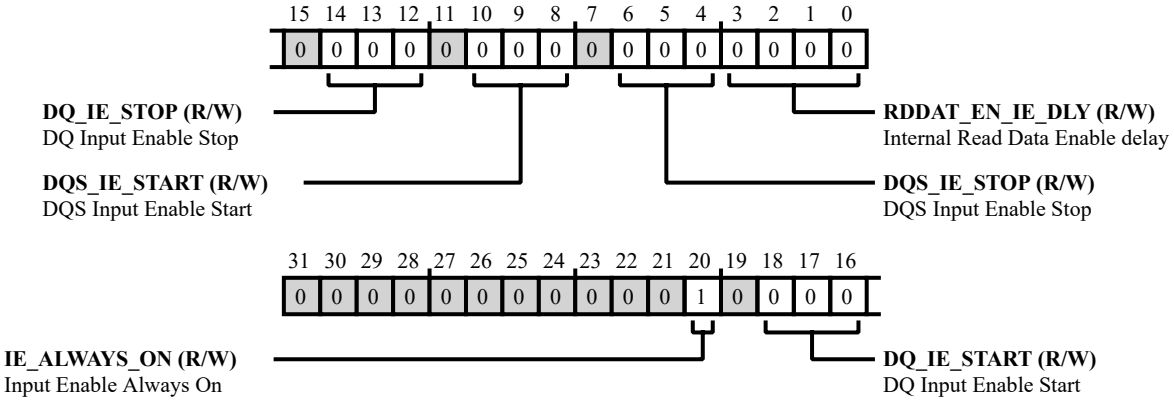

Figure 21-59: XSPI_PHY_IE_TR Register Diagram

Table 21-101: XSPI_PHY_IE_TR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
20 (R/W)	IE_ALWAYS_ON	Input Enable Always On. The XSPI_PHY_IE_TR.IE_ALWAYS_ON bit forces the input enable(s) to be on always.
18:16 (R/W)	DQ_IE_START	DQ Input Enable Start. The XSPI_PHY_IE_TR.DQ_IE_START bit field indicates the start position for the DQ input enable.
14:12 (R/W)	DQ_IE_STOP	DQ Input Enable Stop. The XSPI_PHY_IE_TR.DQ_IE_STOP bit field indicates the stop position for the DQ input enable.
10:8 (R/W)	DQS_IE_START	DQS Input Enable Start. The XSPI_PHY_IE_TR.DQS_IE_START bit field indicates the start position for the DQS input enable.
6:4 (R/W)	DQS_IE_STOP	DQS Input Enable Stop. The XSPI_PHY_IE_TR.DQS_IE_STOP bit field indicates the stop position for the DQS input enable.
3:0 (R/W)	RDDAT_EN_IE_DLY	Internal Read Data Enable delay. The XSPI_PHY_IE_TR.RDDAT_EN_IE_DLY bit field indicates the number of clocks of delay for the DFI_RDDATA_EN signal to line it up with the true (normal) DFI read data position. The controller must deliver an early version of the read data enable to allow time for the input pads to turn on and this field allows the PHY to create the original timing.

PHY Observable Points Register

The XSPI_PHY_OB0 register holds observable points in the PHY.

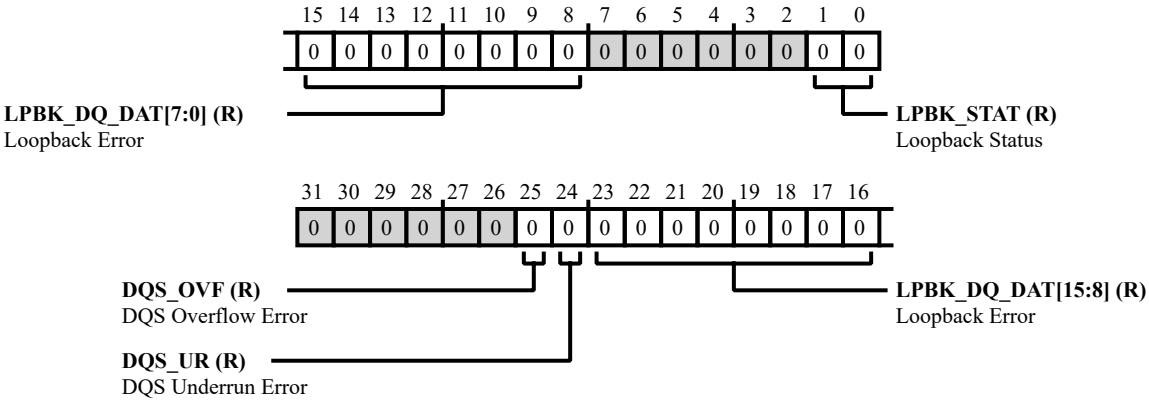

Figure 21-60: XSPI_PHY_OB0 Register Diagram

Table 21-102: XSPI_PHY_OB0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
25 (R/NW)	DQS_OVF	DQS Overflow Error. The XSPI_PHY_OB0.DQS_OVF bit indicates that the logic gate was closed too late. For example, the number of DQS strobes exceed the capacity of the entry FIFO. It indicates that XSPI_PHY_GATE_LPBK_CTL.RD_DEL_SE signal value is too high and DFI_RDDATA are corrupted. It is possible that overflow status is asserted with underrun status - in such case the overflow takes the precedence. The XSPI_PHY_DLL_CTL.DLL_RST_N bit or RST_N signal clears this flag.
24 (R/NW)	DQS_UR	DQS Underrun Error. The XSPI_PHY_OB0.DQS_UR bit indicates that the logic gate had to be forced closed. It indicates that either the DQS strobe did not appear during read or XSPI_PHY_GATE_LPBK_CTL.RD_DEL_SEL signal value is too low and DFI_RDDATA are corrupted. The XSPI_PHY_DLL_CTL.DLL_RST_N bit or RST_N signal clears this flag.
23:8 (R/NW)	LPBK_DQ_DAT	Loopback Error. If errors are encountered in loopback test, the XSPI_PHY_OB0.LPBK_DQ_DAT bit field reports the actual data or the expected data, depending on the setting of the XSPI_PHY_GATE_LPBK_CTL.LPBK_FAIL_MUXSEL bit. This field is not clear by the clear state of the loopback. If there are no errors in loopback test, the value is zero (or value from previous state).

Table 21-102: XSPI_PHY_OB0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
1:0 (R/NW)	LPBK_STAT	Loopback Status. The `XSPI_PHY_OB0.LPBK_STAT` bit field indicates the loopback status. Bit0 - loopback start; Defines the status of the loopback mode. 0 = Not in loopback mode; 1 = In loopback mode. Bit1 - loopback status; Defines the status of the loopback mode. 0 = Last Loopback test had no errors; 1 = Last loopback test contained data errors.

PHY Revision ID Register

The XSPI_PHY_REVID register contains the release identification number.

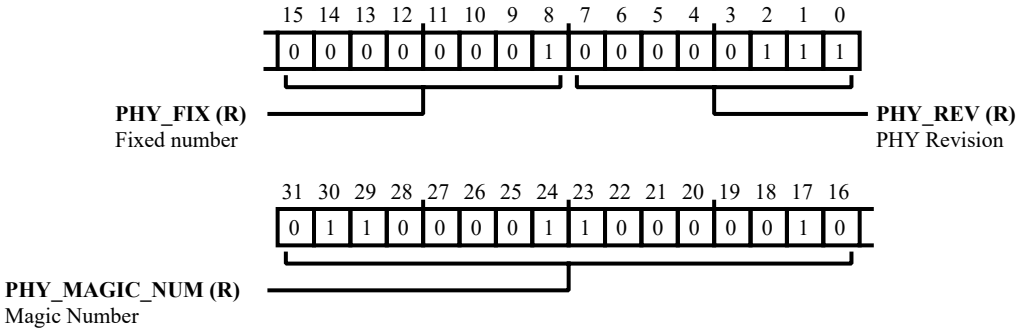

Figure 21-61: XSPI_PHY_REVID Register Diagram

Table 21-103: XSPI_PHY_REVID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/NW)	PHY_MAGIC_NUM	Magic Number. The XSPI_PHY_REVID.PHY_MAGIC_NUM bit field indicates the magic number.
15:8 (R/NW)	PHY_FIX	Fixed number. The XSPI_PHY_REVID.PHY_FIX bit field indicates the fixed number (minor revision number).
7:0 (R/NW)	PHY_REV	PHY Revision. The XSPI_PHY_REVID.PHY_REV bit field indicates the PHY revision number.

PHY Static Aging Register

The XSPI_PHY_STATIC_TGL register controls the static aging feature of the PHY.

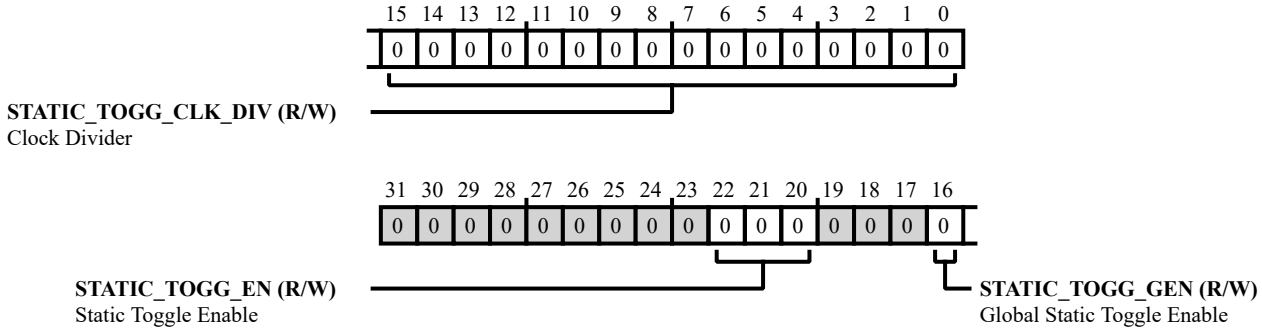

Figure 21-62: XSPI_PHY_STATIC_TGL Register Diagram

Table 21-104: XSPI_PHY_STATIC_TGL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
22:20 (R/W)	STATIC_TOGG_EN	Static Toggle Enable. The XSPI_PHY_STATIC_TGL.STATIC_TOGG_EN bit field enables the toggle signal during static activity. When cleared (=0), the feature is disabled. Bit 0 - Bus requester delay line enable Bit 1 - Read path delay line enable Bit 2 - Write path delay line enable
16 (R/W)	STATIC_TOGG_GEN	Global Static Toggle Enable. The XSPI_PHY_STATIC_TGL.STATIC_TOGG_GEN bit enables the toggle signal during static activity.
15:0 (R/W)	STATIC_TOGG_CLK_DIV	Clock Divider. The XSPI_PHY_STATIC_TGL.STATIC_TOGG_CLK_DIV bit field indicates the clock divider used to create the toggle signal.

PHY Deskew Write Register

The XSPI_PHY_WR_DESKEW_PAD_CTL0 register holds the values of the phase detect block for each DQ bit on the write path.

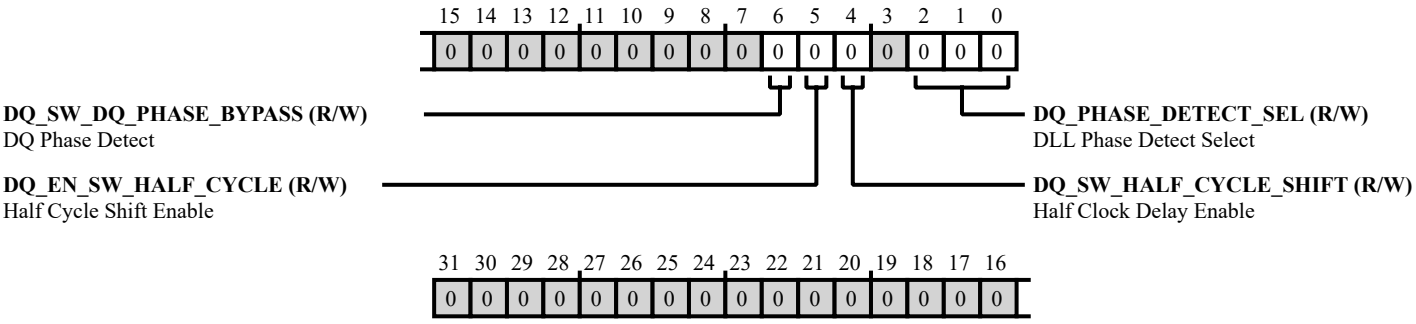

Figure 21-63: XSPI_PHY_WR_DESKEW_PAD_CTL0 Register Diagram

Table 21-105: XSPI_PHY_WR_DESKEW_PAD_CTL0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W)	DQ_SW_DQ_PHASE_BYPASS	DQ Phase Detect. When XSPI_PHY_WR_DESKEW_PAD_CTL0.DQ_SW_DQ_PHASE_BYPASS is set (=1), the clock write delay line configuration is used to determine the HALF_CYCLE_SHIFT. When XSPI_PHY_WR_DESKEW_PAD_CTL0.DQ_SW_DQ_PHASE_BYPASS is cleared (=0), the phase detect circuit is used to determine the HALF_CYCLE_SHIFT.	
		0	Use phase detect circuit
		1	Use the clock write delay line configuration. A delay line configuration of 0x00-0x7f means HALF_CYCLE_SHIFT= 0 and a delay line configuration of 0x80-0xff means HALF_CYCLE_SHIFT = 1.
5 (R/W)	DQ_EN_SW_HALF_CYCLE	Half Cycle Shift Enable. When XSPI_PHY_WR_DESKEW_PAD_CTL0.DQ_EN_SW_HALF_CYCLE is set (=1), it enables the software half cycle shift. This determines whether the write data is transferred to the clock write domain on the positive or negative edge of the PHY clock. This field is valid when DQ_SW_DQ_PHASE_BYPASS =0. Note: If the user chooses to control the half cycle shift manually, it is important that DQ_SW_HALF_CYCLE_SHIFT = 0 if the delay is less than a 1/2 cycle and DQ_SW_HALF_CYCLE_SHIFT = 1 if the delay is greater than a 1/2 cycle. It is recommended to allow the hardware to control this automatically.	
		0	Hardware automatically controls shifting needed for the write level delay line.
		1	DQ_SW_HALF_CYCLE_SHIFT field defines the shift

Table 21-105: XSPI_PHY_WR_DESKEW_PAD_CTL0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W)	DQ_SW_HALF_CYCLE_SHIFT	Half Clock Delay Enable. When `XSPI_PHY_WR_DESKEW_PAD_CTL0.DQ_SW_HALF_CYCLE_SHIFT` is set (=1), a half clock delay is added to the write data path.	
		0	No effect
		1	Adds a half clock delay to the write data path
2:0 (R/W)	DQ_PHASE_DETECT_SEL	DLL Phase Detect Select. The `XSPI_PHY_WR_DESKEW_PAD_CTL0.DQ_PHASE_DETECT_SEL` bit field indicates the DLL phase detect selector for DQ generation to handle the clock domain crossing between the clock and clock write signal. It indicates the number of delay elements to be inserted between the phase detect flip-flops. Defaults to 0x0.	
		0	One delay element
		1	Two delay elements
		2	Three delay elements
		3	Four delay elements
		4	Five delay elements
		5	Six delay elements
		6	Seven delay elements
		7	Eight delay elements

Program Sequence Configuration Register 0

The XSPI_PROG_SEQ_CFG0 register configures the program sequence for profile 1 and SPI NAND in ACMD and direct work modes.

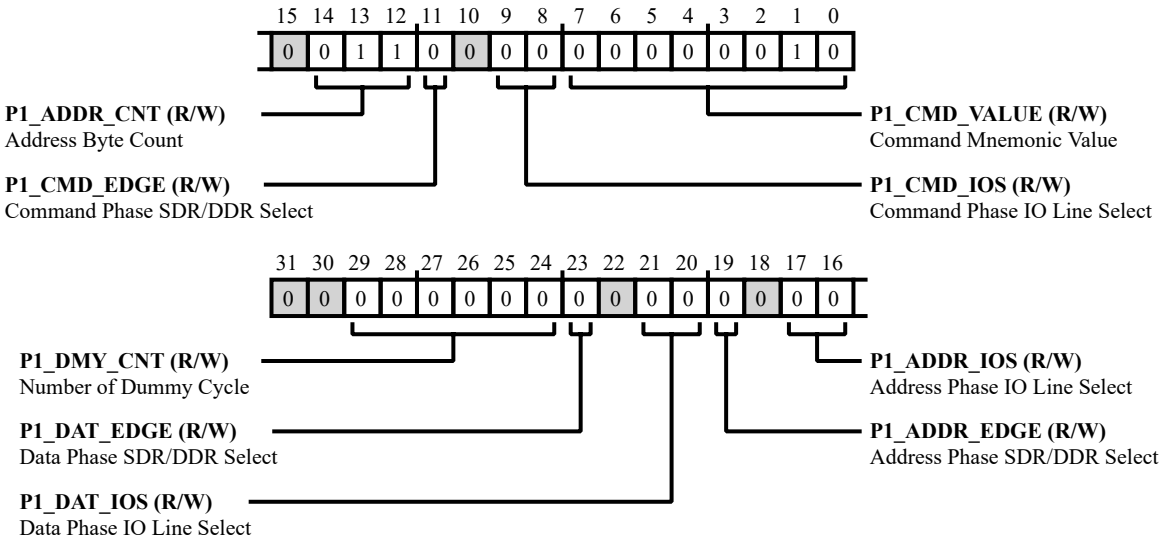

Figure 21-64: XSPI_PROG_SEQ_CFG0 Register Diagram

Table 21-106: XSPI_PROG_SEQ_CFG0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
29:24 (R/W)	P1_DMY_CNT	Number of Dummy Cycle. The XSPI_PROG_SEQ_CFG0.P1_DMY_CNT bit field indicates the number of dummy cycles in profile 1. If 0, dummy cycles are disabled.	
23 (R/W)	P1_DAT_EDGE	Data Phase SDR/DDR Select. The XSPI_PROG_SEQ_CFG0.P1_DAT_EDGE bit selects between SDR/DDR mode for the data phase.	
21:20 (R/W)	P1_DAT_IOS	Data Phase IO Line Select. The XSPI_PROG_SEQ_CFG0.P1_DAT_IOS bit field indicates the number of data lines used to send the data phase.	
		0	One data line used (for example, serial)
		1	Two data lines used
		2	Four data lines used
		3	Eight data lines used
19 (R/W)	P1_ADDR_EDGE	Address Phase SDR/DDR Select. The XSPI_PROG_SEQ_CFG0.P1_ADDR_EDGE bit selects between SDR/DDR mode for the address phase.	

Table 21-106: XSPI_PROG_SEQ_CFG0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
17:16 (R/W)	P1_ADDR_IOS	Address Phase IO Line Select. The `XSPI_PROG_SEQ_CFG0.P1_ADDR_IOS` bit field indicates the number of data lines used to send the address phase.	
		0	One data line used (for example, serial)
		1	Two data lines used
		2	Four data lines used
		3	Eight data lines used
14:12 (R/W)	P1_ADDR_CNT	Address Byte Count. The `XSPI_PROG_SEQ_CFG0.P1_ADDR_CNT` bit field indicates the number of address bytes.	
11 (R/W)	P1_CMD_EDGE	Command Phase SDR/DDR Select. The `XSPI_PROG_SEQ_CFG0.P1_CMD_EDGE` bit selects between SDR/DDR mode for the command phase.	
9:8 (R/W)	P1_CMD_IOS	Command Phase IO Line Select. The `XSPI_PROG_SEQ_CFG0.P1_CMD_IOS` bit field indicates the number of data lines used to send the command phase.	
		0	One data line used (for example, serial)
		1	Two data lines used
		2	Four data lines used
		3	Eight data lines used
7:0 (R/W)	P1_CMD_VALUE	Command Mnemonic Value. The `XSPI_PROG_SEQ_CFG0.P1_CMD_VALUE` bit field indicates the command mnemonic value.	

Program Sequence Configuration Register 1

The XSPI_PROG_SEQ_CFG1 register configures the program sequence for profile 1 and SPI NAND in ACMD and direct work modes.

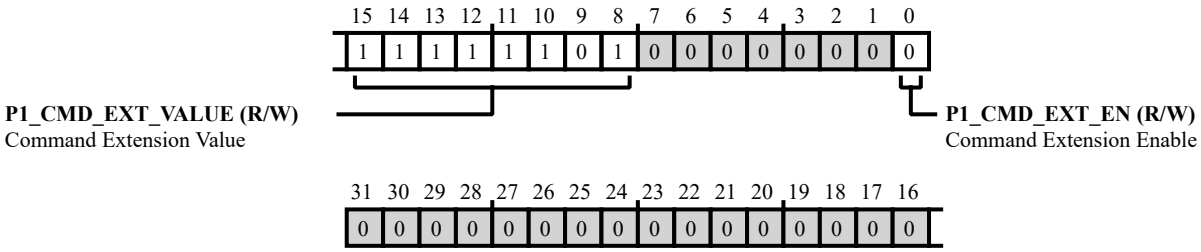

Figure 21-65: XSPI_PROG_SEQ_CFG1 Register Diagram

Table 21-107: XSPI_PROG_SEQ_CFG1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W)	P1_CMD_EXT_VALUE	Command Extension Value. The XSPI_PROG_SEQ_CFG1.P1_CMD_EXT_VALUE bit field indicates the command extension value.
0 (R/W)	P1_CMD_EXT_EN	Command Extension Enable. The XSPI_PROG_SEQ_CFG1.P1_CMD_EXT_EN bit enables the command extension.

Program Sequence Configuration Register 2

The XSPI_PROG_SEQ_CFG2 register configures the program sequence for profile 2 in ACMD and direct work modes.

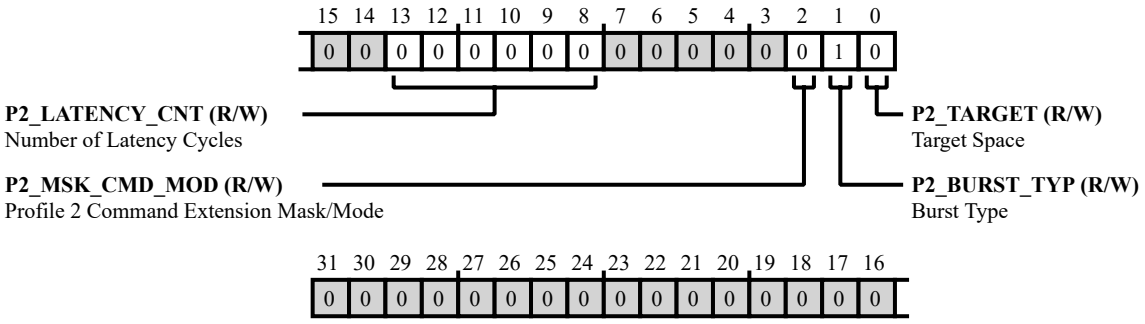

Figure 21-66: XSPI_PROG_SEQ_CFG2 Register Diagram

Table 21-108: XSPI_PROG_SEQ_CFG2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
13:8 (R/W)	P2_LATENCY_CNT	Number of Latency Cycles. The XSPI_PROG_SEQ_CFG2.P2_LATENCY_CNT bit field indicates the number of latency cycles for profile 2 - HR only. When XSPI_PROG_SEQ_CFG2.P2_LATENCY_CNT is cleared (=0), latency cycles are disabled. Configure the XSPI_PROG_SEQ_CFG2.P2_LATENCY_CNT bit field to N-1, where N is the number of latency clock cycles expected by the memory device.	
2 (R/W)	P2_MSK_CMD_MOD	Profile 2 Command Extension Mask/Mode. The XSPI_PROG_SEQ_CFG2.P2_MSK_CMD_MOD bit indicates the profile 2 command extension variant. This influences bits [44:40] of the CA. When XSPI_PROG_SEQ_CFG2.P2_MSK_CMD_MOD is set (=1), CA[44:40] is configured to all ones. In direct work mode, when XSPI_PROG_SEQ_CFG2.P2_MSK_CMD_MOD is cleared (=0), bits [44:40] of the CA are configured to (sAWADDR[45:41] logically AND'ed with DAC_ADDR_MASk[12:8]). In ACMD work mode, when XSPI_PROG_SEQ_CFG2.P2_MSK_CMD_MOD is cleared (=0), bits [44:40] of the CA are cleared (= 0).	
1 (R/W)	P2_BURST_TYP	Burst Type. The XSPI_PROG_SEQ_CFG2.P2_BURST_TYP bit indicates the burst type; it corresponds to the 45th Command/Address (CA) bit assignment. Although the user can set wrapped burst, the controller itself does not currently support wrapping bursts and therefore must always have this bit set (=1).	
		0	Wrapped burst
		1	Linear burst

Table 21-108: XSPI_PROG_SEQ_CFG2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	P2_TARGET	Target Space. The `XSPI_PROG_SEQ_CFG2.P2_TARGET` bit indicates the target space, it corresponds to the 46th Command/Address (CA) bit assignment.	
		0	Memory space
		1	Register space

Read Sequence Configuration Register 0

The XSPI_READ_SEQ_CFG0 register configures the read sequence for profile 1 and SPI NAND in ACMD and direct work modes.

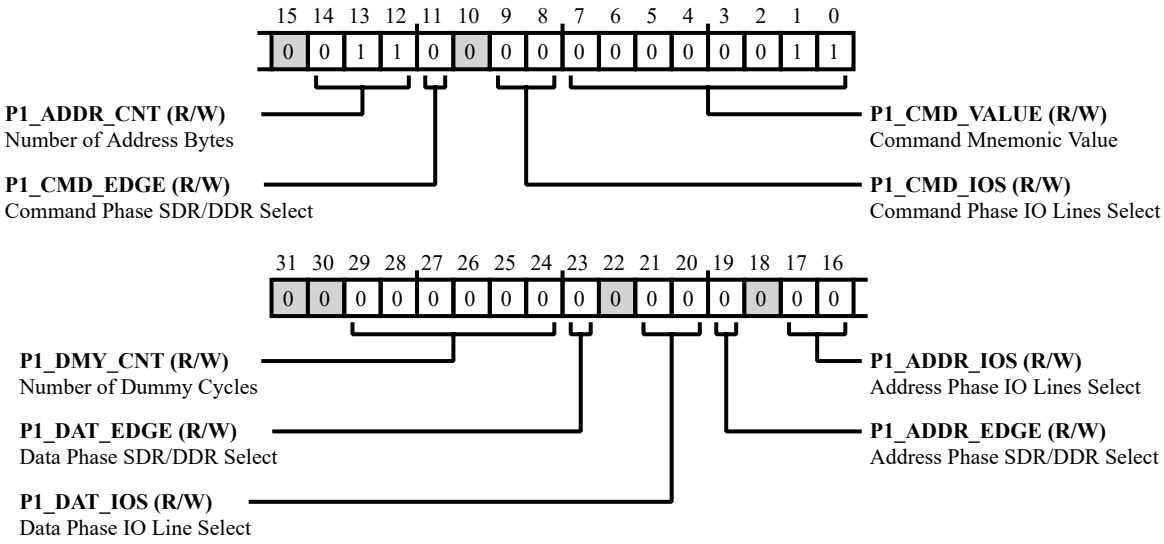

Figure 21-67: XSPI_READ_SEQ_CFG0 Register Diagram

Table 21-109: XSPI_READ_SEQ_CFG0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
29:24 (R/W)	P1_DMY_CNT	Number of Dummy Cycles. The XSPI_READ_SEQ_CFG0.P1_DMY_CNT bit field indicates the number of dummy cycles. If 0 - dummy cycles disabled. This field is used when sending mode-bits is disabled. Otherwise, the read_seq_p1_mb_dummy_cnt must be used.	
23 (R/W)	P1_DAT_EDGE	Data Phase SDR/DDR Select. The XSPI_READ_SEQ_CFG0.P1_DAT_EDGE bit selects between SDR/DDR mode for data phase.	
21:20 (R/W)	P1_DAT_IOS	Data Phase IO Line Select. The XSPI_READ_SEQ_CFG0.P1_DAT_IOS bit field indicates the number of data lines used to send the data phase.	
		0	One data line used (for example, serial)
		1	Two data lines used
		2	Four data lines used
		3	Eight data lines used

Table 21-109: XSPI_READ_SEQ_CFG0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
19 (R/W)	P1_ADDR_EDGE	Address Phase SDR/DDR Select. The `XSPI_READ_SEQ_CFG0.P1_ADDR_EDGE` bit selects between SDR/DDR mode for address phase.	
17:16 (R/W)	P1_ADDR_IOS	Address Phase IO Lines Select. The `XSPI_READ_SEQ_CFG0.P1_ADDR_IOS` bit field indicates the number of data lines used to send the address phase.	
		0	One data line used (for example, serial)
		1	Two data lines used
		2	Four data lines used
		3	Eight data lines used
14:12 (R/W)	P1_ADDR_CNT	Number of Address Bytes. The `XSPI_READ_SEQ_CFG0.P1_ADDR_CNT` bit field indicates the number of address bytes.	
11 (R/W)	P1_CMD_EDGE	Command Phase SDR/DDR Select. The `XSPI_READ_SEQ_CFG0.P1_CMD_EDGE` bit selects between SDR/DDR mode for command phase.	
9:8 (R/W)	P1_CMD_IOS	Command Phase IO Lines Select. The `XSPI_READ_SEQ_CFG0.P1_CMD_IOS` bit field indicates the number of data lines used to send the command phase.	
		0	One data line used (for example, serial)
		1	Two data lines used
		2	Four data lines used
		3	Eight data lines used
7:0 (R/W)	P1_CMD_VALUE	Command Mnemonic Value. The `XSPI_READ_SEQ_CFG0.P1_CMD_VALUE` bit field indicates the command mnemonic value.	

Read Sequence Configuration Register 1

The XSPI_READ_SEQ_CFG1 register configures the read sequence for profile 1 and SPI NAND in ACMD and direct work modes.

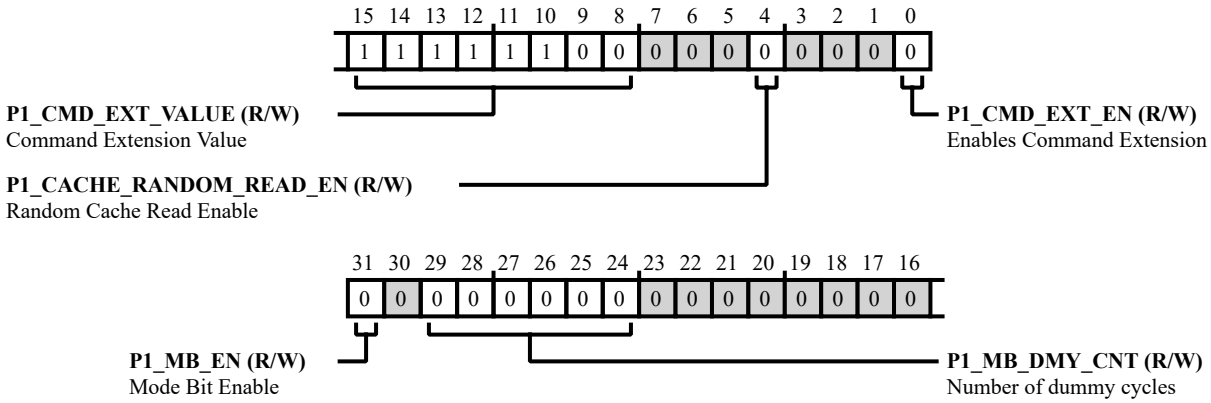

Figure 21-68: XSPI_READ_SEQ_CFG1 Register Diagram

Table 21-110: XSPI_READ_SEQ_CFG1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	P1_MB_EN	Mode Bit Enable. When XSPI_READ_SEQ_CFG1.P1_MB_EN is set (=1), the mode bits as defined in the XSPI_XIP_GCTL.XIP_DIS_MB_VAL field, are sent following the address bytes.
29:24 (R/W)	P1_MB_DMY_CNT	Number of dummy cycles. The XSPI_READ_SEQ_CFG1.P1_MB_DMY_CNT bit field indicates the number of dummy cycles. When XSPI_READ_SEQ_CFG1.P1_MB_DMY_CNT is cleared (=0), dummy cycles are disabled. This field is used when the sending mode bits function is enabled.
15:8 (R/W)	P1_CMD_EXT_VALUE	Command Extension Value. The XSPI_READ_SEQ_CFG1.P1_CMD_EXT_VALUE bit enables the command extension value.
4 (R/W)	P1_CACHE_RAN-DOM_READ_EN	Random Cache Read Enable. The XSPI_READ_SEQ_CFG1.P1_CACHE_RANDOM_READ_EN bit changes behavior of the read sequence to utilize the read page cache random/read page cache random last commands. This field is not used in direct mode. This bit is only applicable to the SPI NAND profile.

Table 21-110: XSPI_READ_SEQ_CFG1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W)	P1_CMD_EXT_EN	Enables Command Extension. The `XSPI_READ_SEQ_CFG1.P1_CMD_EXT_EN` bit enables command extension.

Read Sequence Configuration Register 2

The XSPI_READ_SEQ_CFG2 register configures the read sequence for profile 2 in ACMD and direct work modes.

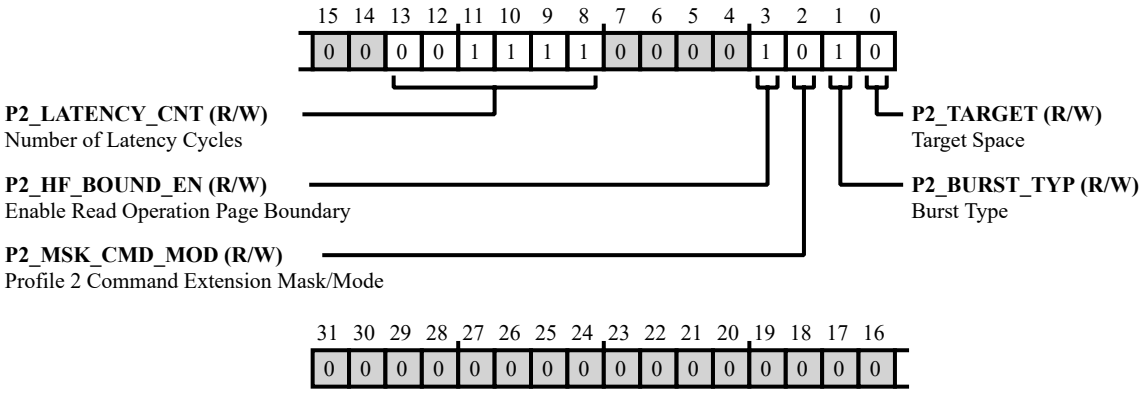

Figure 21-69: XSPI_READ_SEQ_CFG2 Register Diagram

Table 21-111: XSPI_READ_SEQ_CFG2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
13:8 (R/W)	P2_LATENCY_CNT	Number of Latency Cycles. The XSPI_READ_SEQ_CFG2.P2_LATENCY_CNT bit field indicates the number of latency cycles. When XSPI_READ_SEQ_CFG2.P2_LATENCY_CNT is cleared (=0), latency clock cycles are disabled. Configure XSPI_READ_SEQ_CFG2.P2_LATENCY_CNT to N-1, where N is the number of latency clock cycles expected by the memory device.	
3 (R/W)	P2_HF_BOUND_EN	Enable Read Operation Page Boundary. The XSPI_READ_SEQ_CFG2.P2_HF_BOUND_EN bit field is used by the controller to calculate read transaction crossing page boundary. It is valid only when profile 2 - HF is selected.	
		0	Disable
		1	Enable

Table 21-111: XSPI_READ_SEQ_CFG2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	P2_MSK_CMD_MOD	Profile 2 Command Extension Mask/Mode. The `XSPI_READ_SEQ_CFG2.P2_MSK_CMD_MOD` bit field indicates the profile 2 command extension variant.This bit influences bits [44:40] of Command/Address. When `XSPI_READ_SEQ_CFG2.P2_MSK_CMD_MOD` is set (=1), bits [44:40] of Command/Address is set to 1. In direct work mode, when `XSPI_READ_SEQ_CFG2.P2_MSK_CMD_MOD` is cleared (=0), bits [44:40] of Command/Address is set to (sARADDR[45:41] logically AND'ed with dac_addr_mask[12:8]). In ACMD work mode, when `XSPI_READ_SEQ_CFG2.P2_MSK_CMD_MOD` is cleared (=0), bits [44:40] of Command/Address is cleared.	
1 (R/W)	P2_BURST_TYP	Burst Type. The `XSPI_READ_SEQ_CFG2.P2_BURST_TYP` bit indicates the burst type; it corresponds to 45th Command/Address (CA) bit assignment. Although the user can set wrapped burst, the controller itself does not currently support wrapping bursts; therefore, configure `XSPI_READ_SEQ_CFG2.P2_BURST_TYP` = 1.	
		0	Wrapped burst
		1	Linear burst
0 (R/W)	P2_TARGET	Target Space. The `XSPI_READ_SEQ_CFG2.P2_TARGET` bit indicates the target space; it corresponds to 46th Command/Address (CA) bit assignment.	
		0	Memory space
		1	Register space

Revision ID Register

The XSPI_REVID register contains the release identification number.

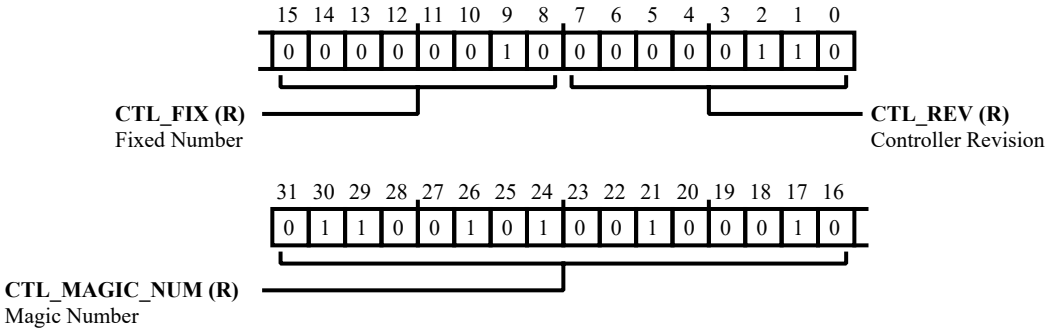

Figure 21-70: XSPI_REVID Register Diagram

Table 21-112: XSPI_REVID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/NW)	CTL_MAGIC_NUM	Magic Number. The XSPI_REVID.CTL_MAGIC_NUM bit field indicates the controller's magic number. It is a unique number characteristic for the xSPI controller.
15:8 (R/NW)	CTL_FIX	Fixed Number. The XSPI_REVID.CTL_FIX bit field indicates the fixed number (minor revision number).
7:0 (R/NW)	CTL_REV	Controller Revision. The XSPI_REVID.CTL_REV bit field indicates the controller revision number.

Reset Sequence Configuration Register 0

The XSPI_RST_SEQ_CFG0 register configures the reset sequence for profile 1 and SPI NAND in ACMD work mode.

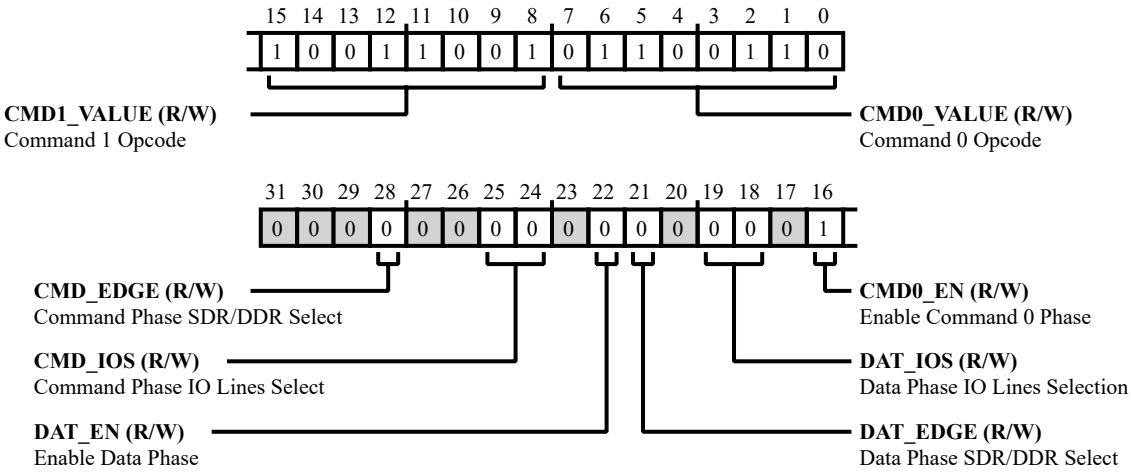

Figure 21-71: XSPI_RST_SEQ_CFG0 Register Diagram

Table 21-113: XSPI_RST_SEQ_CFG0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
28 (R/W)	CMD_EDGE	Command Phase SDR/DDR Select. The XSPI_RST_SEQ_CFG0.CMD_EDGE bit selects between SDR/DDR mode for both command phases.	
25:24 (R/W)	CMD_IOS	Command Phase IO Lines Select. The XSPI_RST_SEQ_CFG0.CMD_IOS bit field indicates the number of data lines used to send commands for both command phases.	
		0	One data line used (for example, serial)
		1	Two data lines used
		2	Four data lines used
		3	Eight data lines used
22 (R/W)	DAT_EN	Enable Data Phase. The XSPI_RST_SEQ_CFG0.DAT_EN bit enables sending the data phase (confirmation byte in) following the CMD1 phase.	
21 (R/W)	DAT_EDGE	Data Phase SDR/DDR Select. The XSPI_RST_SEQ_CFG0.DAT_EDGE bit selects between SDR/DDR mode for the data phase (confirmation byte in) following the CMD1 phase.	

Table 21-113: XSPI_RST_SEQ_CFG0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
19:18 (R/W)	DAT_IOS	Data Phase IO Lines Selection. The `XSPI_RST_SEQ_CFG0.DAT_IOS` bit field indicates the number of lines used to send the data phase (confirmation byte in) following the CMD1 phase.	
		0	One data line used (for example, serial)
		1	Two data lines used
		2	Four data lines used
		3	Eight data lines used
16 (R/W)	CMD0_EN	Enable Command 0 Phase. The `XSPI_RST_SEQ_CFG0.CMD0_EN` bit enables the CMD0 phase.	
15:8 (R/W)	CMD1_VALUE	Command 1 Opcode. The `XSPI_RST_SEQ_CFG0.CMD1_VALUE` bit field indicates the command mnemonic value for the CMD1 phase.	
7:0 (R/W)	CMD0_VALUE	Command 0 Opcode. The `XSPI_RST_SEQ_CFG0.CMD0_VALUE` bit field indicates the command mnemonic value for the CMD0 phase.	

Reset Sequence Configuration Register 1

The XSPI_RST_SEQ_CFG1 register configures the reset sequence for profile 1 and SPI NAND in ACMD work mode.

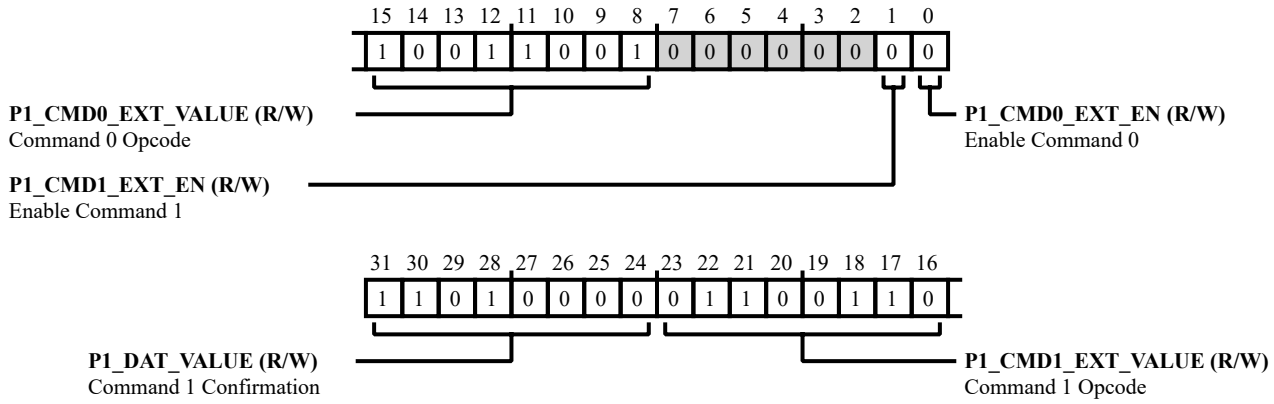

Figure 21-72: XSPI_RST_SEQ_CFG1 Register Diagram

Table 21-114: XSPI_RST_SEQ_CFG1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	P1_DAT_VALUE	Command 1 Confirmation. Value of confirmation byte in (if enabled) the following CMD1 phase.
23:16 (R/W)	P1_CMD1_EXT_VALUE	Command 1 Opcode. Command extension value of the CMD1 phase (if enabled).
15:8 (R/W)	P1_CMD0_EXT_VALUE	Command 0 Opcode. Command extension value of the CMD0 phase (if enabled).
1 (R/W)	P1_CMD1_EXT_EN	Enable Command 1. Command extension enable for the CMD1 phase.
0 (R/W)	P1_CMD0_EXT_EN	Enable Command 0. Command extension enable for the CMD0 phase.

Host DMA Buffer Address Register 0

The XSPI_SDMA_ADDR0 register stores the buffer address in the host memory that is used as a sink/source for the host DMA transfer. The host DMA address is based on the memory pointer field that was programed by the host as part of the CDMA/PIO command.

A single CDMA/PIO command can trigger multiple transfers on the host interface, so the host DMA address value is automatically incremented and updated before each DMA transfer.

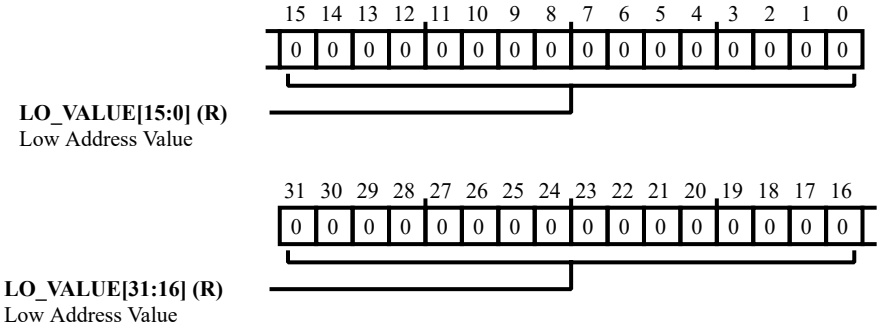

Figure 21-73: XSPI_SDMA_ADDR0 Register Diagram

Table 21-115: XSPI_SDMA_ADDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	LO_VALUE	Low Address Value. The XSPI_SDMA_ADDR0.LO_VALUE bit field indicates the lower part of the SDMA destination/source address.

Host DMA Buffer Address Register 1

The XSPI_SDMA_ADDR1 register stores the buffer address in the host memory that is used as a sink/source for the host DMA transfer. The host DMA address is based on the memory pointer field that was programed by the host as part of the CDMA/PIO command.

A single CDMA/PIO command can trigger multiple transfers on the host interface, so the host DMA address value is automatically incremented and updated before each DMA transfer.

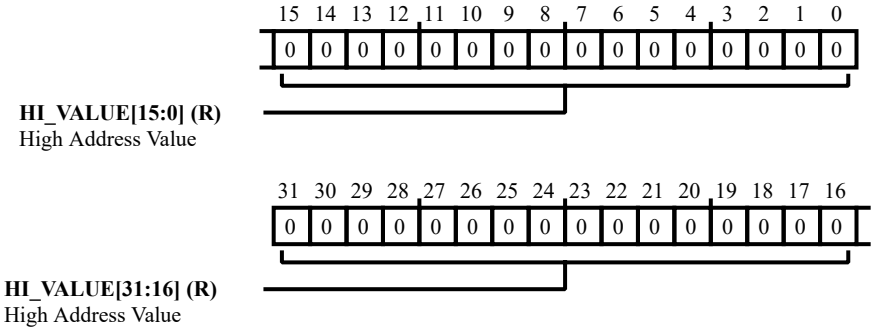

Figure 21-74: XSPI_SDMA_ADDR1 Register Diagram

Table 21-116: XSPI_SDMA_ADDR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	HI_VALUE	High Address Value. The XSPI_SDMA_ADDR1.HI_VALUE bit field indicates the higher part of the SDMA destination/source address.

Host DMA Block Size Register

The XSPI_SDMA_SIZ register contains the transferred data block size for the host DMA module.

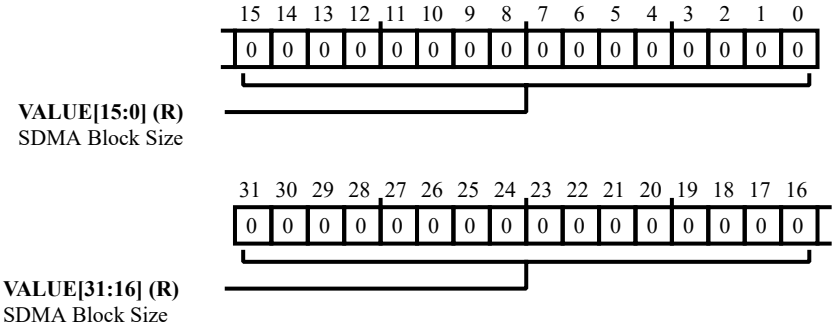

Figure 21-75: XSPI_SDMA_SIZ Register Diagram

Table 21-117: XSPI_SDMA_SIZ Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	SDMA Block Size. The XSPI_SDMA_SIZ.VALUE bit field indicates the transferred data block size in bytes for the host DMA module. Data size is rounded up to the data bus word size.

Host DMA Thread Status Register

The XSPI_SDMA_TRD_STAT register contains information for the current host DMA transaction as related to the execution thread.

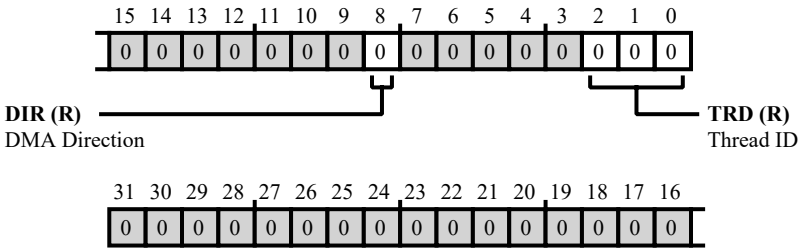

Figure 21-76: XSPI_SDMA_TRD_STAT Register Diagram

Table 21-118: XSPI_SDMA_TRD_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
8 (R/NW)	DIR	DMA Direction. The XSPI_SDMA_TRD_STAT.DIR bit field indicates the transfer direction related to current host DMA transfer (0-read; 1-write).
2:0 (R/NW)	TRD	Thread ID. The XSPI_SDMA_TRD_STAT.TRD bit field indicates the thread number associated with transferred data block for the host DMA module.

Sequence Configuration Register 0

The XSPI_SEQ_GCTL0 register configures common values for sequences in CDMA, PIO and direct work modes.

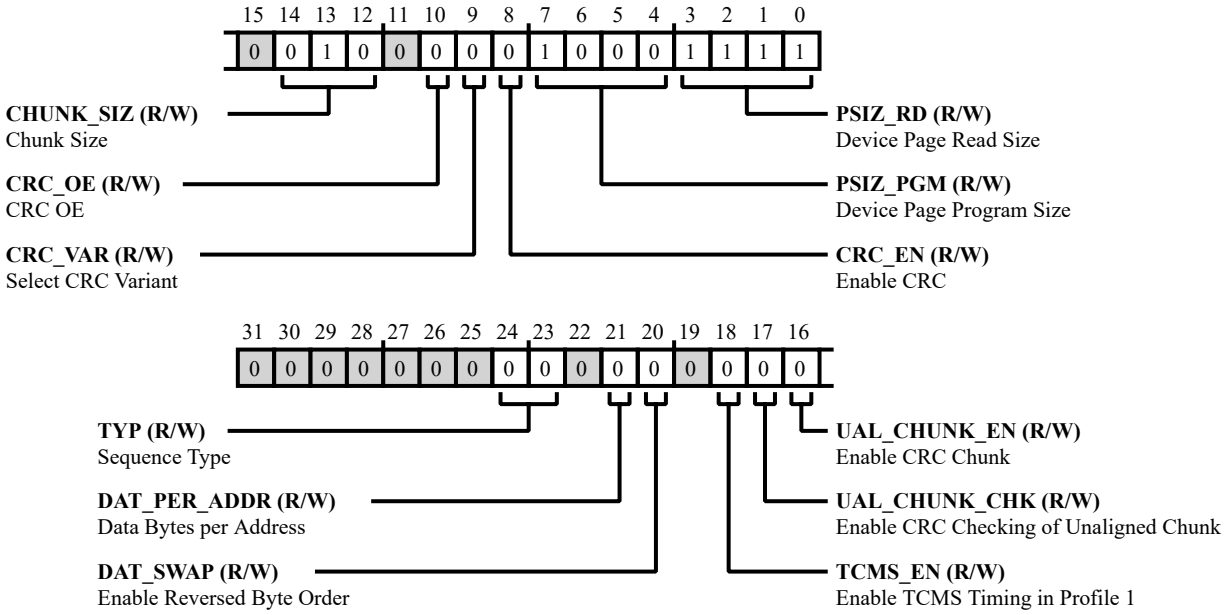

Figure 21-77: XSPI_SEQ_GCTL0 Register Diagram

Table 21-119: XSPI_SEQ_GCTL0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
24:23 (R/W)	TYP	Sequence Type. The XSPI_SEQ_GCTL0.TYP bit field indicates the sequence type (common for all sequences).	
		0	Profile 1
		1	Profile 2 - HF (HyperFlash)
		2	Profile 2 - HR (HyperRAM)
		3	SPI NAND

Table 21-119: XSPI_SEQ_GCTL0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
21 (R/W)	DAT_PER_ADDR	Data Bytes per Address. The `XSPI_SEQ_GCTL0.DAT_PER_ADDR` bit indicates the data organization of the xSPI memory. Note that the xSPI address/pointer specified during sending CDMA/PIO and direct command is always byte-aligned (for example, when this field is set, the xSPI address must be even).	
		0	1B per single memory address. No translation of xSPI address.
		1	2B per single memory address. Translation of xSPI address from byte address to word address is performed automatically.
20 (R/W)	DAT_SWAP	Enable Reversed Byte Order. When set (=1), the `XSPI_SEQ_GCTL0.DAT_SWAP` bit enables reverse byte order. The `XSPI_SEQ_GCTL0.DAT_SWAP` bit can be set only when data phase reflects octal DDR mode. In other modes the `XSPI_SEQ_GCTL0.DAT_SWAP` bit must be cleared (=0).	
		0	Disable
		1	Enable
18 (R/W)	TCMS_EN	Enable TCMS Timing in Profile 1. When set (=1), the `XSPI_SEQ_GCTL0.TCMS_EN` bit enables tCMS timing in profile 1. Refer to the XSPI_MINICTL_DEV_ACTIVE_MAX register at offset 0x1018 for further details.	
		0	Disable
		1	Enable
17 (R/W)	UAL_CHUNK_CHK	Enable CRC Checking of Unaligned Chunk. Setting the `XSPI_SEQ_GCTL0.UAL_CHUNK_CHK` bit enables the checking of a CRC unaligned chunk from the flash device. It can be set (=1) only if crc_ual_chunk_en = 1. Otherwise, the `XSPI_SEQ_GCTL0.UAL_CHUNK_CHK` bit must be cleared (=0) .	
		0	Disable
		1	Enable
16 (R/W)	UAL_CHUNK_EN	Enable CRC Chunk. Setting the `XSPI_SEQ_GCTL0.UAL_CHUNK_EN` bit enables taking into consideration the command address to determine after how many bytes CRC data slice is expected to be returned by the flash device.	
		0	Disable
		1	Enable

Table 21-119: XSPI_SEQ_GCTL0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
14:12 (R/W)	CHUNK_SIZ	Chunk Size. The `XSPI_SEQ_GCTL0.CHUNK_SIZ` field indicates the number of bytes after which CRC occurs.	
		0	N/A
		1	8B
		2	16B
		3	32B
		4	64B
		5	128B
		6	256B
		7	512B
10 (R/W)	CRC_OE	CRC OE. The `XSPI_SEQ_GCTL0.CRC_OE` field determines whether the controller expects the xSPI device to toggle CRC data on both SPI clock edges in CRC->CRC# sequence.	
		0	Disable
		1	Enable
9 (R/W)	CRC_VAR	Select CRC Variant. The `XSPI_SEQ_GCTL0.CRC_VAR` bit indicates the CRC variant.	
		0	Address Transfer Phase Only. CRC is calculated for all bytes of address transfer phase only and put on the bus after the address transfer phase.
		1	Sequence. CRC is calculated for all bytes in sequence and put on the bus after all bytes in the sequence.
8 (R/W)	CRC_EN	Enable CRC. When set (=1), the `XSPI_SEQ_GCTL0.CRC_EN` bit enables dynamic CRC calculation that is based on all previous bytes in the current sequence. Software puts this value on the xSPI flash interface. Not required by Legacy Hyper flash and xSPI Profile 2.0 Devices but can be useful for external flash Monitor to control data integrity.	
		0	Disable
		1	Enable

Table 21-119: XSPI_SEQ_GCTL0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
7:4 (R/W)	PSIZ_PGM	Device Page Program Size. The `XSPI_SEQ_GCTL0.PSIZ_PGM` bit field indicates the page size of device being used for program operations. Number of bytes in page = 2^{page_size}. Allowed values are: 4'b0000 - 1B 4'b0001 - 2B ... 4'b1000 - 256B 4'b1001 - 512B 4'b1010 - 1024B 4'b1011 - 2048B 4'b1100 - 4096B 4'b1111 - N/A This field is not used in direct mode for profile 2 - HR or when SPI NAND device is selected.
3:0 (R/W)	PSIZ_RD	Device Page Read Size. The `XSPI_SEQ_GCTL0.PSIZ_RD` bit field indicates the page size of the device used for read operations. Number of bytes in page = 2^{page_size}. Allowed values are: 4'b0000 - 1B 4'b0001 - 2B ... 4'b1000 - 256B 4'b1001 - 512B 4'b1010 - 1024B 4'b1011 - 2048B 4'b1100 - 4096B 4'b1101 - N/A ... 4'b1111 - unlimited (controller sends all data with single xSPI command)

Sequence Configuration Register 1

The XSPI_SEQ_GCTL1 register configures common values for sequences in CDMA, PIO and direct work modes.

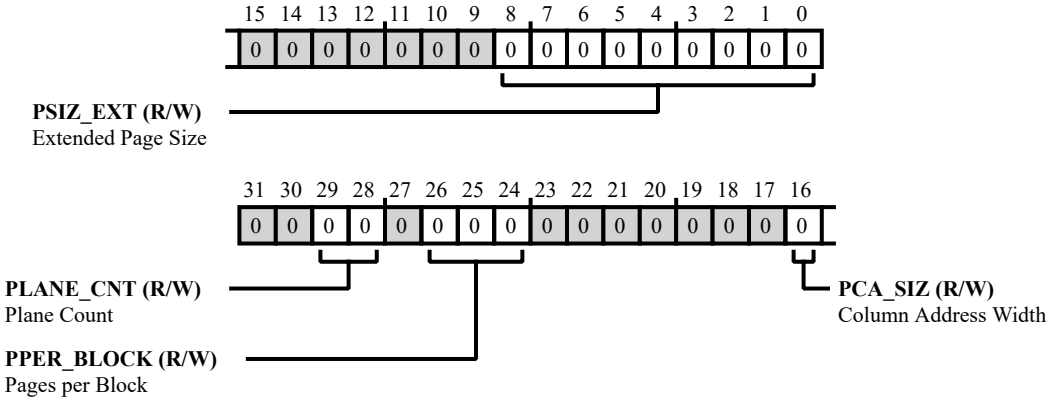

Figure 21-78: XSPI_SEQ_GCTL1 Register Diagram

Table 21-120: XSPI_SEQ_GCTL1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
29:28 (R/W)	PLANE_CNT	Plane Count. The XSPI_SEQ_GCTL1.PLANE_CNT bit field indicates the number of planes in the SPI NAND device (encoded as 2^N).	
		0	Single plane
		1	Two planes
		2	Four planes
		3	Reserved
26:24 (R/W)	PPER_BLOCK	Pages per Block. The XSPI_SEQ_GCTL1.PPER_BLOCK bit field indicates the number of pages per blocks for SPI NAND device (encoded as 2^N):	
		0	1 page per block
		1	2 pages per block
		2	4 pages per block
		3	8 pages per block
		4	16 pages per block
		5	32 pages per block
		6	64 pages per block
		7	128 pages per block

Table 21-120: XSPI_SEQ_GCTL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W)	PCA_SIZ	Column Address Width. The `XSPI_SEQ_GCTL1.PCA_SIZ` bit indicates the width of the column address for SPI NAND devices. The value of this field is used to calculate the next page address when the data size specified in the sequence exceeds the current page capacity.	
		0	12 bit address width
		1	13 bit address width
8:0 (R/W)	PSIZ_EXT	Extended Page Size. The `XSPI_SEQ_GCTL1.PSIZ_EXT` bit field indicates the extended page size area (spare area size) for SPI NAND devices. The number of data bytes transmitted to/from each page is extended by a value of this field. This field is not used in direct mode.	

Short Polling Count Register

The XSPI_SHORTPOL_GCTL register contains the status monitor cycle count value.

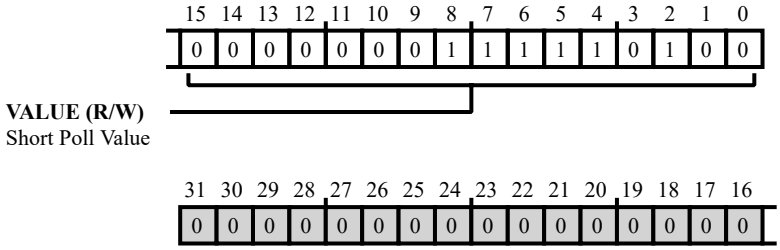

Figure 21-79: XSPI_SHORTPOL_GCTL Register Diagram

Table 21-121: XSPI_SHORTPOL_GCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Short Poll Value. The XSPI_SHORTPOL_GCTL.VALUE bit field indicates the minimum number of system clocks after a long polling delay before the controller starts to poll for status if the controller was busy during the first status poll attempt. The long polling value should be significantly larger the short polling value.

Status Checking Sequence Configuration Register 0

The XSPI_STAT_SEQ_CFG0 register configures the status checking sequence for profile 1 and SPI NAND in ACMD and direct work modes.

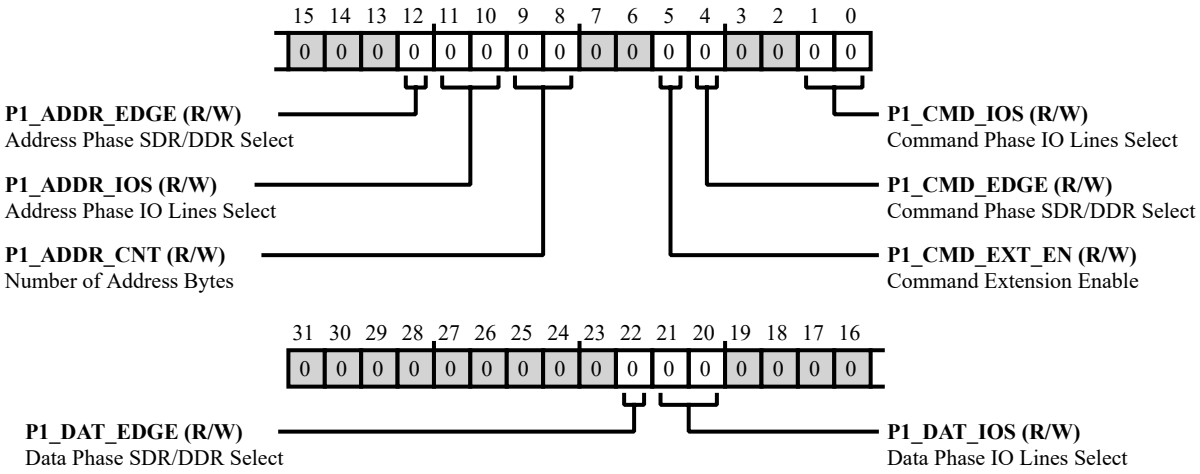

Figure 21-80: XSPI_STAT_SEQ_CFG0 Register Diagram

Table 21-122: XSPI_STAT_SEQ_CFG0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
22 (R/W)	P1_DAT_EDGE	Data Phase SDR/DDR Select. The XSPI_STAT_SEQ_CFG0.P1_DAT_EDGE bit selects between SDR/DDR mode for data phase.	
21:20 (R/W)	P1_DAT_IOS	Data Phase IO Lines Select. The XSPI_STAT_SEQ_CFG0.P1_DAT_IOS bit field indicates the number of data lines used to send the data phase.	
		0	One data line used (for example, serial)
		1	Two data lines used
		2	Four data lines used
		3	Eight data lines used
12 (R/W)	P1_ADDR_EDGE	Address Phase SDR/DDR Select. The XSPI_STAT_SEQ_CFG0.P1_ADDR_EDGE bit selects between SDR/DDR mode for address phase.	

Table 21-122: XSPI_STAT_SEQ_CFG0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11:10 (R/W)	P1_ADDR_IOS	Address Phase IO Lines Select. The `XSPI_STAT_SEQ_CFG0.P1_ADDR_IOS` bit field indicates the number of data lines used to send the address phase.	
		0	One data line used (for example, serial)
		1	Two data lines used
		2	Four data lines used
		3	Eight data lines used
9:8 (R/W)	P1_ADDR_CNT	Number of Address Bytes. The `XSPI_STAT_SEQ_CFG0.P1_ADDR_CNT` bit field indicates the number of address bytes for all status sequences.	
		0	One address byte
		1	Two address bytes
		2	Three address bytes
		3	Four address bytes
5 (R/W)	P1_CMD_EXT_EN	Command Extension Enable. The `XSPI_STAT_SEQ_CFG0.P1_CMD_EXT_EN` bit enables the command extension.	
4 (R/W)	P1_CMD_EDGE	Command Phase SDR/DDR Select. The `XSPI_STAT_SEQ_CFG0.P1_CMD_EDGE` bit selects between SDR/DDR mode for command phase.	
1:0 (R/W)	P1_CMD_IOS	Command Phase IO Lines Select. The `XSPI_STAT_SEQ_CFG0.P1_CMD_IOS` bit field indicates the number of data lines used to send the command.	
		0	One data line used (for example, serial)
		1	Two data lines used
		2	Four data lines used
		3	Eight data lines used

Status Checking Sequence Configuration Register 1

The XSPI_STAT_SEQ_CFG1 register configures the status checking sequence for profile 1 and SPI NAND ACMD and direct work modes.

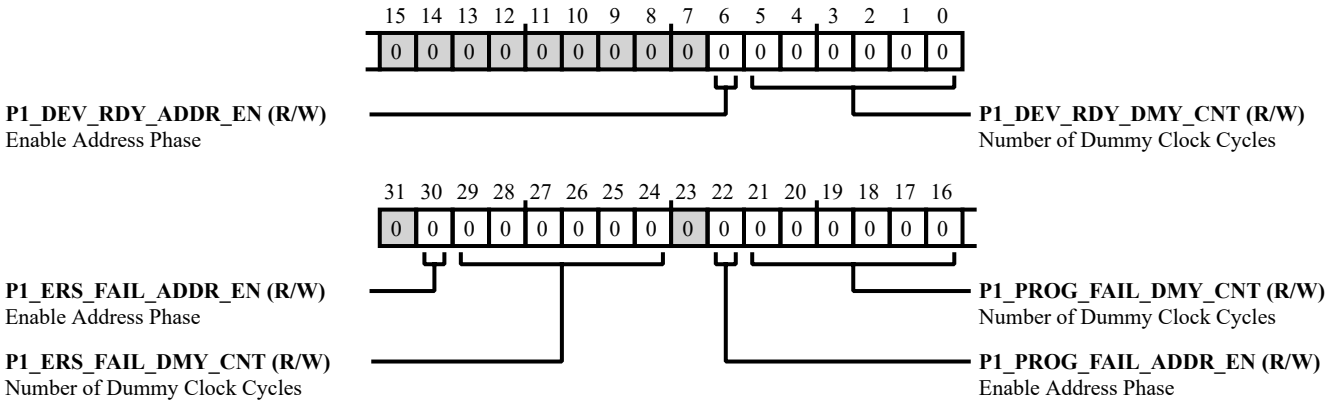

Figure 21-81: XSPI_STAT_SEQ_CFG1 Register Diagram

Table 21-123: XSPI_STAT_SEQ_CFG1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
30 (R/W)	P1_ERS_FAIL_ADDR_EN	Enable Address Phase. The XSPI_STAT_SEQ_CFG1.P1_ERS_FAIL_ADDR_EN bit enables the address phase for checking the fail status after the erase operation. This field is not used in direct work mode.
29:24 (R/W)	P1_ERS_FAIL_DMY_CNT	Number of Dummy Clock Cycles. The XSPI_STAT_SEQ_CFG1.P1_ERS_FAIL_DMY_CNT bit field indicates the number of dummy clock cycles used to check the fail status after the erase operation. This field is not used in direct work mode.
22 (R/W)	P1_PROG_FAIL_ADDR_EN	Enable Address Phase. The XSPI_STAT_SEQ_CFG1.P1_PROG_FAIL_ADDR_EN bit enables the address phase for checking the fail status after the program operation.
21:16 (R/W)	P1_PROG_FAIL_DMY_CNT	Number of Dummy Clock Cycles. The XSPI_STAT_SEQ_CFG1.P1_PROG_FAIL_DMY_CNT bit field indicates the number of dummy clock cycles used to check the fail status after the program operation.
6 (R/W)	P1_DEV_RDY_ADDR_EN	Enable Address Phase. The XSPI_STAT_SEQ_CFG1.P1_DEV_RDY_ADDR_EN bit enables the address phase for checking the ready/busy status after the program/erase and soft reset/read (only for SPI NAND) operation.

Table 21-123: XSPI_STAT_SEQ_CFG1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
5:0 (R/W)	P1_DEV_RDY_DMY_CNT	Number of Dummy Clock Cycles. The `XSPI_STAT_SEQ_CFG1.P1_DEV_RDY_DMY_CNT` bit field indicates the number of dummy clock cycles needed to check the ready/busy status after program/erase or soft reset/read (only for SPI NAND) operation.

Status Checking Sequence Configuration Register 10

The XSPI_STAT_SEQ_CFG10 register configures the status checking sequence for SPI NAND devices in ACMD and direct work modes.

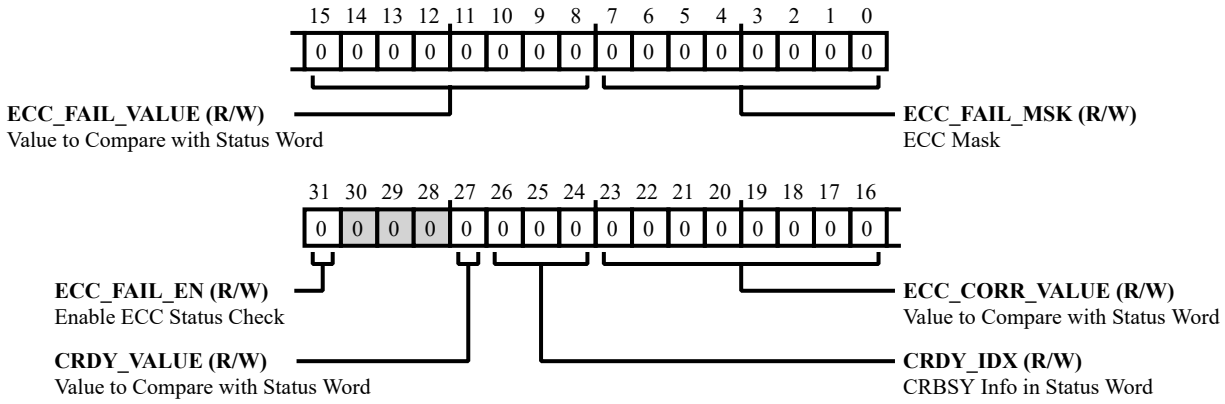

Figure 21-82: XSPI_STAT_SEQ_CFG10 Register Diagram

Table 21-124: XSPI_STAT_SEQ_CFG10 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	ECC_FAIL_EN	Enable ECC Status Check. The XSPI_STAT_SEQ_CFG10.ECC_FAIL_EN bit enables checking ECC status after a read page operation.
27 (R/W)	CRDY_VALUE	Value to Compare with Status Word. The XSPI_STAT_SEQ_CFG10.CRDY_VALUE bit indicates the value to be compared with the selected status bit in order to detect if the device is in a ready state after the read page cache random operation (CRBSY bit). This field is not used in direct work mode.
26:24 (R/W)	CRDY_IDX	CRBSY Info in Status Word. The XSPI_STAT_SEQ_CFG10.CRDY_IDX bit field indicates which bit of the status word contains the Cache Read Busy (CRBSY) bit information for the SPI NAND read page cache random operation. This field is not used in direct work mode.
23:16 (R/W)	ECC_CORR_VALUE	Value to Compare with Status Word. The XSPI_STAT_SEQ_CFG10.ECC_CORR_VALUE bit field indicates the value to be compared with the status word masked by the XSPI_STAT_SEQ_CFG10.ECC_FAIL_MSK field in order to detect if the device returned a correctable ECC error during SPI NAND page read operation. This can be used to detect a single range of correctable errors returned by the xSPI device.

Table 21-124: XSPI_STAT_SEQ_CFG10 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W)	ECC_FAIL_VALUE	Value to Compare with Status Word. The `XSPI_STAT_SEQ_CFG10.ECC_FAIL_VALUE` bit field indicates the value to be compared with the status word masked by the XSPI_STAT_SEQ_CFG10.ECC_FAIL_MSK field in order to detect if the device returned an uncorrectable ECC error during SPI NAND page read operation.
7:0 (R/W)	ECC_FAIL_MSK	ECC Mask. The `XSPI_STAT_SEQ_CFG10.ECC_FAIL_MSK` bit field indicates the mask used to select which bits of status word carries the ECC status.

Status Checking Sequence Configuration Register 2

The XSPI_STAT_SEQ_CFG2 register configures the status checking sequence for profile 1 and SPI NAND in ACMD and direct work modes.

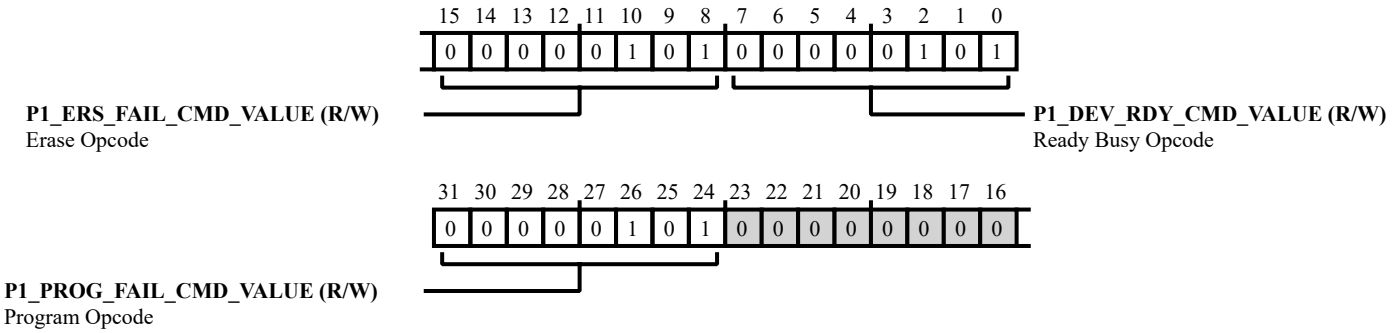

Figure 21-83: XSPI_STAT_SEQ_CFG2 Register Diagram

Table 21-125: XSPI_STAT_SEQ_CFG2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	P1_PROG_FAIL_CMD_VALUE	Program Opcode. The XSPI_STAT_SEQ_CFG2.P1_PROG_FAIL_CMD_VALUE bit field contains the command mnemonic value that is used to check the fail status after program operation.
15:8 (R/W)	P1_ERS_FAIL_CMD_VALUE	Erase Opcode. The XSPI_STAT_SEQ_CFG2.P1_ERS_FAIL_CMD_VALUE bit field contains the command mnemonic value that is used to check the fail status after the erase operation. This field is not used in direct work mode.
7:0 (R/W)	P1_DEV_RDY_CMD_VALUE	Ready Busy Opcode. The XSPI_STAT_SEQ_CFG2.P1_DEV_RDY_CMD_VALUE bit field contains the command mnemonic value that is used to check the ready/busy status after program/erase and soft erase/read (only for SPI NAND) operation.

Status Checking Sequence Configuration Register 3

The XSPI_STAT_SEQ_CFG3 register configures the status checking sequence for profile 1 and SPI NAND in ACMD and direct work modes.

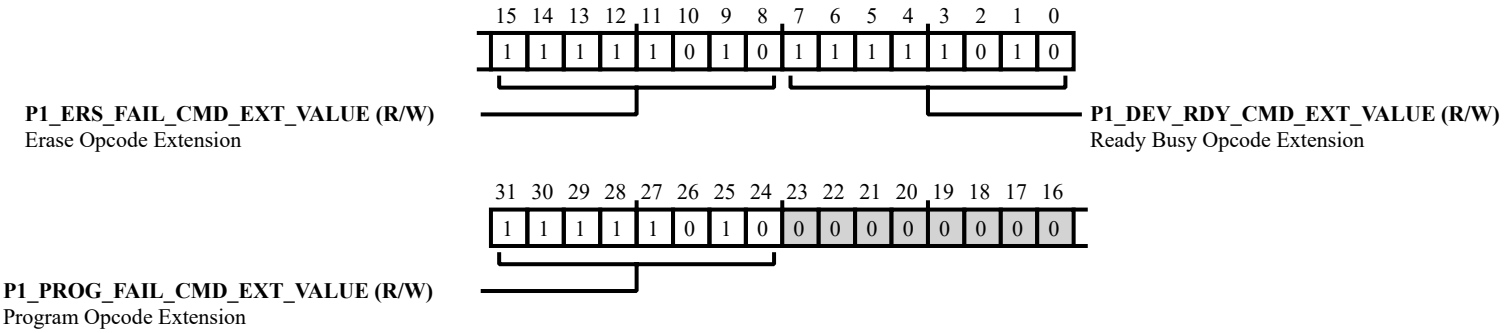

Figure 21-84: XSPI_STAT_SEQ_CFG3 Register Diagram

Table 21-126: XSPI_STAT_SEQ_CFG3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	P1_PROG_FAIL_CMD_EXT_VALUE	Program Opcode Extension. The XSPI_STAT_SEQ_CFG3.P1_PROG_FAIL_CMD_EXT_VALUE bit field contains the command mnemonic value that is used to check the fail status after the program operation.
15:8 (R/W)	P1_ERS_FAIL_CMD_EXT_VALUE	Erase Opcode Extension. The XSPI_STAT_SEQ_CFG3.P1_ERS_FAIL_CMD_EXT_VALUE bit field contains the command mnemonic value that is used to check the fail status after the erase operation. This field is not used in direct work mode.
7:0 (R/W)	P1_DEV_RDY_CMD_EXT_VALUE	Ready Busy Opcode Extension. The XSPI_STAT_SEQ_CFG3.P1_DEV_RDY_CMD_EXT_VALUE bit field contains the command mnemonic value that is used to check the ready/busy status after the program/erase and soft reset/read (only for SPI NAND) operation.

Status Checking Sequence Configuration Register 4

The XSPI_STAT_SEQ_CFG4 register configures the status checking sequence for profile 2 - HF in ACMD and direct work modes.

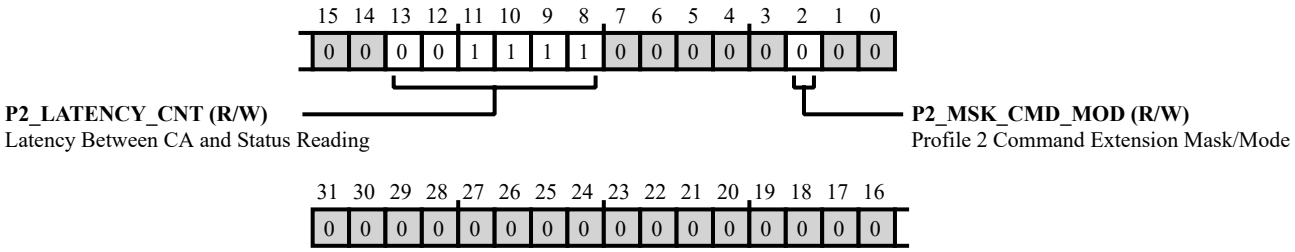

Figure 21-85: XSPI_STAT_SEQ_CFG4 Register Diagram

Table 21-127: XSPI_STAT_SEQ_CFG4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
13:8 (R/W)	P2_LATENCY_CNT	Latency Between CA and Status Reading. The XSPI_STAT_SEQ_CFG4.P2_LATENCY_CNT bit field indicates the number of latency cycles between the CA and status reading. Configure XSPI_STAT_SEQ_CFG4.P2_LATENCY_CNT to N-1, where N is the number of latency clock cycles expected by the memory device.
2 (R/W)	P2_MSK_CMD_MOD	Profile 2 Command Extension Mask/Mode. The XSPI_STAT_SEQ_CFG4.P2_MSK_CMD_MOD bit field indicates the profile 2 command extension variant. The value of this field influences bits[44:40] of the Command/Address (CA). If this bit is set (=1), bits [44:40] of the CA are set (=1). Otherwise, bits [44:40] of the CA are cleared (=0).

Status Checking Sequence Configuration Register 5

The XSPI_STAT_SEQ_CFG5 register configures the status checking sequence for profile 1, SPI NAND and profile 2 - HF in ACMD and direct work modes.

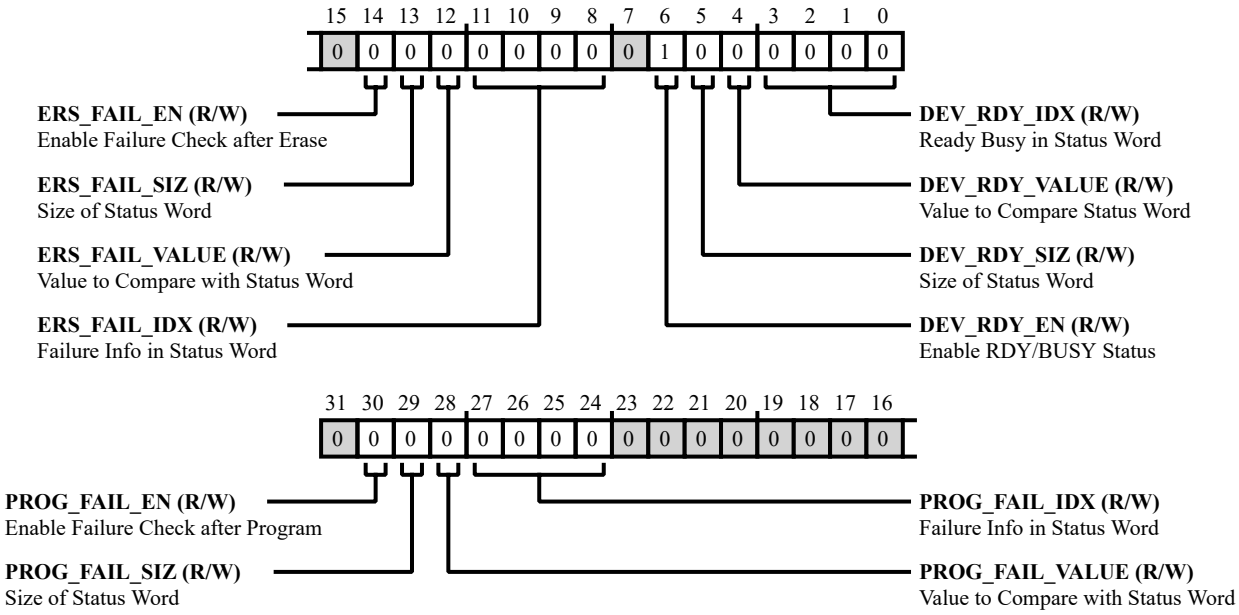

Figure 21-86: XSPI_STAT_SEQ_CFG5 Register Diagram

Table 21-128: XSPI_STAT_SEQ_CFG5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
30 (R/W)	PROG_FAIL_EN	Enable Failure Check after Program. The XSPI_STAT_SEQ_CFG5.PROG_FAIL_EN bit enables checking the fail status after program operation.
29 (R/W)	PROG_FAIL_SIZ	Size of Status Word. The XSPI_STAT_SEQ_CFG5.PROG_FAIL_SIZ bit indicates the size of the status word (0-1B, 1-2B).
28 (R/W)	PROG_FAIL_VALUE	Value to Compare with Status Word. The XSPI_STAT_SEQ_CFG5.PROG_FAIL_VALUE bit indicates the value to be compared with selected status bit in order to detect that the device is in fail state after program operation.
27:24 (R/W)	PROG_FAIL_IDX	Failure Info in Status Word. The XSPI_STAT_SEQ_CFG5.PROG_FAIL_IDX bit field indicates which bit of the status word contains the failure information after the program command.

Table 21-128: XSPI_STAT_SEQ_CFG5 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/W)	ERS_FAIL_EN	Enable Failure Check after Erase. The `XSPI_STAT_SEQ_CFG5.ERS_FAIL_EN` bit enables checking the fail status after an erase operation. This field is not used in direct work mode.
13 (R/W)	ERS_FAIL_SIZ	Size of Status Word. The `XSPI_STAT_SEQ_CFG5.ERS_FAIL_SIZ` bit indicates the size of status word (0-1B, 1-2B). This field is not used in direct work mode.
12 (R/W)	ERS_FAIL_VALUE	Value to Compare with Status Word. The `XSPI_STAT_SEQ_CFG5.ERS_FAIL_VALUE` bit indicates the value to be compared with the selected status bit in order to detect that the device is in the ready state after erase operation. This field is not used in direct work mode.
11:8 (R/W)	ERS_FAIL_IDX	Failure Info in Status Word. The `XSPI_STAT_SEQ_CFG5.ERS_FAIL_IDX` bit field indicates which bit of the status word contains the failure information after the erase command. This field is not used in direct work mode.
6 (R/W)	DEV_RDY_EN	Enable RDY/BUSY Status. The `XSPI_STAT_SEQ_CFG5.DEV_RDY_EN` bit enables checking the ready/busy status after program/erase operations.
5 (R/W)	DEV_RDY_SIZ	Size of Status Word. The `XSPI_STAT_SEQ_CFG5.DEV_RDY_SIZ` bit indicates the size of status word (0-1B, 1-2B).
4 (R/W)	DEV_RDY_VALUE	Value to Compare Status Word. The `XSPI_STAT_SEQ_CFG5.DEV_RDY_VALUE` bit indicates the value to be compared with selected status bit in order to detect that the device is ready after a program/erase or soft reset/read (only for SPI NAND) operation.
3:0 (R/W)	DEV_RDY_IDX	Ready Busy in Status Word. The `XSPI_STAT_SEQ_CFG5.DEV_RDY_IDX` bit field indicates which bit of the status word contains the ready/busy information to be polled after a program/erase or soft erase/read (only for SPI NAND) operation.

Status Checking Sequence Configuration Register 7

The XSPI_STAT_SEQ_CFG7 register configures the status checking sequence for profile 1, SPI NAND and profile 2 - HF in ACMD and direct work modes.

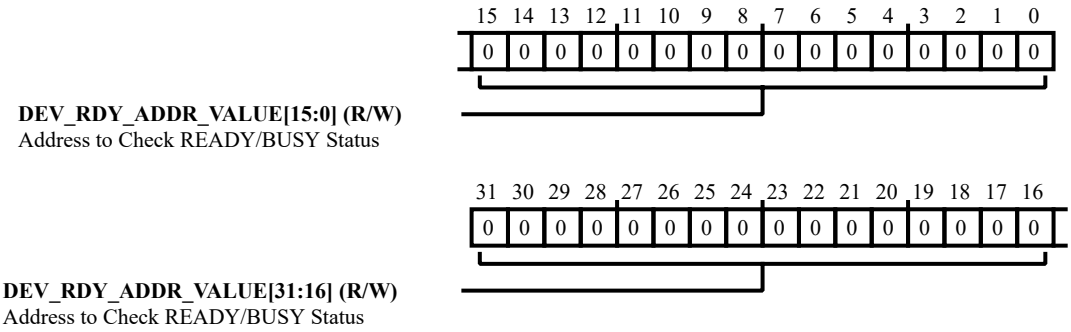

Figure 21-87: XSPI_STAT_SEQ_CFG7 Register Diagram

Table 21-129: XSPI_STAT_SEQ_CFG7 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	DEV_RDY_ADDR_VALUE	Address to Check READY/BUSY Status. The XSPI_STAT_SEQ_CFG7.DEV_RDY_ADDR_VALUE bit field indicates the value of the address used to check the ready/busy status after the program/erase and soft reset/read (only for SPI NAND) operation.

Status Checking Sequence Configuration Register 8

The XSPI_STAT_SEQ_CFG8 register configures the status checking sequence for profile 1, SPI NAND and profile 2 - HF in ACMD and direct work modes.

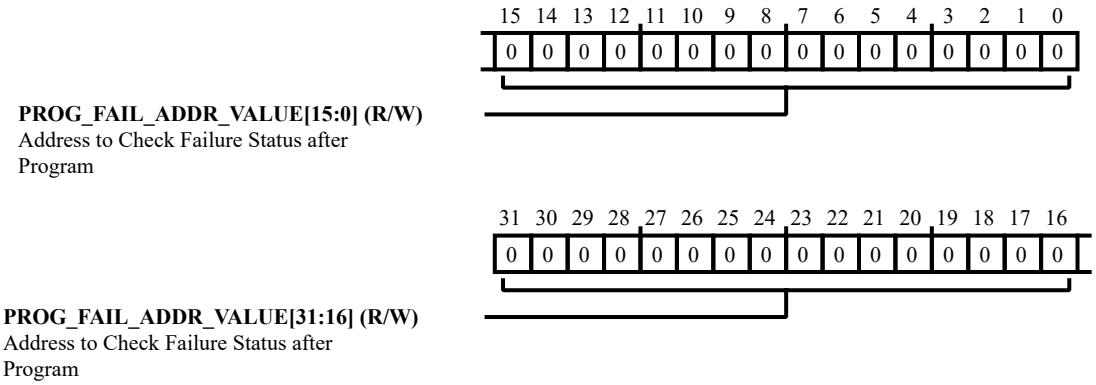

Figure 21-88: XSPI_STAT_SEQ_CFG8 Register Diagram

Table 21-130: XSPI_STAT_SEQ_CFG8 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	PROG_FAIL_ADDR_VALUE	Address to Check Failure Status after Program. The XSPI_STAT_SEQ_CFG8.PROG_FAIL_ADDR_VALUE bit field indicates the value of the address used to check the fail status after the program operation.

Status Checking Sequence Configuration Register 9

The XSPI_STAT_SEQ_CFG9 register configures the status checking sequence for profile 1, SPI NAND and profile 2 - HF in ACMD work mode.

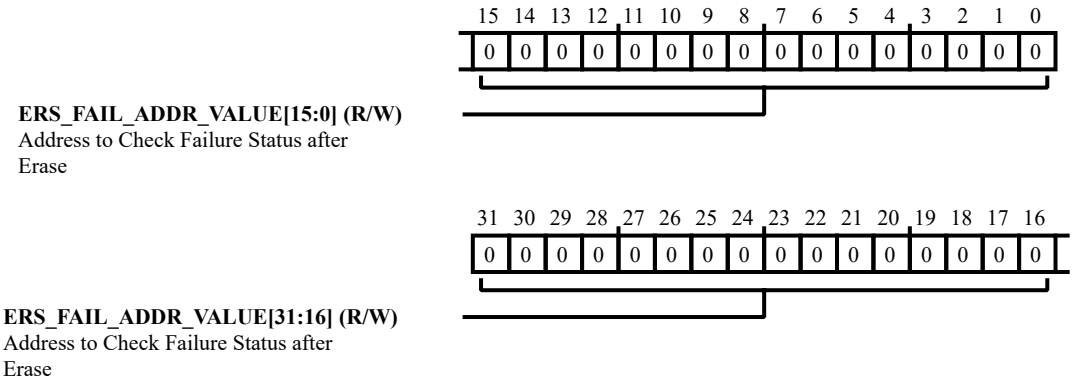

Figure 21-89: XSPI_STAT_SEQ_CFG9 Register Diagram

Table 21-131: XSPI_STAT_SEQ_CFG9 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	ERS_FAIL_ADDR_VALUE	Address to Check Failure Status after Erase. The XSPI_STAT_SEQ_CFG9.ERS_FAIL_ADDR_VALUE bit field indicates the value of the address used to check fail status after erase operation.

Auto Command Engine Interrupt Status Thread Register

Each bit of the field corresponds to an auto command engine thread and holds the descriptor status for that selected thread. It is set only when INT bit of descriptor is set.

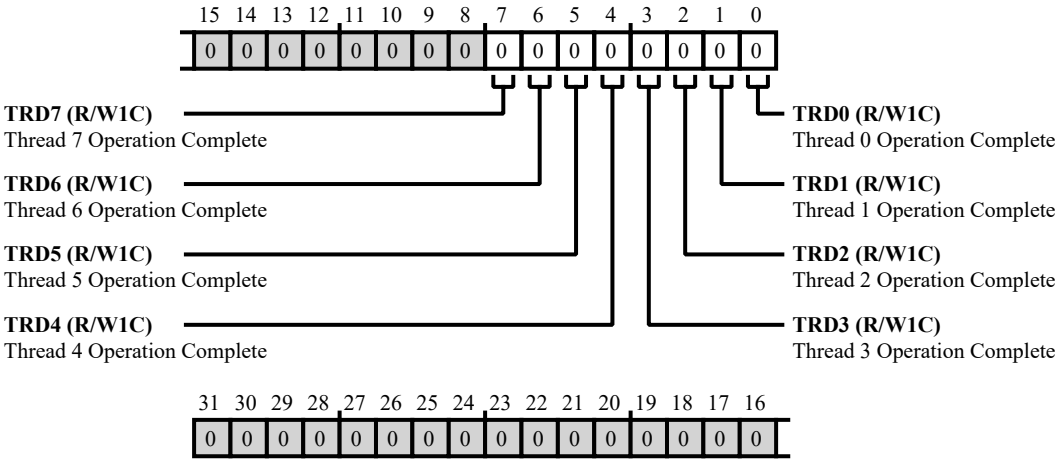

Figure 21-90: XSPI_TRD_COMP_ISTAT Register Diagram

Table 21-132: XSPI_TRD_COMP_ISTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7 (R/W1C)	TRD7	Thread 7 Operation Complete. Thread 7 operation complete flag.
6 (R/W1C)	TRD6	Thread 6 Operation Complete. Thread 6 operation complete flag.
5 (R/W1C)	TRD5	Thread 5 Operation Complete. Thread 5 operation complete flag.
4 (R/W1C)	TRD4	Thread 4 Operation Complete. Thread 4 operation complete flag.
3 (R/W1C)	TRD3	Thread 3 Operation Complete. Thread 3 operation complete flag.
2 (R/W1C)	TRD2	Thread 2 Operation Complete. Thread 2 operation complete flag.
1 (R/W1C)	TRD1	Thread 1 Operation Complete. Thread 1 operation complete flag.
0 (R/W1C)	TRD0	Thread 0 Operation Complete. Thread 0 operation complete flag.

Thread Error Interrupt Enable Register

If the selected bit of the XSPI_TRD_ERR_INT_EN register is set, the rising edge of the corresponding bit in the XSPI_TRD_COMP_ISTAT register causes the setting of the external interrupt line.

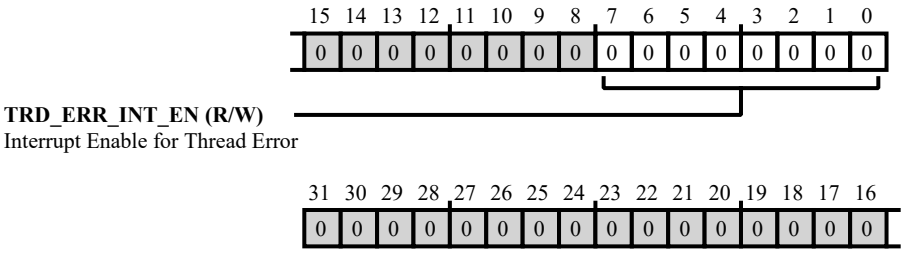

Figure 21-91: XSPI_TRD_ERR_INT_EN Register Diagram

Table 21-133: XSPI_TRD_ERR_INT_EN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	TRD_ERR_INT_EN	Interrupt Enable for Thread Error. Interrupt enable for detecting a thread error.

Thread Error Interrupt Status Register

The XSPI_TRD_ERR_ISTAT register can be read to determine whether a particular thread (in the auto command engine) has encountered an error condition.

To get more information on the error, software must read the status field of the descriptor (CDMA mode) or the appropriate status register (PIO mode).

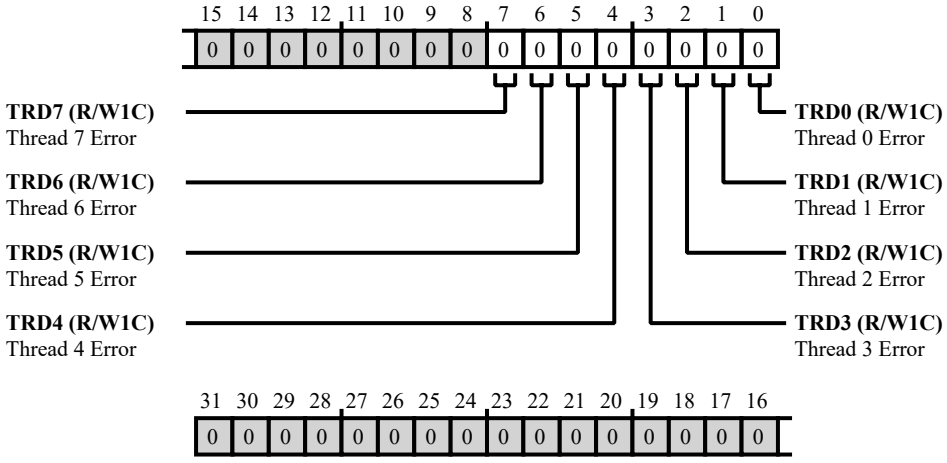

Figure 21-92: XSPI_TRD_ERR_ISTAT Register Diagram

Table 21-134: XSPI_TRD_ERR_ISTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7 (R/W1C)	TRD7	Thread 7 Error. Thread 7 error.
6 (R/W1C)	TRD6	Thread 6 Error. Thread 6 error.
5 (R/W1C)	TRD5	Thread 5 Error. Thread 5 error.
4 (R/W1C)	TRD4	Thread 4 Error. Thread 4 error.
3 (R/W1C)	TRD3	Thread 3 Error. Thread 3 error.
2 (R/W1C)	TRD2	Thread 2 Error. Thread 2 error.
1 (R/W1C)	TRD1	Thread 1 Error. Thread 1 error.

Table 21-134: XSPI_TRD_ERR_ISTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W1C)	TRD0	Thread 0 Error. Thread 0 error.

Auto Command Engine Thread Status Register

The XSPI_TRD_STAT register indicates the auto command engine thread status (ACMD mode only).

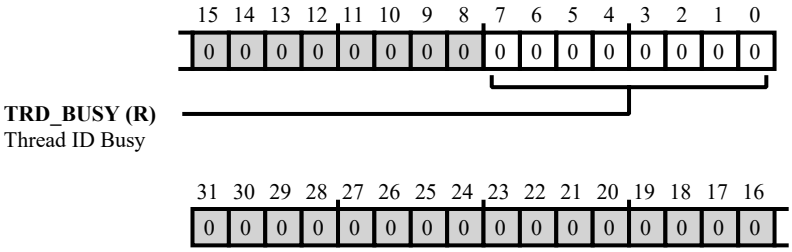

Figure 21-93: XSPI_TRD_STAT Register Diagram

Table 21-135: XSPI_TRD_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/NW)	TRD_BUSY	Thread ID Busy. The XSPI_TRD_STAT.TRD_BUSY bit indicates the auto command engine thread busy status. When set, the corresponding thread is currently busy.

WEL Sequence Configuration Register

The XSPI_WE_SEQ_CFG0 register configures the Write Enable Latch (WEL) sequence for profile 1 and SPI NAND in ACMD and direct work modes.

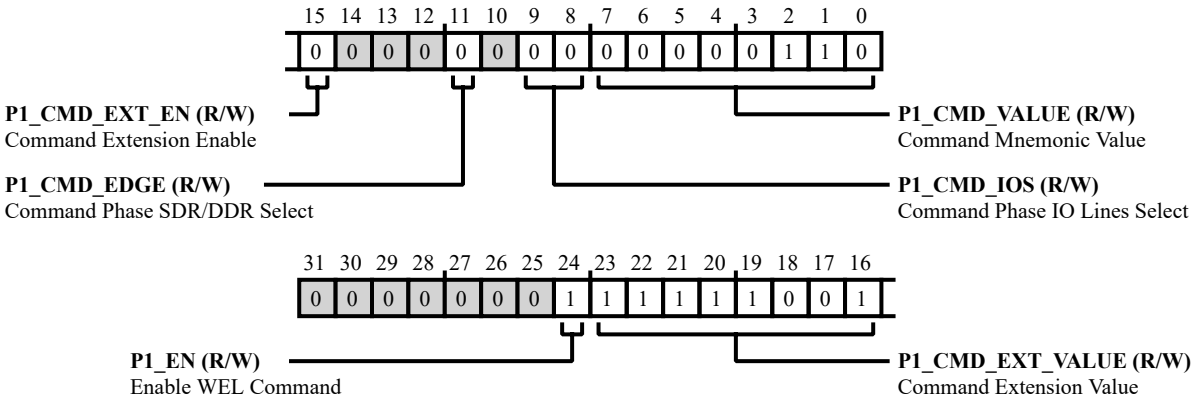

Figure 21-94: XSPI_WE_SEQ_CFG0 Register Diagram

Table 21-136: XSPI_WE_SEQ_CFG0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
24 (R/W)	P1_EN	Enable WEL Command. The XSPI_WE_SEQ_CFG0.P1_EN bit enables the WEL command.	
23:16 (R/W)	P1_CMD_EXT_VALUE	Command Extension Value. The XSPI_WE_SEQ_CFG0.P1_CMD_EXT_VALUE bit field indicates the command extension value.	
15 (R/W)	P1_CMD_EXT_EN	Command Extension Enable. The XSPI_WE_SEQ_CFG0.P1_CMD_EXT_EN bit enables the command extension.	
11 (R/W)	P1_CMD_EDGE	Command Phase SDR/DDR Select. The XSPI_WE_SEQ_CFG0.P1_CMD_EDGE bit selects between SDR/DDR mode for command phase.	
9:8 (R/W)	P1_CMD_IOS	Command Phase IO Lines Select. The XSPI_WE_SEQ_CFG0.P1_CMD_IOS bit field indicates the number of data lines used to send the command phase.	
		0	One data line used (for example, serial)
		1	Two data lines used
		2	Four data lines used
		3	Eight data lines used

Table 21-136: XSPI_WE_SEQ_CFG0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	P1_CMD_VALUE	Command Mnemonic Value. The `XSPI_WE_SEQ_CFG0.P1_CMD_VALUE` bit field indicates the command mnemonic value.

Device Control Register

The XSPI_WORKMODE_CTL register controls the device working modes.

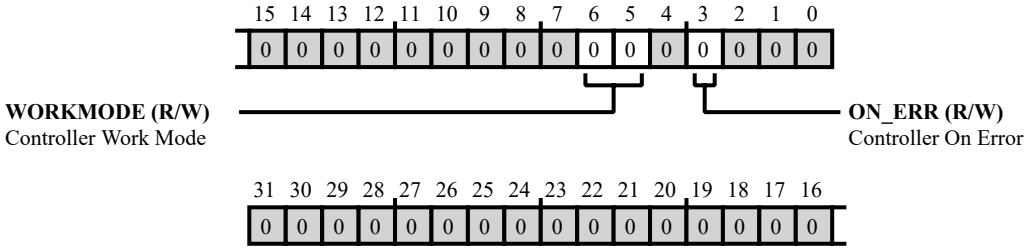

Figure 21-95: XSPI_WORKMODE_CTL Register Diagram

Table 21-137: XSPI_WORKMODE_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
6:5 (R/W)	WORKMODE	Controller Work Mode. The XSPI_WORKMODE_CTL.WORKMODE bit field indicates the work mode of the controller. Allowed values are 00 - Direct mode 01 - STIG mode 11 - ACMD mode
3 (R/W)	ON_ERR	Controller On Error. This control bit is relevant only for ACMD work mode. If the XSPI_WORKMODE_CTL.ON_ERR bit is cleared (=0) and an error occurs, the controller drops execution of all further operations programmed in a single thread at the page (for read or program commands) or sector (for the sector erase command) boundary. The XSPI_WORKMODE_CTL.ON_ERR bit applies to both command DMA and PIO work modes. When XSPI_WORKMODE_CTL.ON_ERR is set (=1), execution continues.

XIP Configuration Register

The XSPI_XIP_GCTL register configures the controller in XIP work mode in CDMA, PIO and direct work modes.

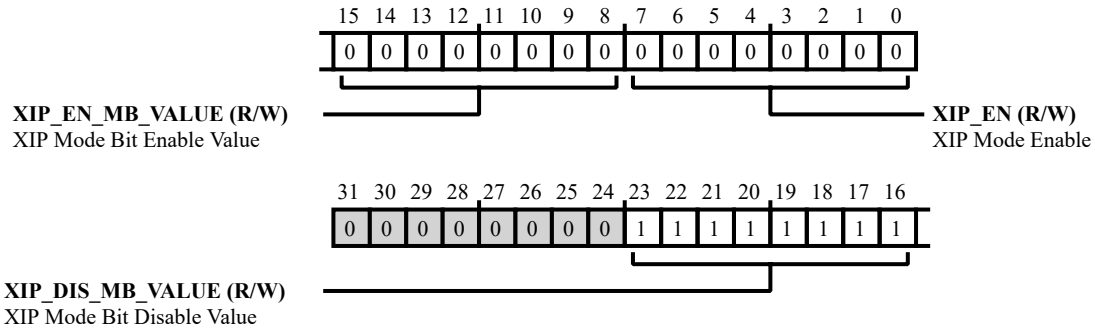

Figure 21-96: XSPI_XIP_GCTL Register Diagram

Table 21-138: XSPI_XIP_GCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:16 (R/W)	XIP_DIS_MB_VALUE	XIP Mode Bit Disable Value. The XSPI_XIP_GCTL.XIP_DIS_MB_VALUE bit field indicates the value of the mode bits required to disable XIP mode.
15:8 (R/W)	XIP_EN_MB_VALUE	XIP Mode Bit Enable Value. The XSPI_XIP_GCTL.XIP_EN_MB_VALUE bit field indicates the value of the mode bits required to enable XIP mode.
7:0 (R/W)	XIP_EN	XIP Mode Enable. The XSPI_XIP_GCTL.XIP_EN bit field indicates the XIP mode enabled for a selected memory bank. When XIP mode is enabled, only read sequences are valid. Invoking any other command sequence is ignored and CMD_ERROR/DSC_ERROR/XSPI_ISTAT.DIR_CMD_ERR =1.

22 Universal Asynchronous Receiver/Transmitter (UART)

The UART module is a full-duplex peripheral compatible with PC-style industry-standard UARTs. The UART converts data between serial and parallel formats. The serial communication follows an asynchronous protocol that supports various word lengths, stop bits, bit rates, and parity-generation options. Multiple events can generate interrupts.

The UART is logically compliant to EIA-232E, EIA-422, EIA-485 and LIN standards, but usually requires external transceiver devices to meet electrical requirements. In IrDA (Infrared Data Association) mode, the UART meets the half-duplex IrDA SIR (9.6/115.2 Kbps rate) protocol. In multi-drop bus mode, the UART meets the full-duplex MDB/ICP v2.0 protocol.

The UART module supports partial modem status and control functionality to allow for hardware flow control.

The UART is a DMA-capable peripheral with separate transmit and receive DMA controller channels. The use of DMA requires minimal software intervention as the DMA engine moves the data. The UART can also use a programmed core mode of operation. The core mode requires software management of the data flow using either interrupts or polling.

The UART can use one of the peripheral timers for a hardware-assisted auto-baud detection mechanism. The timers are external to the UART.

NOTE: The UARTs (UART0, UART1, and UART2) operate in the SCLK0 domain.

UART Features

Each UART includes the following features.

- 5–8 data bits
- Programmable extra stop bit and programmable extra half-stop bit
- Even, odd, and sticky parity bit options
- Extra 8-stage receive FIFO with programmable threshold interrupt request
- Flexible transmit and receive interrupt request timing

- Three interrupt outputs for receive, transmit, and status
- Independent DMA operation for receive and transmit
- Programmable automatic request to send (RTS)/clear to send (CTS) hardware flow control
- False start bit detection
- SIR IrDA operation mode
- MDB/ICP v2.0 operation mode
- Internal loopback
- Improved bit rate granularity
- LIN break command/Inter-frame gap transmission support

Table 22-1: UART Specifications

Feature	Availability
Protocol	
Controller-Capable	Yes
Target-Capable	Yes
Transmission Simplex	Yes
Transmission Half-Duplex	Yes
Transmission Full-Duplex	Yes
Access Type	
Data Buffer	Yes
Core Data Access	Yes
DMA Data Access	Yes
DMA Channels	2 (per UART Port)
DMA Descriptor	Yes
Boot Capable	Yes (Target Mode)
Local Memory	No
Clock Operation	SCLK/16

UART Functional Description

The following sections provide details on the UARTs functionality.

ADSP-2184x UART Register List

The Universal Asynchronous Receiver/Transmitter module (UART) is a full-duplex peripheral compatible with PC-style industry-standard UARTs. The UART converts data between serial and parallel formats. The serial communication follows an asynchronous protocol that supports various word length, stop bit, parity, and interrupt generation options. A set of registers governs UART operations. For more information on UART functionality, see the UART register descriptions.

UART Block Diagram

The ***UART Block Diagram*** figure shows a simplified block diagram of one UART module and how it interconnects to the processor system.

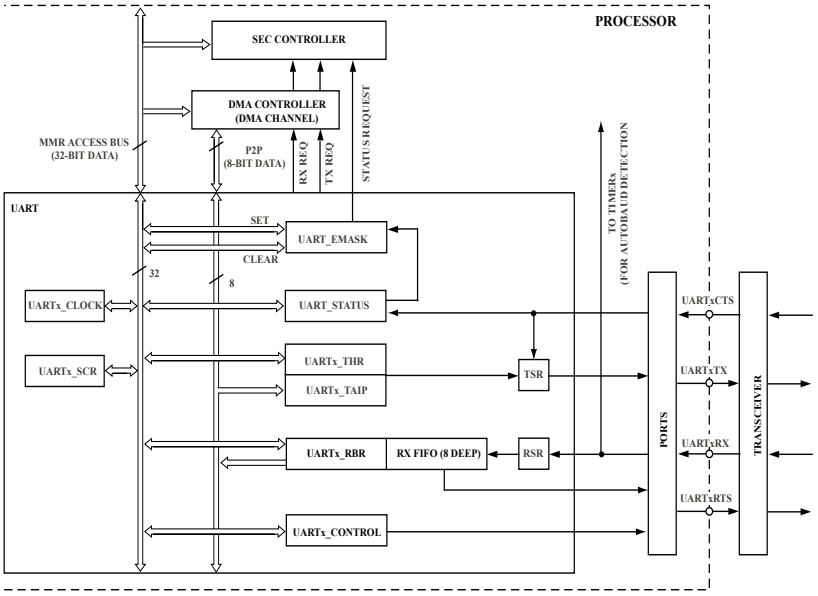

Figure 22-1: UART Block Diagram

UART Architectural Concepts

The following sections provide information about the UART architecture.

Internal Interface

The UART is a DMA-capable peripheral with support for separate transmit and receive DMA controller channels. It operates in either DMA or programmed core modes. The core mode requires software management of the data flow

using either interrupts or polling. The DMA method requires minimal software intervention, as the DMA engine itself moves the data. The UART_RBR and UART_THR registers also connect to one of the peripheral DMA buses.

All UART registers are 32 bits, and the registers connect to the peripheral MMR bus. Not all MMRs can be used, and unused bits are zero-filled. The UART has three interrupt outputs described as follows.

- The transmit and receive request outputs can function as DMA requests and connect to the DMA controller. Therefore, if the DMA is not enabled, the DMA controller simply forwards the request to the system event controller (SEC).
- The status interrupt output connects directly to the SEC . On many processors, the alternative capture input () of one of the GP timers also senses the UART_RX pin. When configured in capture mode, the processor can then use the GP timer to detect the bit rate of the received signal.

External Interface

Each UART features a UART_RX (receive) pin and a UART_TX (transmit) pin available through the general-purpose ports. These two pins usually connect to an external transceiver device that meets the electrical requirements of full-duplex or half-duplex standards. For example, EIA-232, EIA-422, 4-wire EIA-485 for full-duplex or 2-wire EIA-485, LIN for half-duplex. Additionally, the UART features a pair of clear-to-send, input pins (UART_CTS), and request-to-send, output pins (UART_RTS) for hardware flow control. UART signals are multiplexed with other functions at the pin level.

Hardware Flow Control

To prevent the UART transmitter from sending data while the receiving counterpart is not ready, the UART features a UART_RTS/UART_CTS hardware flow control mechanism. The UART_RTS signal is an output that connects to the UART_CTS input of the communication partner. If data transfer is bidirectional, the figure shows the ***UART Hardware Flow Control*** handshake.

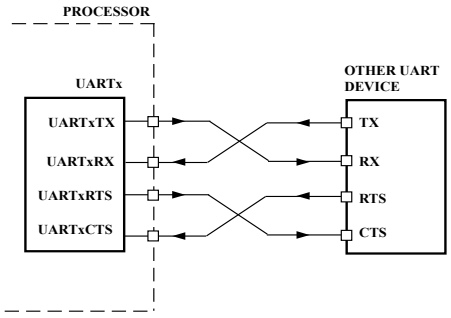

Figure 22-2: UART Hardware Flow Control

In both DMA and core mode, the receiver can deassert the UART_RTS signal to indicate that its receive buffer is almost full. Continued data transfers can cause an overrun error. The transmitter pauses when the UART_CTS input is in a deasserted state. In this state, the transmitter completes transmission of the data currently held in the transmit shift register (UART_TSR) but it does not continue with the data in the transmit hold register (UART_THR). If the UART_CTS pin is asserted again, the transmitter resumes and loads the content of UART_THR register into the UART_TSR register.

Bit Rate Generation

The peripheral clock (SCLK) and the 16-bit divisor in the UART_CLK register characterize the sample clock. The UART uses the UART_CTL.EN bit to enable the clock. By default, every serial bit is oversampled 16 times. The bit clock is 1/16th of the sample clock. If not in IrDA mode, the bit clock can equal the sample clock if the UART_CLK.EDBO bit is set, so that the following equation applies:

$$\text{Bit Rate} = \text{SCLK}/(16^{(1-\text{EDBO})} \times \text{Divisor})$$

The ***UART Bit Rate Examples with 100 MHz SCLK*** table provides example divide factors required to support standard baud rates at an SCLK of 100 MHz.

Table 22-7: UART Bit Rate Examples with 100 MHz SCLK

Bit Rate (bits/sec)	EDBO = 0			EDBO = 1		
	DL	Actual	% Error	DL	Actual	% Error
2400	2604	2400.15	0.006	41667	2399.98	0.001
4800	1302	4800.31	0.006	20833	4800.08	0.002
9600	651	9600.61	0.006	10417	9599.69	0.003
19200	326	19171.78	0.147	5208	19201.23	0.006
38400	163	38343.56	0.147	2604	38402.46	0.006
57600	109	57339.45	0.452	1736	57603.69	0.006
115200	54	115740.74	0.469	868	115207.37	0.006
921600	7	892857.14	3.119	109	917431.19	0.452
1500000	4	1562500	4.167	67	1492537.31	0.498
3000000	2	3125000	4.167	33	3030303.03	1.01
6250000	1	6250000	0	16	6250000	0

NOTE: Carefully select the SCLK frequencies. Even multiples of the bit rate can decrease the error percentage.

Setting the bit clock equal to the sample clock (UART_CLK.EDBO =1) improves the bit rate granularity and the bit clock matches with the bit rate of the communication partner. Use UART_CLK.EDBO mode only when bit rate accuracy is not acceptable in the UART_CLK.EDBO=0 mode.

The UART_CLK.EDBO=1 mode is not intended to increase the speed of operation beyond the electrical limitations of the UART transfer protocol.

Autobaud Detection

At the chip level, the $\overline{\text{UART_RX}}$ pin is typically routed to an alternate capture input (TIMER_ACI[nn]) of a general-purpose timer. When working in width capture mode, the processor uses this general-purpose timer to detect the bit rate applied to the $\overline{\text{UART_RX}}$ pin automatically by an external device. It often uses the capture capabilities of the timer to supervise the bit rate at run time. If the UART communicates with any device supplied

by a weak clock oscillator that drifts over time, the processor can then readjust its UART bit rate dynamically, as required.

Often, the processor uses autobaud detection for initial bit rate negotiations where it is most likely a completer device waiting for the host to send a predefined autobaud character. This situation is common for UART booting. Do not enable the UART_CTL.EN bit while autobaud detection is in-process, to prevent the UART from starting a receive operation with incorrect bit rate matching. Alternatively, set the UART_CTL.LOOP_EN bit to disconnect the UART from its UART_RX pin.

A software routine can detect the pulse widths of serial stream bit cells. The sample base of the timer is synchronous with the UART operation (all derived from the same SCLK). The UART uses pulse widths to calculate the bit rate divider as follows:

Divisor = TIMER_TMR[n]_WID/($16^{(1–EDBO)}$ × Number of captured UART bits)

To increase the number of timer counts and the resolution of the captured signal, do not measure just the pulse width of a single bit. Instead, enlarge the pulse of interest over more bits. Traditionally, a NULL character (ASCII 0x00) is used in autobaud detection, as shown in the ***Autobaud Detection*** figure.

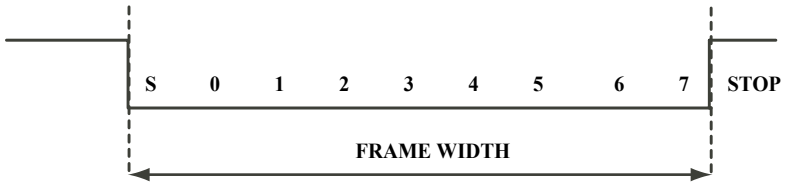

Figure 22-3: Autobaud Detection

Because the example frame encloses 8 data bits and 1 start bit, apply the following formula:

Divisor = TIMER_TMR[n]_WID/($16^{(1–EDBO)}$ × 9)

NOTE: For processor-specific mapping of timer alternate capture inputs to the UARTs of the processor, see "Width Capture (WIDCAP) Mode" in the "*General-Purpose Timer (TIMER)*" chapter.

Real receive signals often have asymmetrical falling and rising edges, and the sampling logic level is not exactly in the middle of the signal voltage range. At higher bit rates, such pulse-width-based autobaud detection does not always return adequate results without extra conditioning of the analog signal. Measure signal periods to work around this issue.

For example, predefine the ASCII character “@” (0x40) as the autobaud detection character and measure the period between two subsequent falling edges. As shown in the ***Autobaud Detection Character 0x40*** figure, measure the period between the falling edge of the start bit and the falling edge after bit 6. Since this period encloses 8 bits, apply the following formula:

Divisor = TIMER_TMR[n]_PER/($16^{(1–EDBO)}$ × 8)

or:

- Divisor = TIMER_TMR[n]_PER>> 7, if UART_CLK.EDBO=0

- Divisor = TIMER_TMR[n]_PER>> 3, if UART_CLK.EDBO=1

The ***Autobaud Detection Character 0x40*** figure shows the ASCII "@" (0x40) detection character.

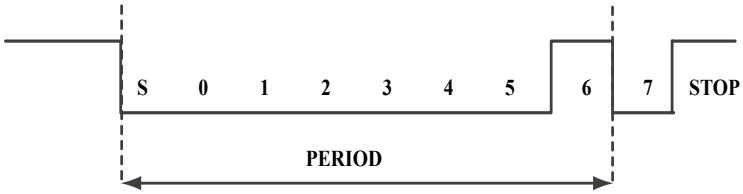

Figure 22-4: Autobaud Detection Character 0x40

UART Debug Features

The UART can automatically calculate and transmit a parity bit. The ***UART Parity*** table summarizes parity behavior assuming 8-bit data words (UART_CTL.WLS=b#11).

Table 22-8: UART Parity

PEN	STP	EPS	Data (hex)	Data (binary, LSB first)	Parity
0	x	x	x	x	None
1	0	0	0x60	0000 0110	1
1	0	0	0x57	1110 1010	0
1	0	1	0x60	0000 0110	0
1	0	1	0x57	1110 1010	1
1	1	0	x	x	1
1	1	1	x	x	0

The two force error bits, UART_CTL.FPE and UART_CTL.FFE, are intended for test purposes. They are useful for debugging software, especially in loopback mode.

The UART can be set to internal loopback mode (UART_CTL.LOOP_EN=1). Loopback mode disconnects the input of the receiver from the receive pin and internally redirects the transmit output to the receiver. The transmit pin remains active and continues to transmit data externally as well. Loopback mode also forces the UART_RTS pin to deassert, disconnects the UART_STAT.CTS bit from the UART_CTS input pin, and connects the internal version of UART_RTS to the UART_STAT.CTS bit.

Additionally, the UART_TX pin can be forced to zero asynchronously using the UART_CTL.SB bit.

UART Operating Modes

The following sections describe the main operating modes of the UART.

- UART Mode
- IrDA SIR Mode

- Multi-Drop Bus Mode

UART Mode

The UART mode follows an asynchronous serial communication protocol with these options:

- 1 start bit
- 5–8 data bits
- Address bit (available in MDB mode only)
- None, even, odd or sticky parity
- One, 1½, or two stop bits (1½ stop bits valid only in 5-bit word length)

The `UART_CTL` register controls the format of received and transmitted character frames. Data is always transmitted and received with the least significant bit (LSB) first.

The ***Bit Stream on a UART TX Pin Transmitting an "S" Character (0x53)*** figure shows a typical physical bit stream measured on a `UART_TX` pin.

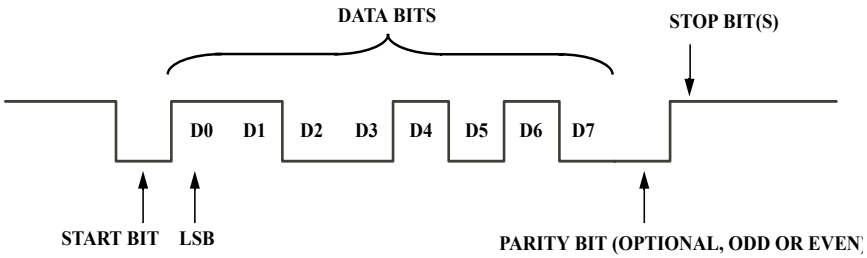

Figure 22-5: Bit Stream on a UART TX Pin Transmitting an "S" Character (0x53)

IrDA SIR Mode

The UART also supports serial data communication by way of infrared signals, according to the recommendations of the Infrared Data Association (IrDA). The physical layer known as IrDA SIR (9.6/115.2 Kbps rate) is based on return-to-zero-inverted (RZI) modulation. The UART does not support pulse position modulation.

Using the 16x data rate clock, RZI modulation is achieved by inverting and modulating the non-return-to-zero (NRZ) code normally transmitted by the UART. On the receive side, the UART uses a 16x clock to determine an IrDA pulse sample window, from which it recovers the RZI modulated NRZ code.

NOTE: The `UART_CLK.EDBO` bit is not valid in IrDA mode. Clear (=0) this bit in this mode.

Multi-Drop Bus Mode

The UART uses a protocol for point-to-point connections as well as in networks where the EIA-485 standard is representative of UART-based bus systems. The EIA-232 standard defines point-to-point connections. In such networks, node addressing is important.

In a multidrop bus (MDB) network, for example, an address bit enhances the UART frame. The address bit is inserted between the data bits and the optional parity bit. To configure the UART for MDB mode, set the mode of operation bits (UART_CTL.MOD [5:4]) to 01.

By convention, the address bit is transmitted low for regular data bytes. When set, it marks special address bytes that require the attention of all nodes on the network.

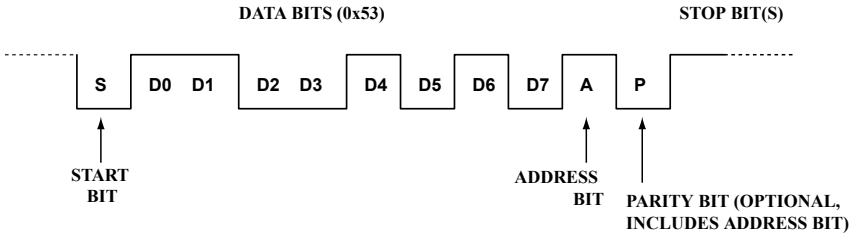

Figure 22-6: UART Frame with Address Bit

All transmit operations are processed through the transmit buffer register (UART_THR), so all DMA data transmissions clear the address bit. If data is written to the transmit address or insert pulse register (UART_TAIP) instead, the same transmit operation is initiated with the only exception that the address bit is sent high.

The UART uses the UART_STAT.ADDR bit of the receiver to signal whether the previously received frame had the address bit set or not. Hardware updates it every time a new frame is received. When the enable address word interrupt bit (UART_IMSK.EAWI) is set, the reception of an address byte triggers a special status interrupt request.

The address sticky bit (UART_STAT.ASTKY) is the sticky version of the UART_STAT.ADDR bit. Hardware sets it whenever the UART_STAT.ADDR bit is set. Software can clear the UART_STAT.ASTKY bit with a W1C operation.

In MDB mode, only address bytes progress to the receive FIFO by default. Data bytes are gated unless the UART_STAT.ASTKY bit is set. The receiver ignores all traffic on the UART bus. This way, the processor can go into low-power mode and interrupt activity does not load the processor every time a frame is transmitted on the UART bus. If, however, an address frame is transmitted, the receiver immediately samples all further traffic. A software routine can analyze the received data, decide whether it was of relevance for the local network node, and W1C the UART_STAT.ASTKY bit if it was not.

Software can overrule of the hardware address frame detection by setting the UART_STAT.ADDR bit and (indirectly) the UART_STAT.ASTKY bit with a W1S operation.

The MDB mode follows an asynchronous serial communication protocol with the following options.

- 1 start bit
- 5–8 data bits
- Address bit
- None, even, odd or sticky parity
- One, 1½, or two stop bits (1½ stop bits are valid only in 5-bit word length)

NOTE: If the address bit and parity bit are both enabled, the parity check and generation includes the address bit in its parity calculation.

UART Data Transfer Modes

The UART can transfer data using both the core and DMA. Receive and transmit paths operate independently except that the bit rate and the frame format are identical for both transfer directions. Transmit and receive channels are both buffered. The UART_THR register buffers the transmit shift register (UART_TSR) and the UART_RBR register buffers the receive shift register (UART_RSR).

UART Mode Transmit Operation (Core)

In core mode, the processor core moves data to and from the UART. A write to the UART_THR register initiates the transmit operation. If no former operation is pending, the UART_THR register passes the data immediately to the UART_TSR register. There, it is shifted out at the bit rate characterized by the UART_CLK register, with start, stop, and parity bits appended as defined by the UART_CTL register.

The UART_THR register and the UART_TSR register can be modeled as a two-stage transmit buffer. The least significant bit (LSB) always transmits first. This bit is bit 0 of the value written to the UART_THR register.

UART Mode LIN Break Command

Some UART-based protocols demand synchronization methods that are not native to standard UART implementations. For example, the Local Interconnect Network (LIN) protocol requires a low-pulse of well-defined transmit length as a prologue to every multi-byte message. Its length must be at least 13 bit-times.

With previous UARTs, there were two options to implement this protocol:

- A null byte is transmitted with a temporarily lowered bit rate, or
- A software counter generates the period, and the asynchronous set break (SB) mechanisms pull the transmit pin low

Since both methods have their disadvantages, the newer UART introduces a new inter-frame gap technique.

The feature is not available in MDB or IrDA operating modes. However, in standard UART mode (bits UART_CTL.MOD [5:4] =00), a write to the UART_TAIP register initiates the transmission of an inter-frame pulse. If the transmit buffer is not empty, the UART first transmits all bytes in the queue. It only initiates with pulse generation after the last stop bit of the last byte has been shifted out.

The value written into the UART_TAIP register defines the nature and the duration of the transmitted pulse. Bits [6:0] control the duration in bit-times and bit [7] controls the value (duration = UART_TAIP[6:0] / UART_CLK[15:0]). If UART_TAIP[7] is set, and an active high pulse is issued, the number of stop bits is extended. If UART_TAIP[7] is cleared, a low pulse is generated. Invert the polarity using the UART_CTL.FCPOL bit. Writing a value of 13 into the UART_TAIP register generates the break command as required by the LIN protocol.

NOTE: If the UART_CTL.TPOLC bit is enabled, an inverted most-significant bit can be transmitted.

NOTE: If another transmission is pending (in the UART_TSR register), the UART_TAIP initiated pulse is queued until after all pending operations have finished and all stop bits are transmitted.

The transmission of break command/inter-frame gap precedes transmission of the number of stop bits as set in the UART_CTL.STB and UART_CTL.STBH bit fields.

The UART receiver can detect break commands through the break indicator (UART_STAT.BI) flag. This flag reports that an entire UART frame has been received in low state. It does not report whether the duration of the received low pulse was exact or at least 13 bit-times as LIN controllers transmit. Typically, the break indicator meets LIN requirements. The processor can use GP timers to determine the pulse width more precisely, if necessary.

Each $\overline{\text{UART_RX}}$ pin is also routed to a GP timer through its alternate capture input (TACI). This functionality is not only useful for bit rate detection (*autobaud*) but also helps to measure the pulse widths precisely on the $\overline{\text{UART_RX}}$ input. Additionally, the GP timers can issue an interrupt request or a fault condition when the received pulse width is shorter than a bit time or longer than the worst-case break condition. The windowed watchdog width mode of the GP timers controls this functionality.

UART Mode Receive Operation (Core)

The receive operation uses the same data format as the transmit configuration except that one valid stop bit is always sufficient. The UART_CTL.STB and UART_CTL.STBH bits have no impact on the receiver.

The UART receiver senses the falling edges of the receive input. When it detects an edge, the receiver starts sampling the input according to settings in the UART_CLK register. The receiver samples the start bit (majority sampling) close to its midpoint. If sampled low, it assumes a valid start condition. Otherwise, it discards the detected falling edge.

After detection of the start bit, the received word is shifted into the UART_RSR register.

After the corresponding stop bit is received, the content of the UART_RSR register is transferred to the 8-deep receive FIFO and is accessible by reading the UART_RBR register.

The receive FIFOs and the UART_RBR register act as a 9-stage receive buffer. If the stop bit of the ninth word is received before software reads the UART_RBR register, an overrun error is reported. Overruns protect data in the UART_RBR register and the receive FIFO from being overwritten by further data until the software clears the UART_STAT.OE bit. However, the data in the UART_RSR register is immediately destroyed as soon as the overrun occurs.

The sampling clock is 16 times faster than the bit clock. The receiver oversamples every bit 16 times and makes a majority-decision based on the middle three samples. This functionality improves immunity against noise and hazards on the line. The receiver disregards spurious pulses of less than two times the sampling clock period.

Normally, the receiver samples every incoming bit at exactly the 7th, 8th, and 9th sample clock. If, however, the UART_CLK.EDBO bit is set to 1, the receiver samples bits approximately at 7/16th, 8/16th, and 9/16th of their period. This configuration achieves better bit rate granularity and accuracy as required at high operation speeds. Hardware design must ensure that the incoming signal is stable between 6/16th and 10/16th of the nominal bit period.

Reception starts when the UART receiver detects a falling edge on the UART_RX input pin. The receiver attempts to see a start bit. The data is shifted into the UART_RSR register. After the ninth sample of the first, the receiver processes the stop bit and copies the received data to the 8-stage receive FIFO. The UART_RSR recovers for further data reception.

The receiver samples data bits close to their midpoint. Because the receiver clock is typically asynchronous to the data rate of the transmitter, the sampling point can drift relative to the center of the data bits. The sampling point is synchronized again with each start bit, so the error accumulates only over the length of a single word. The polarity of received data is selectable, using the UART_CTL.RPOLC bit.

NOTE: The receiver checks for only a single stop bit. After the third sample of the first stop bit has been received (at time 9/16th of the stop bit duration), the receiver immediately acts (status update). It then prepares for new falling edge detection (start detection).

IrDA Transmit Operation

To generate the IrDA pulse transmitted by the UART, the normal NRZ output of the transmitter is first inverted if the UART_CTL.TPOLC bit is configured for active-low operation. In this configuration, a zero is transmitted as a high pulse of 16 UART clock periods and a one is transmitted as a low pulse for 16 UART clock periods. Then, six UART clock periods delay the leading edge of the pulse. Similarly, eight UART clock periods truncate the trailing edge of the pulse. For a 16-cycle UART clock period, this operation results in the final representation of the original zero as a high pulse of only 3/16 clock periods. The ***IrDA Transmit Pulse*** figure shows how the pulse is centered around the middle of the bit time. The final IrDA pulse is fed to the off-chip infrared driver.

This modulation approach ensures a pulse width output from the UART of three cycles high out of every 16 UART clock cycles. As shown in the ***IrDA Transmit Pulse*** figure, the error terms associated with the bit rate generator are small and well within the tolerance of most infrared transceiver specifications.

NOTE: In IrDA mode, writes to the UART_TAIP register are equivalent to writes to the UART_THR register.

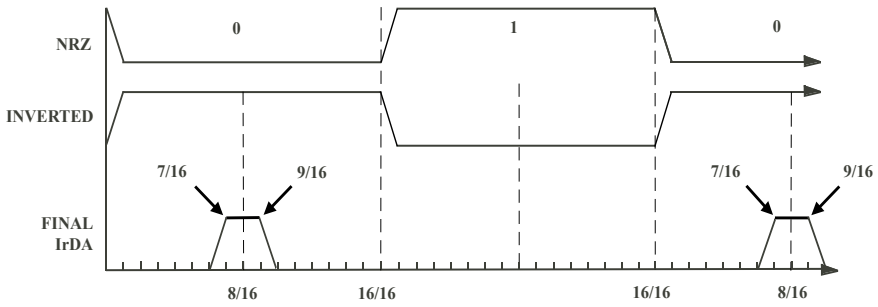

Figure 22-7: IrDA Transmit Pulse

IrDA Receive Operation

The IrDA receiver function is more complex than the transmit function. The receiver must discriminate the IrDA pulse and reject noise. The receiver looks for the IrDA pulse in a narrow window centered around the middle of the expected pulse.

Glitch filtering is accomplished by counting 16 system clocks from the time the receiver detects an initial pulse. If the pulse is absent when the counter expires, the receiver interprets it as a glitch. Otherwise, the receiver interprets it as a zero. This assessment is acceptable because glitches originating from on-chip capacitive cross-coupling typically do not last for more than a fraction of the system clock (SCLK) period. Appropriate shielding avoids sources outside of the chip and not part of the transmitter. The only other source of a glitch is the transmitter itself. The processor relies on the transmitter to perform within specification. If the transmitter violates the specification, unpredictable results can occur. The 4-bit counter adds an extra level of protection at a minimal cost.

NOTE: Because SCLK can change across systems, the longest glitch tolerated is inversely proportional to the SCLK frequency.

A counter that is clocked at the 16x bit-time sample clock determines the receive sampling window. The sampling window is resynchronized with each start bit by centering the sampling window around the start bit.

The polarity of receive data is selectable, using the `UART_CTL.RPOLC` bit. The ***IrDA Receiver Pulse Detection*** figure provides examples of each polarity type.

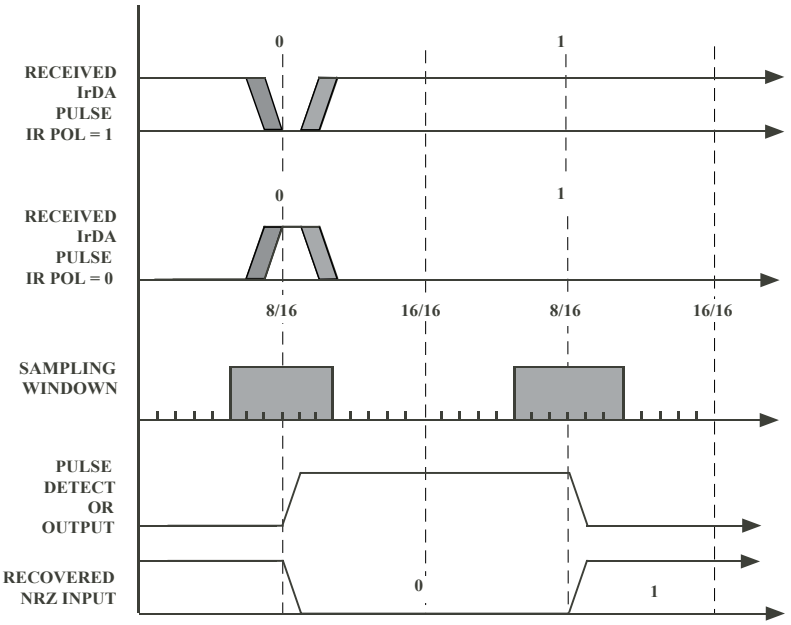

Figure 22-8: IrDA Receiver Pulse Detection

MDB Transmit Operation

In MDB mode, receive and transmit paths operate independently from each other, except for sharing bit rate and frame formats for both transfer directions.

Transmit operation is initiated by writing the `UART_THR` or `UART_TAIP` registers. A write to the `UART_THR` register transmits the written word with the appending address bit set low. A write to the `UART_TAIP` register transmits the written word with the appended address bit set high. The data is moved into the `UART_TSR` register, where it is shifted out at the bit rate programmed by the `UART_CLK` register, with start, stop, address, and parity bits appended, as required.

If DMA is enabled, the DMA engine always writes the data into the UART_THR register, and the written word is transmitted with the appending address bit set low.

The polarity of transmit data is selectable, using the UART_CTL.TPOLC bit.

MDB Receive Operation

Receive operations use the same data format as the transmit configuration, except that the number of stop bits is always assumed to be 1. After detection of the start bit, the received word is shifted into the UART_RSR register at the programmed bit.

Normally, the receiver samples every incoming bit at exactly the 7th, 8th, and 9th sample clock. If, however, the UART_CLK.EDBO bit is set, the receiver samples the bits approximately at 7/16th, 8/16th, and 9/16th of their period. This configuration achieves better bit rate granularity and accuracy needed at high operation speeds. Hardware design must ensure that the incoming signal is stable between 6/16th and 10/16th of the nominal bit period.

After the appropriate number of bits (including address, parity, and stop bits) is received, the UART_RSR register is transferred to the receive FIFO and accessible through the UART_RBR register.

The polarity of receive data is selectable, using the UART_CTL.RPOLC bit.

DMA Mode

In DMA mode, separate receive and transmit DMA channels move data between the UART and memory. The software does not have to move data; it just must set up the appropriate transfers either through the descriptor mechanism or through autobuffer mode.

DMA channels provide a 4-deep FIFO, resulting in total buffer capabilities of 6 words at the transmit side and 9 words at the receive side. In DMA mode, the bus activity and arbitration mechanism determine the latency. The processor loading and interrupt priorities do not determine the latency.

To enable UART DMA, first set up the system DMA control registers. Then, enable the UART_IMSK.ERBFI or UART_IMSK.ETBEI interrupts. This sequence is necessary because these interrupt request lines double as DMA request lines. With DMA enabled, once these requests are received, the DMA control unit generates a direct memory access. If DMA is not enabled, the UART interrupt is passed on to the system interrupt handling unit. The status interrupt for the UART goes directly to the system event controller (SEC), bypassing the DMA unit completely.

For transmit DMA, programs must set the DMA_CFG.SYNC bit. With this bit set, interrupt generation is delayed until the entire DMA FIFO is drained to the UART module. The UART transmit DMA interrupt service routine can disable the DMA or to clear the UART_IMSK.ETBEI control bit only when the DMA_CFG.SYNC bit is set. Otherwise, up to four data bytes can be lost.

When the UART_IMSK.ETBEI bit is set, an initial transmit DMA request is issued immediately. The program then clears the UART_IMSK.ETBEI bit through the DMA service routine.

In DMA transmit mode, the UART_IMSK.ETBEI bit enables the peripheral request to the DMA FIFO. The DMA_CFG.EN bit enables the strobe on the memory side. If the DMA count is less than the DMA FIFO depth,

which is 4, then the DMA interrupt can be requested before the UART_IMSK.ETBEI bit is set. If this behavior is unwanted, set the DMA_CFG.SYNC bit.

Regardless of the DMA_CFG.SYNC setting, the DMA stream has not left the UART transmitter completely at the time the interrupt request is generated. Transmission can abort in the middle of the stream, causing data loss, when the UART clock was disabled without extra synchronization with the UART_STAT.TEMT bit.

The UART provides functionality to avoid resource-consuming polling of the UART_STAT.TEMT bit. The UART_IMSK_SET.EDTPTI bit enables the UART_STAT.TEMT bit to trigger a DMA interrupt. To delay the DMA completion interrupt until the last data word of a STOP DMA has left the UART, keep the DMA_CFG.INT bit cleared and set the UART_IMSK_SET.EDTPTI bit instead. Then, the normal DMA completion interrupt is suppressed. Later, the UART_STAT.TEMT event triggers a DMA interrupt after the last word of the DMA has left the UART transmit buffers. If DMA_CFG.INT and UART_IMSK.EDTPTI are set, when finishing STOP mode, the DMA requests two interrupts.

The DMA of the UART module supports 8-bit and 16-bit operation, but not 32-bit operation. It does not support sign-extension.

Mixing DMA and Core Modes

Switching from DMA mode to core operation dynamically requires some consideration, especially for transmit operations. By default, the interrupt timing of the DMA is synchronized with the memory side of the DMA FIFOs. Normally, the transmit DMA completion interrupt is generated after the last byte is copied from the memory into the DMA FIFO. The transmit DMA interrupt service routine is not yet permitted to disable the DMA_CFG.EN bit. The interrupt is requested when the DMA_STAT.IRQDONE bit is set. The DMA_STAT.RUN bit, however, remains set until the data has completely left the transmit DMA FIFO.

When planning to switch from a DMA to core mode, set the DMA_CFG.SYNC bit in the word of the last descriptor or work unit before handing over control. Then, after the interrupt request occurs, software can write new data into the UART_THR register as soon as the UART_STAT.THRE bit permits. If the DMA_CFG.SYNC bit cannot be set, software can poll the DMA_STAT.RUN bit instead. Alternatively, using the UART_IMSK.EDTPTI bit can avoid expensive status bit polling.

When switching from core to DMA operation, ensure that the first DMA request is issued properly. If the DMA is enabled while the UART is still transmitting, no precaution is required. If, however, the DMA is enabled after the UART_STAT.TEMT bit is high, pulse the UART_IMSK.ETBEI bit to initiate DMA transmission.

Setting Up Hardware Flow Control

The following steps show how to set up UART hardware flow control:

1. Configure automatic or manual hardware flow control for the receiver through the UART_CTL.ARTS bit, or the transmitter through the UART_CTL.ACTS bit.
2. Configure $\overline{\text{UART_CTS}}$ and $\overline{\text{UART_RTS}}$ polarity through the UART_CTL.FCPOL bit.

On reset, when the UART is not yet enabled and the port multiplexing has not been programmed, the $\overline{\text{UART_RTS}}$ pin is not driven. Some applications require a resistor to pull the $\overline{\text{UART_RTS}}$ signal to either state during reset.

UART Event Control

Status flags in the UART_STAT register are available to signal data reception, parity, and error conditions, if necessary.

DMA and Interrupt Multiplexing

See the *Direct Memory Access (DMA)* chapter for information on DMA multiplexing. Several interrupts and DMA channels in the UART can be multiplexed.

NOTE: To operate in interrupt mode without using DMA channels, set the UART_IMSK.ELSI bit. This configuration redirects receive and transmit requests to the status interrupt output. The status interrupt goes directly to the SEC without going through the DMA controller.

Interrupt Masks

Each UART features a set of interrupt mask registers: UART_IMSK, UART_IMSK_SET, and UART_IMSK_CLR. The UART_IMSK register supports read/write operations. Writing ones to the UART_IMSK_SET register enables interrupts, writing ones to the UART_IMSK_CLR register disables them. Reads from either register return the enabled bits. This way, different interrupt service routines can control transmit, receive, and status interrupt requests independently and easily.

The UART module uses the UART_IMSK registers to enable requests for system handling of empty or full states of data registers. Unless polling is used as a means of action, the UART_IMSK.ERBFI and UART_IMSK.ETBEI bits in this register are normally set.

Each UART module has three interrupt outputs. It uses one for transmission, one for reception, and one for reporting status events. The UART module routes transmit and receive requests through the DMA controller. The status request goes directly to the system event controller (SEC).

If the associated DMA channel is enabled, the request functions as a DMA request. If the DMA channel is disabled, it simply forwards the request to the SEC. A DMA channel must be associated with the UART module to enable transmit and receive interrupts. Otherwise, transmit and receive requests cannot be forwarded.

NOTE: To operate in interrupt mode without using DMA channels, set the UART_IMSK.ELSI bit. This configuration redirects receive and transmit requests to the status interrupt request output. The status interrupt goes directly to the SEC without going through the DMA controller.

Interrupt Servicing

Interrupt service routines (ISRs) perform UART writes and reads. Separate interrupt lines are provided for transmit, receive, and status. The UART_IMSK register group enables the independent interrupts individually. To enable UART transmit interrupts, set the UART_CTL.EN bit.

The ISRs evaluate the status bits in the UART_STAT register to determine the signaling interrupt source. The system event controller for the processor assigns and unmasks interrupts. The ISRs must clear the interrupt latches explicitly. To reduce interrupt frequency on the receive side in core mode, use the UART_IMSK.ERFCI status

interrupt as an alternative to the regular UART_IMSK.ERBFI receive interrupt. Hardware must ensure that at least two (if UART_CTL.RFIT=0) or four (if UART_CTL.RFIT=1) words are available in the receive buffer by the time the interrupt is requested.

Transmit Interrupts

The UART module uses the UART_IMSK_SET.ETBEI bit to enable transmit interrupt requests.

The UART_THR and UART_TAIP registers are the same physical register, and both affect the signaling of the UART_STAT.TEMT, UART_STAT.TFI, and UART_STAT.THRE bits similarly.

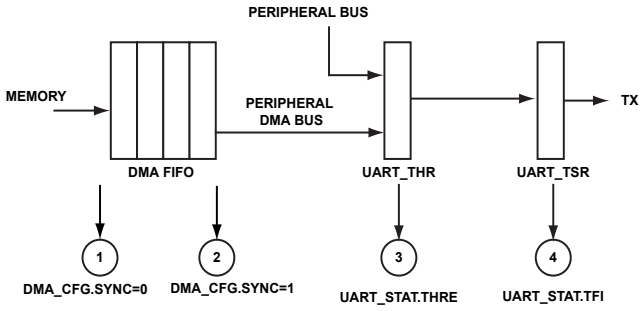

Figure 22-9: Transmit Interrupts

The UART module asserts the transmit request along with the UART_STAT.THRE bit, indicating that the transmit buffer is ready for new data. The UART_STAT.THRE bit resets to 1. When the UART_IMSK_SET.ETBEI bit is set, the UART module immediately issues an interrupt or DMA request. This way, no special handling of the first character is required when transmission of a string is initiated. Set the UART_IMSK_SET.ETBEI bit and let the interrupt service routine load the first character from memory and write it to the UART_THR register in the normal manner. ISRs can clear the UART_IMSK.ETBEI bit through the UART_IMSK_CLR register when the string transmission has completed.

Hardware clears the UART_STAT.THRE bit when new data is written to the UART_THR register. These write operations also clear the transmit interrupt request. However, they also initiate further transmission. If continued transmission is undesirable, the UART module can alternatively clear the transmit request through the UART_IMSK_CLR.ETBEI bit register. Transfers of data from the UART_THR register to the UART_TSR register reset this status flag in the UART_STAT register.

ISRs can interrogate the UART_STAT.TEMT bit to discover any ongoing transmission. The sticky counterpart of the UART_STAT.TEMT bit, UART_STAT.TFI, indicates when the transmit buffer has drained and can trigger a status interrupt. When data is pending in either one of these registers, the UART_STAT.TEMT flag is low. As soon as all data has left the UART_TSR register, the UART_STAT.TEMT bit goes high again and indicates that all pending transmit operations (including stop bits) have finished. Then, it is safe to disable the UART_CTL.EN bit or to three-state off-chip line drivers. Then, the UART module can generate an interrupt either through the status interrupt channel when the UART_IMSK.ETFI bit is set, or through the DMA controller when enabled by the UART_IMSK.EDTPTI bit.

When enabled by the UART_IMSK.ETBEI bit, the UART_STAT.THRE flag requests data along the peripheral command lines to the DMA controller (referred to as TXREQ). This signal is routed through the DMA controller. If the associated DMA channel is enabled, the TXREQ signal functions as a DMA request, otherwise the DMA controller simply forwards it to the SEC. Alternatively the UART_IMSK.ETXS bit can redirect the transmit interrupts to the UART status interrupt.

With interrupts disabled, the UART module can poll the status flags to determine when data is ready to move. Because polling is processor intensive; it is not typically used in real-time signal processing environments. Since read operations from UART_STAT registers have no side effects, different software threads can interrogate these registers without mutual impacts.

Polling the SEC_SSTAT[n] register without enabling the interrupts by the SEC_CCTL[n] register is an alternate method of operation to consider. Software can write up to two words into the UART_THR register before enabling the UART clock. As soon as the UART_CTL.EN bit is set, the UART module sends those two words.

Receive Interrupts

The UART module uses the UART_IMSK_SET.ERBFI bit to enable receive interrupt requests. If set, the UART_STAT.DR flag requests an interrupt on the dedicated RXREQ output, indicating that new data is available in the UART_RBR register. This signal is routed through the DMA controller. If the associated DMA channel is enabled, the RXREQ signal functions as a DMA request; otherwise the DMA controller simply forwards it to the SEC. Alternatively, if no DMA channel is assigned to the UART, the UART_IMSK.ERXS bit can redirect the receive interrupts to the UART status interrupt. When software reads the UART_RBR register, hardware clears the UART_STAT.DR bit again, which, in turn, clears the receive interrupt request.

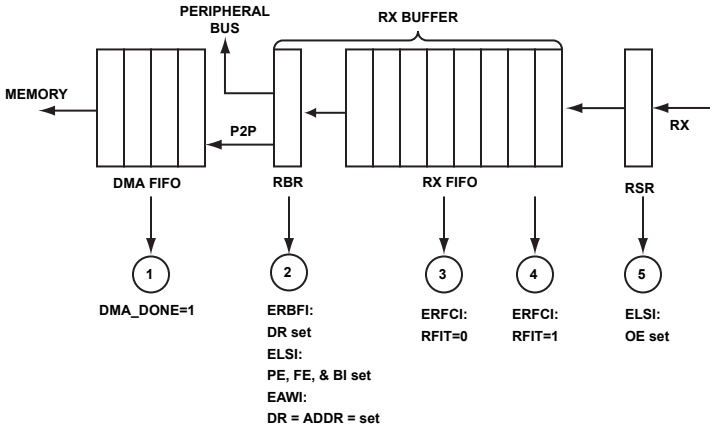

Figure 22-10: Receive Interrupts

Hardware updates the following:

- UART_STAT.DR bits
- UART_STAT.ADDR bits
- UART_STAT.ASTKY bits
- UART_STAT.PE bits

- UART_STAT.FE bits
- UART_STAT.BI bits
- UART_RBR register

The UART_STAT.OE bit is updated as soon as an overflow condition occurs (for example when a stop bit for a frame is received and the receive FIFO is full). When software does not read the UART_RBR register in time, the received data is protected from being overwritten by new data until software clears the UART_STAT.OE bit. Only the content of the UART_RSR register can be overwritten in the overrun case.

The UART module uses the UART_STAT.RFCS bit to monitor the state of the 8-deep receive FIFO. It uses the UART_CTL.RFIT bit to control the behavior of the buffer. If UART_CTL.RFIT is zero, the UART_STAT.RFCS bit is set when the receive buffer holds four or more words. If UART_CTL.RFIT is set, the UART_STAT.RFCS bit is set when the receive buffer holds seven or more words. Hardware clears the UART_STAT.RFCS bit when a core or DMA reads the UART_RBR register and when the buffer is flushed below the level of four (UART_CTL.RFIT=0) or seven (UART_CTL.RFIT=1). If the associated interrupt bit UART_IMSK.ERFCI is enabled, a status interrupt request is reported when the UART_STAT.RFCS bit is set.

If errors are detected during reception, an interrupt can be requested from the status interrupt output. This status interrupt request goes directly to the SEC. The bit enables status interrupt requests.

The controller detects the following error conditions, shown with their associated bits in the UART_STAT register.

- Overrun error (UART_STAT.OE bit)
- Parity error (UART_STAT.PE bit)
- Framing error or invalid stop bit (UART_STAT.FE bit)
- Break indicator (UART_STAT.BI bit)

Status Interrupts

The UART module uses status interrupt channels for the following purposes:

- Line status interrupt requests
- Flow control interrupt requests
- Receive FIFO threshold interrupt requests
- Transmission finished interrupt request

The UART module uses the UART_IMSK.ELSI bit to enable the line status interrupts. If set, the status interrupt request is asserted with one of the UART_STAT.BI, UART_STAT.FE, UART_STAT.PE, or UART_STAT.OE receive errors bits. A W1C operation to the UART_STAT register clears the error bits. Once all error conditions are cleared, the interrupt request deasserts.

The UART module uses the UART_IMSK_SET.ERFCI bit to enable the receive FIFO count interrupt. If set, a status interrupt request is generated when the UART_STAT.RFCS is active. The UART_STAT.RFCS bit

indicates a receive buffer threshold level. If the UART_CTL.RFIT bit is cleared, software can safely read two words out of the UART_RBR register by the time the UART_STAT.RFCS interrupt occurs.

If the UART_CTL.RFIT bit is set, software can safely read four words. The interrupt request and the UART_STAT.RFCS bit are cleared when the UART_RBR is read enough of times, so that the receive buffer drains below the threshold of two (UART_CTL.RFIT=0) or four (UART_CTL.RFIT=1). Because in DMA mode a status service routine may not be permitted to read UART_RBR, this interrupt is only recommended in core mode. In DMA mode, use this functionality for error recovery only.

The UART module uses the UART_IMSK_SET.EDSSI bit to enable the flow control interrupts. If active, a status interrupt is generated when the sticky UART_STAT.SCTS bit register is set, indicating that the UART_CTS input of the transmitter been reasserted. A W1C operation to the UART_STAT.SCTS bit clears the interrupt request.

The UART module uses the UART_IMSK_SET.ETFI bit to enable the transmission finished interrupt. If active, a status interrupt request is asserted when the UART_STAT.TFI bit is set. The UART_STAT.TFI is the sticky version of the UART_STAT.TEMT bit, indicating that a byte that started transmission has finished. A W1C operation to the UART_STAT.TFI bit clears the interrupt request.

Multi-Drop Bus Events

Several status bits and interrupt features in the UART_STAT and UART_IMSK registers facilitate efficient data handling in multi-drop bus mode. These features include the address (UART_STAT.ADDR) bit, the address sticky (UART_STAT.ASTKY) bit and the enable address word interrupt (UART_IMSK.EAWI). One of the key features of the multi-drop bus protocol is its address bit. The address bit signifies to the completer that the requester is transmitting an address word (all read it) or a data word (only the addressed target reads its). The UART hardware provides an efficient method of handling the situation described with the use of UART_STAT.ASTKY bit.

NOTE: The UART module uses the UART_STAT.ASTKY bit in multi-drop bus mode to indicate when an address operation for a peripheral is occurring. The UART_STAT.ASTKY bit is a sticky version of the UART_STAT.ADDR bit. Hardware sets the bit whenever the UART_STAT.ADDR bit is set. Only software clears it with a W1C operation. With the UART_STAT.ASTKY bit set, words are received regardless of the mode bit or address bit setting. With the UART_STAT.ASTKY bit cleared, only address words (mode bit =1) are received and words with mode bit =0 are ignored in MDB mode. This bit does not affect reception in non-MDB modes. (Words with mode bit =0 are not moved from the UART_RSR register to the receive FIFO.)

UART Programming Model

The following sections provide basic procedures for configuring various UART operations.

Detecting Autobaud

To detect Autobaud:

1. Ensure that the timer is disabled.

2. Configure the following bits: UART_CTL.MOD =00, UART_CTL.LOOP_EN =1, UART_CTL.WLS =11 (8-bit data), and UART_CTL.EN =1
3. Configure the following bits: TIMER_TMR[n]_CFG.TMODE =1101, TIMER_TMR[n]_CFG.OUTDIS =1, TIMER_TMR[n]_CFG.IRQMODE =10 and enable the timer.
4. Send test data through the host device and wait for the timer interrupt and disable the timer.

   The bit rate can be derived from the timer period register value according to the formula provided in the Autobaud Detection section.

Using Common Initialization Steps

When using the core or the DMA to execute transfers, the following steps are common to all UART modes.

1. All UART signals are multiplexed and compete with other functions at pin level. First, program the port registers according to the guidelines in the PORT chapter.
2. Program the UART_CLK register. Refer to Bit Rate Generation topic.
3. Program the UART_CTL register and enable the UART clock.

Using Core Transfers

Write data into the UART_THR register, when the UART_STAT.THRE bit is set, to initiate a core transmit operation. If the UART_STAT.DR bit is set, received data can be read from the UART_RBR register.

Using DMA Transfers

1. Make sure that the UART_IMSK.ETBEI or the UART_IMSK.ERBFI bits are cleared before configuring the DMA.
2. Configure the dedicated DMA channel.
3. Set the UART_IMSK.ETBEI or UART_IMSK.ERBFI bits to start the transfer.

Using Interrupts

Each UART features three interrupt signal outputs.

1. Enable individual interrupts in the system event controller (SEC)
2. Register IRQ handlers.
3. Use the interrupts mask registers to enable specific IRQ events.

Setting Up Hardware Flow Control

1. Configure automatic or manual hardware flow control for the receiver through the UART_CTL.ARTS bit, or the transmitter through the UART_CTL.ACTS bit.
2. Configure $\overline{\text{UART_CTS}}$ and $\overline{\text{UART_RTS}}$ polarity through the UART_CTL.FCPOL bit.

ADSP-2184x UART Register Descriptions

UART (UART) contains the following registers.

Table 22-9: ADSP-2184x UART Register List

Name	Description
UART_CLK	Clock Rate Register
UART_CTL	Control Register
UART_IMSK	Interrupt Mask Register
UART_IMSK_CLR	Interrupt Mask Clear Register
UART_IMSK_SET	Interrupt Mask Set Register
UART_RBR	Receive Buffer Register
UART_RSR	Receive Shift Register
UART_RXCNT	Receive Counter Register
UART_SCR	Scratch Register
UART_STAT	Status Register
UART_TAIP	Transmit Address/Insert Pulse Register
UART_THR	Transmit Hold Register
UART_TSR	Transmit Shift Register
UART_TXCNT	Transmit Counter Register

Clock Rate Register

The UART_CLK register divides the system clock (SCLK) down to the bit clock.

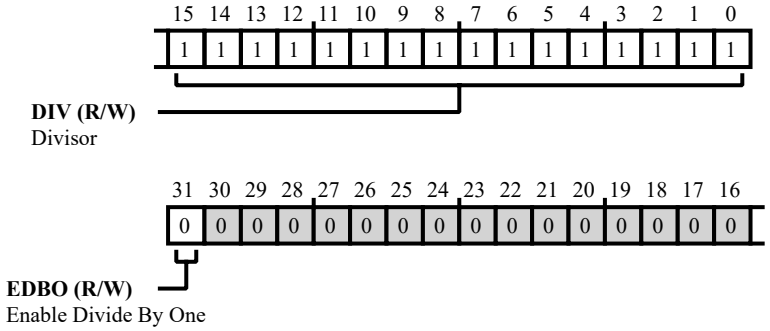

Figure 22-11: UART_CLK Register Diagram

Table 22-10: UART_CLK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	EDBO	Enable Divide By One. The UART_CLK.EDBO bit enables the bypassing of the divide-by-16 prescaler in bit clock generation. This functionality improves bit rate granularity, especially at high bit rates. Do not set this bit in IrDA mode. Note: Properly select the SCLK frequencies. Even multiples of bit rate decrease the error percentage. Setting the bit clock equal to the sample clock (UART_CLK.EDBO =1) improves the bit rate granularity and the bit clock matches with the bit rate of the communication partner. The disadvantage is that the power dissipation is higher and sample points are not always accurate. Therefore, use UART_CLK.EDBO=1 mode only when bit rate accuracy is not acceptable in the UART_CLK.EDBO=0 mode. The UART_CLK.EDBO=1 mode is not intended to increase the speed of operation beyond the electrical limitations of the UART transfer protocol.	
		0	Bit clock prescaler = 16
		1	Bit clock prescaler = 1
15:0 (R/W)	DIV	Divisor. The UART_CLK.DIV provides the divisor for the UART's clock bit rate calculation. The bit rate is defined by: Bit Rate = SCLK / ($16^{(1-EDBo)}$ x UART_CLK.DIV)	

Control Register

The UART_CTL register provides enable and disable control for UART and IrDA mode of operation. It also provides UART line control, permitting selection of the format of received and transmitted character frames. Modem feature control also is available from this register, including partial modem functionality to allow for hardware flow control and loopback mode.

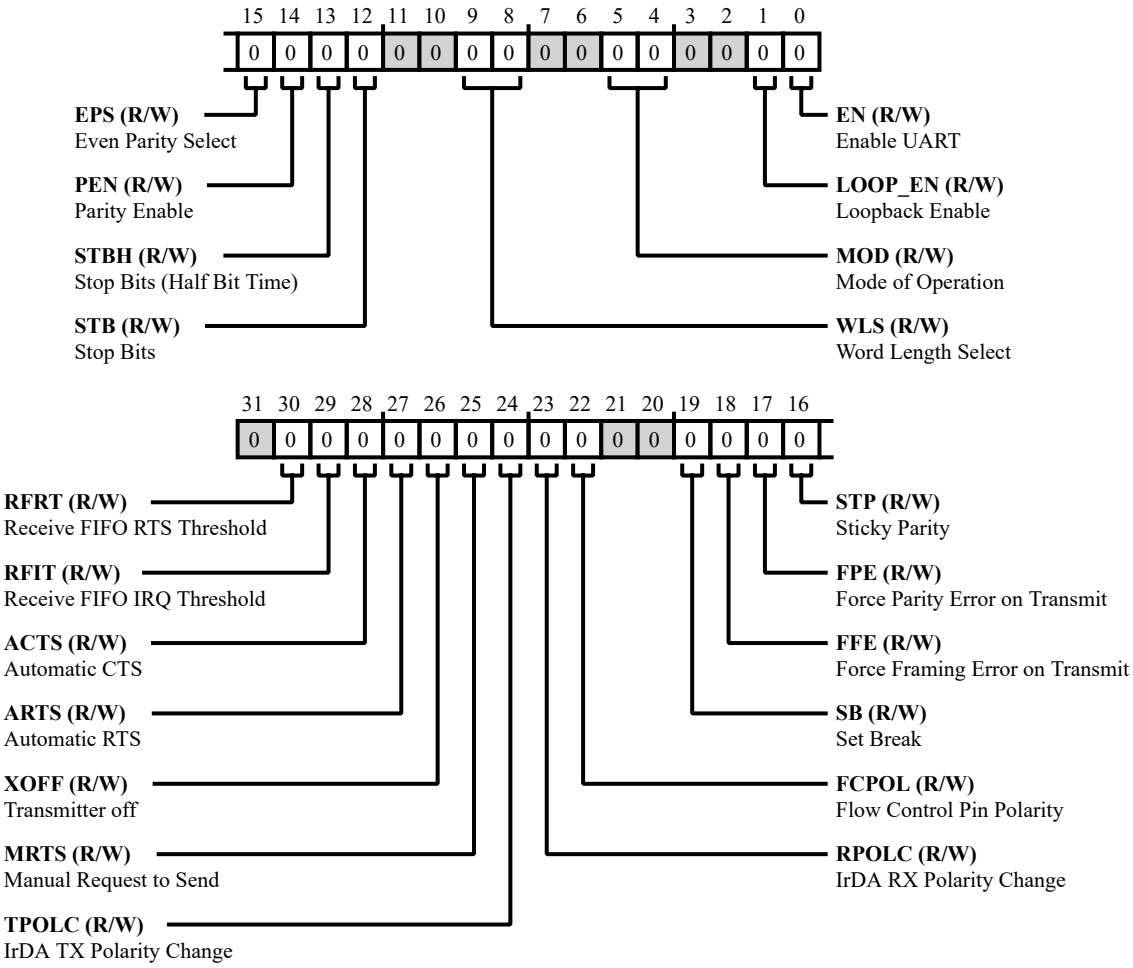

Figure 22-12: UART_CTL Register Diagram

Table 22-11: UART_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
30 (R/W)	RFRT	Receive FIFO RTS Threshold. The UART_CTL.RFRT bit controls UART_RTS pin assertion and deassertion timing. This bit is ignored if UART_CTL.ARTS is cleared. If set, the UART_RTS pin is deasserted when the receive buffer already holds seven words and an eighth start bit is detected. It is reasserted when the FIFO contains seven words or less. If cleared, the UART_RTS pin is deasserted when the RX buffer already holds four words and a fifth start bit is detected. The UART_RTS pin is reasserted when the RX buffer contains no more than 4 words.	
		0	Deassert RTS if RX FIFO word count > 4; assert if <= 4
		1	Deassert RTS if RX FIFO word count > 7; assert if <= 7
29 (R/W)	RFIT	Receive FIFO IRQ Threshold. The UART_CTL.RFIT bit controls the timing of the UART_STAT.RFCS bit. If UART_CTL.RFIT is cleared, the receive threshold is two. If UART_CTL.RFIT is set, the threshold is four words in the receive buffer.	
		0	Set RFCS=1 if RX FIFO count >= 4
		1	Set RFCS=1 if RX FIFO count >= 7
28 (R/W)	ACTS	Automatic CTS. The UART_CTL.ACTS bit must be set to enable the UART_CTS input pin for UART_TX handshaking. If enabled, the UART_STAT.CTS bit holds the value (if UART_CTL.FCPOL is set) or complement value (if UART_CTL.FCPOL is cleared) of the UART_CTS input pin. The UART_STAT.CTS bit can be used to determine whether the external device is ready to receive data (if UART_STAT.CTS is set) or whether it is busy (if UART_STAT.CTS is cleared). If UART_CTL.ACTS is cleared, the UART_TX handshaking protocol is disabled, and the UART_TX line transmits data whenever there is data to send, regardless of the value of UART_CTS. Software can pause ongoing transmission by setting the UART_CTL.XOFF bit.	
		0	Disable TX handshaking protocol
		1	Enable TX handshaking protocol
27 (R/W)	ARTS	Automatic RTS. The UART_CTL.ARTS bit must be set to enable the UART_RTS input pin for UART_TX handshaking. If set, the hardware guarantees a minimal UART_RTS pin deassertion pulse width of at least the number of data bits defined by the UART_CTL.WLS bit field. If cleared, the UART_RTS pin is not generated automatically by hardware. The UART_RTS pin can still be manually controlled by the UART_CTL.MRTS bit, and software is responsible for UART_RTS pulse width control (if needed).	
		0	Disable RX handshaking protocol.
		1	Enable RX handshaking protocol.

Table 22-11: UART_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
26 (R/W)	XOFF	Transmitter off. The UART_CTL.XOFF bit (if set) turns off transmission (XOFF) by preventing the content of THR from being continued to TSR. When set, this bit turns on transmission (XON). The state of the UART_CTL.XOFF bit is ignored if the UART_CTL.ACTS bit is set.	
		0	Transmission ON, if ACTS=0
		1	Transmission OFF, if ACTS=0
25 (R/W)	MRTS	Manual Request to Send. The UART_CTL.MRTS bit controls the state of the UART_RTS output pin when the UART_CTL.ARTS bit is cleared. When UART_CTL.MRTS is cleared, the UART deasserts the UART_RTS pin, signaling to the external device that the UART is not ready to receive. When UART_CTL.MRTS is set, the UART asserts the UART_RTS pin, signaling to the external device that the UART is ready to receive.	
		0	Deassert RTS pin when ARTS=0
		1	Assert RTS pin when ARTS=0
24 (R/W)	TPOLC	IrDA TX Polarity Change. The UART_CTL.TPOLC bit selects the active low or high polarity for IrDA communications. This bit is effective only in IrDA mode. If set, in IrDA mode, the UART_TX pin idles high. In UART or MDB mode, it is inverted-NRZ. If cleared, in IrDA mode, the UART_TX pin idles low. In UART or MDB mode, it is NRZ.	
		0	Active-low TX polarity setting
		1	Active-high TX polarity setting
23 (R/W)	RPOLC	IrDA RX Polarity Change. The UART_CTL.RPOLC bit selects the active low or high polarity for IrDA communications. This bit is effective only in IrDA mode. If set, in IrDA mode, the UART_RX pin idles high. In UART or MDB mode, it is inverted-NRZ. If cleared, in IrDA mode, the UART_RX pin idles low. In UART or MDB mode, it is NRZ.	
		0	Active-low RX polarity setting
		1	Active-high RX polarity setting

Table 22-11: UART_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
22 (R/W)	FCPOL	Flow Control Pin Polarity. The UART_CTL.FCPOL bit selects the polarities of the UART_CTS and UART_RTS pins. When the UART_CTL.FCPOL bit is cleared, the UART_RTS and UART_CTS pins are active low, and the UART is halted when the UART_RTS and UART_CTS pin state is high. When UART_CTL.FCPOL bit is set, the UART_RTS and UART_CTS pins are active high, and the UART is halted when the UART_RTS and UART_CTS pin state is low.	
		0	Active low CTS/RTS
		1	Active high CTS/RTS
19 (R/W)	SB	Set Break. If set, the UART_CTL.SB bit forces the UART_TX pin to low asynchronously, regardless of whether or not data is currently transmitted. This bit functions even when the UART clock is disabled. Because the UART_TX pin normally drives high, it can be used as a flag output pin, if the UART is not used. (For example, if UART_CTL.TPOLC is cleared, drive UART_TX pin low; or if UART_CTL.TPOLC is set, drive UART_TX pin high.)	
		0	No force
		1	Force TX pin to 0
18 (R/W)	FFE	Force Framing Error on Transmit. The UART_CTL.FFE bit is intended for test purposes. This bit is useful for debugging software, especially in loopback mode.	
		0	Normal operation
		1	Force error
17 (R/W)	FPE	Force Parity Error on Transmit. The UART_CTL.FPE bit is intended for test purposes. This bit is useful for debugging software, especially in loopback mode.	
		0	Normal operation
		1	Force parity error

Table 22-11: UART_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W)	STP	Sticky Parity. The UART_CTL.STP bit controls whether the parity is generated by hardware based on the data bits or whether it is set to a fixed value. If this bit is cleared, the hardware calculates the parity bit value based on the data bits. Then, the EPS bit determines whether odd or even parity mode is chosen. If this bit is set, odd parity is used. That means that the total count of logical-1 data bits including the parity bit must be an odd value. Even parity is chosen by UART_CTL.STP cleared and UART_CTL.EPS set. Then, the count of logical-1 bits must be a even value. If the UART_CTL.STP bit is set, hardware parity calculation is disabled. In this case, the sent and received parity equals the inverted UART_CTL.EPS bit.	
		0	No forced parity
		1	Force (Stick) parity to defined value (if PEN=1)
15 (R/W)	EPS	Even Parity Select.	
		0	Odd parity
		1	Even parity
14 (R/W)	PEN	Parity Enable. The UART_CTL.PEN bit enables parity transmission and parity check. The UART_CTL.PEN bit inserts one additional bit between the most significant data bit and the first stop bit. The polarity of this so-called parity bit depends on data and the UART_CTL.STP and UART_CTL.EPS control bits. Both transmitter and receiver calculate the parity value. The receiver compares the received parity bit with the expected value and issues a parity error if they do not match. If the UART_CTL.PEN bit is cleared, the UART_CTL.STP and the UART_CTL.EPS bits are ignored.	
		0	Disable
		1	Enable parity transmit and check
13 (R/W)	STBH	Stop Bits (Half Bit Time).	
		0	0 half-bit-time stop bit
		1	1 half-bit-time stop bit
12 (R/W)	STB	Stop Bits. The UART_CTL.STB bit controls how many stop bits are appended to transmitted data.	
		0	1 stop bit
		1	2 stop bits

Table 22-11: UART_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9:8 (R/W)	WLS	Word Length Select. The UART_CTL.WLS field determines whether the transmitted and received UART word consists of 5, 6, 7, or 8 data bits.	
		0	5-bit word
		1	6-bit word
		2	7-bit word
		3	8-bit word
5:4 (R/W)	MOD	Mode of Operation. The UART_CTL.MOD selects the UART operation mode (UMOD).	
		0	UART mode
		1	MDB mode
		2	IrDA SIR mode
1 (R/W)	LOOP_EN	Loopback Enable. The UART_CTL.LOOP_EN bit enables UART loopback mode. When set, this bit disconnects the input of the receiver from the UART_RX pin, and internally redirects the transmit output to the receiver. The UART_TX pin remains active and continues to transmit data externally as well. Loopback mode also forces the UART_RTS pin to its deassertive state, disconnects the UART_CTS bit from the UART_CTS input pin, and directly connects the UART_CTL.MRTS bit to the UART_STAT.CTS bit. In loopback mode, setting the UART_CTL.MRTS bit sets the UART_STAT.CTS bit and enables the transmitter of the UART. Clearing the UART_CTL.MRTS bit clears the UART_STAT.CTS bit and disables the transmitter of the UART.	
		0	Disable
		1	Enable
0 (R/W)	EN	Enable UART. The UART_CTL.EN enables the UART clocks. This bit also resets the state machine and control registers when cleared. Using this bit to disable the UART -- when not used -- reduces power consumption.	
		0	Disable
		1	Enable

Interrupt Mask Register

The UART_IMSK register indicates the interrupt mask status (unmasked, if set, or masked, if cleared) of the UART status interrupt requests. This register is not a data register. Instead, it is controlled by the UART_IMSK_SET and UART_IMSK_CLR register pair. Writing ones to the UART_IMSK_SET register enables (unmasks) interrupt requests, and writing ones to the UART_IMSK_CLR register disables (masks) them. Reads from either register return the enabled bits.

The UART_IMSK register is used to enable requests for system handling of empty or full states of UART data registers. Unless polling is used as a means of action, the UART_IMSK.ERBFI and UART_IMSK.ETBEI bits are normally set. Setting this register without enabling system DMA causes the UART to notify the processor of the data inventory state using interrupts. For proper operation in this mode, system interrupts must be enabled, and appropriate interrupt handling routines must be present.

Each UART features three separate interrupt channels to handle the data transmit, data receive, and line status events independently, regardless of whether DMA is enabled or not. If no DMA channels are assigned to the UART, set the UART_IMSK.ELSI bit to reroute the transmit and receive interrupts to the status interrupt request output.

With system DMA enabled, the UART uses DMA to transfer data to or from the processor. Dedicated DMA channels are available for receive and transmit operations. Line error handling can be configured independently from the receive or transmit setup.

The DMA of the UART is enabled by first setting up the system DMA control registers and then enabling the UART_IMSK.ERBFI and UART_IMSK.ETBEI interrupts. This configuration is because the interrupt request lines double as DMA request lines. Depending on whether DMA is enabled or not, upon receiving these requests, the DMA control unit either generates a direct memory access or passes the UART interrupt on to the system interrupt handling unit(s). However, the error interrupt for the UART goes directly to the system interrupt handling unit(s), bypassing the DMA unit completely.

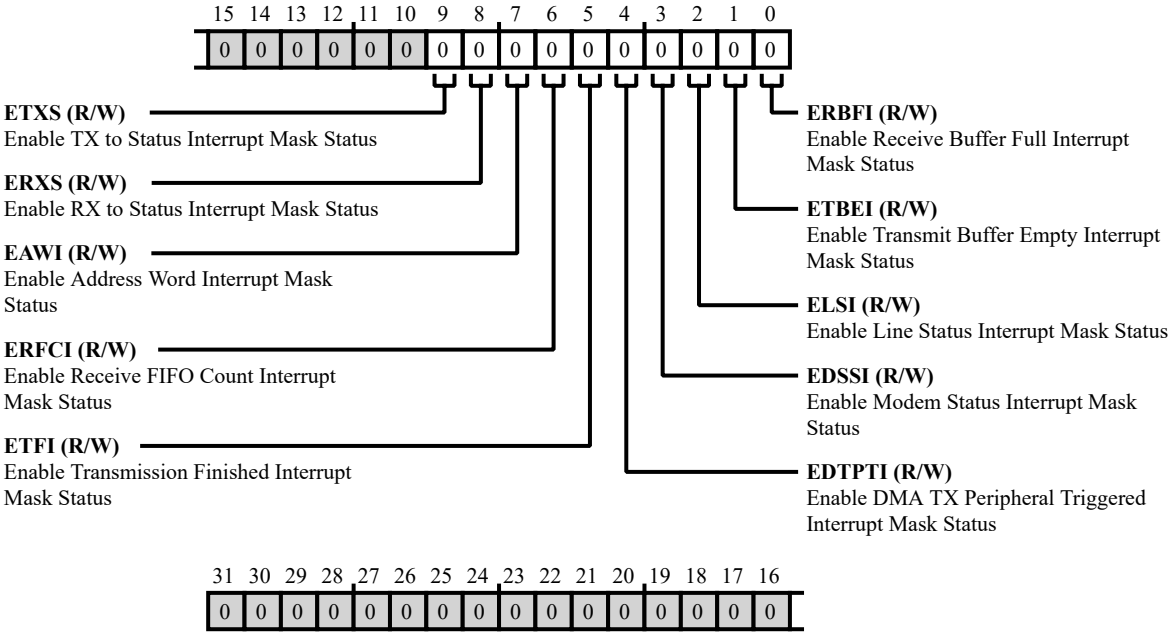

Figure 22-13: UART_IMSK Register Diagram

Table 22-12: UART_IMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	ETXS	Enable TX to Status Interrupt Mask Status. If set (interrupt unmasked), the `UART_IMSK.ETXS` bit indicates re-direction of the TX interrupt requests to status interrupt output. If cleared, TX interrupt requests are routed to normal interrupt outputs.	
		0	Interrupt is masked
		1	Interrupt is unmasked
8 (R/W)	ERXS	Enable RX to Status Interrupt Mask Status. If set (interrupt unmasked), the `UART_IMSK.ERXS` bit indicates re-direction of RX interrupt requests to status interrupt output. If cleared, RX interrupt requests are routed to normal interrupt outputs.	
		0	Interrupt is masked
		1	Interrupt is unmasked
7 (R/W)	EAWI	Enable Address Word Interrupt Mask Status. If set (interrupt unmasked), the `UART_IMSK.EAWI` bit indicates generation of a status interrupt request when an Address word in MDB-mode is present in the `UART_RBR`. A received word is an address word if the `UART_STAT.ADDR` bit is set.	
		0	Interrupt is masked
		1	Interrupt is unmasked

Table 22-12: UART_IMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W)	ERFCI	Enable Receive FIFO Count Interrupt Mask Status. If set (interrupt unmasked), the UART_IMSK.ERFCI bit indicates enabling of the receive buffer threshold interrupt request if signaled by the UART_STAT.RFCS bit. Read the UART_RBR register sufficient times to clear the interrupt request.	
		0	Interrupt is masked
		1	Interrupt is unmasked
5 (R/W)	ETFI	Enable Transmission Finished Interrupt Mask Status. If set (interrupt unmasked) the UART_IMSK.ETFI bit indicates enabling of interrupt generation on the status interrupt channel when the transmit buffer register, the transmit address register, and the transmit shift register are all empty as indicated by the UART_STAT.TFI. The UART_IMSK.ETFI interrupt can be used to avoid expensive polling of the UART_STAT.TEMT bit, when the UART clock or line drivers should be disabled after transmission has completed. W1C the UART_STAT.TFI bit to clear the interrupt request. In DMA operation, the UART_IMSK.ETFI bits functionality might be preferred.	
		0	Interrupt is masked
		1	Interrupt is unmasked
4 (R/W)	EDTPTI	Enable DMA TX Peripheral Triggered Interrupt Mask Status. If set (interrupt unmasked), the UART_IMSK.EDTPTI bit indicates enabling of the DMA completion interrupt request to be delayed until the data has left the UART completely. This bit is required for DMA transmit operation only. If set, the UART can generate a DMA interrupt request by the time the UART_STAT.TEMT bit goes high after the last DMA data word is transmitted. When UART_IMSK.EDTPTI is set, usually the DMA_CFG.INT field is cleared to 00 in a STOP mode DMA. This set up suppresses the normal completion interrupt request, and the UART_STAT.TEMT event is signaled through the DMA controller and triggers the DMA interrupt. If both (DMA_CFG.INT not 00 and UART_IMSK.EDTPTI set), two interrupts are requested at the end of a STOP mode DMA.	
		0	Interrupt is masked
		1	Interrupt is unmasked
3 (R/W)	EDSSI	Enable Modem Status Interrupt Mask Status. If set (interrupt unmasked), the UART_IMSK.EDSSI bit indicates enabling of a modem status interrupt request on the same status interrupt channel when the UART_STAT.SCTS bit is set. This indicates UART_CTS pin re-assertion. Write-1-to-clear (W1C) the UART_STAT.SCTS bit to clear the interrupt request.	
		0	Interrupt is masked
		1	Interrupt is unmasked

Table 22-12: UART_IMSK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	ELSI	Enable Line Status Interrupt Mask Status. If set (interrupt unmasked), the `UART_IMSK.ELSI` bit indicates that redirection of TX and RX interrupt requests to the status interrupt output of the UART by OR'ing them with the `UART_STAT.OE`, `UART_STAT.PE`, `UART_STAT.FE`, and `UART_STAT.BI` interrupt requests. Set this bit when no DMA channel is associated with the UART. Enabling `UART_IMSK.ELSI` disables the RX/TX interrupt channels and negates the `UART_IMSK.EDTPTI` bit.	
		0	Interrupt is masked
		1	Interrupt is unmasked
1 (R/W)	ETBEI	Enable Transmit Buffer Empty Interrupt Mask Status. If set (interrupt unmasked), the `UART_IMSK.ETBEI` bit indicates generation of a TX interrupt request if the `UART_STAT.THRE` bit is set.	
		0	Interrupt is masked
		1	Interrupt is unmasked
0 (R/W)	ERBFI	Enable Receive Buffer Full Interrupt Mask Status. If set (interrupt unmasked), the `UART_IMSK.ERBFI` indicates generation of an RX interrupt request if the `UART_STAT.DR` bit is set.	
		0	Interrupt is masked
		1	Interrupt is unmasked

Interrupt Mask Clear Register

The UART_IMSK indicates interrupt mask status (unmasked if set, masked if cleared) of UART status interrupts. This register is not a data register. Instead it is controlled by the UART_IMSK_SET and UART_IMSK_CLR register pair. Writing ones to UART_IMSK_SET enables (unmasks) interrupt requests, and writing ones to UART_IMSK_CLR disables (masks) them. Reads from either register return the enabled bits. For more information, see the UART_IMSK register description.

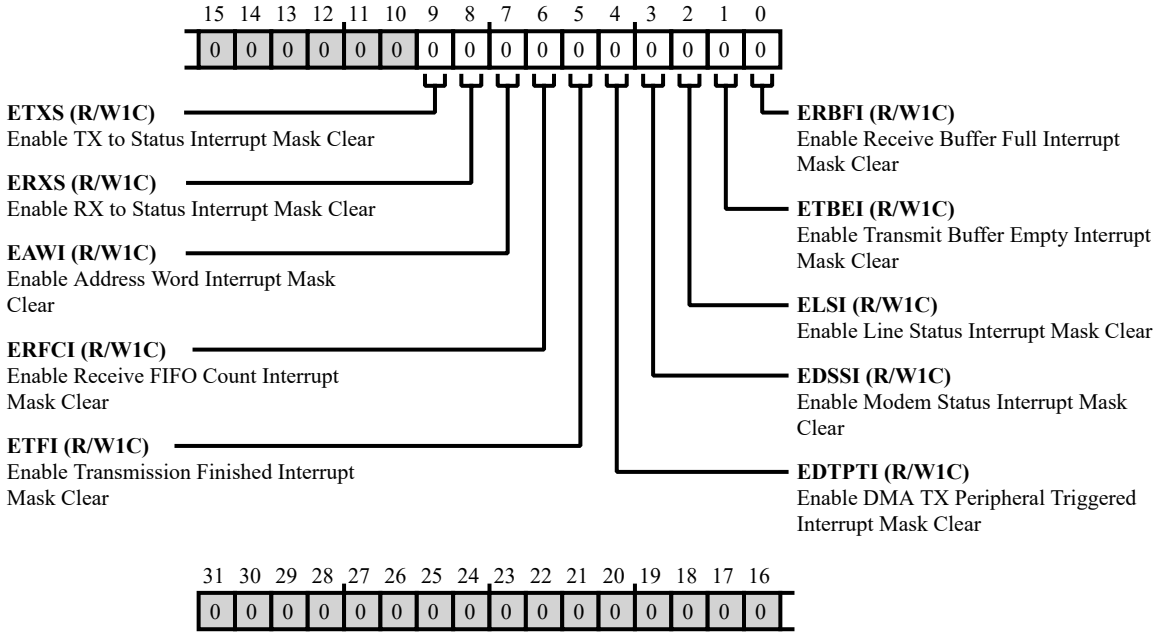

Figure 22-14: UART_IMSK_CLR Register Diagram

Table 22-13: UART_IMSK_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W1C)	ETXS	Enable TX to Status Interrupt Mask Clear.	
		0	No action
		1	Mask interrupt
8 (R/W1C)	ERXS	Enable RX to Status Interrupt Mask Clear.	
		0	No action
		1	Mask interrupt
7 (R/W1C)	EAWI	Enable Address Word Interrupt Mask Clear.	
		0	No action
		1	Mask interrupt

Table 22-13: UART_IMSK_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6 (R/W1C)	ERFCI	Enable Receive FIFO Count Interrupt Mask Clear.	
		0	No action
		1	Mask interrupt
5 (R/W1C)	ETFI	Enable Transmission Finished Interrupt Mask Clear.	
		0	No action
		1	Mask interrupt
4 (R/W1C)	EDTPTI	Enable DMA TX Peripheral Triggered Interrupt Mask Clear.	
		0	No action
		1	Mask interrupt
3 (R/W1C)	EDSSI	Enable Modem Status Interrupt Mask Clear.	
		0	No action
		1	Mask interrupt
2 (R/W1C)	ELSI	Enable Line Status Interrupt Mask Clear.	
		0	No action
		1	Mask interrupt
1 (R/W1C)	ETBEI	Enable Transmit Buffer Empty Interrupt Mask Clear.	
		0	No action
		1	Mask interrupt
0 (R/W1C)	ERBFI	Enable Receive Buffer Full Interrupt Mask Clear.	
		0	No action
		1	Mask interrupt

Interrupt Mask Set Register

The UART_IMSK indicates interrupt request mask status (unmasked if set, masked if cleared) of UART status interrupts. This register is not a data register. Instead it is controlled by the UART_IMSK_SET and UART_IMSK_CLR register pair. Writing ones to UART_IMSK_SET enables (unmasks) interrupt requests, and writing ones to UART_IMSK_CLR disables (masks) them. Reads from either register return the enabled bits. For more information, see the UART_IMSK register description.

1 (R/W1S)	ETBEI	Enable Transmit Buffer Empty Interrupt Mask Set.	
		0	No action
		1	Unmask interrupt
0 (R/W1S)	ERBFI	Enable Receive Buffer Full Interrupt Mask Set.	
		0	No action
		1	Unmask interrupt

Receive Buffer Register

The read-only UART_RBR register is the UART's receive buffer. It is updated when there is pending data in the receive FIFO. Newly available data is signaled by the UART_STAT.DR bit.

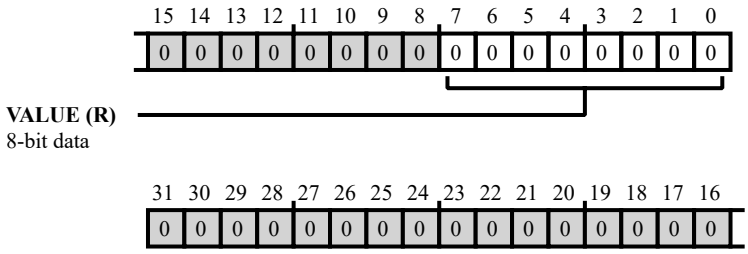

Figure 22-16: UART_RBR Register Diagram

Table 22-15: UART_RBR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/NW)	VALUE	8-bit data.

Receive Shift Register

The read only UART_RSR register which returns the content of the UART's receive shift register.

The frame data is moved into this shift register after polarity inversion, if any (including the native polarity inversion in the IrDA case).

In the case of the longest frame (MDB, with parity mode, and 8 bit data word-length), the start bit may be shifted out and not available for reading at the end of the frame reception. This register is NOT reset at the start of frame. If read, in the middle of a frame reception, data corresponding the previous frame may not have entirely shifted out (for example, the read data that have been read may NOT correspond entirely to the frame being received).

Because the UART is receiving only 1 stop bit, the UART_RSR contains only 1 stop bit even if more than one stop bit is present in the actual transfer. This register may be considered as storing the 10 most recently received bits (taking into consideration the stop bit receive limitation above).

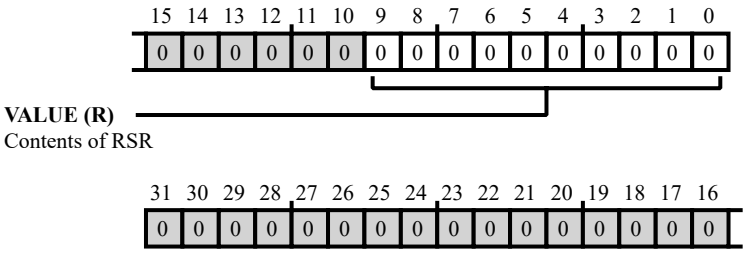

Figure 22-17: UART_RSR Register Diagram

Table 22-16: UART_RSR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
9:0 (R/NW)	VALUE	Contents of RSR.

Receive Counter Register

The UART_RXCNT register returns the content of 16-bit counter in the UART receiver. This count is used for baud rate clock generation (the lower [15:0] is the count data).

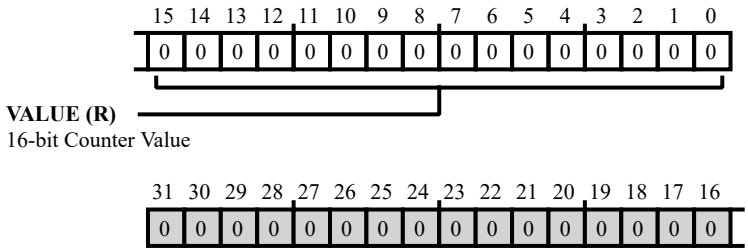

Figure 22-18: UART_RXCNT Register Diagram

Table 22-17: UART_RXCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	VALUE	16-bit Counter Value.

Scratch Register

The UART_SCR registers contain 8-bit scratch pad data. These registers are used for general purpose data storage and do not control the UART hardware in any way.

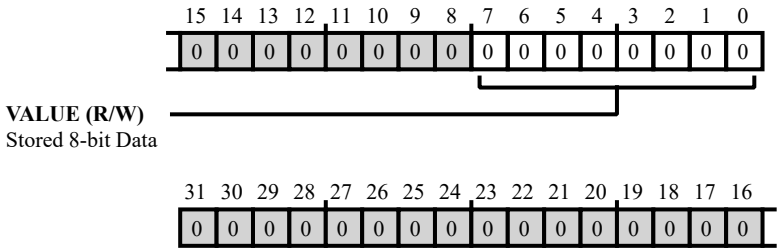

Figure 22-19: UART_SCR Register Diagram

Table 22-18: UART_SCR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	Stored 8-bit Data.

Status Register

The UART_STAT register contains the UART line status and UART modem status, as indicated by the current states of the UART's UART_CTS pin and internal receive buffers. Writes to this register can perform write-one-to-clear (W1C) operations on most status bits. Reading this register has no side effects.

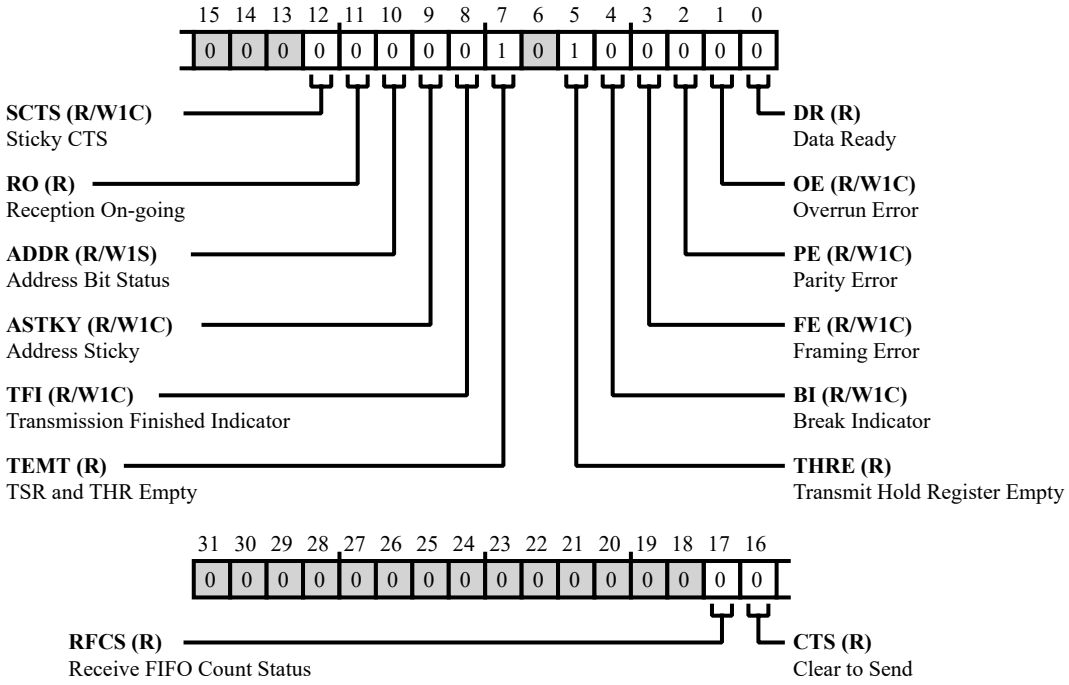

Figure 22-20: UART_STAT Register Diagram

Table 22-19: UART_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/NW)	RFCS	Receive FIFO Count Status. The UART_STAT.RFCS bit is set when the receive buffer holds more or equal entries than a certain threshold. The threshold is controlled by the UART_CTL.RFIT bit. If UART_CTL.RFIT is cleared, the threshold is four entries. If UART_CTL.RFIT is set, the threshold is seven entries. The UART_STAT.RFCS bit is cleared when the UART_RBR register is read sufficient times until the buffer is drained below the threshold. The UART_STAT.RFCS bit can trigger a status interrupt request if enabled by the UART_IMSK_SET.ERFCI bit.	
		0	RX FIFO has less than 4 (7) entries when RFIT=0 (1)
		1	RX FIFO has at least 4 (7) entries when RFIT=0 (1)

Table 22-19: UART_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/NW)	CTS	Clear to Send. The UART_STAT.CTS bit holds the value (if UART_CTL.FCPOL set) or the complement value (if UART_CTL.FCPOL cleared) of the UART_CTS input pin. The UART_CTL.ACTS bit must be set to enable this feature. The core can read the value of the UART_STAT.CTS bit to determine whether the external device is ready to receive (UART_STAT.CTS set) or if it is busy (UART_STAT.CTS cleared). If UART_CTL.ACTS is cleared, the UART_TX handshaking protocol is disabled, and the UART transmits data as long as there is data to transmit, regardless of the value of UART_STAT.CTS. When UART_CTL.ACTS is cleared, the software can pause transmission temporarily by setting the XOFF bit. Note that in loopback mode (UART_CTL.LOOP_EN set), the UART_STAT.CTS bit is disconnected from the UART_CTS input pin. Instead, the bit is directly connected to the UART_CTL.MRTS bit.	
		0	Not clear to send (External device not ready to receive)
		1	Clear to send (External device ready to receive)
12 (R/W1C)	SCTS	Sticky CTS. The UART_STAT.SCTS bit is a sticky bit that is set when UART_STAT.CTS transitions from 0 to 1. The UART_STAT.SCTS bit is cleared by software with a W1C operation. This bit can trigger a line status interrupt request if enabled by the UART_IMSK_SET.EDSSI bit.	
		0	CTS has not transitioned from low to high
		1	CTS has transitioned from low to high
11 (R/NW)	RO	Reception On-going.	
		0	No data reception in progress
		1	Data reception in progress
10 (R/W1S)	ADDR	Address Bit Status. The UART_STAT.ADDR bit is used to mirror the address bit of the word in UART_RBR in multi-drop bus protocol, and is enabled only in MDB mode. The UART_STAT.ADDR bit is updated by hardware upon detecting a received word with the address bit in UART_RBR set or cleared. Additionally, software can set the ADDR bit with a write-1-to-set (W1S) operation.	
		0	Address bit is low
		1	Address bit is high

Table 22-19: UART_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W1C)	ASTKY	Address Sticky. The UART_STAT.ASTKY bit is used in multi-drop bus mode to indicate whether a peripheral is currently being addressed. This bit is a sticky version of the UART_STAT.ADDR bit and is set by hardware when setting the UART_STAT.ADDR bit. The UART_STAT.ASTKY bit can only be cleared by software with a write-one-to-clear (W1C) operation. With the UART_STAT.ASTKY bit set, words will be received irrespective of the UART_CTL.MOD bit or UART_STAT.ADDR bit selection. With the UART_STAT.ASTKY bit cleared, only address words (UART_CTL.MOD bit set) will be received and words with UART_CTL.MOD bit cleared are ignored (not moved from the RSR to the RX FIFO) in MDB mode. The UART_STAT.ASTKY bit does not affect reception in non-MDB modes.	
		0	ADDR bit has not been set
		1	ADDR bit has been set
8 (R/W1C)	TFI	Transmission Finished Indicator. The UART_STAT.TFI bit is a sticky version of the UART_STAT.TEMT bit. While UART_STAT.TEMT is automatically cleared by hardware when new data is written to the UART_THR register, the sticky UART_STAT.TFI bit remains set, until it is cleared by software (W1C). The UART_STAT.TFI bit enables more flexible transmit interrupt request timing.	
		0	TEMT did not transition from 0 to 1
		1	TEMT transition from 0 to 1
7 (R/NW)	TEMT	TSR and THR Empty. The UART_STAT.TEMT bit indicates that the UART_THR and UART_TAIP registers and the UART_TSR register are empty. In this case, the program is permitted to write to the UART_THR and UART_TAIP registers twice without losing data. The UART_STAT.TEMT bit can also be used as indicator that pending UART transmission is completed. At that time, it is safe to disable the UART_CTL.EN bit or to three-state the off-chip line driver.	
		0	Not empty TSR/THR
		1	TSR/THR Empty

Table 22-19: UART_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/NW)	THRE	Transmit Hold Register Empty. The UART_STAT.THRE bit indicates that the UART transmit channel is ready for new data and software can write to the UART_THR and UART_TAIP registers. Writes to the UART_THR and UART_TAIP registers clear the UART_STAT.THRE. The bit is set again when the UART_THR and UART_TAIP registers are empty and ready to accept data.	
		0	Not empty THR/TAIP
		1	Empty THR/TAIP
4 (R/W1C)	BI	Break Indicator. The UART_STAT.BI bit indicates that the first stop bit is sampled low and the entire data word, including parity bit, consists of low bits only. (This condition indicates that UART_RX was held low for more than the maximum word length.) The UART_STAT.BI bit is updated simultaneously with the UART_STAT.DR bit, that is, by the time the first stop bit is received or when data is loaded from the receive FIFO to the UART_RBR register. The bit is sticky and can be cleared by W1C operations.	
		0	No break interrupt
		1	Break interrupt this indicates UARTxRX was held low(RPOLC=0) / high (RPOLC=1) for more than the maximum word length
3 (R/W1C)	FE	Framing Error. The UART_STAT.FE bit indicates that the first stop bit is sampled. This bit is updated simultaneously with the UART_STAT.DR bit, that is, by the time the first stop bit is received or when data is loaded from the receive FIFO to the UART_RBR register. The UART_STAT.FE bit is sticky and can be cleared by W1C operations. Note that invalid stop bits can be simulated by setting the UART_CTL.FFE bit.	
		0	No error
		1	Invalid stop bit error
2 (R/W1C)	PE	Parity Error. The UART_STAT.PE bit indicates that the received parity bit does not match the expected value. This bit is updated simultaneously with the UART_STAT.DR bit, that is, by the time the first stop bit is received or when data is loaded from the receive FIFO to the UART_RBR register. The UART_STAT.PE bit is sticky and can be cleared by W1C operations. Note that invalid parity bits can be simulated by setting the UART_CTL.FPE bit.	
		0	No parity error
		1	Parity error

Table 22-19: UART_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W1C)	OE	Overrun Error. The UART_STAT.OE bit indicates that further data is received while the internal receive buffer was full. This bit is set when sampling the stop bit of the sixth data word. To avoid overruns, read the UART_RBR register in time. In DMA receive mode, overruns are very unlikely to happen ever. After an overrun occurs, the UART_RBR and receive FIFO are protected from being overwritten by new data until the UART_STAT.OE bit is cleared by software. The content of the UART_RSR register is lost as soon as the overrun occurs. The UART_STAT.OE bit is sticky and can be cleared by W1C operations.	
		0	No overrun
		1	Overrun error
0 (R/NW)	DR	Data Ready. The UART_STAT.DR bit indicates that data is available in the receiver and can be read from the UART_RBR register. The bit is set by hardware when the receiver detects the first valid stop bit. The bit is cleared by hardware when the UART_RBR register is read.	
		0	No new data
		1	New data in RBR

Transmit Address/Insert Pulse Register

The UART_TAIP register and the UART_THR register share the same physical register, but UART_TAIP has different effect than the UART_THR register when UART_TAIP is written to in MDB and UART modes.

In MDB mode, data written to the UART_TAIP register is transmitted as an address frame (as with the UART_CTL.MOD bit set).

In UART mode, a write to UART_TAIP causes a pulse of value UART_TAIP [7] for a duration of UART_TAIP [6:0] x bit time. (There is additional inversion if the UART_CTL.TPOLC bit is set).

Bit time is defined by the UART_CLK register. The transmission of the pulse is followed by stop bit transmission as specified by the UART_CTL.STB and UART_CTL.STBH bits. This could be used for supporting line break command and inter-frame gap.

In IrDA mode, writes to UART_TAIP is treated the same as writes to UART_THR.

Accesses to the UART_TAIP register have the same affects as the UART_THR register with respect to the UART_STAT.THRE, UART_STAT.TEMT, and UART_STAT.TFI flags.

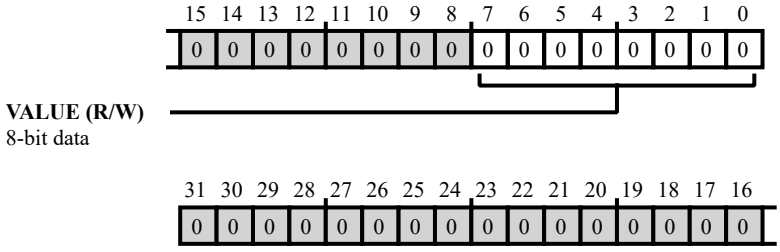

Figure 22-21: UART_TAIP Register Diagram

Table 22-20: UART_TAIP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	8-bit data.

Transmit Hold Register

The write-only UART_THR register is the UART's transmit buffer. The UART_STAT.THRE bit indicates whether data can be written to UART_THR. Writes to this register automatically propagate to the internal UART_TSR register as soon as UART_TSR is ready. Then, transmit operation is initiated immediately.

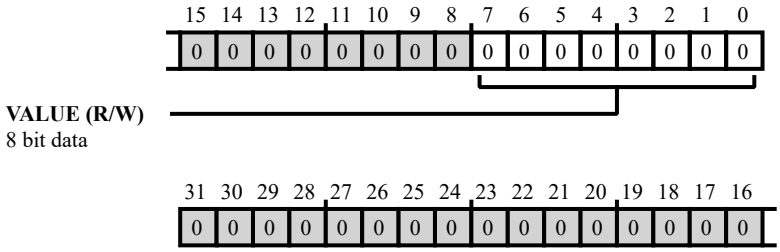

Figure 22-22: UART_THR Register Diagram

Table 22-21: UART_THR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	8 bit data.

Transmit Shift Register

The read only UART_TSR register which returns the content of the UART's transmit shift register.

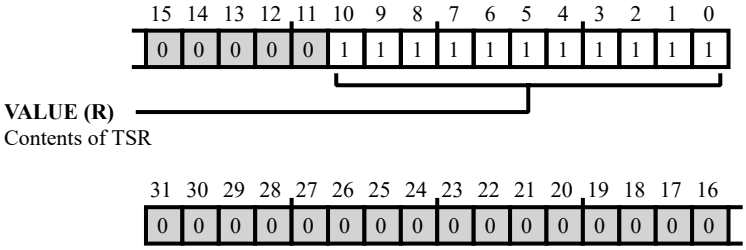

Figure 22-23: UART_TSR Register Diagram

Table 22-22: UART_TSR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
10:0 (R/NW)	VALUE	Contents of TSR.

Transmit Counter Register

The UART_TXCNT read only register returns the content of 16-bit counter in the UART transmitter. This count is used for baud rate clock generation (the lower [15:0] is the count data).

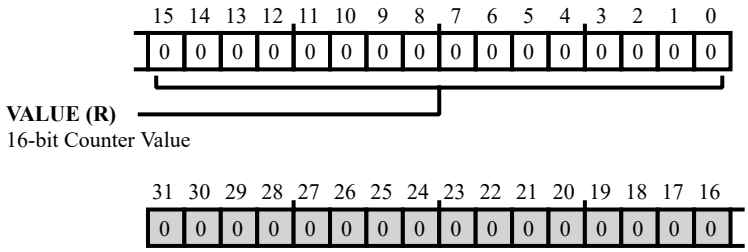

Figure 22-24: UART_TXCNT Register Diagram

Table 22-23: UART_TXCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	VALUE	16-bit Counter Value.

23 General-Purpose Timer (TIMER)

The general-purpose timer (GP Timer) module serves as a collection of system timers that support various system-level functions. These functions include:

- Synchronized PWM waveform output capability
- External signal capture
- External event count
- General time-base functionality

Additionally, interrupt requests can be generated upon completion of timer events. Moreover, GP timers can act both as trigger requesters and trigger completers.

GP Timer Features

Each timer can be individually configured in any of these modes:

- Pin interrupt capture mode
- Windowed watchdog mode
- Pulse-width count and capture (WDTH_CAP) mode
- External Event (EXT_CLK) mode
- Pulse-width modulation (PWM_OUT) mode

Other features include:

- Synchronous operation
- Consistent management of period and pulse width values
- Autobaud detection for UART module (where available)
- Graceful bit pattern termination when stopping
- Support for center-aligned PWM patterns
- Error detection on implausible pattern values

- All read and write accesses to 32-bit registers are atomic
- Every timer has its dedicated interrupt request output

ADSP-2184x TIMER Register List

The General-Purpose Timer block (TIMER) provides timers that may be used for external event capture and measurement, system timing, and PWM waveform generation. A set of registers governs TIMER operations. For more information on TIMER functionality, see the TIMER register descriptions.

Table 23-1: ADSP-2184x TIMER Register List

Name	Description
TIMER_BCAST_DLY	Broadcast Delay Register
TIMER_BCAST_PER	Broadcast Period Register
TIMER_BCAST_WID	Broadcast Width Register
TIMER_DATA_ILAT	Data Interrupt Latch Register
TIMER_DATA_IMSK	Data Interrupt Mask Register
TIMER_ERR_TYPE	Error Type Status Register
TIMER_RUN	Run Register
TIMER_RUN_CLR	Run Clear Register
TIMER_RUN_SET	Run Set Register

Timer Block Diagram

The ***Timer Block Diagram*** shows all of the possible clock sources.

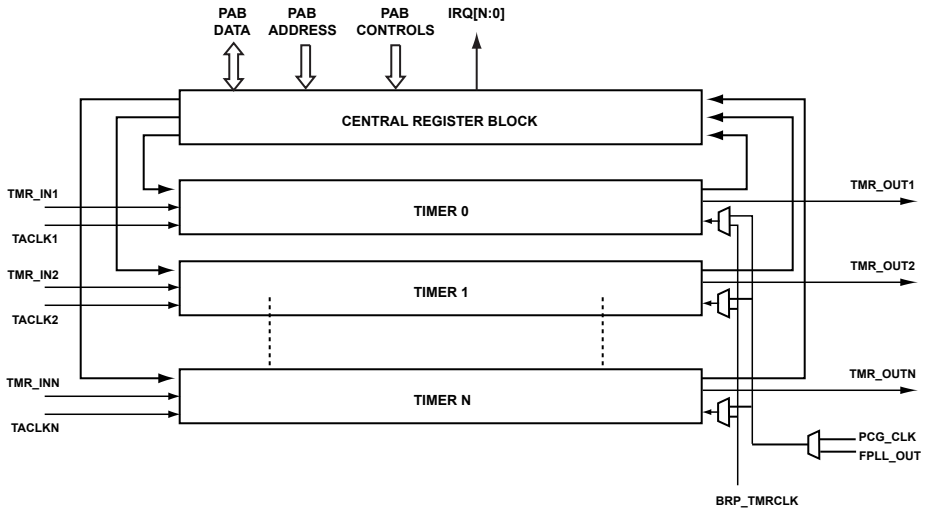

Figure 23-1: Timer Block Diagram

Internal Interface

The processor core always accesses the timer registers through the MMR access bus. Hardware ensures that all read and write operations from and to 32-bit timer registers are atomic. Every timer has a dedicated data interrupt request. There is also one common timer status and error interrupt request output that connects to the system event controller. Whenever a data interrupt request is generated, a data trigger generator pulse is also driven out, if

enabled. Each timer has an individual trigger input line, and each timer can be either started or stopped as a trigger receiver.

In total, the GP timer module can have up to (N + 1) interrupt request output lines and N data trigger lines.

Internal Timer Connections

The Timers support alternate inputs for the clock/capture (see External Interface). Some signals have internal default alternate connections according to the ***Timer Signal Routing*** table.

Table 23-5: Timer Signal Routing

Timer Signal	Connection
TM0_ACLK0	SYS_CLKIN0
TM0_ACI5	DAI0_CRS_PB04
TM0_ACLK5	DAI0_CRS_PB03
TM0_ACI6	DAI1_CRS_PB04
TM0_ACLK6	DAI1_CRS_PB03
TM0_ACI07	CNT0_TO signal
TM0_ACLK7	SYS_CLKIN0
TM0_ACI8	DAI0_PB06
TM0_ACLK8	DAI0_PB05
TM0_ACI9	DAI1_PB06
TM0_ACLK9	DAI1_PB05

External Interface

Each GP timer module can support up to 16 individual timers. However, most processors have less than this number. The exact number of timers available on a given processor is available in the data sheet for the processor.

Every timer has one main input/output signal (`TIMER_TMR[nn]`) and, usually, one auxiliary input pin, used as an alternate capture input (`TIMER_ACI[nn]`). Each timer can either run with a time base of SCLK or can reference an external clock on one of two (`TIMER_ACLK[nn]`) pins. The TMR_ALT_CLK0 signal maps to individual alternate clock ((`TIMER_ACLK[nn]`) pins for one or more timers. For instance, a TM_ACLK3 pin would provide an alternate site to supply an external signal that would serve as reference clock for TMR3. Likewise, the TMR_ALT_CLK1 signal from each timer unit connects internally to provide a single global timer clock pin (`TIMER_CLK`) for the GP timer module. It is used as an additional time base.

GP Timer Operating Modes

The following sections provide information on the various operating modes of the GP timer.

General Operation

The core of every timer is a 32-bit counter that can be interrogated through the read-only TIMER_TMR[n]_CNT register. Once the module enables a timer, it loads the timer TIMER_TMR[n]_CNT register with a starting value.

A timer can operate in one of several different modes, configured through the TIMER_TMR[n]_CFG register for that timer. These modes are: PWMOUT, EXTCLK, WIDCAP, WATCHDOG, PININT, and IDLE. The ***Timer Mode Descriptions*** table summarizes the modes.

Table 23-6: Timer Mode Descriptions

Timer Mode	Description
PWMOUT	Generates single or continuous PWM waveforms with programmable pulse width, period, and delay
EXTCLK	Counts edges of an externally applied waveform
WIDCAP	Captures pulse width or period of an externally applied waveform
WATCHDOG	Monitors pulse width or period of an external signal and compares against a window of acceptable values, optionally generating an interrupt when it falls inside or outside of that window
PININT	Can generate an interrupt request on an active edge applied to a timer pin
IDLE	Idle; no activity

Period, Width and Delay Register Interaction

When the timer is started, writes to the buffer registers are immediately copied through to the double-buffered period, pulse width, and delay registers. These values are then ready for use in the first timer period. When a timer is already running, software can write new values to the TIMER_TMR[n]_PER, TIMER_TMR[n]_WID, and TIMER_TMR[n]_DLY registers. The written values are buffered and do not update into the registers until the end of the current period. (The update occurs when the value in the TIMER_TMR[n]_CNT register equals the value in the TIMER_TMR[n]_PER register.)

If new values are not written to these registers, the value from the previous period is reused. Writes to these registers are atomic; it is not possible for the high word to be written without the low word also being written. Values written to the period, pulse width, and delay registers are always stored in the buffer registers. Reads from the same register always return the current, active value of period, pulse width, or delay value. Written values are not readback until they become active.

The usage of the TIMER_TMR[n]_PER, TIMER_TMR[n]_WID, and TIMER_TMR[n]_DLY registers varies, depending on the mode of the timer specified by the TIMER_TMR[n]_CFG.TMODE bits. See the ***Usage of the Period, Width, and Delay Registers in Different Timer Modes*** table for more information.

Table 23-7: Usage of the Period, Width, and Delay Registers in Different Timer Modes

Timer Mode	TIMER_TMR[n]_PER	TIMER_TMR[n]_WID	TIMER_TMR[n]_DLY
IDLE	Not writable	Not writable	Not writable

Table 23-7: Usage of the Period, Width, and Delay Registers in Different Timer Modes (Continued)

Timer Mode	TIMER_TMR[n]_PER	TIMER_TMR[n]_WID	TIMER_TMR[n]_DLY
WATCHDOG	Update on-the-fly. New value takes effect either at timer start or when an asserting edge on the input signal is sensed.	Read-only. Retains value of last measured width or period of the input signal.	Update on-the-fly. New value takes effect either at timer start or when an asserting edge on the input signal is sensed.
WIDCAP	Read-only. Period value captured at the appropriate time and updated from its buffer register simultaneously with the Width register.	Read-only. Width value captured at the appropriate time and updated from its buffer register simultaneously with the Period register.	Not used
PWMOUT	Update on-the-fly. New value takes effect either at timer start or at the end of the current period. A write followed by immediate read returns the current operating values.	Update on-the-fly. New value takes effect either at timer start or at the end of the current period. A write followed by immediate read returns the current operating values.	Update on-the-fly. New value takes effect either at timer start or at the end of the current period. A write followed by immediate read returns the current operating values.
EXTCLK	Can be updated on-the-fly.	Not used	Not used
PININT	Not used	Not used	Not used

If any of the period, pulse width, and delay registers are not used, then programs cannot write into that register. For example, in WIDCAP mode, the delay registers are not used. So, the program is not allowed to write any value to the TIMER_TMR[n]_DLY register. To prevent undesired operation, program the TIMER_TMR[n]_CFG.TMODE bits before programming the period, width, or delay registers.

If a program changes the TIMER_TMR[n]_CFG.TMODE bits from a status register to writable register (for example in PWMOUT mode), hardware does not clear these registers. These values are automatically overwritten by new values specified by software.

In PWMOUT mode with small periods, there may not be enough time between updates from the buffer registers to write these registers. The next period can use one old value and one new value. To prevent (width + pulse delay) > period errors, write the width and delay registers before the period register when decreasing the values. Write the period register before the width and delay registers when increasing the value.

Single-Pulse PWMOUT Mode

In single-pulse PWMOUT mode, the timer generates a single pulse on the TIMER_TMR[nn] pin. This mode is frequently used to implement a precise delay, often with generating an output trigger. The timer module uses the value in the TIMER_TMR[n]_DLY register to control the assertion of a pulse. The value in the TIMER_TMR[n]_WID register defines the pulse width. The TIMER_TMR[n]_PER is not used and cannot be written in this mode. After completion of the pulse, the timer is automatically stopped, and optionally generates an interrupt. The timer uses the TIMER_TMR[n]_CFG.PULSEHI bit to control pulse polarity.

The timer can be configured to generate a data interrupt request after satisfying various conditions specified by the TIMER_TMR[n]_CFG.IRQMODE bits.

It is not necessary to clear the relevant TIMER_RUN bit to stop the timer cleanly. At the end of the pulse, the timer stops automatically and the corresponding TIMER_RUN bit is cleared. To generate multiple discrete pulses (as opposed to a continuous PWM waveform), write a 1 to the appropriate TIMER_RUN bit, and wait for the timer to stop. Then, write another 1 to the same TIMER_RUN bit.

Continuous PWMOUT Mode

In continuous PWMOUT mode, the timer generates a repetitive pulse with a well-defined period, duty cycle, and pulse position. The TIMER_TMR[n]_DLY, TIMER_TMR[n]_PER, and TIMER_TMR[n]_WID registers are programmed with the values of the required PWM pulse. After the timer is started, the counter counts towards the value programmed in the TIMER_TMR[n]_PER register. Initially, the TIMER_TMR[nn] pin remains in a deasserted state. The pin toggles to an asserted state when the value in the TIMER_TMR[n]_CNT register equals the value in the TIMER_TMR[n]_DLY register.

The timer can control the assertion sense of the TIMER_TMR[nn] pin with the TIMER_TMR[n]_CFG.PULSEHI bit. The TIMER_TMR[nn] pin holds this value for the number of clock cycles specified in the TIMER_TMR[n]_WID register. Then, the pin deasserts and holds this value until the completion of the programmed period. The same waveform is generated repeatedly until the timer is disabled.

The timer can be configured to generate a data interrupt request after satisfying any of various conditions specified by the TIMER_TMR[n]_CFG.IRQMODE bits.

It is important to guarantee that the programmed period is greater than or equal to the sum of width and delay. Similarly, delay must be less than period. Violating either of these criteria results in an unpredictable waveform on the TIMER_TMR[nn] pin until the situation is rectified by writing proper values to these registers.

The maximum frequency possible to generate on the TIMER_TMR[nn] pin is achieved by setting TIMER_TMR[n]_PER to 2 and TIMER_TMR[n]_WID to 1. This operation makes the TIMER_TMR[nn] pin toggle each SCLK clock cycle (assuming the timer is configured to clock internally), producing a duty cycle of 50%.

When the TIMER_STOP_CFG.TMR[nn] bit of a timer is 0, the timer treats a stop operation as a stop-is-pending condition. When terminated with this setting, the timer automatically completes the current waveform and then stops cleanly, remaining in a deasserted state. This functionality prevents truncation of the current pulse and unwanted PWM patterns at the TIMER_TMR[nn] pin. The processor can determine when the timer stops running by polling the corresponding TIMER_RUN.TMR[nn] bit until it reads 0 or by waiting for the last interrupt (if enabled).

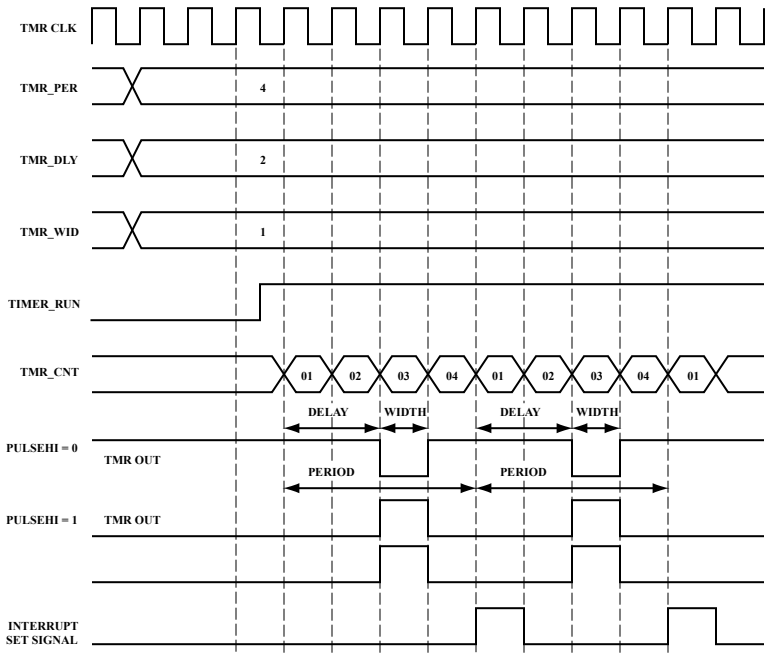

Figure 23-2: Signal Generation in Continuous PWMOUT Mode

The `TIMER_TMR[n]_CFG` register cannot be reconfigured until after the timer stops and the `TIMER_RUN` register reads 0.

Programs can force a timer to stop immediately in PWMOUT mode by writing a 1 to the `TIMER_STOP_CFG` register followed by writing a 1 to the `TIMER_RUN_CLR` register. (Or a program can stop a timer by writing a 0 to the appropriate `TIMER_RUN.TMR[nn]` bit.) This operation stops the timer whether the pending stop is waiting for the end of the current period or the end of the current pulse width. The timer can use this feature to regain immediate control of a timer during an error recovery sequence.

Use this feature carefully, as it can corrupt the PWM pattern generated at the `TIMER_TMR[nn]` pin, though after such a stop the pin deasserts automatically. Each timer samples its `TIMER_RUN.TMR[nn]` bit at the end of each period. It stops cleanly at the end of the first period after the `TIMER_RUN.TMR[nn]` bit is low. A timer that is disabled and then restarted (before the end of the current period), continues to run as if nothing happened. Typically, the program disables a PWMOUT timer and then waits for it to stop itself.

Width Capture (WIDCAP) Mode

The timer uses WIDCAP mode, often called capture mode, to measure pulse widths on the `TIMER_TMR[nn]` or (`TIMER_ACI[nn]`) inputs. The polarity (active high or low) of the input signal can be selected with the `TIMER_TMR[n]_CFG.PULSEHI` bit. The ***Timer Signal Flow in Width Capture Mode*** figure shows the control signal flow for WIDCAP_CAP mode.

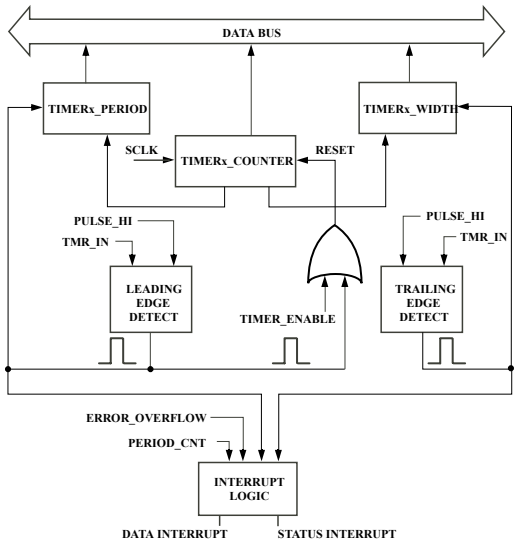

Figure 23-3: Timer Signal Flow in Width Capture Mode

NOTE: SCLK in the ***Timer Signal Flow in Width Capture Mode*** figure is SCLK.

In this mode, the timer uses the `TIMER_TMR[n]_CFG.TINSEL` bit to select between the `TIMER_TMR[nn]` or(`TIMER_ACI[nn]`) input. The internally clocked timer is used to determine the period and pulse width of the externally applied rectangular waveforms.

When a timer is enabled in this mode, the timer resets the count in its `TIMER_TMR[n]_CNT` register to 0x0000 0001. It does not start counting until it detects a leading edge on the selected input pin.

When the timer detects the first leading edge, it starts incrementing. When it detects a trailing edge of a waveform, it captures the current 32-bit value of its `TIMER_TMR[n]_CNT` register into its width buffer register. At the next leading edge, the timer transfers the current 32-bit value of its `TIMER_TMR[n]_CNT` register into its period buffer register. The `TIMER_TMR[n]_CNT` register is reset to 0x0000 0001 again, and the timer continues counting and capturing until it is disabled.

In this mode, programs can measure both the pulse width and the pulse period of a waveform. The timer does not use the `TIMER_TMR[n]_DLY` register in this mode. The timer uses the `TIMER_TMR[n]_CFG.PULSEHI` bit to control the definition of leading edge and trailing edge of the `TIMER_TMR[nn]` /(`TIMER_ACI[nn]`) pin.

In WIDCAP mode, the following events always occur at the same time as one unit:

1. The `TIMER_TMR[n]_PER` register is updated from the period buffer register.
2. The `TIMER_TMR[n]_WID` register is updated from the width buffer register.
3. The `TIMER_DATA_ILAT.TMR[nn]` bit is set (if enabled).
4. A timer data trigger pulse is generated (if enabled).

The `TIMER_TMR[n]_CFG.TMODE` bit 0 controls the point in time at which this set of events is executed. Taken together, these four events are called a measurement report. The `TIMER_STAT_ILAT` register is not

set at a measurement report. A measurement report occurs, at most, once per input signal period. The current TIMER_TMR[n]_CNT value is always copied to the width buffer and period buffer registers at the trailing and leading edges of the input signal, respectively. But these values are not visible to software. A measurement report event samples the captured values into visible registers and sets the timer interrupt request to signal that the TIMER_TMR[n]_PER and the TIMER_TMR[n]_WID registers are ready to be read.

When the TIMER_TMR[n]_CFG.TMODE bit =b#1011, the measurement report occurs just after the width buffer register captures its value at a falling edge. Then, the TIMER_TMR[n]_WID register reports the pulse width measured in the pulse that has ended, but the TIMER_TMR[n]_PER register reports the pulse period measured at the end of the previous period. If only the first trailing edge has occurred, then the first period value has not yet been measured at the first measurement report. So, the period value is not valid. A read of the TIMER_TMR[n]_PER value in this case returns 0. See the ***Example of Width Capture Deasserted Mode (TMODE=b#1011)*** figure for more information.

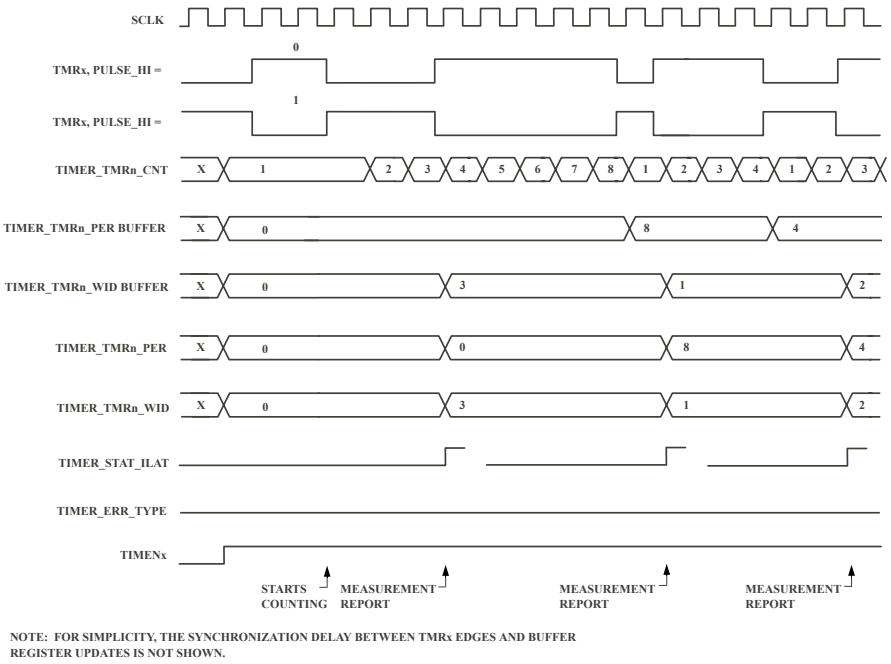

Figure 23-4: Example of Width Capture Deasserted Mode (TMODE=b#1011)

NOTE: SCLK in the ***Example of Width Capture Deasserted Mode (TMODE=b#1011)*** figure is SCLK.

When the TIMER_TMR[n]_CFG.TMODE bit =b#1010, the measurement report occurs just after the period buffer register captures its value at a leading edge. Then, the TIMER_TMR[n]_PER and TIMER_TMR[n]_WID registers report the pulse period and pulse width measured in the period that has ended. Refer to the ***Example of Width Capture Asserted Mode (TMODE=b#1010)*** figure for more information.

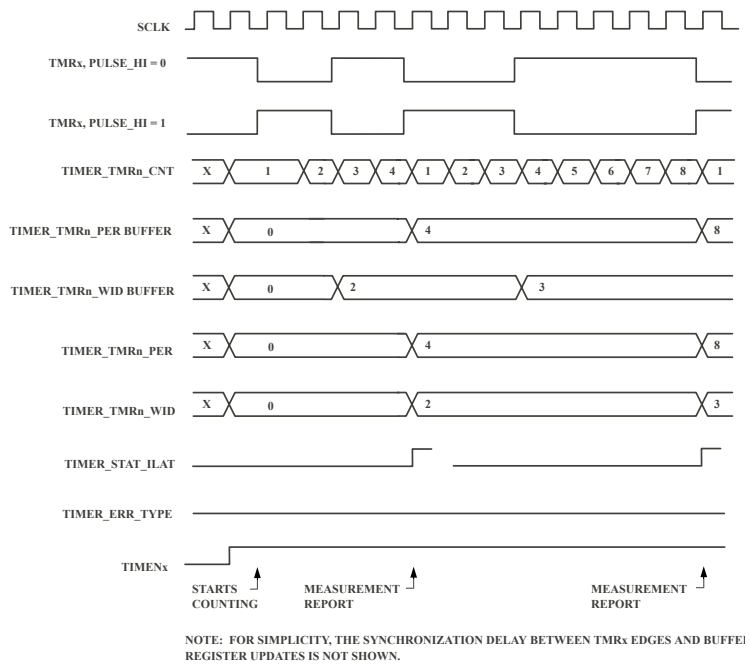

Figure 23-5: Example of Width Capture Asserted Mode (TMODE=b#1010)

NOTE: SCLK in the ***Example of Width Capture Asserted Mode (TMODE=b#1010)*** figure is SCLK.

To measure the pulse width of a waveform that has only one leading edge and one trailing edge, set `TIMER_TMR[n]_CFG.TMODE` = b#1011. When `TIMER_TMR[n]_CFG.TMODE` = b#1010, no period value is captured in the period buffer register. Instead, the timer generates an error report interrupt request (if enabled) when the `TIMER_TMR[n]_CNT` range is exceeded and the counter wraps around. In this case, both the `TIMER_TMR[n]_PER` and `TIMER_TMR[n]_WID` registers read 0 (because no measurement report occurred to copy the value captured in the width buffer register to the `TIMER_TMR[n]_WID` register).

When using the `TIMER_TMR[n]_CFG.TMODE` bit =b#1010 mode to measure the width of a single pulse, programs can disable the timer after taking the interrupt that ends the measurement interval. When desired, restart the timer as appropriate in preparation for another measurement. This procedure prevents the timer from freely running after the width measurement and logging errors generated by the timer count overflowing.

Width Capture Mode Overflow

A timer status interrupt request (when enabled) is generated when the `TIMER_TMR[n]_CNT` register wraps around from 0xFFFF FFFF to 0 in the absence of a leading edge. At that point, the `TIMER_STAT_ILAT` bit is set and the `TIMER_ERR_TYPE` bits change to indicate a count overflow due to a period greater than the range of the counter. This indication is referred to as an error report. A data interrupt request in WIDCAP mode indicates that a new measurement is ready to be read (a measurement report). Similarly, an interrupt request on the timer status interrupt line (shared interrupt request for all timers) indicates an overflow error when generated in this mode.

The `TIMER_TMR[n]_PER` and `TIMER_TMR[n]_WID` registers are never updated at the time an overflow error is signaled. If the timer overflows and the `TIMER_TMR[n]_CFG.TMODE` bit =b#1010, the `TIMER_TMR[n]_PER` and `TIMER_TMR[n]_WID` registers are not updated. If the timer overflows and the

TIMER_TMR[n]_CFG.TMODE bit =b#1011, the TIMER_TMR[n]_PER and TIMER_TMR[n]_WID registers are updated only if a trailing edge is detected at a previous measurement report.

Software can count the number of error reports between measurement report interrupt requests to measure input signal periods longer than 0xFFFF FFFF. Each error report interrupt request adds a full 2^{32}SCLK counts to the total for the period, but the width is ambiguous. Ensure that if software monitors only the status interrupt request, then status interrupt requests from all other timers are masked.

Refer to the ***Example Timing for Width Capture Followed by Period Overflow (TMR_CFG.TMODE=b#1010)*** figure. The period is 0x1 0000 0004, but the pulse width could be either 0x0 0000 0002 or 0x1 0000 0002.

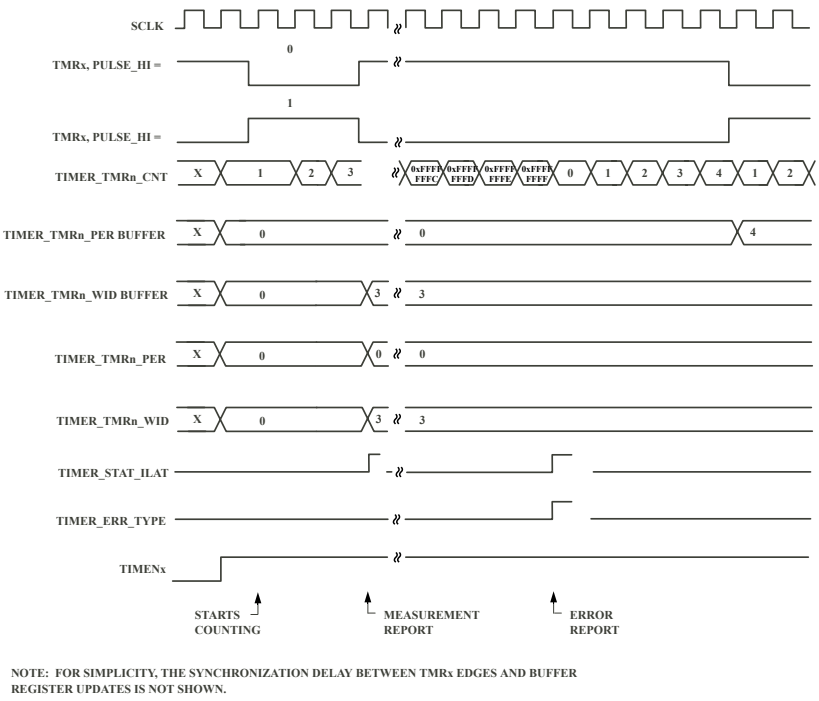

Figure 23-6: Example Timing for Width Capture Followed by Period Overflow (TMR_CFG.TMODE=b#1010)

NOTE: SCLK in the ***Example Timing for Width Capture Followed by Period Overflow*** figure is SCLK.

The waveform applied to the TIMER_TMR[nn] (or (TIMER_ACI[nn])) pin is not required to have a 50% duty cycle. The minimum input low time is little more than one SCLK period. The minimum input high time is a little more than one SCLK period. (Refer to the product data sheet for details.) The maximum TIMER_TMR[nn] input frequency is less than SCLK/2, with a 50% duty cycle. Under these conditions, the WIDCAP mode timer measures: period =2 and pulse width =1.

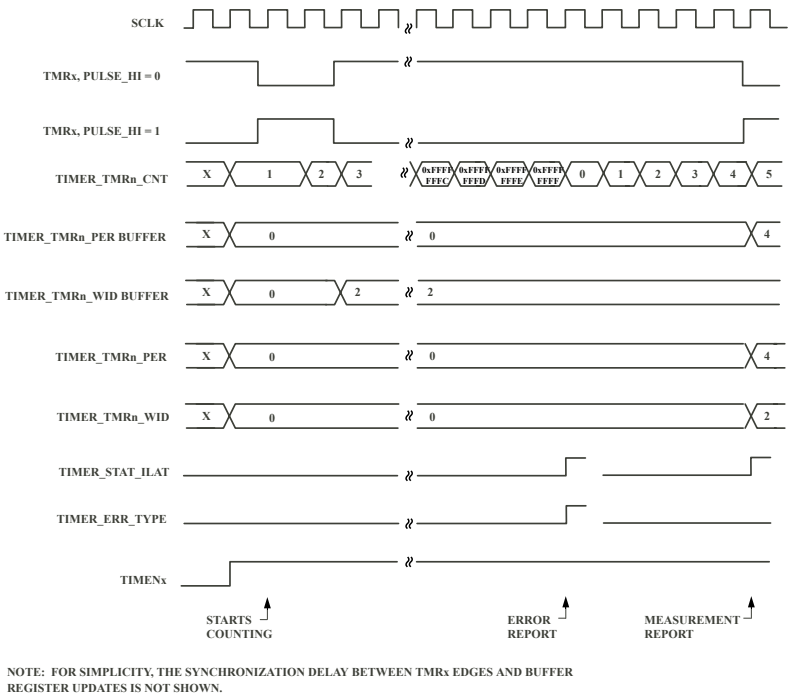

Figure 23-7: Example Timing for Width Capture Followed by Period Overflow (TMR_CFG.TMODE=b#1011)

NOTE: SCLK in the ***Example Timing for Width Capture Followed by Period Overflow*** figure is SCLK.

Windowed Watchdog (WATCHDOG) Modes

In windowed watchdog (WATCHDOG) modes, a timer can take inputs from one of the `TIMER_TMR[nn]` pins or the `TIMER_ACI[nn]` pins. With this mode, the timer can monitor pulse width (width watchdog mode) or pulse period (period watchdog mode) on the input line. It also compares the measured value against a minimum required value and maximum allowed value and generates an interrupt request appropriately. The timer uses the `TIMER_TMR[n]_CFG.PULSEHI` bit to select polarity of the input signal.

The waveform applied to the input pin in watchdog mode is not required to have a 50% duty cycle. The minimum input pulse low time, high time, and total period specifications are available in the product data sheet.

Windowed Watchdog Width Mode

In windowed watchdog width mode, the timer counter monitors the pulse width of an input signal on either the `TIMER_TMR[nn]` pin or one of the alternate clock pins (`TIMER_ACLK[nn]`). Program the minimum pulse width (p_{MIN}) in the `TIMER_TMR[n]_DLY` register and the maximum pulse width (p_{MAX}) in the `TIMER_TMR[n]_PER` register. Both values are programmed in terms of number of clock cycles (SCLK or alternate clock). The timer can generate an interrupt if the deasserting pulse edge occurs:

- Inside the window (p_{MIN} < pulse width ≤ p_{MAX}), or
- Outside the window (pulse width ≤ p_{MIN} or pulse width > p_{MAX})

After enabling the timer in this mode, it always starts counting at the asserting edge of the input signal. Any pulse that is already active when the timer is enabled is ignored.

With the TIMER_TMR[n]_CFG.IRQMODE bit =b#11, the timer generates an interrupt if the timed pulse width exceeds p_{MAX}, or if the pulse width is less than p_{MIN}. After attaining p_{MAX}, the pulse stays at an active level, and the counter keeps on counting until it sees a deasserting edge. When the input pulse is not active, the counter holds its current value until it again sees an asserting edge, or it restarts. An interrupt can also be generated for when the pulse occurs within the specified window condition, by setting TIMER_TMR[n]_CFG.IRQMODE =b#10.

In this mode, a trailing edge on the input pin triggers capturing of pulse width into the TIMER_TMR[n]_WID register. During the inactive portion of the input signal, the internal counter does not increment. The ***Watchdog Width Mode Timing*** figure shows the signal flow in this mode.

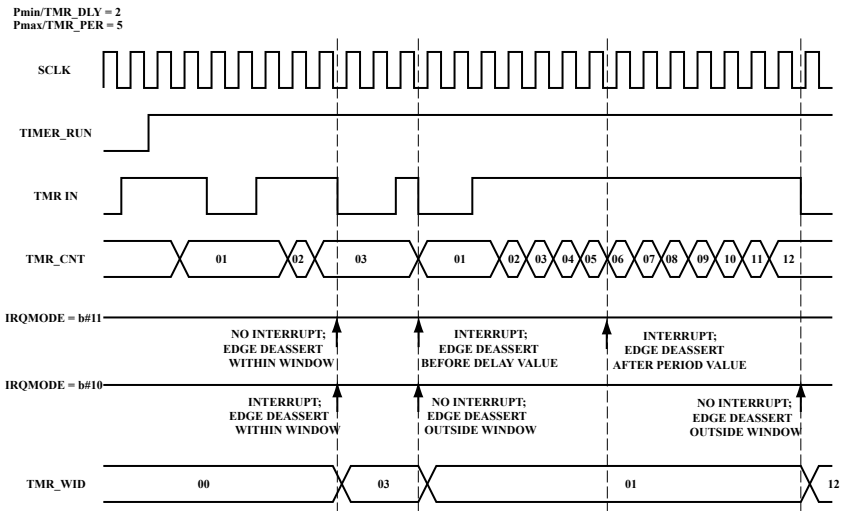

Figure 23-8: Watchdog Width Mode Timing

NOTE: SCLK in the ***Watchdog Width Mode Timing*** figure is SCLK.

To check only the upper limit on pulse width (p_{MAX} but not p_{MIN}), then program p_{MIN} as 0 or 1. In such a case, it is better to use TIMER_TMR[n]_CFG.IRQMODE =b#11. With TIMER_TMR[n]_CFG.IRQMODE = b#10, a pulse width of 1 clock cycle results in an interrupt. For details, see the ***Windowed Watchdog Width Mode Interpretation*** table.

Table 23-8: Windowed Watchdog Width Mode Interpretation

Timer Delay	Timer Period	Incoming Pulse Width	IRQMODE= b#10	IRQMODE= b#11	Error Interrupt?
0 or 1	Anything ≥ 1	PW = 1	Interrupt at deasserting edge of input signal	No Interrupt	No Error Interrupt
		PW ≤ TMR_PER	Interrupt at deasserting edge of input signal	No Interrupt	No Error Interrupt
		PW > TMR_PER	No Interrupt	Interrupt when pulse width exceeds Pmax (Period Register) Value	No Error Interrupt
> 1 but ≤ (Period -1)	Anything > 1	PW ≤ TMR_DLY	No Interrupt	Interrupt at deasserting edge of input signal	No Error Interrupt
		TMR_DLY < PW≤ TMR_PER	Interrupt at deasserting edge of input signal	No Interrupt	No Error Interrupt
		PW > TMR_PER	No Interrupt	Interrupt when pulse width exceeds Pmax (Period Register) Value	No Error Interrupt
≥ Period	-	PW ≤ TMR_PER	Undefined	Undefined	No Error Interrupt
	-	PW > TMR_PER	Undefined	Undefined	b#11 Error Type
-	0	-	Undefined	Undefined	b#10 Error Type

Windowed Watchdog Period Mode

In this mode, the timer monitors the number of clock cycles between two consecutive rising or falling edges of an input signal on one of the `TIMER_TMR[nn]` or `TIMER_ACI[nn]` pins. Program the required minimum number of clock cycles (t_{MIN}) in the `TIMER_TMR[n]_DLY` register and the required maximum allowed number of clock cycles (t_{MAX}) in the `TIMER_TMR[n]_PER` register. Both values are programmed in terms of number of clock cycles (SCLK) or alternate time clock (`TIMER_ACLK[nn]`). The timer can generate an interrupt when two consecutive occurrences of an active edge are:

- Within a specified window (t_{MIN} < Pulse Period ≤ t_{MAX}), or
- Outside a specified window (pulse width ≤ (t_{MIN} or t_{MAX} < pulse width)

When the `TIMER_TMR[n]_CFG.IRQMODE` bit =b#11 and the pulse period > t_{MAX} or is ≤ t_{MIN}, the timer generates an interrupt (if unmasked). After attaining the t_{MAX} value, the counter keeps on counting until it sees an active edge on the input line. An interrupt can also be generated for when the pulse occurs within the specified

window condition, by setting TIMER_TMR[n]_CFG.IRQMODE =b#10. Refer to the ***Watchdog Period Mode Timing*** figure for timer functionality in period watchdog mode.

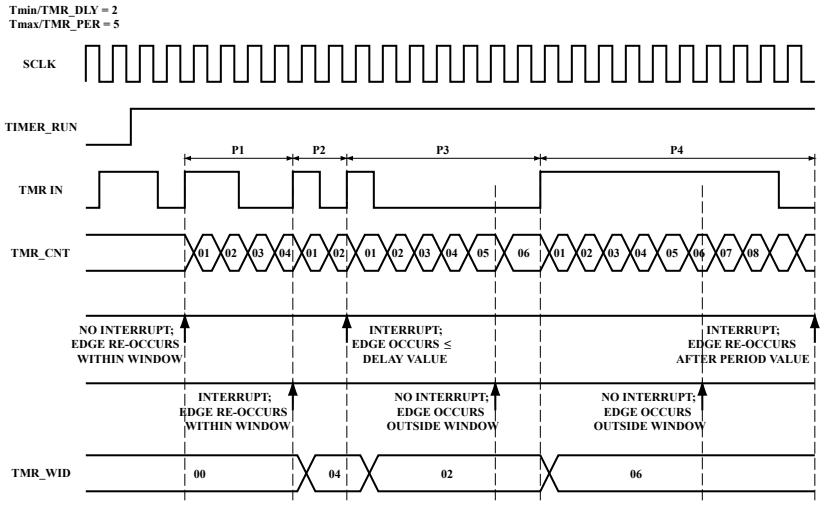

Figure 23-9: Watchdog Period Mode Timing

NOTE: SCLK in the ***Watchdog Period Mode Timing*** figure is SCLK.

To check only the upper limit on period (the t_{MAX} value, not the t_{MIN} value), program t_{MIN} as 0 or 1. For details, refer to the ***Windowed Watchdog Period Mode Interpretation*** table.

Table 23-9: Windowed Watchdog Period Mode Interpretation

Timer Delay	Timer Period	Incoming Pulse Width	IRQMODE=b#10	IRQMODE =b#11	Error Interrupt?
0 or 1	Anything ≥ 2	Pulse Period ≤ TMR_PER	Interrupt at deasserting edge of input signal	No Interrupt	No Error Interrupt
		Pulse Period > TMR_PER	No Interrupt	Interrupt when pulse period crosses Pmax (Period Register) value	No Error Interrupt
> 1 but ≤ Period -1	Anything ≥ 2	Pulse Period ≤ TMR_DLY	No Interrupt	Interrupt at deasserting edge of input signal	No Error Interrupt
		TMR_DLY < Pulse Period ≤TMR_PER	Interrupt at deasserting edge of input signal	No Interrupt	No Error Interrupt
		Pulse Period > TMR_PER	No Interrupt	Interrupt when pulse width exceeds Pmax (Period Register) value	No Error Interrupt

Table 23-9: Windowed Watchdog Period Mode Interpretation (Continued)

Timer Delay	Timer Period	Incoming Pulse Width	IRQMODE=b#10	IRQMODE =b#11	Error Interrupt?
≥ Period	-	Pulse Period < TMR_PER	Undefined	Undefined	No Error Interrupt
		Pulse Period ≥ TMR_PER	Undefined	Undefined	b#11 Error Type
-	0 or 1	-	Undefined	Undefined	b#10 Error Type

Pin Interrupt (PININT) Mode

In PININT mode, any active edges on either the TIMER_TMR[nn] pin or the (TIMER_ACI[nn]) pin can cause an edge-based interrupt, if enabled. (The timer uses the TIMER_TMR[n]_CFG.TINSEL register to select the pin). The event on the input pin can set the TIMER_DATA_ILAT.TMR[nn] bit and issue a system interrupt request. Program the TIMER_TMR[n]_CFG.PULSEHI bit to change active edge polarity.

Since the interrupt request is generated in the SCLK clock domain, the width of the input signal must be more than one SCLK period. Along with generating the interrupt request, the timer also generates a trigger pulse (configured using the TIMER_TRG_MSK register). Due to the configuration of polarity, glitches can cause the generation of an undesired interrupt request at the input. To avoid this problem, programs must ensure that interrupt requests are unmasked only after configuring the desired polarity.

External Clock (EXTCLK) Mode

The timer uses EXTCLK mode, sometimes referred to as the counter mode, to count external events (signal edges), on either the TIMER_TMR[nn] or input pin. The timer works as a counter clocked by an external source (the signal at the pin), which can be asynchronous to SCLK. The current count in the TIMER_TMR[n]_CNT register represents the number of leading-edge events detected. The TIMER_TMR[n]_PER register is programmed with the value of the maximum timer external count before stopping or issuing an interrupt request or trigger.

The TIMER_TMR[n]_CFG.PULSEHI bit determines the polarity of the leading edge on the input pin. The timer uses the TIMER_TMR[n]_CFG.TINSEL bit to select whether the event is counted on the TIMER_TMR[nn] or on the pin. The TIMER_STAT_ILAT.TMR[nn] and TIMER_ERR_TYPE bits are set if *one* of these conditions is met:

- TIMER_TMR[n]_CNT wraps around from 0xFFFF FFFF to 0
- The period = 0 at startup
- TIMER_TMR[n]_CNT register rolls over (from count = period to count = 0x1)

The TIMER_TMR[n]_WID and TIMER_TMR[n]_DLY registers are unused in this mode and must not be written.

The ***EXTCLK Mode Control Flow*** figure shows a flow diagram for EXTCLK mode.

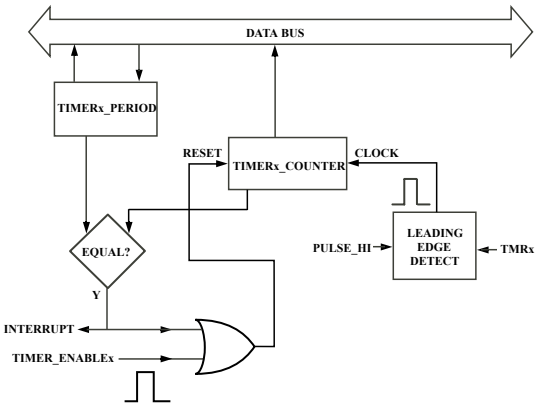

Figure 23-10: EXTCLK Mode Control Flow

The waveform applied to the input pin is not required to have a 50% duty cycle. The minimum input pulse low time, high time, and total period specifications are available in the product data sheet. Program the period to any value from 1 to (2^{32} – 1), inclusive.

After the timer has started, it resets the `TIMER_TMR[n]_CNT` register to 0x0 and then waits for the first leading edge on the input pin. This edge causes `TIMER_TMR[n]_CNT` to be incremented to the value 0x1, and every subsequent leading edge increments it by one. After the `TIMER_TMR[n]_CNT` register reaches the value programmed in the `TIMER_TMR[n]_PER` register, the corresponding `TIMER_DATA_ILAT` bit is set, and an interrupt and trigger are both generated (if enabled). The next leading-edge reloads the `TIMER_TMR[n]_CNT` register with 0x1, and the timer continues counting until it is disabled.

GP Timer Programming Concepts

Using the features, operating modes, and event control for the GP timer to their greatest potential requires an understanding of some GP timer-related concepts.

Setting Up Constantly Changing Timer Conditions

This task shows how to use different period, pulse width, and delay settings for each of the first three timer periods after the timer starts.

1. Program the first set of `TIMER_TMR[n]_PER`, `TIMER_TMR[n]_WID`, and `TIMER_TMR[n]_DLY` register values.
2. Enable the timer using the `TIMER_RUN` register.
3. Immediately program the second set of `TIMER_TMR[n]_PER`, `TIMER_TMR[n]_WID`, and `TIMER_TMR[n]_DLY` register values, as needed.
4. Wait for the first timer interrupt request.
5. Program the third set of `TIMER_TMR[n]_PER`, `TIMER_TMR[n]_WID`, and `TIMER_TMR[n]_DLY` register values.

Each new setting is then programmed when the preceding timer interrupt request is received.

Configuring, Enabling, and Disabling One or More Timers

1. Configure the relevant timers for the operating mode and other properties using the TIMER_TMR[n]_CFG register.
2. Write a 1 to the representative TIMER_RUN.TMR[nn] bit. Or use the TIMER_RUN_SET register to avoid disturbing the settings of other timers that are not going through configuration.

   The timer is enabled and operating.
3. To stop one or more timers, first program the TIMER_STOP_CFG register to determine whether to stop immediately or gracefully upon receiving a stop command.

   ADDITIONAL INFORMATION: PWMOUT modes are the only modes where a timer can be configured for graceful termination.
4. Write a 0 to the representative TIMER_RUN.TMR[nn] bits to stop the timer according to their TIMER_STOP_CFG settings. Alternately, write a 1 to the appropriate TIMER_RUN_CLR.TMR[nn] bits to avoid disturbing the settings of other timers that are not terminating.

   The timers stop.

Configuring Timer Data and Status Interrupts

1. Configure the TIMER_TMR[n]_CFG.IRQMODE bit field with the desired interrupt properties.
2. Unmask the interrupt source at the system event controller.
3. Set the TIMER_TMR[n]_CFG.IRQMODE field but leave the interrupt masked at the system level to poll the TIMER_DATA_ILAT.TMR[nn] bit of the timer without generating an interrupt.
4. Use the TIMER_STAT_IMSK register to generate interrupt requests by overflow or error conditions (incorrect programming values). The timer uses the TIMER_STAT_ILAT.TMR[nn] bits to report interrupt errors, when the timer status interrupt source is unmasked at the system event controller.
5. To poll the TIMER_STAT_ILAT.TMR[nn] bit of the timer without generating an interrupt, unmask the corresponding bit in the TIMER_STAT_IMSK register, but leave the interrupt masked at the system level.

Configuring the Timer as a Trigger Receiver

The timer can be configured to either start or stop or toggle between these two states on the input trigger pulse depending on the configuration of the TIMER_TMR[n]_CFG.TGLTRIG and TIMER_TMR[n]_CFG.RCVTRIG bits.

- If TIMER_TMR[n]_CFG.TGLTRIG bit =0 and TIMER_TMR[n]_CFG.RCVTRIG bit =1 then the trigger pulse starts timer, if it is stopped.

- If TIMER_TMR[n]_CFG.TGLTRIG bit =0 and TIMER_TMR[n]_CFG.RCVTRIG bit =0 then the trigger pulse stops timer, if it is running.
- When TIMER_TMR[n]_CFG.TGLTRIG bit =0, the trigger pulse has no effect when the timer is already in the requested state.

If TIMER_TMR[n]_CFG.TGLTRIG bit is 1, the trigger pulse starts the timer if it is stopped, or stops the timer if it is running. The TIMER_TMR[n]_CFG.RCVTRIG bit has no effect on trigger mechanism. In continuous PWMOUT mode, the timer stops gracefully or abruptly depending on the stop mechanism programmed in the TIMER_STOP_CFG_CLR register. In other modes, the timer stops immediately.

Ordered Trigger Toggle Mode

The timer can be configured to either start or stop the timer on the input trigger pulse depending on the configuration of the TIMER_TMR[n]_CFG.TGLTRIG and TIMER_TMR[n]_CFG.ORDTGLTRIG bits.

- If TIMER_TMR[n]_CFG.TGLTRIG bit is 1 and TIMER_TMR[n]_CFG.ORDTGLTRIG bit is 0, then the input trigger pulse on trigger receiver 0 or trigger receiver 1 starts the timer if it is stopped, or stops the timer if it is running.
- If TIMER_TMR[n]_CFG.TGLTRIG bit is 1 and TIMER_TMR[n]_CFG.ORDTGLTRIG bit is 1, then the input trigger pulse on trigger receiver 0 starts timer if it is stopped. If the timer is running, it stops when the input trigger pulse on trigger receiver 1 is detected.

  Trigger receiver 0 cannot toggle the timer from the run to halt state. Trigger receiver 1 cannot toggle the timer from the halt to run state.

NOTE: The timer state is not toggled by writes to the TIMER_RUN, TIMER_RUN_SET, and TIMER_RUN_CLR registers in this mode.

Using the Timer Broadcast Feature

The broadcast feature provides a means to update period, width, and delay registers simultaneously across more than one timer.

1. Enable the appropriate broadcast bits (TIMER_TMR[n]_CFG.BPEREN, TIMER_TMR[n]_CFG.BWIDEN are TIMER_TMR[n]_CFG.BDLYEN) for the timers involved in the broadcast. The use of these bits depends on which broadcast registers the timer uses (TIMER_BCAST_PER, TIMER_BCAST_WID, or TIMER_BCAST_DLY).
2. Program the TIMER_BCAST_PER register (for example), to broadcast the period setting across the multiple timers enabled.

   The enabled timers load their TIMER_TMR[n]_PER registers with the value specified in the TIMER_BCAST_PER register.
3. Repeat Step 2 as needed for the TIMER_BCAST_WID and TIMER_BCAST_DLY register settings.

Timer Illegal States

The following sections use these definitions:

- Startup. The first clock period during which the timer counter is running after the timer is started by writing the TIMER_RUN register.
- Rollover. The time when the current count in TIMER_TMR[n]_CNT matches the value in TIMER_TMR[n]_PER and the counter is reloaded with the value 1.
- Overflow. The timer counter was incremented instead of doing a rollover when it was holding the maximum count value of 0xFFFF FFFF. The counter does not have a large enough range to express the next greater value and so it erroneously loads a new value of 0x0000 0000.
- Unchanged. No new error.

When the TIMER_ERR_TYPE register is designated unchanged, it displays the previously reported error code orb# 00 when there has been no error since this timer was enabled.

When the TIMER_STAT_ILAT register is unchanged, it reads 0 when there has been no error or overflow since this timer was enabled. Or, it reads 0 if software has performed a W1C to clear any previous error. If software has not acknowledged a previous error, the TIMER_STAT_ILAT register reads 1. Software can read the TIMER_STAT_ILAT register to check for errors. If a particular bit of a timer is set in this register, software can then read the TIMER_ERR_TYPE register for more information. Once detected, software can W1C the appropriate TIMER_STAT_ILAT bit to acknowledge the error.

Read the following tables as:

- In mode __ at event __,
- if TIMER_TMR[n]_PER is __ and TIMER_TMR[n]_WID is __ and TIMER_TMR[n]_DLY is __,
- then TIMER_ERR_TYPE is __ and TIMER_STAT_ILAT is __.

Startup error conditions do not prevent the timer from starting. Similarly, overflow and rollover error conditions do not stop the timer. Illegal cases can cause unwanted behavior of the TIMER_TMR[nn] pins.

NOTE: For PININT mode, the timer does not use error functionality.

Continuous PWMOUT Mode

Table 23-10: Startup Event

TIMER_TMR[n]_PER	TIMER_TMR[n]_DLY	TIMER_TMR[n]_WID	TIMER_TMR[n]_WID + TIMER_TMR[n]_DLY	TIMER_ERR_TYPE	TIMER_STAT_ILAT (if enabled)
≤ 1	Anything other than period [*1]	Anything	Anything	b#10	Set

Table 23-10: Startup Event (Continued)

TIMER_TMR[n]_PER	TIMER_TMR[n]_DLY	TIMER_TMR[n]_WID	TIMER_TMR[n]_WID + TIMER_TMR[n]_DLY	TIMER_ERR_TYPE	TIMER_STAT_ILAT (if enabled)
≥ 2	Anything including 0, excluding TMR_PER value	Anything including 0	≤ PERIOD	Unchanged	Unchanged
	Anything including 0	Anything including 0	> PERIOD	Unchanged *2(Detected at rollover)	Unchanged (Detected at rollover)
	Anything	Anything	> 2^{32} – 1	b#11	Set
	=Period	=0	=Period	No error	Unchanged (Detected at rollover)

*1 If delay = period, the #10 error is rolled to a #11 error.

*2 This case is not detected at startup, but when the timer counts to the complete period.

Table 23-11: Rollover Event

TIMER_TMR[n]_PER	TIMER_TMR[n]_DLY	TIMER_TMR[n]_WID	TIMER_TMR[n]_WID + TIMER_TMR[n]_DLY	TIMER_ERR_TYPE	TIMER_STAT_ILAT (if enabled)
≥ 1	Anything	Anything	Anything	b#10[timer running at SCLK] b#11 [timer running at ALT_CLKx]	Set
≥ 2	Anything including 0, excluding TMR_PER value	Anything including 0	≤PERIOD	Unchanged	Unchanged
	Anything including 0, excluding TMR_PER value	Anything >0	>PERIOD	b#11	Set
	Anything	Anything	> 2^{32}– 1	b#11	Set
	= Period*1	=0	=Period	b#11	Set
	>Period	=0	>Period	Unchanged	Unchanged

*1 In case of graceful termination, this error is not generated.

Table 23-12: Overflow Event (On TMR_PER Register Programming Error Only)

TIMER_TMR[n]_PER	TIMER_TMR[n]_DLY	TIMER_TMR[n]_WID	TIMER_TMR[n]_WID + TIMER_TMR[n]_DLY	TIMER_ERR_TYPE	TIMER_STAT_ILAT (if enabled)
Anything	Anything	Anything	Anything	b#01	Set

Single Pulse PWMOUT Mode

For single pulse PWMOUT mode, there are no rollover events.

Table 23-13: Startup Event

TIMER_TMR[n]_PER	TIMER_TMR[n]_DLY	TIMER_TMR[n]_WID	TIMER_TMR[n]_WID + TIMER_TMR[n]_DLY	TIMER_STAT_ILAT (if enabled)	TIMER_STAT_ILAT (if enabled)
N/A	Anything	== 0	Anything	b#11*1	Set
N/A	Anything including 0	≥1	≤ 2^{32}- 1	Unchanged	Unchanged
N/A	Anything including 0	≥1	> 2^{32}- 1	b#11	Set

*1 The timer does not run in this case.

Table 23-14: Overflow Event (On another error, such as DELAY + WIDTH ≥ 2^{32}- 1)

	TIMER_TMR[n]_DLY		TIMER_TMR[n]_WID + TIMER_TMR[n]_DLY		TIMER_STAT_ILAT (if enabled)
Anything	Anything	Anything	Anything	b#01	Set

WIDCAP Mode

For WIDCAP mode, the TIMER_TMR[n]_PER and TIMER_TMR[n]_WID registers are read-only and the TIMER_TMR[n]_DLY register is not used. Therefore, no startup or rollover errors are possible.

Table 23-15: Overflow Event

ADSP-2184x TIMER Register Descriptions

General-Purpose Timer Block (TIMER) contains the following registers.

Table 23-22: ADSP-2184x TIMER Register List

Name	Description
TIMER_BCAST_DLY	Broadcast Delay Register
TIMER_BCAST_PER	Broadcast Period Register
TIMER_BCAST_WID	Broadcast Width Register
TIMER_DATA_ILAT	Data Interrupt Latch Register
TIMER_DATA_IMSK	Data Interrupt Mask Register
TIMER_ERR_TYPE	Error Type Status Register
TIMER_RUN	Run Register
TIMER_RUN_CLR	Run Clear Register
TIMER_RUN_SET	Run Set Register
TIMER_STAT_ILAT	Status Interrupt Latch Register
TIMER_STAT_IMSK	Status Interrupt Mask Register
TIMER_STOP_CFG	Stop Configuration Register
TIMER_STOP_CFG_CLR	Stop Configuration Clear Register
TIMER_STOP_CFG_SET	Stop Configuration Set Register
TIMER_TMR[n]_CFG	Timer n Configuration Register

Table 23-22: ADSP-2184x TIMER Register List (Continued)

Name	Description
TIMER_TMR[n]_CNT	Timer n Counter Register
TIMER_TMR[n]_DLY	Timer n Delay Register
TIMER_TMR[n]_PER	Timer n Period Register
TIMER_TMR[n]_WID	Timer n Width Register
TIMER_TRG_IE	Trigger Receiver Enable Register
TIMER_TRG_MSK	Trigger Generator Mask Register

Broadcast Delay Register

For timers with TIMER_TMR[n]_CFG.BDLYEN enabled, a write to the TIMER_BCAST_DLY register concurrently updates the delay (TIMER_TMR[n]_DLY) registers of only those timers. A read of the TIMER_BCAST_DLY register returns 0x00000000, and no bus error is generated. To read back a written value, read that TMR's TIMER_TMR[n]_DLY register.

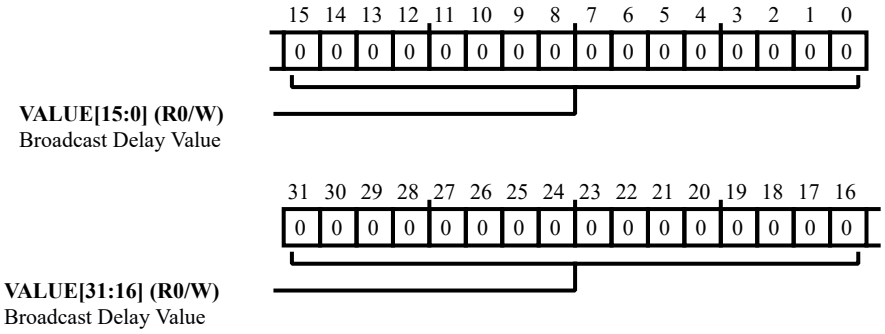

Figure 23-11: TIMER_BCAST_DLY Register Diagram

Table 23-23: TIMER_BCAST_DLY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R0/W)	VALUE	Broadcast Delay Value. A write to the TIMER_BCAST_DLY.VALUE bit field concurrently updates the delay (TIMER_TMR[n]_DLY) registers of only those timers. A read of the TIMER_BCAST_DLY.VALUE bit field returns 0x0000 0000, and no bus error is generated.

Broadcast Period Register

For timers with TIMER_TMR[n]_CFG.BPEREN enabled, a write to the TIMER_BCAST_PER register concurrently updates the period (TIMER_TMR[n]_PER) registers of only those timers. A read of TIMER_BCAST_PER returns 0x00000000, and no bus error is generated. To read back a written value, read that TMR's TIMER_TMR[n]_PER register.

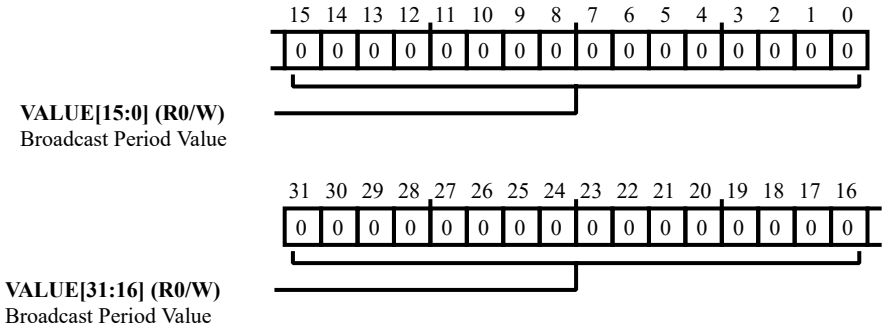

Figure 23-12: TIMER_BCAST_PER Register Diagram

Table 23-24: TIMER_BCAST_PER Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R0/W)	VALUE	Broadcast Period Value. A write to the TIMER_BCAST_PER.VALUE bit field concurrently updates the period (TIMER_TMR[n]_PER) registers of only those timers. A read of the TIMER_BCAST_PER.VALUE bit fields returns 0x0000 0000, and no bus error is generated.

Broadcast Width Register

For timers with TIMER_TMR[n]_CFG.BWIDEN enabled, a write to the TIMER_BCAST_WID register concurrently updates the width (TIMER_TMR[n]_WID) registers of only those timers. A read of the TIMER_BCAST_WID register returns 0x00000000, and no bus error is generated. To read back a written value, read that TMR's TIMER_TMR[n]_WID register.

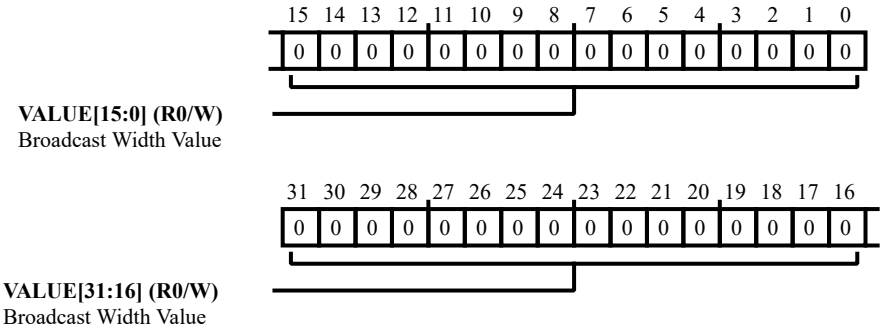

Figure 23-13: TIMER_BCAST_WID Register Diagram

Table 23-25: TIMER_BCAST_WID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R0/W)	VALUE	Broadcast Width Value. A write to the TIMER_BCAST_WID.VALUE bit field concurrently updates the width (TIMER_TMR[n]_WID) registers of only those timers. A read of the TIMER_BCAST_WID.VALUE bit field returns 0x0000 0000, and no bus error is generated.

Data Interrupt Latch Register

The TIMER_DATA_ILAT holds the latched interrupt status for interrupt requests that have been unmasked (enabled) by the TIMER_DATA_IMSK register and generated according to the conditions selected by the TIMER_TMR[n]_CFG.IRQMODE bits. If a bit in TIMER_DATA_ILAT is already set and the corresponding interrupt is masked in TIMER_DATA_IMSK, the latch holds its old value, leaving the interrupt request asserted until it is reset by software with a W1C operation.

Note that interrupt service routines (ISRs) should clear the appropriate bits in TIMER_DATA_ILAT before returning from the ISR, to ensure that the interrupt is not re-issued. To make sure that no timer event is missed, the latch should be reset at the very beginning of the ISR when in EXTCLK mode.

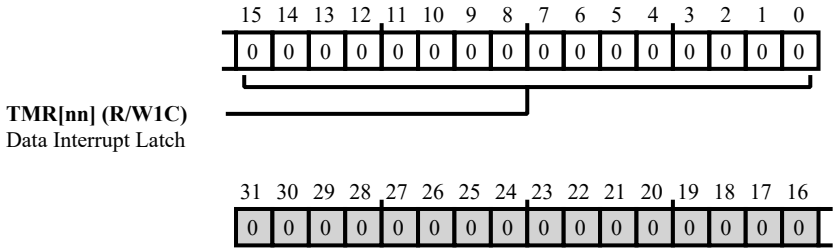

Figure 23-14: TIMER_DATA_ILAT Register Diagram

Table 23-26: TIMER_DATA_ILAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W1C)	TMR[nn]	Data Interrupt Latch. For all TIMER_DATA_ILAT.TMR[nn] bits, status of =0 indicates no interrupt is latched, and status of =1 indicates a latched interrupt (indicating an unmasked interrupt request from a timer with a condition matching the one selected with corresponding TIMER_TMR[n]_CFG.IRQMODE bit has occurred).

Data Interrupt Mask Register

Each timer may generate a unique processor data interrupt request signal. The `TIMER_DATA_IMSK` register contains an interrupt mask for these requests, masking (disabling) or unmasking (enabling) the interrupts as programmed. The reset value of the `TIMER_DATA_IMSK` register is 0xFFFF, masking these interrupts after reset.

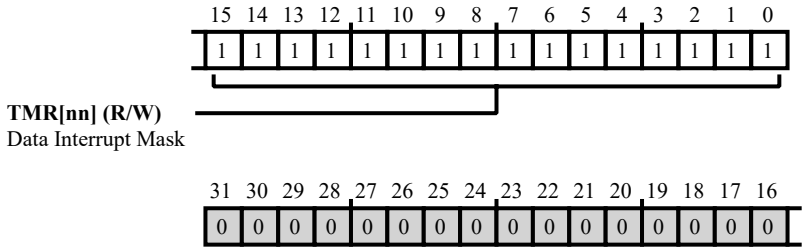

Figure 23-15: TIMER_DATA_IMSK Register Diagram

Table 23-27: TIMER_DATA_IMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	TMR[nn]	Data Interrupt Mask. For all `TIMER_DATA_IMSK.TMR[nn]` bits, write =0 unmasks (enables) the corresponding data interrupt request, and write =1 masks (disables) the corresponding data interrupt request.

Error Type Status Register

The TIMER_ERR_TYPE register contains error type status bits for each timer. These bits indicate the type of error (if any) in a running timer. This register is read-only. These status bits are cleared at reset and when a particular timer is enabled.

Each time an error request interrupt is latched in the TIMER_STAT_ILAT register, the corresponding TERRx bits in the TIMER_ERR_TYPE register are loaded with a code that identifies the type of error that was detected. This status value is held until the next error or until a particular timer is restarted. No bus error is generated if a write is performed on the TIMER_ERR_TYPE register.

		3	WID or DLY Register Programming Error

Run Register

The TIMER_RUN allows all timers to be enabled simultaneously, permitting them to run synchronously. For each timer, there is a single start/stop control bit. Writing a 1 to this bit starts the corresponding timer; writing a 0 stops the timer with mechanism specified in the timer stop configuration TIMER_STOP_CFG register.

The start/stop control bits can be set/reset individually or in any combination. While starting or stopping one particular timer directly with this register, software must perform a read-modify write, so the bits corresponding to other timers remain unchanged. To avoid this need, software can use the TIMER_RUN_CLR register.

Reading the TIMER_RUN register shows the start status for the corresponding timer. A 1 indicates that the timer is running.

If a timer is in run state (corresponding run bit is =1), a software write of 1 in this bit does not have any effect on the timer state. The write does not result in restarting the timer.

Note that the TIMER_RUN register is not used in PININT mode. PININT mode starts as soon as the TIMER_TMR[n]_CFG.TMODE bits are set to 111.

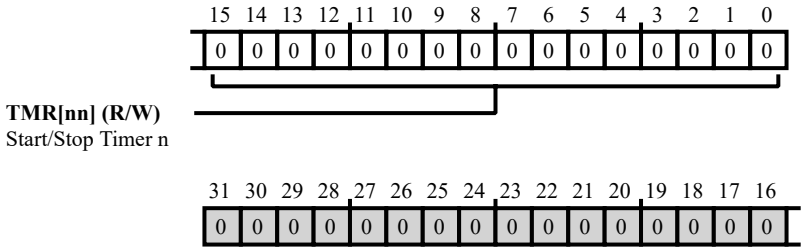

Figure 23-17: TIMER_RUN Register Diagram

Table 23-29: TIMER_RUN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	TMR[nn]	Start/Stop Timer n. For all TIMER_RUN.TMR[nn] bits, write =0 for stop, and write =1 for start. Read =1 when timer is running.

Run Clear Register

The TIMER_RUN_CLR register is an alias register, providing a mechanism to clear a specific start/stop bit in the TIMER_RUN register without affecting other bits in TIMER_RUN. To stop a particular timer, software must write a 1 into the corresponding TIMER_RUN_CLR bit. Writing a 0 has no effect. Because TIMER_RUN_CLR is a write-only register, the result of any write to this register must be checked by reading the TIMER_RUN register. A read of the TIMER_RUN_CLR returns 0x0000.

Note that the stopping mechanism of a timer may be abrupt or graceful (after completion of current waveform period) depending on the selection in the TIMER_STOP_CFG register.

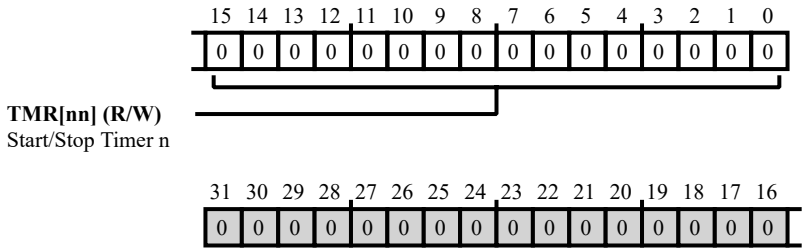

Figure 23-18: TIMER_RUN_CLR Register Diagram

Table 23-30: TIMER_RUN_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R0/W1C)	TMR[nn]	RUN Clear Alias. For all TIMER_RUN_CLR.TMR[nn] bits, write =0 has no effect, and write =1 for stop (clearing the corresponding in start/stop bit in the TIMER_RUN register). Using TIMER_RUN_CLR to clear start/stop bits permits stopping specific timers without influencing run status of other timers.

Run Set Register

The TIMER_RUN_SET register is an alias register, providing a mechanism to set a specific start/stop bit in the TIMER_RUN register without affecting other bits in TIMER_RUN. To start a particular timer, software must write a 1 into the corresponding TIMER_RUN_SET bit. Writing a zero has no effect. For an example, to start timer 3 without affecting any other timer, write 0x0008 into TIMER_RUN_SET. Because TIMER_RUN_SET is a write-only register, the result of any write to this register must be checked by reading the TIMER_RUN register. A read of the TIMER_RUN_SET returns 0x0000.

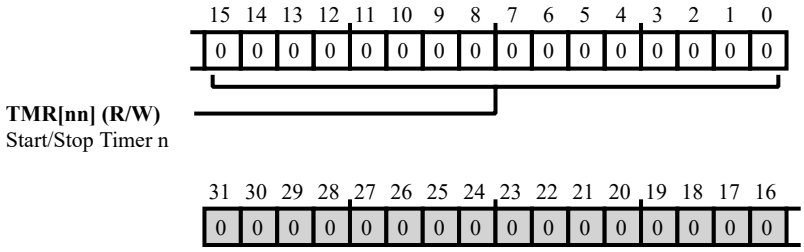

Figure 23-19: TIMER_RUN_SET Register Diagram

Table 23-31: TIMER_RUN_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R0/W1S)	TMR[nn]	RUN Set Alias. For all TIMER_RUN_SET.TMR[nn] bits, write =0 has no effect, and write =1 for start (setting the corresponding start/stop bit in the TIMER_RUN register). Using TIMER_RUN_SET to set start/stop bits permits starting specific timers without influencing the run status of other timers.

Status Interrupt Latch Register

The TIMER_STAT_ILAT holds the latched interrupt status for error interrupt requests, indicating a timer overflow condition or indicating that prohibited programming has occurred for a timer. These interrupt status bits are sticky and are W1C. The bits in the TIMER_STAT_ILAT register provide information regarding each timer interrupt request source.

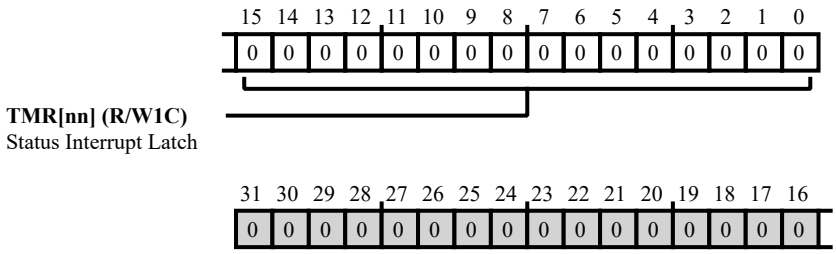

Figure 23-20: TIMER_STAT_ILAT Register Diagram

Table 23-32: TIMER_STAT_ILAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W1C)	TMR[nn]	Status Interrupt Latch. For all TIMER_STAT_ILAT.TMR[nn] bits, status of 0 indicates no error interrupt request is latched, and status of 1 indicates a timer counter overflow or programming error interrupt request is latched.

Status Interrupt Mask Register

While each timer may generate a status interrupt request, these requests are OR'ed to generate a single status interrupt signal to the system event controller. The TIMER_STAT_IMSK register contains an interrupt mask for these requests, masking (disabling) or unmasking (enabling) the interrupts as programmed. The reset value of the TIMER_STAT_IMSK register is 0xFFFF, masking these interrupts after reset.

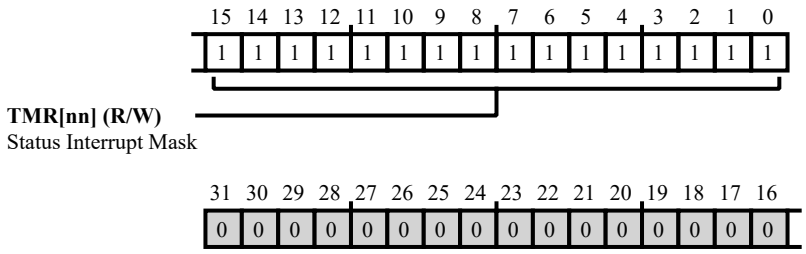

Figure 23-21: TIMER_STAT_IMSK Register Diagram

Table 23-33: TIMER_STAT_IMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	TMR[nn]	Status Interrupt Mask. For all TIMER_STAT_IMSK.TMR[nn] bits, write =0 unmasks (enables) the corresponding status interrupt request, and write =1 masks (disables) the corresponding status interrupt request.

Stop Configuration Register

The TIMER_STOP_CFG register selects the stop mode for each timer. Timers may be stopped abruptly (immediate halt - all modes) or gracefully in PWMOUT modes (single pulse and continuous). The halt is achieved through either a write =0 to the corresponding bit in TIMER_RUN or a write =1 to the corresponding bit in TIMER_RUN_CLR. A read of TIMER_STOP_CFG returns the last value written.

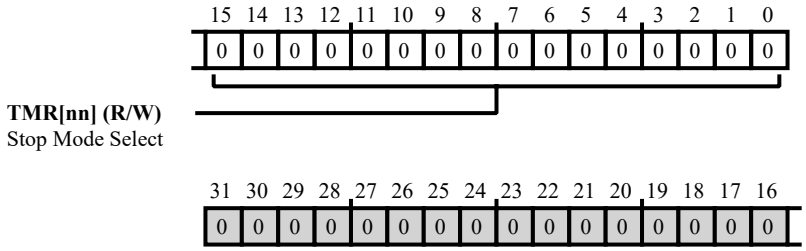

Figure 23-22: TIMER_STOP_CFG Register Diagram

Table 23-34: TIMER_STOP_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	TMR[nn]	Stop Mode Select. For all TIMER_STOP_CFG.TMR[nn] bits, write =0 for graceful termination (PWMOUT modes only), and write =1 for abrupt (immediate halt) on stop.

Stop Configuration Clear Register

This is an alias register, providing a mechanism to clear a specific bit in the TIMER_STOP_CFG register without affecting other bits in TIMER_STOP_CFG. To clear a bit in TIMER_STOP_CFG, software must write a 1 to the corresponding bit of TIMER_STOP_CFG_CLR register. Writing a zero has no effect. Because the TIMER_STOP_CFG_CLR register is a write-only register, the result of any write to this register must be checked by reading the TIMER_STOP_CFG register. A read of the TIMER_STOP_CFG_CLR register returns 0x0000.

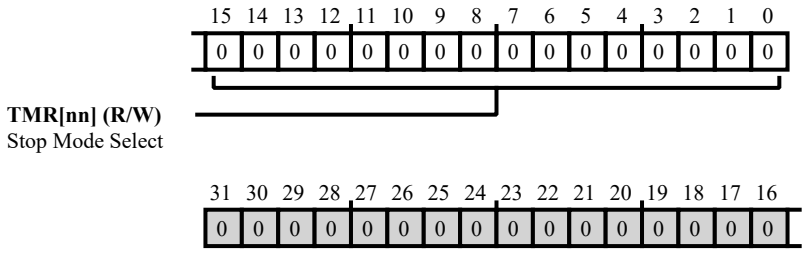

Figure 23-23: TIMER_STOP_CFG_CLR Register Diagram

Table 23-35: TIMER_STOP_CFG_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R0/W1C)	TMR[nn]	STOP_CFG Clear Alias. For all TIMER_STOP_CFG_CLR.TMR[nn] bits, write =0 has no effect, and write =1 for graceful stop in PWMOUT modes (clearing the corresponding stop mode select bit in the TIMER_STOP_CFG register). Using TIMER_STOP_CFG_CLR to clear stop mode bits permits configuring specific timers without influencing the stop mode configuration of other timers.

Stop Configuration Set Register

This is an alias register, providing a mechanism to set a specific bit in the TIMER_STOP_CFG register without affecting other bits in TIMER_STOP_CFG. To set a bit in the TIMER_STOP_CFG register, software must write a 1 to the corresponding bit of the TIMER_STOP_CFG_SET register. Writing a zero has no effect. Because the TIMER_STOP_CFG_SET register is a write-only register, the result of any write to this register must be checked by reading the TIMER_STOP_CFG register. A read of the TIMER_STOP_CFG_SET register returns 0x0000.

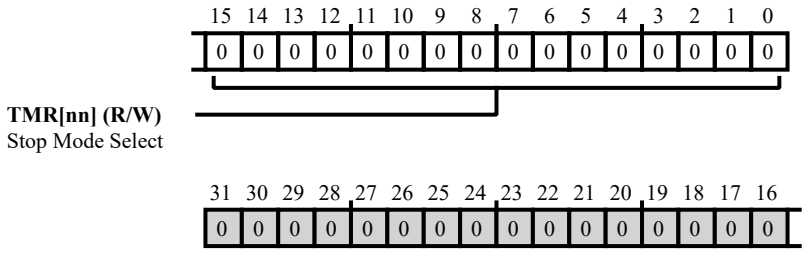

Figure 23-24: TIMER_STOP_CFG_SET Register Diagram

Table 23-36: TIMER_STOP_CFG_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R0/W1S)	TMR[nn]	STOP_CFG Set Alias. For all TIMER_STOP_CFG_SET.TMR[nn] bits, write =0 has no effect, and write =1 for abrupt stop (setting the corresponding stop mode select bit in the TIMER_STOP_CFG register). Using TIMER_STOP_CFG_SET to set stop mode bits permits configuring specific timers without influencing the stop mode configuration of other timers.

Timer n Configuration Register

Each timer has a TIMER_TMR[n]_CFG register that specifies its operating mode. Only write to a TIMER_TMR[n]_CFG register when the corresponding timer is not running.

After disabling a timer operating in PWMOUT mode, verify that the timer has stopped running by checking the start/stop status of the timer in the TIMER_RUN register before writing to the timer's TIMER_TMR[n]_CFG register.

Note that a timer's TIMER_TMR[n]_CFG register may be read at any time.

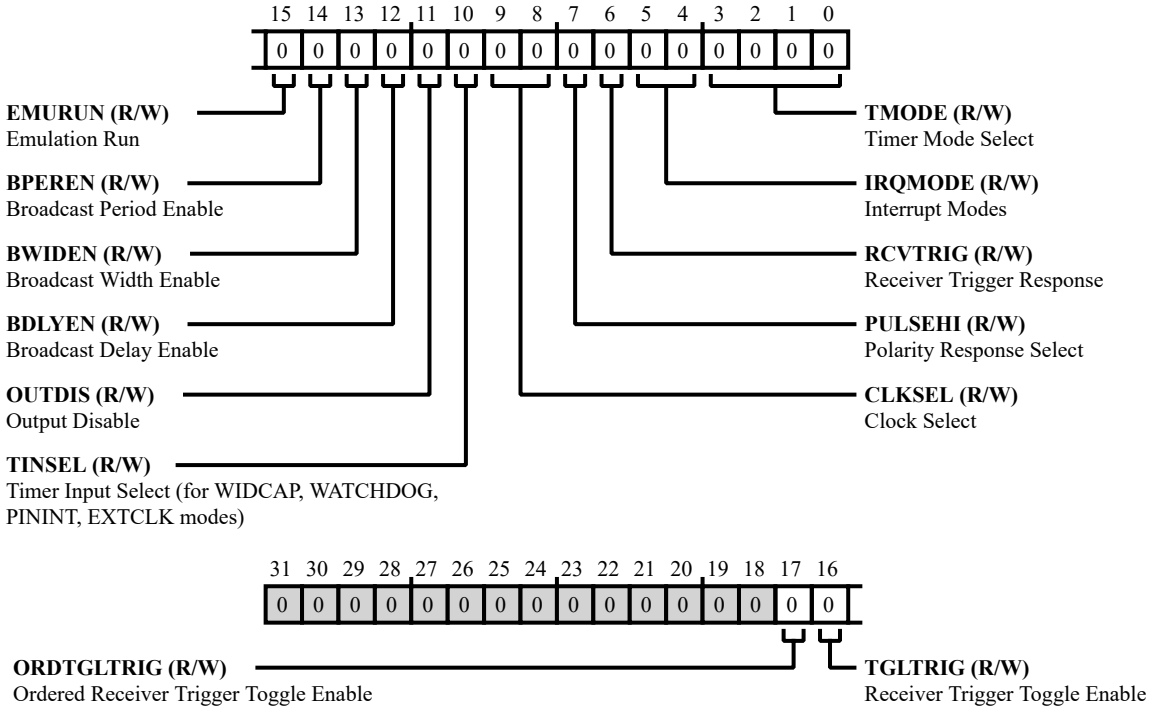

Figure 23-25: TIMER_TMR[n]_CFG Register Diagram

Table 23-37: TIMER_TMR[n]_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W)	ORDTGLTRIG	Ordered Receiver Trigger Toggle Enable. The TIMER_TMR[n]_CFG.ORDTGLTRIG bit controls ordered receive trigger toggle mode. The timer(receiver) state is not toggled by writes to the TIMER_RUN, TIMER_RUN_SET and TIMER_RUN_CLR registers when this bit is enabled.	
		0	No effect
		1	Trigger pulse on trigger receiver 0 starts the timer if it is in the halt state. Trigger pulse in trigger receiver 1 stops the timer if it is running.
16 (R/W)	TGLTRIG	Receiver Trigger Toggle Enable. The TIMER_TMR[n]_CFG.TGLTRIG bit stops the timer if it is running and starts the timer if it is halted (in the stop state). If the TIMER_TMR[n]_CFG.TGLTRIG bit is set, then the setting of the TIMER_TMR[n]_CFG.RCVTRIG bit is ignored.	
		0	Receiver trigger response depends on RCVTRIG bit
		1	Receiver trigger toggles timer state
15 (R/W)	EMURUN	Emulation Run. The TIMER_TMR[n]_CFG.EMURUN bit causes the timer to run (count) during emulation.	
		0	Stop Timer During Emulation
		1	Run Timer During Emulation
14 (R/W)	BPEREN	Broadcast Period Enable. The TIMER_TMR[n]_CFG.BPEREN bit enables updates to the TIMER_TMR[n]_PER register simultaneously across more than one timer.	
		0	Disable Broadcast to PER Register
		1	Enable Broadcast to PER Register
13 (R/W)	BWIDEN	Broadcast Width Enable. The TIMER_TMR[n]_CFG.BWIDEN bit enables updates to the TIMER_TMR[n]_WID register simultaneously across more than one timer.	
		0	Disable Broadcast to WID Register
		1	Enable Broadcast to WID Register

Table 23-37: TIMER_TMR[n]_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	BDLYEN	Broadcast Delay Enable. The `TIMER_TMR[n]_CFG.BDLYEN` bit enables updates to the `TIMER_TMR[n]_DLY` register simultaneously across more than one timer.	
		0	Disable Broadcast to DLY Register
		1	Enable Broadcast to DLY Register
11 (R/W)	OUTDIS	Output Disable. The `TIMER_TMR[n]_CFG.OUTDIS` bit enables or disables the timer pin output buffer.	
		0	Enable TMR Pin Output Buffer
		1	Disable TMR Pin Output Buffer
10 (R/W)	TINSEL	Timer Input Select (for WIDCAP, WATCHDOG, PININT, EXTCLK modes).	
		0	Use TMR Pin Input
		1	Use TMR Alternate Capture Input
9:8 (R/W)	CLKSEL	Clock Select. The `TIMER_TMR[n]_CFG.CLKSEL` bit field selects the TIMER clock to use.	
		0	Use SCLK
		1	Use TMR_ALT_CLK0 as TMR Clock
		3	Use TMR_ALT_CLK1 as TMR Clock
7 (R/W)	PULSEHI	Polarity Response Select. The `TIMER_TMR[n]_CFG.PULSEHI` bit defines specific behaviors of the timer based on the operating mode. For more information, see the specific operating mode in the Programming Concepts section.	
		0	Negative Response or Pulse. A Negative Edge Response or Negative Action Pulse on the TMR pin.
		1	Positive Response or Pulse. A Positive Edge Response or Positive Action Pulse on the TMR pin.
6 (R/W)	RCVTRIG	Receiver Trigger Response. The `TIMER_TMR[n]_CFG.RCVTRIG` bit controls the trigger response. The trigger pulse has no effect (to stop or start the timer) if the timer is already in the requested state.	
		0	Pulse Stops Timer if it is Running
		1	Pulse Starts Timer if it is Stopped

Table 23-37: TIMER_TMR[n]_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5:4 (R/W)	IRQMODE	Interrupt Modes. The TIMER_TMR[n]_CFG.IRQMODE bit field selects the interrupt request mode. Note that any mismatched combination of the TIMER_TMR[n]_CFG.IRQMODE and the TIMER_TMR[n]_CFG.TMODE bits results in no interrupt being generated. In WIDCAP modes, the position of the interrupt is controlled with the TIMER_TMR[n]_CFG.TMODE bit, and the TIMER_TMR[n]_CFG.IRQMODE bit is ignored. Whenever an interrupt is generated, a trigger generator pulse is also occurs, when enabled in the TIMER_TRG_MSK register.	
		0	Active Edge Mode. The timer generates an interrupt at every active edge. The active edge polarity depends on the state of the TIMER_TMR[n]_CFG.PULSEHI bit. Valid for PININT mode only.
		1	Delay Expired Mode. The timer generates an interrupt when the TIMER_TMR[n]_CNT value reaches the value in the TIMER_TMR[n]_DLY register. This mode is valid for all PWMOUT modes.
		2	Width Plus Delay Expired Mode. The timer generates an interrupt when the TIMER_TMR[n]_CNT value reaches the value in the TIMER_TMR[n]_WID register plus the value in the TIMER_TMR[n]_DLY register. (PWMOUT modes only) The timer generates an interrupt if the deasserting edge is within the specified window. (WATCHDOG modes only)
		3	Period Expired Mode. The timer generates an interrupt when the TIMER_TMR[n]_CNT value reaches the value in the TIMER_TMR[n]_PER register. (Continuous PWMOUT and EXTCLK modes only) The timer generates an interrupt if the deasserting edge is outside the specified window.(WATCHDOG modes only)
3:0 (R/W)	TMODE	Timer Mode Select. The TIMER_TMR[n]_CFG.TMODE bit field selects the operating mode of each timer.	
		0-7	Idle Mode
		8	Period Watchdog Mode
		9	Width Watchdog Mode

Timer n Counter Register

The TIMER_TMR[n]_CNT register holds the current timer count. After enabling, the count is re-initialized to either 0x0 or 0x1, depending on the configuration and mode. The TIMER_TMR[n]_CNT register is read-only and may be read at any time (whether the timer is running or stopped). Reading the TIMER_TMR[n]_CNT register returns an atomic 32-bit value.

Depending on the timer operation mode, the counter increment can be clocked by a number of sources, including SCLK, the TMR or alternate capture input pins, ACLK[n]. The counter retains its value after the timer is disabled.

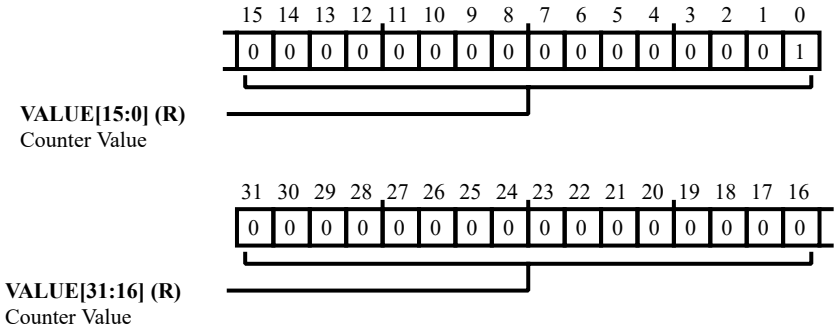

Figure 23-26: TIMER_TMR[n]_CNT Register Diagram

Table 23-38: TIMER_TMR[n]_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Counter Value. The TIMER_TMR[n]_CNT.VALUE bit field holds the current timer count.

Timer n Delay Register

The TIMER_TMR[n]_DLY register holds the delay value for the corresponding timer. This register's use is based on the selected timer mode.

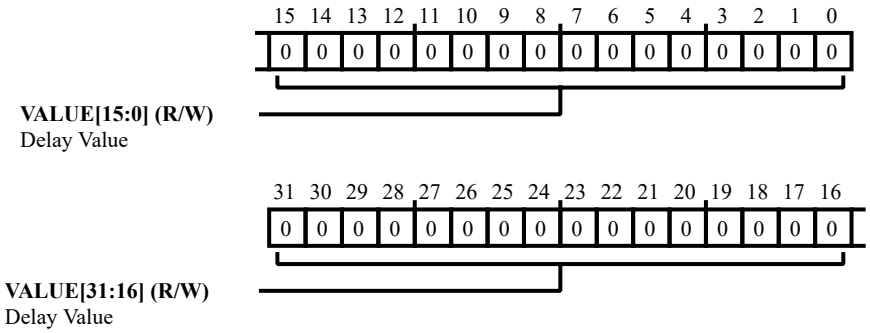

Figure 23-27: TIMER_TMR[n]_DLY Register Diagram

Table 23-39: TIMER_TMR[n]_DLY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Delay Value. The TIMER_TMR[n]_DLY.VALUE bit field holds the delay value for the corresponding timer.

Timer n Period Register

The TIMER_TMR[n]_PER register holds the period value for the corresponding timer. This register's use is based on the selected timer mode.

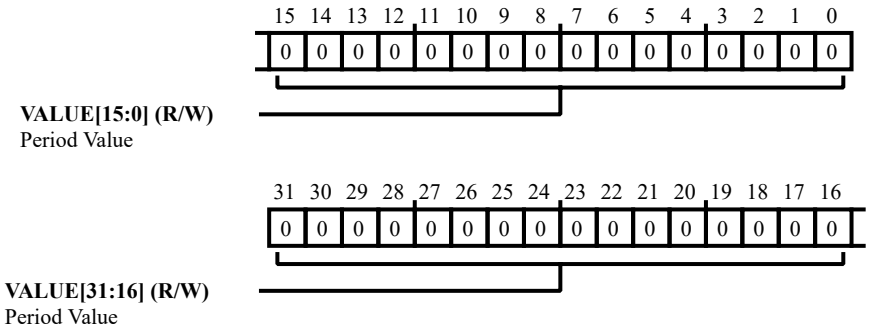

Figure 23-28: TIMER_TMR[n]_PER Register Diagram

Table 23-40: TIMER_TMR[n]_PER Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Period Value. The TIMER_TMR[n]_PER.VALUE bit field holds the period value for the corresponding timer.

Timer n Width Register

The TIMER_TMR[n]_WID register holds the width value for the corresponding timer. This register's use is based on the selected timer mode.

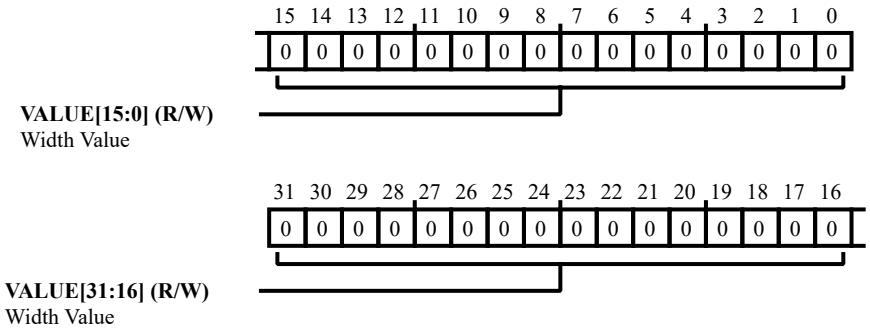

Figure 23-29: TIMER_TMR[n]_WID Register Diagram

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Width Value. The TIMER_TMR[n]_WID.VALUE bit field holds the width value for the corresponding timer.

Trigger Receiver Enable Register

As a trigger receiver, each timer can generate a unique data trigger pulse signal. The TIMER_TRG_IE contains trigger input enable bits for these signals, disabling or enabling the triggers as programmed. The reset value of the TIMER_TRG_IE register is 0xFFFF, masking these triggers after reset.

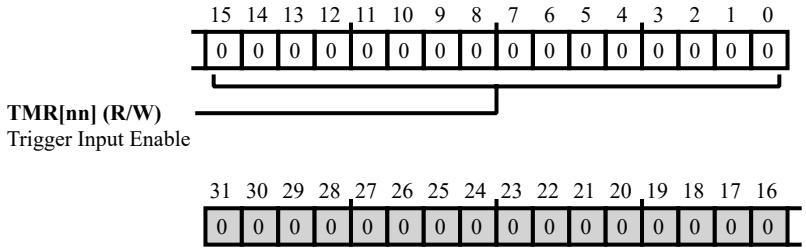

Figure 23-30: TIMER_TRG_IE Register Diagram

Table 23-42: TIMER_TRG_IE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	TMR[nn]	Trigger Input Enable. For all TIMER_TRG_IE.TMR[nn] bits, write =0 disables the corresponding trigger input, and write =1 enables the corresponding trigger input.

Trigger Generator Mask Register

As a trigger generator, each timer can generate a unique data trigger pulse signal. The TIMER_TRG_MSK register contains a trigger mask for these outputs, masking (disabling) or unmasking (enabling) the triggers as programmed. The reset value of the TIMER_TRG_MSK register is 0xFFFF, masking these triggers after reset.

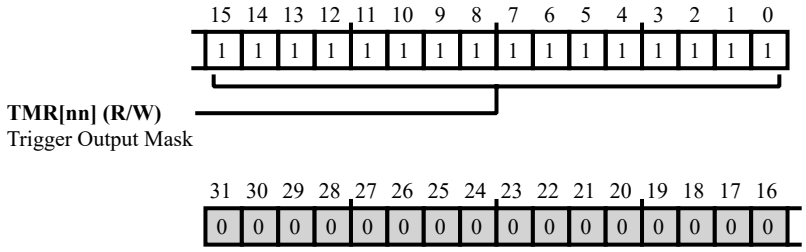

Figure 23-31: TIMER_TRG_MSK Register Diagram

Table 23-43: TIMER_TRG_MSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	TMR[nn]	Trigger Output Mask. For all TIMER_TRG_MSK.TMR[nn] bits, write =0 unmasks (enables) the corresponding data trigger output, and write =1 masks (disables) the corresponding data trigger output.

24 Pulse-Width Modulator (PWM)

The pulse-width modulator (PWM) module is a flexible and programmable waveform generator. With minimal CPU intervention, the PWM peripheral can generate complex waveforms for:

- Motor control
- Pulse-coded modulation (PCM)
- Digital-to-analog conversion (DAC)
- Power switching
- Power conversion

The PWM module has four PWM pairs capable of three-phase PWM generation for source inverters for AC induction and DC brushless motors.

PWM Features

Each PWM generation unit features:

- 16-bit center-based PWM generation unit
- Programmable PWM pulse width
- Single or double update modes
- Programmable dead time and switching frequency
- Two's-complement implementation that permits smooth transition to full-on and full-off states
- Dedicated asynchronous PWM trigger shutdown signal
- Debounce filter option on trip inputs that allows the system programmer to filter out short transient signals
- Expanded clocking system with the PCG and the fractional PLL that can be fed to the PWM using the CDU multiplexer
- The PWM trip 1b input can be conditionally sourced from the TRU generator output. The PWM sync input can also be conditionally sourced using the TRU generator output

Functional Description

The following sections provide details on the functionality of the PWM.

- Architectural Concepts
- Timer Units
- Channel Timing Control Unit
- Output Disable and Cross-Over Modes
- Sync Operation Modes

ADSP-2184x PWM Register List

The Pulse-Width Modulator unit (PWM) includes multiple timers (providing period flexibility) and channels (providing mode, interrupt, and pulse shape flexibility), permitting a wide variety of PWM output options for motor control and other applications. A set of registers governs PWM operations. For more information on PWM functionality, see the PWM register descriptions.

Table 24-1: ADSP-2184x PWM Register List

Name	Description

PWM Definitions

The following definitions are helpful when using the PWM module.

Chopping

Used to simplify the design of isolated gate drive circuits for PWM inverters. If using a transformer coupled power device gate drive amplifier, then the active PWM signal must be chopped at a high frequency.

Dead-Time

A short delay introduced between turning off one PWM signal (for example, AH) and turning on the complementary signal (for example, AL). This short time delay permits turning off a power switch (AH in this case) to completely recover its blocking capability before the complementary switch is turned on. This time delay prevents a potentially destructive short-circuit condition from developing across the dc link capacitor of a typical voltage source inverter.

Duty Cycle

The proportion of on time to the regular interval or period of time (expressed in percent, 100% being fully on). A low duty cycle corresponds to low power, because the power is off for most of the time.

Switching Frequency

The average value of voltage (and current) fed to the load is controlled by turning the switch between supply and load on and off at a fast rate. The longer the switch is on compared to the off periods, the higher the total power supplied to the load.

Architectural Concepts

A clock, whose period is t_{PCLK}, drives the PWM controller. The PWM generator produces four pairs (four high-side and four low-side) of PWM signals on the eight PWM output pins. Each high and low pair signal constitutes a channel. For example, the `PWM_AL` and `PWM_AH` signals make up channel A, and the `PWM_BL` and `PWM_BH` signals make up channel B, and so on.

Each pair of channel outputs references either a main timer or an independent timer. These timers operate on a switching frequency determined by the `PWM_TM0` through `PWM_TM4` registers. There are two duty registers for every PWM output. The registers enable generation of symmetrical or asymmetrical waveforms. The waveforms produce lower harmonic distortion in three-phase PWM inverters, with minimal CPU intervention.

Block Diagram

The ***PWM Block Diagram*** figure shows a block diagram that represents the main functional blocks of the PWM controller.

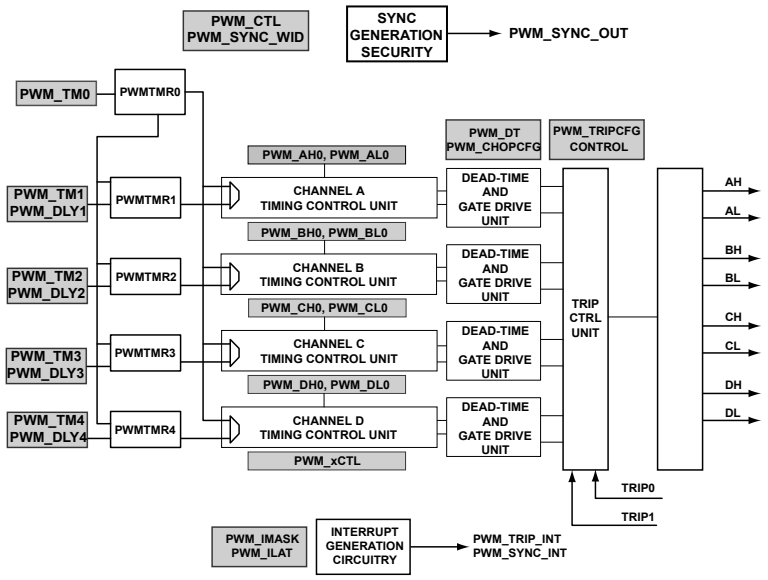

Figure 24-1: PWM Block Diagram

The following list describes the primary diagram blocks.

- Each pair of PWM signals references either the main timer or the independent timer.
- PWMTMR0 is the main timer and can trigger the delayed start of the other timers.
- Timing control units, one for each channel, together form the core of the PWM. The unit generates the required complex waveforms on the high-side and low-side outputs for the respective channel.
- Dead-time insertion occurs after generating the ideal PWM output pair.
- The gate drive unit generates the high-frequency chopping signal and then mixes it with the required PWM output signals.
- The PWM shutdown and interrupt controller manage the various PWM shutdown modes for the timing unit and generates the needed interrupt signals.
- The PWM sync pulse control unit generates the internal `PWM_SYNC` pulse and also controls whether the external `PWM_SYNC` input pulse is used.

Enhanced PWM Clocking

To support low jitter and high precision audio clock-based PWM generation for audio applications, an expanded clocking scheme is used for the Precision Clock Generator (PCG) and Fractional PLL (Frac-N PLL) clocks. The clocks input the signals to the PWM clock using the chip CDU multiplexer on the CDU clock output, which is connected to the main PWM input clock PCLK. The default clock for CDU clock output remains the system clock, SYSCLK.

The alternate clock sources are 16 PCG clocks: eight from each of the individual digital audio interface instances (DAI0 and DAI), from each PCG output, and one Frac-N PLL clock output. The 16 PCG clock sources are multiplexed and the resulting output is again multiplexed with the

Frac-N PLL clock output (FPLL_OUT) using a 2:1 multiplexer. The multiplexer control bits are derived from the MISCREG_CLK_MUX_SEL.PCG_CLKSELFMISCREG_CLK_MUX_SEL.PCG_CLKSEL and MISCREG_CLK_MUX_SEL.PCG_CLKSELF bit fields.

Synchronizers between SYSCLK and PCLK are provided for all system-connected PWM signals using MMRG, SEC, TRU and CTI. The *Enhanced PWM Clocking Diagram* illustrates the enhanced clocking scheme.

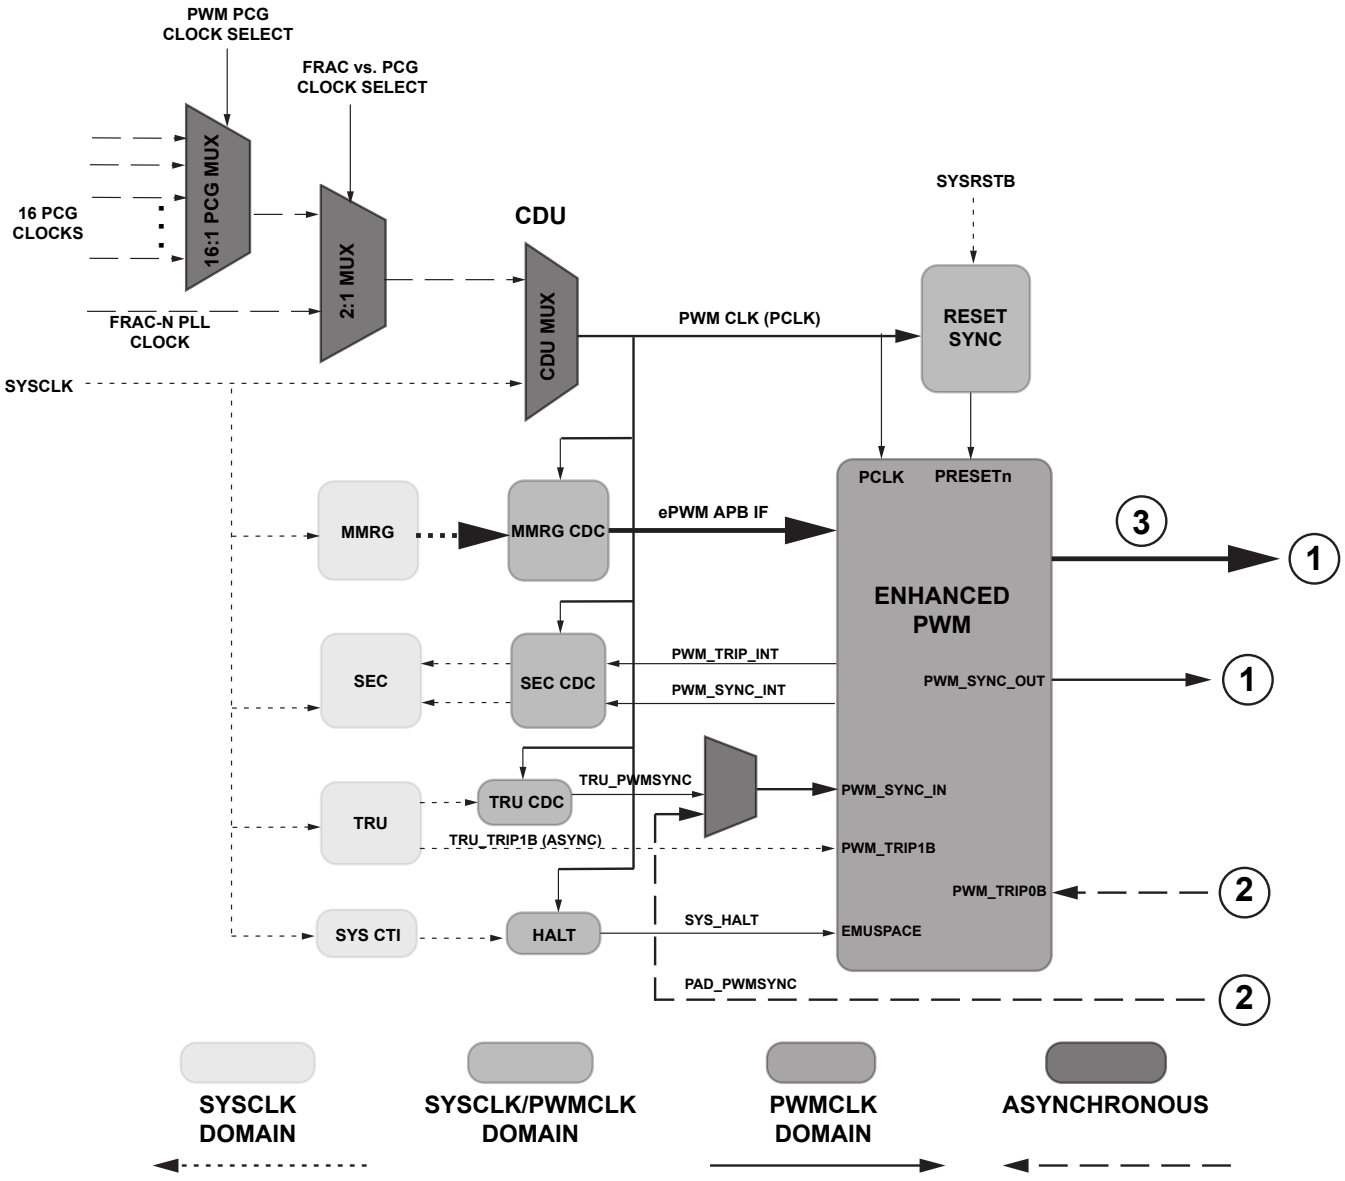

Figure 24-2: Enhanced PWM Clocking Diagram

1	To PINMUX and PADS (Combo path)
2	From PADS (Asynchronous)
3	PWM CHANNELS (xH, xL, x = A, B, C, and D)

CAUTION: Engineers should not configure the PWM_TMx [Timer (0-4) Period Register] to less than two. This configuration results in PWM waveform periods that exceed 125 MHz, having a minimum period of 2 ns, and a total period of 2*TMx (2 * 2 * 2 ns = 8 ns). The processor has a pad limitation of 125 MHz.

Timer Units

Five timers make up the time base for the PWM module. The main timer, PWMTMR0 operates at a switching frequency determined by the period register PWM_TM0. The four remaining timers (PWMTMR1 through PWMTMR4) can operate at independent switching frequencies determined by their respective registers.

The respective time registers (PWM_TM1 through PWM_TM4) can be programmed to work at a multiple of the main timer frequency. In this case, the PWM_DLYA through PWM_DLYD registers control the lead-lag phase of a given timer based on the main timer PWMTMR0.

NOTE: The delayed operation of a timer requires one of the following:

- The register value of the timer must be equal to the PWM_TM0 register value.
- The PWM_TM0 value must be an integer multiple of each register of the timer. Non-integer multiples are not allowed.

PWM Timer Period (PWM_TM) Registers

The 16-bit read/write PWM period registers (PWM_TM0 through PWM_TM4) control the PWM switching frequency. The fundamental timing unit of the PWM controller is t_{PCLK}. Therefore, the time increment (t_{PCLK}) is 10 ns for a 100-MHz system clock (PCLK) frequency, f_{PCLK}. The value written to the register of a timer is effectively the number of t_{PCLK} clock increments in one half of a PWM period. The following equation describes the required timer register value as a function of the desired PWM switching frequency (f_{PWM}):

$$PWM_TM = f_{PCLK}/2 \times f_{PWM}$$

Therefore, the PWM switching period (T_s) is:

$$T_s = 2 \times PWM_TM \times t_{PCLK}$$

For example, for an f_{PCLK} of 100 MHz and a desired PWM switching frequency (f_{PWM}) of 10 kHz (T_s = 100 ms), the correct value to load into the timer register is:

$$PWM_TM = 100 \times 10^6 \div 2 \times 10 \times 10^3 = 5000$$

The largest value that can be written to the 16-bit timer register is 0xFFFF = 65,535. For an f_{PCLK} of 100 MHz, this value corresponds to a minimum PWM switching frequency of:

$$f_{PWM(min)} = 100 \times 10^6 \div 2 \text{ x } 65535 = 762 \text{ Hz}$$

NOTE: Timer register values of 0 and 1 are not defined. Do not use these values when the PWM outputs or PWM is enabled.

Timer Unit Operation

The PWM timers are up-down counters, and they operate on the peripheral clock with a period of t_{CK}. The period of the PWM timer is divided into two halves. In the first half, the timer roughly counts down from PWM_TMx/2 to –PWM_TMx/2. During this half, the PWM_STAT.TMR0PHASE through PWM_STAT.TMR4PHASE bits are held at 0. In the second half of the period, the timer roughly counts up from –PWM_TMx/2 to PWM_TMx/2. The PWM_STAT.TMR0PHASE through PWM_STAT.TMR4PHASE bits indicates a 1 during this half.

The actual partition of the periods varies slightly between odd and even values of the half-period, in the PWM_TM1 - PWM_TM4 registers.

If a timer register value is odd, for example 11, then that timer loads +5 at the beginning of the period. The timer counts down from +5 to –5 in the first half, reloads –5 at the midpoint and counts up from –5 to +5 in the second half. The reload values at the period and mid-period boundaries are the same as the previous count. The timer counts 2 × 11 half-periods = 22 total counts in the entire period as shown in the ***Operation of Timer for Odd Value of PWM_TM*** figure.

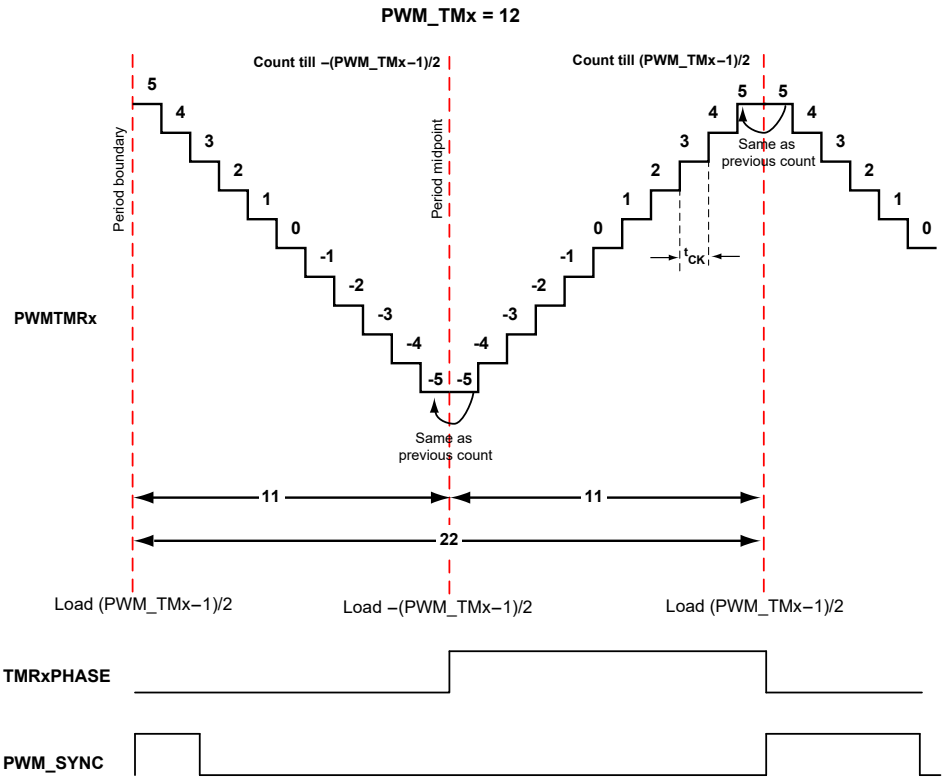

Figure 24-3: Operation of Timer for Odd Value of PWM_TM

When the timer register value is even, for example 12, then that timer loads +5 at the beginning of the period. The timer counts from +5 to –6 in the first half, reloads –5 at the midpoint and counts up from –5 to +6 in the second half. The reload values at the period and mid-period boundaries are different from the previous count. It counts 2 × 12 half-periods = 24 total counts in the entire period as shown in the ***Operation of Timer for Even Value of PWM_TM*** figure.

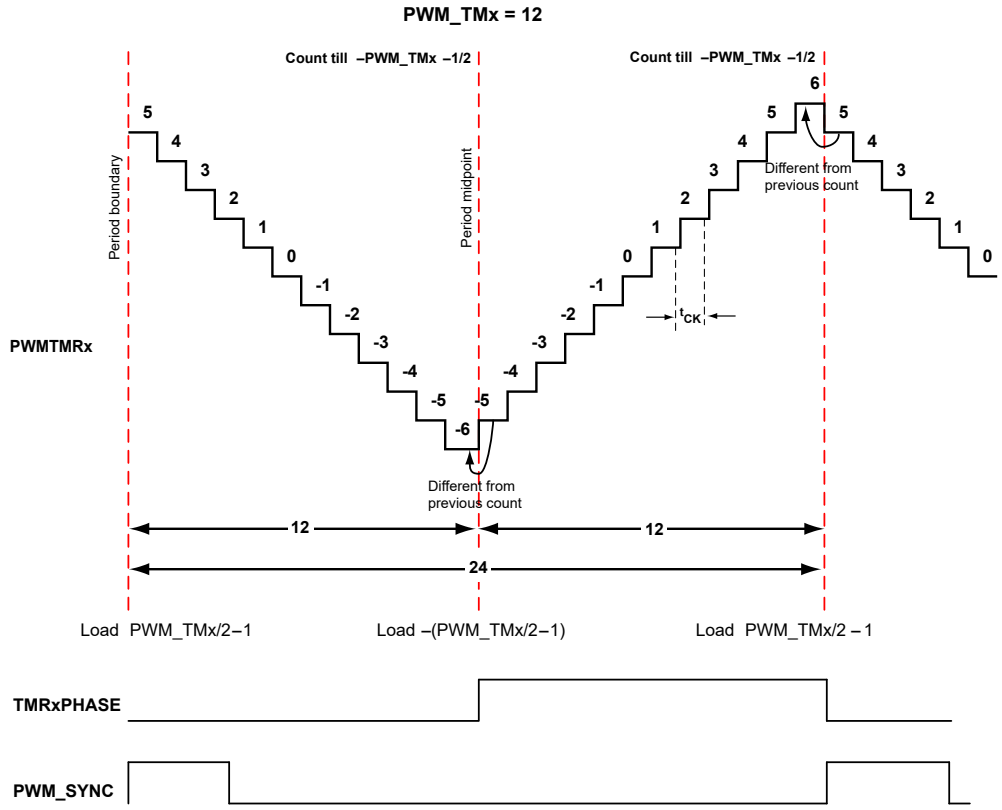

Figure 24-4: Operation of Timer for Even Value of PWM_TM

NOTE: In the operation discussed in this section, double-buffering of all channel registers and the timer registers takes place at the period boundary of the respective timers.

Phase Offset Control

The PWM timers (PWMTMR1 through PWMTMR4) can operate with a programmable phase lag relative to the main timer, PWMTMR0. To implement phase offset for a channel, use the counter-registers for channel delay (`PWM_DLYA` - `PWM_DLYD`) with the PWMTMR0 and set the `PWM_CTL.DLYAEN` bit to l.

Phase offset works as follows.

1. If phase lag is used for channel A (and channel A uses PWMTMR1 to generate a duty cycle), when PWMTMR0 reaches its period boundary, it triggers the `PWM_DLYA` register. The register counts out the number PCLK cycles that are equal to the value programmed in the `PWM_DLYA` register.
2. At the end of this count, the `PWM_DLYA` register sends out a trigger to PWMTMR1. It receives a synchronization pulse in every period of PWMTMR0 at a point delayed from its period boundary by the value in the `PWM_DLYA` register.

For more information on how channels can reference different timers for their outputs, see Channel Timing Control Unit.

NOTE: Satisfy the following conditions when using this feature on timer y for channel Y relative to PWMTMRx.

- Program the PWM_DLY[n] register to a value less than 2 × PWM_TM[n].
- PWM_TM0 = N × PWM_TM[n], where N is an integer.

The function of PWM_TM[n] (PWMTMR1 in the example) differs in cases where PWM_TM0 = PWM_TM1 (Case 1) to cases where PWM_TM0 = N × PWM_TM1 (Case 2). The following examples describe both cases.

Case 1: PWM_TM0 = PWM_TMy

When PWM_TM0 = PWM_TMy, PWMTMRy restarts its period after receiving the synchronization pulse from the channel delay register (PWM_DLY[n]). If the trigger from the PWM_DLY[n] register is late, PWMTMRy holds its count until the trigger occurs. If the trigger is a bit early, PWMTMRy reloads without regard to whether it has completed its current period. As a result, PWMTMRy resyncs with PWMTMR0 with the phase lag programmed in the PWM_DLYA register in every one of its periods.

In this case, the expiration of the delay registers (PWM_DLY[n]) is the period boundary of PWMTMRy. Now, all the double buffered registers related to the given channel update (except the delay registers which are double buffered at the period boundary of PWMTMR0).

The *Phase Offset Control Using DELAY* figure shows an example where:

- PWM_TM0, PWM_TM1, and PWM_TM2 are programmed with the same value.
- PWM_DLYA and PWM_DLYB are programmed with values DELAY1 and DELAY2 respectively, such that DELAY2 > DELAY1.
- The outputs of Channel A are referenced to PWMTMR1. The outputs of channel B are referenced to PWMTMR2.

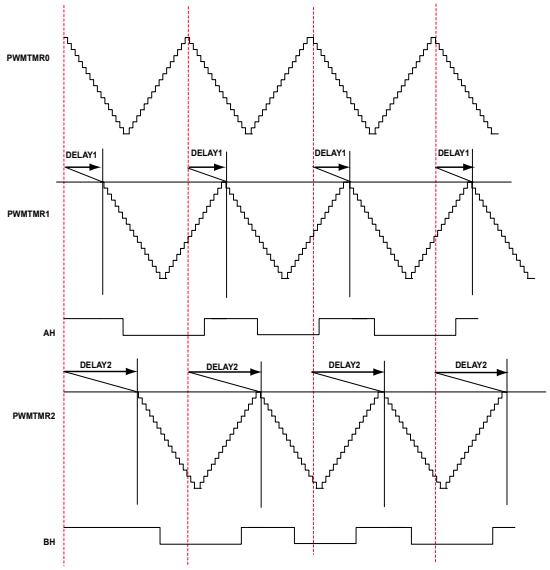

Figure 24-5: Phase Offset Control Using DELAY

The delay registers are double buffered and the new value of DELAY reloads at the period boundary of PWMTMR0. The two options exist when the new value is different from the older one. The behavior of

PWMTMRy in both these cases is discussed. The ***Impact of New DELAY Value on Timer Count for Equal Timer Periods*** figure shows the behavior in the two cases. It is assumed that channel B references its outputs to PWMTMR0 and channel A references its outputs to PWMTMR1.

1. The new delay value is higher than the previous value. Here the corresponding PWMTMRy allows more than one time period between consecutive triggers from the channel delay (`PWM_DLYA` - `PWM_DLYD`) registers. In this case, after reaching its period boundary, PWMTMRy holds its count at the period boundary and waits for the trigger from the channel delay register. The ***Impact of New DELAY Value on Timer Count for Equal Timer Periods*** figure shows case A functionality.
2. The next delay value programmed is smaller than the previous value. Here, the corresponding PWMTMRy allows only less than one time period between consecutive triggers from the channel delay register. Though the trigger comes earlier in this case, before PWMTMRy has counted out one full period, it reloads and starts its period again. The ***Impact of New DELAY Value on Timer Count for Equal Timer Periods*** figure shows case B functionality.

Therefore, PWMTMR1 waits and obeys a synchronization pulse from the `PWM_DLYA` register in every one of its periods.

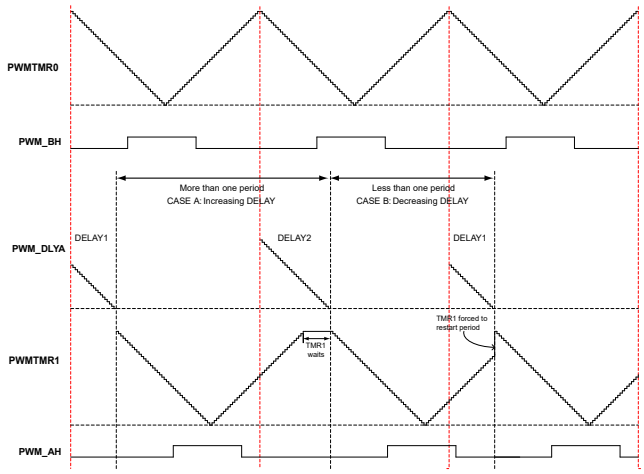

Figure 24-6: Impact of New DELAY Value on Timer Count for Equal Timer Periods

Case 2: PWM_TM0 = N x PWM_TMy

In this case, within a single period of PWMTMR0 a program can fit multiple periods (N) of PWMTMRy. Additionally, the channel delay register is triggered only once every N periods of PWMTMRy.

The operation is as follows: Every Nth period of PWMTMRy, PWMTMRy expects a synchronization pulse from the `PWM_DLY[n]` register. When this register counts out that period and the trigger has not yet arrived, PWMTMRy waits at the end of the period for the trigger. PWMTMRy starts counting down once the trigger arrives. If the trigger comes earlier, PWMTMRy restarts immediately without waiting to complete the period count.

In the intervening periods, PWMTMRy operates independently. As the period ends, PWMTMRy reloads and starts the next period without intervention from the channel delay register.

The *Impact of DELAY Value Change for the Multiple Timer Periods* shows an example with N = 2. PWMTMRy syncs up with PWMTMR0 every second period, and is free running across every odd period boundary.

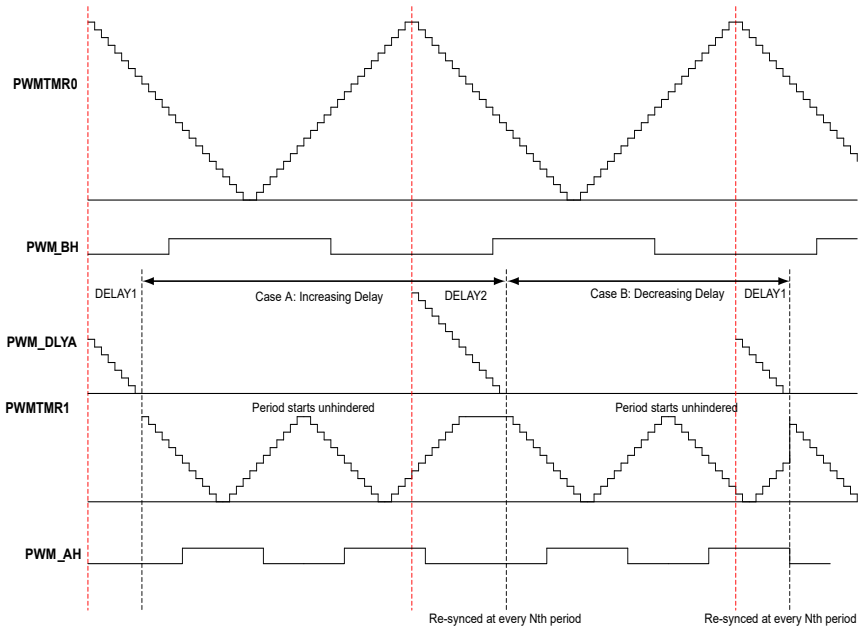

Figure 24-7: Impact of DELAY Value Change for Multiple Timer Periods

Channel Timing Control Unit

The channel timing control unit is the core of the PWM. There are four separate channels, each channel controlling a pair of output signals – the high-side output and the low-side output.

Channel Control

The `PWM_CHANCFG` register controls the static configuration of all the channels and is initialized once before the beginning of a PWM operation.

NOTE: The `PWM_CHANCFG` register is not double buffered. Do not change the contents of the register once the PWM is enabled.

Each channel works with a reference timer base. The time base can be either the main timer PWMTMR0 or the appropriate PWMTMRx. Configure the time base with the `PWM_CHANCFG.REFTMRA` bit field as follows.

- Channel A works with PWMTMR0 or PWMTMR1
- Channel B works with PWMTMR0 or PWMTMR2
- Channel C works with PWMTMR0 or PWMTMR3
- Channel D works with PWMTMR0 or PWMTMR4

The double-buffered channel control registers (`PWM_ACTL` through `PWM_DCTL`) contain bits that control the dynamic pulse behavior of the channel outputs. These registers have bits that enable or disable outputs and select the pulse position of outputs (explained in the following section).

Pulse Positioning and Duty Cycle Registers

The PWM uses the PULSEMODEHI and PULSEMODELO bit fields of the PWM_ACTL - PWM_DCTL registers to define the region within the timer period where the output pulses are positioned.

- When the PWM_CHANCFG.MODELSC bit is 0, the PWM uses the PULSEMODEHI field to specify the pulse positioning for both the high-side and low-side outputs of the channel.
- When the bit is 1, the PWM uses PWM_ACTL.PULSEMODELO to define the pulse positioning for the low-side output of the channel. It uses the PWM_ACTL.PULSEMODEHI to define the pulse positioning for the high-side output of the channel.

Each channel output has two duty-cycle registers: PWM_AH0 and PWM_AH1 for the high-side output, and PWM_AL0 and PWM_AL1 for the low-side output. These registers determine the width of the output pulses. When the PWM_CHANCFG.MODELSC bit is 0, the high-side duty-cycle registers are used to determine the width of the output pulse for the low side. The duty cycle range that can be programmed into these registers is between – PWM_TM[n]/2 and + PWM_TM[n]/2 , when ignoring dead time.

When including dead time for channel A, for PULSEMODEs 00 and 01, the programmed duty cycle is modified. The range is limited between the values [–PWM_TM[n]/2 + PWM_CHA_DT] and [+PWM_TM[n]/2 + PWM_CHA_DT] considering the high-side output. For PULSEMODEs 10 and 11, the high-side duty cycle registers range is limited between values [PWM_TM[n]/2 + PWM_CHA_DT] and [–PWM_TM[n]/2 – PWM_CHA_DT].

The following section explains dead time in detail.

- Switching Dead Time (PWM_DT) Register

NOTE: Values programmed into these registers that fall outside these limits result in over or under modulation.

Duty Cycle and Pulse Positioning Control

The PWM_ACTL.PULSEMODEHI and PWM_ACTL.PULSEMODELO fields control how the duty cycle registers modify the waveform of the high and low-side outputs. (The PWM_ACTL.PULSEMODEHI and PWM_ACTL.PULSEMODELO fields are referred to as *pulse mode* in the subsequent discussion.)

- Pulse mode = 00 – Produce a symmetrical pulse waveform around the center of the PWM period. In this mode, PWM uses only one of the duty cycle registers for an output. For example, for the AH output, PWM uses only the PWM_AH0 register. In this mode, the values in the duty cycle registers are scaled such that a value of 0 produces a 50% duty cycle.
- Pulse mode = 01 – Produce an asymmetrical pulse waveform around the center of the PWM period. In this mode, PWM uses both duty cycle registers. For example, for the PWM_AH output, PWM uses the PWM_AH0 and PWM_AH1 registers. In this mode, if the PWM_AH1 register is programmed with the same value as the PWM_AH0 register, the output is identical to the output when pulse mode =00.
- Pulse mode = 10 or 11 – Produce pulse waveforms either on the first half or the second half of the PWM period respectively. PWM uses both PWM_AH0 and PWM_AH1 registers.

  Pulse mode = 10. If the low side works from the low-side duty-cycle registers, strictly adhere to the condition PWM_AL0> PWM_AL1.

In pulse mode = 11. If the low side works from the low-side duty-cycle registers, strictly adhere to the condition PWM_AL0< PWM_AL1.

The ***Pulse Positioning Modes*** figure shows the pulse positioning modes as previously described for PWM_AH. In the figure, DUTY0 is the value in the PWM_AL0 register and DUTY1 is the value in the PWM_AH1 register. The step signal, count, indicates the output of the timer for channel A. In the example, the signal is configured as active high and dead time is zero.

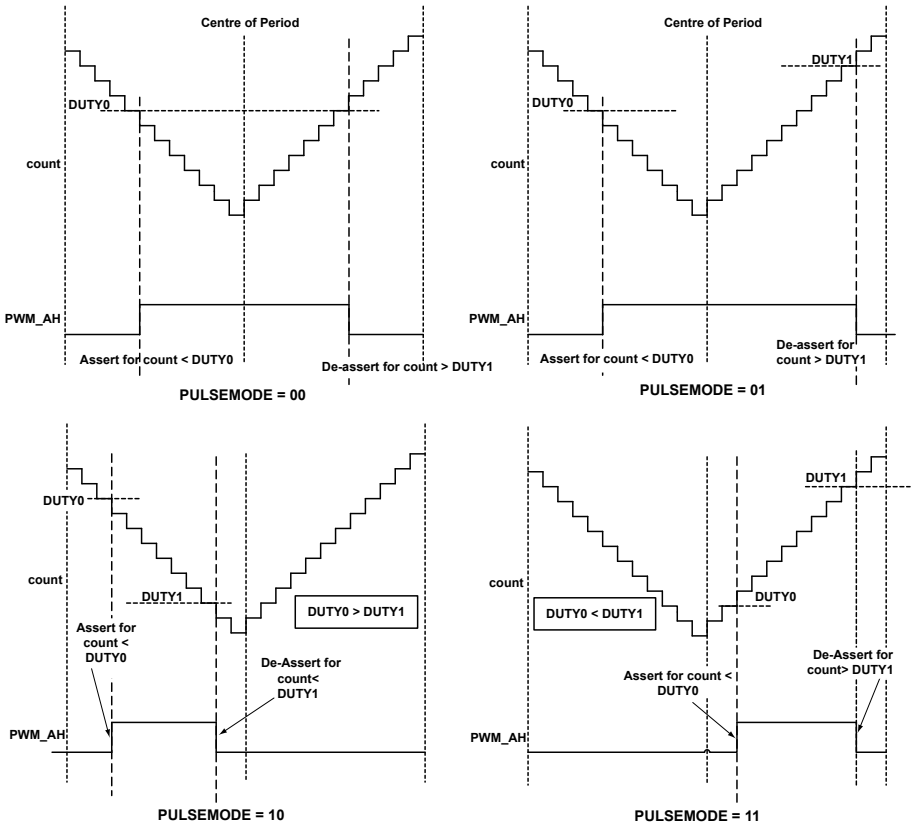

Figure 24-8: Pulse Positioning Modes

Channel Low Side Output Dependent Operation Mode and Dead Time

The low-side output waveform can be programmed to depend on the waveform of the high-side output or to be independent. The PWM uses the PWM_CHANCFG.MODELSC bit to control this functionality.

For example, channel A produces the high-side output PWM_AH and the low-side output PWM_AL. When the PWM_CHANCFG.MODELSC bit =0, the low-side output is also generated using the high-side duty-cycle registers for pulse width, the PWM_ACTL.PULSEMODEHI bits for pulse positioning and the PWM_CHANCFG.POLAH bit for polarity. If the PWM_CH[n]_DT register is 0, the low-side output is an inverted version of the high-side output.

When the PWM_CH[n]_DTregister is programmed with a non-zero value, both the high-side and low-side outputs are scaled symmetrically about the points of transition in the zero dead time case. The PWM scales the output by the value programmed in the PWM_CH[n]_DT register.

The ***Channel Outputs in Dependent Mode for Pulse Mode*** figures show the high and low-side outputs for the case with zero and non-zero dead time for PWM_ACTL.PULSEMODEHI =00 and 01. DUTY0 is the value programmed into the PWM_AH0 register. DUTY1 is the value programmed into the PWM_AH1 register. The PWM_CHANCFG.POLAH bit =1, indicates that both signals are active high. The PWM_CHA_DT register holds the value DT.

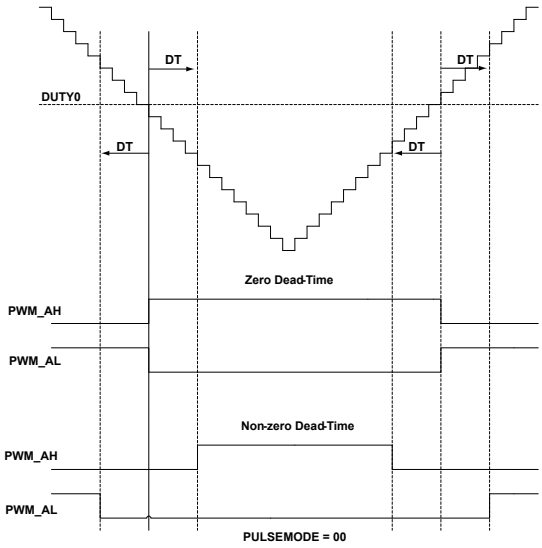

Figure 24-9: Channel Outputs in Dependent Mode for Pulse Mode = 00

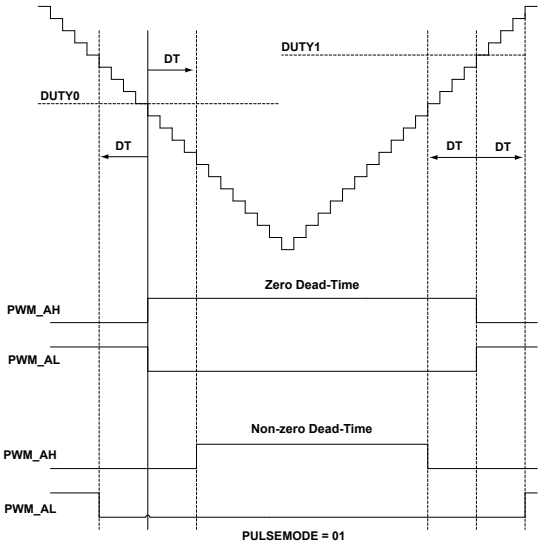

Figure 24-10: Channel Outputs in Dependent Mode for Pulse Mode = 01

The following pair of figures shows the high and low-side outputs for the case with zero and non-zero dead-time for PWM_ACTL.PULSEMODEHI =10 and 11. In the figures, DUTY0 is the value programmed into PWM_AH0 register and DUTY1 is the value programmed into the PWM_AH1 register. PWM_CHANCFG.POLAH is 1 indicating that both signals are active high. The channel dead-time registers hold the value DT.

NOTE: Using dead time, the guidelines for programming the duty-cycle registers in pulse modes 10 and 11 given in Duty Cycle and Pulse Positioning Control are modified as follows:

Pulse mode 10: PWM_xH0 – DT > PWM_xH1 + DT

Pulse mode 11: PWM_xH0 + DT < PWM_xH1 – DT

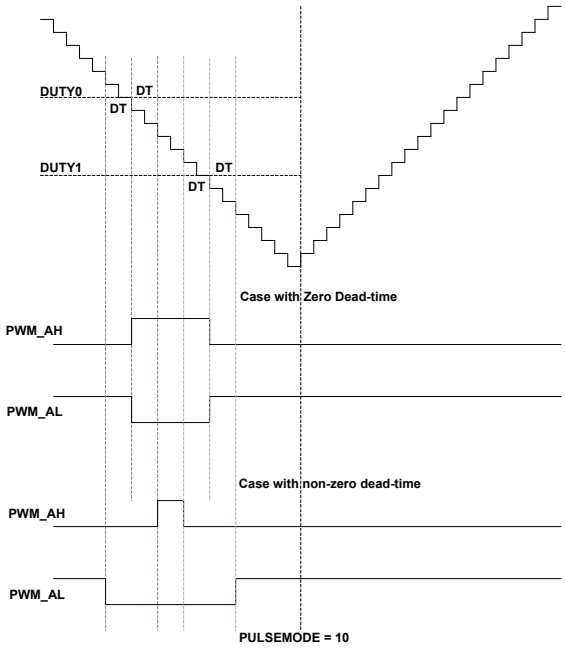

Figure 24-11: Channel Outputs in Dependent Mode for Pulse Mode = 10

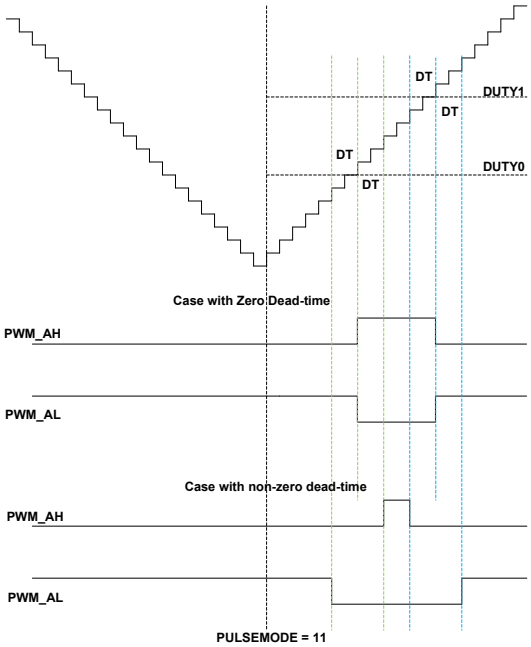

Figure 24-12: Channel Outputs in Dependent Mode for Pulse Mode = 11

Channel High Side and Low Side Outputs, Independent Operation Mode

Independent control of the PWM_AH0 and PWM_AL0 channel outputs is possible by setting the PWM_CHANCFG.MODELSA bit to 1. In this case, the PWM module:

- Generates PWM_AH using the PWM_AH0 register
- Uses the PWM_AH1 register to configure pulse width
- Uses the PWM_ACTL.PULSEMODEHI bit to configure pulse position
- Uses the PWM_CHANCFG.POLAH bit to configure polarity
- Generates PWM_AL using PWM_AL0
- Uses the PWM_AL1 register to configure pulse width
- Uses the PWM_ACTL.PULSEMODELO bit to configure pulse position
- Uses the PWM_CHANCFG.POLAL bit to configure polarity

NOTE: In independent mode, the dead-time insertion is not applicable. The hardware forces dead time to zero.

The ***PWM_AH and PWM_AL in Independent Operation Mode*** figure shows an example of the independent mode of operation where PWM_AH and PWM_AL work from different register bits.

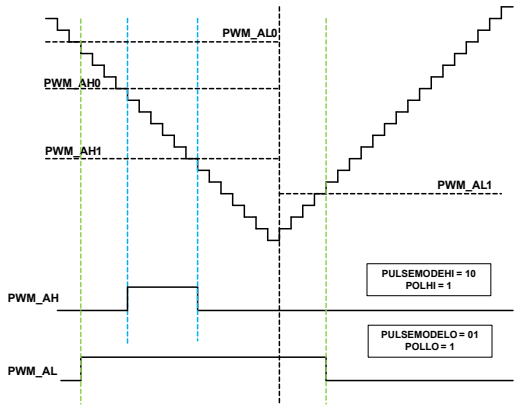

Figure 24-13: PWM_AH and PWM_AL in Independent Operation Mode

PWM_AH and PWM_AL can be positioned in the timer period with a given phase difference between them. Program the PWM_ACTL.PULSEMODEHI and PWM_ACTL.PULSEMODELO bits to different values to achieve this positioning as shown in the ***Channel Outputs Controlled Independently*** figure.

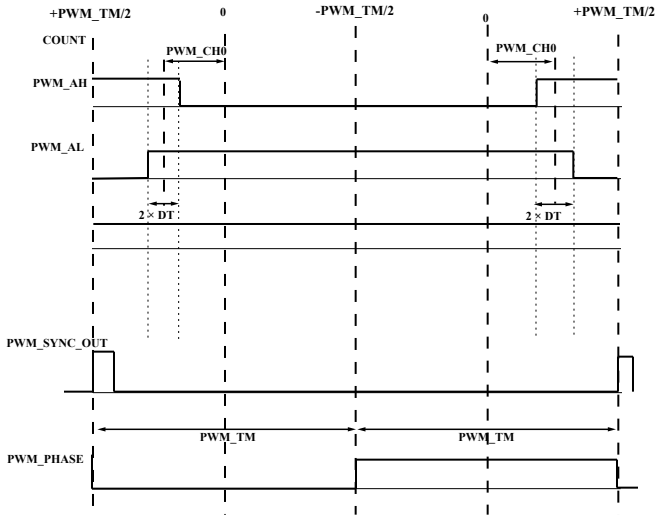

Figure 24-14: Channel Outputs Controlled Independently

Switched Reluctance Motors Application

In typical power converter configurations for switched or variable reluctance motors, motor winding is connected between the two power switches of a given inverter leg. To allow for a complete circuit in the motor winding, turn on both switches at the same time.

PWM uses switched reluctance motors in the following configurations: hard chop, alternate chop, soft chop—bottom on, and soft chop— top on.

The ***Four SR Mode Types, Active High PWM Output Signals*** figure shows the four SR mode types as active high PWM output signals.

Hard chop mode contains independently programmed rising edges of the high and low signals of a channel in the same PWM half cycle. Both signals contain independently programmed falling edges in the next PWM half cycle. The `PWM_CHANCFG.POLAH` and `PWM_CHANCFG.POLAL` bits are programmed to same values.

Alternate chop mode is similar to normal PWM operation except that the PWM channel high and low signal edges are always opposite and are independently programmed. The `PWM_CHANCFG.POLAH` and `PWM_CHANCFG.POLAL` bits are programmed to opposite values. The low-side invert is the only difference between hard chop mode and alternate chop mode.

Soft chop - bottom on uses a 100% duty on the low side of the channel. Soft chop - top on uses a 100% duty on the high side of the channel. Similar to hard chop mode, PWM uses the `PWM_AH0` duty register for the high channel and the `PWM_AL0` duty register for the low channel.

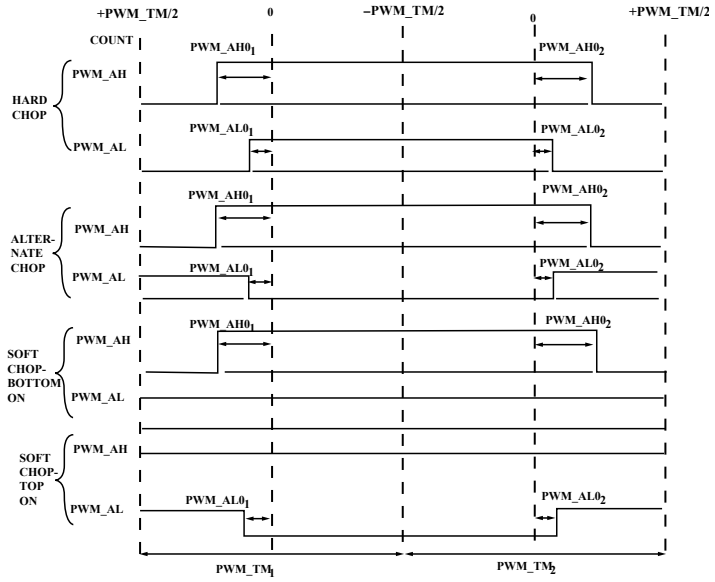

Figure 24-15: Four SR Mode Types, Active High PWM Output Signals

Switching Dead Time (PWM_DT) Register

The second important parameter that must be set up in the initial configuration of the PWM controller is the switching dead time. Dead time is a short delay introduced between turning off one PWM signal (for example, AH) and turning on the complementary signal (for example, AL). This short time delay permits turning off a power switch (AH in this case) to completely recover its blocking capability before the complementary switch is turned on. This time delay prevents a potentially destructive short-circuit condition from developing across the DC link capacitor of a typical voltage source inverter.

The 10-bit, read/write channel A through channel D dead-time registers (`PWM_CHA_DT` through `PWM_CHD_DT`) control the dead time for channel-x. If the value carried by any dead-time register is PWMDT, the dead time, Td, for that channel is:

T_d = PWM_CH[n]_DT × 2 × t_{PCLK}

Therefore, a dead-time value of 0x00A introduces a 200-ns delay (for an PCLK of 100 MHz). The delay occurs between turning off any PWM signal (for example, AH) and then turning on its complementary signal (for example, AL). The length of dead time can be programmed in increments of 2 × t_{PCLK} (or 20 ns for an PCLK of 100 MHz). The channel A through channel D dead-time registers have a maximum value of 0x3FF (1023 decimal) and correspond to a maximum programmed dead time of:

$T_{d(max)}$ = 1023 × 2 × t_{PCLK} = 1023 × 2 × 10 × 10^{-9} = 20.5 µs for an f_{PCLK} rate of 100 MHz.

Write 0 to the `PWM_CHA_DT` through `PWM_CHD_DT` registers to program the dead time.

Duty Cycle with Dead Time Control: Calculations for PULSEMODE 00

The duty cycle registers are scaled so that a value of 0 represents a 50% PWM duty cycle. The switching signals produced are also adjusted to incorporate the programmed dead-time value using the channel dead-time registers

(PWM_CHA_DT through PWM_CHD_DT). The unit in this case produces active low signals so that a low level corresponds to a command to turn-on the associated power device.

The ***Dead Time Between Outputs in Dependent Mode*** figure shows a typical pair of PWM outputs, PWM_AH and PWM_AL. The time values in the figure indicate the integer value in the associated register and can be converted to time by multiplying by the fundamental time increment, t_{CK}. In the example, channel A is working from PWM_TM0.

In the example, the pulse mode is set to 00 so that the switching patterns are perfectly symmetrical about the mid-point of the switching period. The dead time is incorporated by moving the switching instants of both PWM signals away from the instant set by the PWM_AH0 register. Both switching edges are moved by an equal amount (DT × t_{CK}) to preserve the symmetrical output patterns. Also shown is the PWM_SYNC output pulse whose rising edge denotes the beginning of the switching period, and the PWM_STAT.TMR0PHASE bit.

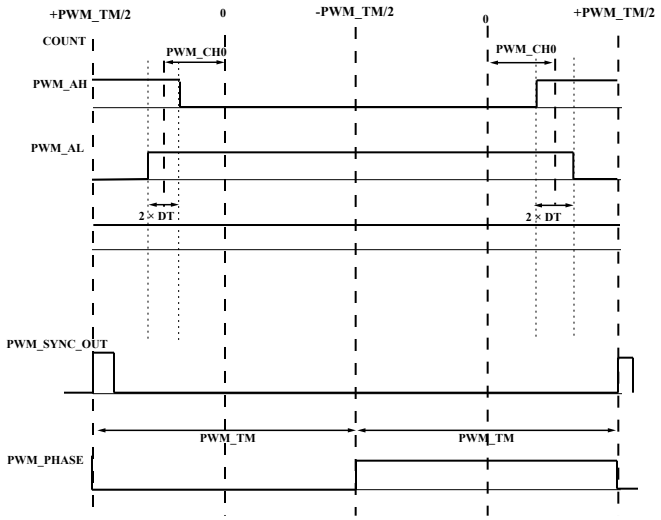

Figure 24-16: Dead Time Between Outputs in Dependent Mode

The PWM timing unit produces the resulting on-times (active low) of the PWM signals over the full PWM period (two half-periods). The figure illustrates this timing. The timing can be written per the following equation.

T_{AH} = (PWM_TM0 + 2 × (PWM_AH0 – PWM_CH[n]_DT)) × t_{CK};

Range of T_{AH} is [0:2 × PWM_TM0 × t_{CK}]

T_{AL} = (PWM_TM0 – 2 × (PWM_AH0 + PWM_CH[n]_DT)) × t_{CK};

Range of T_{AL} is [0:2 × PWM_TM0 × t_{CK}]

$$d_{AH} = \frac{T_{AH}}{Ts} = \frac{1}{2} + \frac{PWM_AH0 - DT}{PWM_TM}$$

$$d_{AL} = \frac{T_{AL}}{Ts} = \frac{1}{2} - \frac{PWM_AH0 + DT}{PWM_TM0}$$

The negative values of T_{AH} and T_{AL} are not permitted and the minimum permissible value is zero, corresponding to a 0% duty cycle. In a similar fashion, the maximum value is T_s, the PWM switching period, corresponding to a 100% duty cycle. Calculation of duty for other pulse modes can be similarly executed.

Special Consideration for PWM Operation in Over-Modulation

The PWM timing unit can produce PWM signals with variable duty cycle values at the PWM output pins. In pulse modes 00 and 01, at the extremities of the modulation process, duty cycles of 0% and 100% occur. In pulse modes 01 and 10, at the extremities of the modulation process, duty cycles of 0% and 50% occur. The modulation is called *full off* when the lower extremity of modulation is set for any PWM timer period for the corresponding channel. The modulation is called *full on* when the higher extremity of modulation is set for any PWM timer period for the corresponding channel. In between, for other duty cycle values, the operation is termed *normal modulation*.

Full On Modulation

In pulse modes 00 and 01, a PWM channel is in full on modulation if the high-side output of that channel is asserted. The output is asserted for the whole duration of the period of the PWM timer that channel is referencing. The conditions for full on modulation are:

- PWM_xH0 - DT > PWM_TMy/2 for pulse mode 00
- PWM_xH1 - DT > PWM_TMy/2 for pulse modes 00 and 01

In pulse mode 10, a PWM channel is in full on modulation if the high-side output of that channel is asserted. The output is asserted for the whole duration of the first half period of the PWM timer that the channel is referencing. The conditions for full on modulation are:

- PWM_xH0 - DT > PWM_TMy/2 for pulse mode 10
- PWM_xH1 + DT < PWM_TMy/2 for pulse mode 10

In pulse mode 11, a PWM channel is in full on modulation if the high-side output of that channel is asserted. The output is asserted for the whole duration of the second half period of the PWM timer that the channel is referencing. The conditions for full on modulation are:

- PWM_xH0 + DT < PWM_TMy/2 for pulse mode 11
- PWM_xH1 - DT > PWM_TMy/2 for pulse mode 11

Full Off Modulation

In pulse modes 00 and 01, a PWM channel is in full off modulation if the high-side output of that channel is deasserted. The output is deasserted for the whole duration of the period of the PWM timer that channel is referencing. The conditions for full off modulation are:

- PWM_xH0 - DT < PWM_TMy/2 for pulse mode 00
- PWM_xH1 - DT < PWM_TMy/2 for pulse modes 00 and 01

In pulse mode 10, a PWM channel is in full off modulation if the high-side output of that channel is deasserted. The output is deasserted for the whole duration of the first half period of the PWM timer that the channel is referencing. In the second half-period, it is deasserted anyway. The conditions for full off modulation are:

- PWM_xH0 - DT < PWM_TMy/2 for pulse mode 10
- PWM_xH1 + DT < PWM_xH0 DT for pulse mode 10

In pulse mode 11, a PWM channel is in full off modulation if the high-side output of that channel is deasserted. The output is deasserted for the whole duration of the second half period of the PWM timer that the channel is referencing. In the first half of the period, it is deasserted anyway. The conditions for full off modulation are:

- PWM_xH0 + DT > PWM_TMy/2 for pulse mode 11
- PWM_xH1 - DT > PWM_xH0 + DT for pulse mode 11

Normal Modulation

All other cases of modulation fall under this category.

Emergency Dead-Time Delays

Sometimes, during modulation transition, it is necessary to insert more emergency dead-time delays to prevent potential shoot through conditions in the inverter. (For example, when the PWM transitions into or out of full on or full off modulation.) Disabling and enabling usage (related to the `PWM_ACTL.DISHI` and `PWM_ACTL.DISLO` bits) also can potentially cause outputs to violate shoot-through condition criteria. Another case is when large values vary the phase delay of a PWM timer. These transitions are detected automatically. If appropriate for safety, an emergency dead-time is inserted to prevent shoot through conditions.

There is another atypical case for the insertion of the additional emergency dead time. It occurs when both PWM signals do not toggle within a dead time of each other. In this case, insert more emergency dead time into one of the PWM signals of a given pair during these transitions. The dead-time delay is inserted into the PWM signal that is toggling into the on-state. In effect, an amount ($2 \times DT \times t_{CK}$) from the rising edge of the opposite output delays the turn-on of this signal. After this delay, the PWM signal is allowed to turn-on provided the desired output is still scheduled to be in the on-state after the emergency dead-time delay.

The ***Over Modulation Transition Example*** figure illustrates two examples of such a transition. In the figure, `PWM_ACTL.PULSEMODEHI` is kept at 1. The `PWM_AH` signal has been in full on modulation for some time and, during the current period, its pulse mode is changed to 10, keeping the full on condition. At the half-period boundary, `PWM_AH` is forced to transition to a deasserted state because pulse mode is 10. An emergency dead-time is inserted on the low-side output.

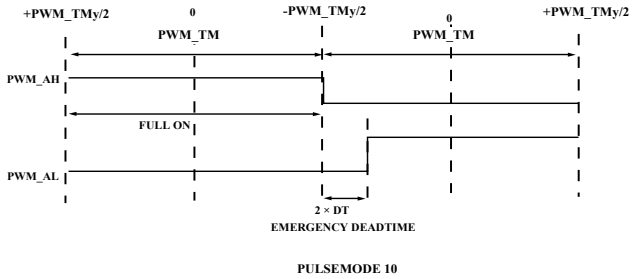

Figure 24-17: Over Modulation Transition Example

Gate Drive Unit

The gate drive unit of the PWM adds features that simplify the design of isolated gate drive circuits for PWM inverters. When using a transformer coupled power device gate drive amplifier, the active PWM signal must be chopped at a high frequency. The `PWM_CHOPCFG` register allows the programming of this chopping mode for high frequency. The chopped active PWM signals can be required for the high-side drivers only, for the low-side drivers only, or for both the high-side and low-side switches. Therefore, independent control of this mode for both high and low-side switches is included with two separate control bits in the `PWM_CHANCFG` register.

The ***High-Side and Low-Side Outputs With Gate Chop Enabled*** figure shows the typical PWM output signals with high-frequency chopping enabled on both high-side and low-side signals. Chopping of the PWM outputs is enabled by setting bits in `PWM_CHANCFG` register. The 8-bit `PWM_CHOPCFG.VALUE` value controls the high frequency chopping. The following equation gives the period of this high frequency carrier.

$T_{chop} = [4 \times (CHOPDIV + 1)] \times t_{CK}$

and the chopping frequency is therefore an integral subdivision of the peripheral clock frequency:

$f_{chop} = f_{CK}/[4 \times (CHOPDIV + 1)]$

The `PWM_CHOPCFG.VALUE` value can range from 0 to 255, corresponding to a programmable chopping frequency rate from 122 kHz to 31.25 MHz for a 125 MHz, f_{CK} rate. Program the gate drive features before enabling the PWM controller. Do not change the gate drive features during normal operation of the controller. Following a reset, clear all bits of the `PWM_CHANCFG` register so that high frequency chopping is disabled, by default.

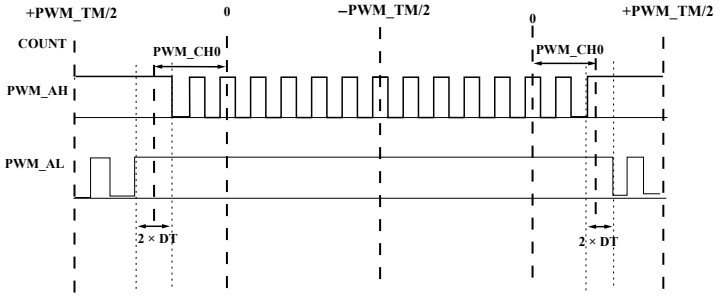

Figure 24-18: High-Side and Low-Side Outputs With Gate Chop Enabled

Output Control Feature Precedence

The order of applying output control features to the PWM signal is important and significant. Use the following order for applying the signal features to the PWM output signal.

1. Duty generation
2. Cross-over
3. High-side or low-side disable
4. Emergency dead-time insertion
5. Gate-drive chopping
6. Polarity

Operating Modes

The PWM generator is capable of operating in the following modes:

- Sync Operation Modes
- Output Disable and Cross-Over Modes
- Emulation Mode

Sync Operation Modes

The PWMx_SYNC pins can operate as internally generated or externally generated. If its internally generated, PWMs can drive the signal to synchronize other PWMs and other devices. If externally generated, the PWMs can be synchronized externally.

External (Triggered) PWM Sync Generation

By setting the PWM_CTL.EXTSYNC bit, the PWM is configured in a mode to expect an external PWM_SYNC signal on the PWM_SYNC_IN pin through the TRU. The trigger source can be any TRU1 trigger generator. Multiple PWM units can be precisely synchronized by selecting the same trigger generator as the sources for each PWM sync trigger receiver. Examples of useful trigger generators include:

- A PWM_SYNC GPIO controller. This option allows synchronizing the PWMs to an off-chip timing source. (The PWM_CTL.EXTSYNC bit must be programmed to 1 to enable the GPIO input.) The PWM_SYNC GPIO pads are connected through the pin mux to configurable trigger generators using PWM generator IDs TRGM_SYS_PWMn_SYNC_IN. Using the TRU, these generators can be connected to the PWM_SYNC trigger recievers in any desired combination.
- A TTU trigger output. This option can include a member of a TTU trigger group, which can also control the timing of other devices such as ADCs, SINC filter inputs, or GP timers. The TTU supports relative trigger delays so that timing offsets can be applied to manage system latencies with precision.

- A general-purpose timer trigger generator
- A software trigger generator. This option allows starting one or more PWM units simultaneously by an MMR write.

The external PWM_SYNC signal only determines the operation of the main timer PWMTMR0.

Synchronize the external sync by setting the PWM_CTL.EXTSYNCSEL bit to 0 (assumes the external PWM_SYNC selected is asynchronous).

The external PWM_SYNC period is expected to be an integer multiple of the value of the PWM_TM0 period register. When the rising edge of the external PWM_SYNC is detected, the PWMTMR0 timer is restarted at the beginning of its period. If the external PWM_SYNC period is not exactly an integer multiple of the internal PWM_SYNC, the behavior of the PWM channel outputs which are referenced to PWMTMR0 are clipped.

CAUTION: Do not change the value of the PWM_CTL.EXTSYNC bit while the PWM is enabled (PWM_CTL.GLOBEN =1).

Output Disable and Cross-Over Modes

Each PWM_ACTL channel control register contains separate enable bits for the high and low-side signals. The PWM module uses the PWM_ACTL.DISHI and PWM_ACTL.DISLO bits in the channel A control register to enable or disable the PWM_AH and PWM_AL outputs respectively. If the disable bit is set (=1), then the corresponding PWM output is disabled, irrespective of the value of the corresponding duty cycle register. This PWM output signal remains in the OFF state as long as the corresponding enable or disable bit is set.

The cross-over bit (PWM_ACTL.XOVR) allows programs to send the low-side output through the high-side output pin and the high-side output through the low-side output pin.

One example uses the following configuration:

- The PWM_AH0 register =0
- The PWM_CHANCFG.MODELSC bit =0
- The PWM_ACTL.DISLO bit =1
- The PWM_ACTL.XOVR bit =1

The low-side output remains off, as in the case without crossover. The difference in cross-over is that the high-side output changes character and becomes like the low-side. What actually occurs is that the low-side duty cycle is sent to the high-side output pins, and the high-side duty cycle is sent to the low side pins. Because the PWM_ACTL.DISLO bit =1, the low-side pin remains off (see Output Control Feature Precedence).

The ***XOVR and DISHI/DISLO Functionality*** figure shows this example. In case 1, PWM_ACTL.XOVR =0; and in case 2, PWM_ACTL.XOVR =1.

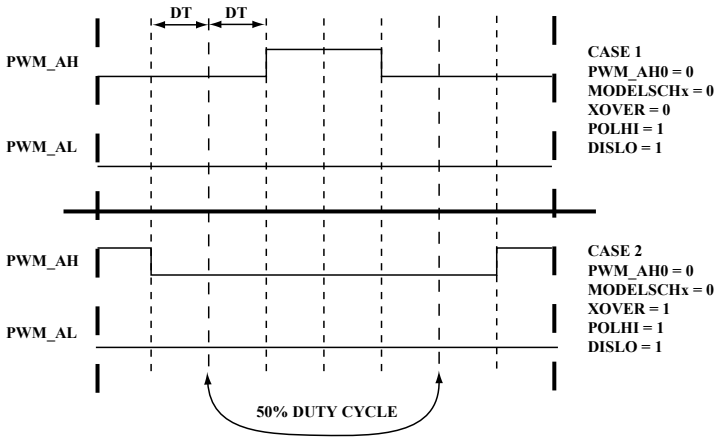

Figure 24-19: XOVR and DISHI/DISLO Functionality

Brushless DC Motor (Electronically Commutated Motor) Control

In the control of an electronically commutated motor (ECM), only two inverter legs are switched at any time. Often, the high-side device in one leg must be switched on at the same time as the low-side driver in a second leg. It is possible to turn on the high-side switch of phase A and the low-side switch of phase B at the same time by:

- Programming identical values for the duty cycles for two PWM channels (for example, `PWM_CH0` = `PWM_CH1`), and
- Setting the `PWM_BCTL.XOVR` bit to crossover the BH and BL pair of PWM signals

To control ECM, normally the third inverter leg (phase C in this example) is disabled for a number of PWM cycles. To implement this function, both the `PWM_CH` and `PWM_CL` outputs are disabled by setting the `PWM_CCTL.DISHI` and `PWM_CCTL.DISLO` bits.

In normal ECM operation, each inverter leg is disabled for certain time periods so that the PWM channel registers change based on the position of the rotor shaft (motor commutation).

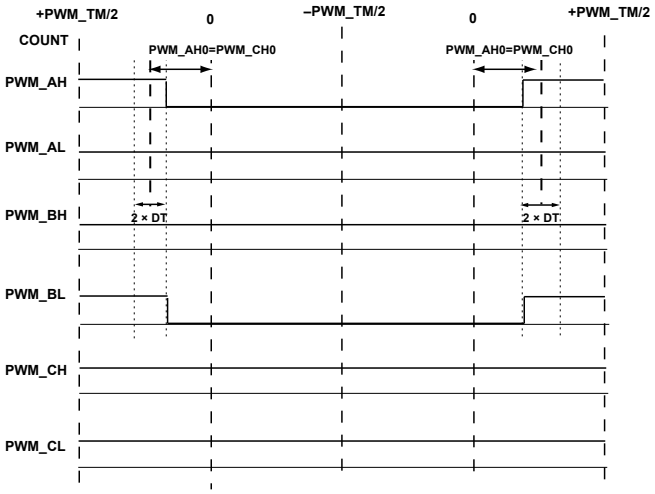

Figure 24-20: ECM Control

Emulation Mode

Depending upon system configuration, a debug halt may be presented to the PWM unit. The PWM has local control of its response to an emulator halt based on the PWM_CTL.EMURUN bit setting.

- PWM_CTL.EMURUN =1. When the processor is halted in emulation mode, the outputs continue to toggle and be driven out of the PWM block. The counters and status register bits are set or reset according to the PWM timer count or period settings.
- PWM_CTL.EMURUN =0. When the processor is halted in emulation mode, the outputs are shut down (enter their inactive state based on polarity), and all counters that affect status register bits are paused.

  The PWM_STAT.EMU bit is set.
- At restart, the PWM counters resume from their paused value. The outputs are still held in their inactive state.

  To reactivate the outputs, clear the PWM_STAT.EMU bit with a W1C operation.

NOTE: The PWM_STAT.EMU bit is not cleared by disabling the PWM or writing 0 to the PWM_CTL.EMURUN bit.

Emergency dead time is not ensured on re-enabling the outputs by a W1C operation to the PWM_STAT.EMU bit.

Event Control

The PWM uses bits in the PWM_IMSK and PWM_ILAT registers for event control. These registers allow masking and show masked interrupt request status bits, respectively. The interrupt status bits are latched and held on the interrupt event. The software must write a 1 to clear the interrupt status bit, usually during the interrupt service routine.

The timer period (TMRxPER) interrupt requests are configured using the PWM_ILAT.TMR0PER - PWM_ILAT.TMR4PER bits. The PWM uses the interrupts to execute an interrupt service routine (ISR) periodically. The ISR updates the PWM channel control and duty registers (according to a control algorithm based on expected operation and sampled existing operation). The TMRxPER interrupts also can trigger an ADC to sample data for use during the ISR.

The PWM uses the PWM_CTL.INTSYNCREF bit field to control the PWM_SYNC interrupt request. The PWM uses the bit field to assign the interrupt request to a system user interrupt of the core. The PWM_SYNC can be configured to be either internal or externally driven using the PWM_CTL.EXTSYNC bit. When configured as an external sync, the signal can be further configured as synchronous or asynchronous using the PWM_CTL.EXTSYNCSEL bit.

As an example, when the PWM_SYNC interrupt is serviced:

- The ADC samples data
- The data is algorithmically interpreted

- New PWM channel duties are calculated and written to the PWM

More sophisticated implementations include different startup, run time, and shutdown algorithms to determine PWM channel duties based on expected behavior and further features.

During the PWM_SYNC interrupt driven control loop, only the channel delay registers, the duty registers, and the channel C high pulse duty register values are typically updated. To see programming limitations on the PWM registers, see the "Register Descriptions".

Status information about the PWM is available in the PWM_STAT register, which stores all status bits, including raw interrupt status bits. In particular, the period boundary of each timer is available, as well as status bits. The PWM uses the status bits to indicate whether the operation is in the first half or the second half of the timer. Additionally, the TRIP status is also available. For more information on TRIP interrupts, see Trip Control Unit .

Trip Control Unit

The PWM output signals can be shut-off in a number of different ways. The trip inputs ($\overline{\texttt{PWM_TRIP[n]}}$) can be mapped to provide either a temporary or permanent shutdown on any channel outputs (hi/lo/pair). This shutdown mechanism is asynchronous, so that the associated PWM output disable circuitry does not go through any clocked logic. This functionality ensures correct PWM shutdown even in the event of a loss of the processor clock. In addition to the hardware shutdown features, the PWM system can be shut down in software with the PWM_CTL.SWTRIP bit.

During any external trip event (if not disabled), the PWM outputs are turned off. When a PWM output is turned off, it means that the output level is held at a polarity opposite that given in the PWM_CHANCFG.POLAH through PWM_CHANCFG.POLDH (channel high side polarity) bits. The PWM sync pulse continues to operate, when it is already enabled. A PWMTRIP interrupt occurs if unmasked, to notify the software of this event. In dependent mode of operation, both high and low-side outputs refer to the channel high side polarity bits.

Even if the clock to the PWM is damaged, an external trip event turns off the PWM outputs. In this case, the PWMTRIP interrupt request may not occur.

The PWM trip unit processes hardware or software fault conditions and shuts down the PWM channel outputs immediately on the occurrence of these conditions. The PWM can enable the shutdown mechanism separately for each channel. The design also allows for a self-restart mechanism to be enabled on a channel. Self-restart reenables the channel outputs following the fault condition (allowed only on hardware trips) when the PWMTMRy that the channel is using reaches its period boundary.

Program the PWM_TRIPCFG.MODE0A bits to specify the restart mechanism for a channel that has been tripped.

1. If the PWM_TRIPCFG.MODE0A bit =0, once tripped, a trip condition is registered on this channel in the PWM_STAT.FLTTRIPA bit and the outputs of that channel are immediately shut down. This condition is called a *fault trip* condition. To resume channel output when a fault trip occurs, write a 1 to clear the PWM_STAT.FLTTRIPA bit. A processor write cannot clear the bit when the trip condition is still active. The raw trip status is available for both pins in the PWM_STAT.RAWTRIP0 register bits.
2. If the PWM_TRIPCFG.MODE0A bit =1, once tripped, a trip condition is registered on this channel in the PWM_STAT.SRTRIPA bit and the outputs of that channel are immediately shut down. This condition

is called a *self-restart trip* condition. If the trip condition is not active at the next period boundary of the PWMTMRy that the channel is using, the status register bit is cleared. The outputs are restored.

In addition to the hardware trip conditions, a global software trip bit in the PWM_CTL register allows for a software-forced fault trip condition. When the global software trip bit is set to 1, irrespective of the values in the PWM_TRIPCFG register, it sets all the PWM_STAT.FLTTRIPA bits and also gates the channel outputs. To remove the trip condition from the channel, perform a W1C on the PWM_STAT.FLTTRIPA bit of the particular channel.

If the PWM_TRIPCFG.EN0A bit is set to 1 to, for any channel, then the occurrence of a fault condition on the PWMTRIPy bit is logged in the PWM_STAT.FLTTRIPA register bit. If the corresponding PWM_IMSK.TRIP0 bit = 1, then an interrupt request is generated. Tripping a channel output does not interfere with PWM_SYNC generation.

The ***Operation Under Hardware Fault Conditions*** figure shows an example where PWMTRIP0 is enabled on channel A as self-restart trip. Channel A works with the PWM_CHANCFG.POLAH bit =1. In period 2, the PWM_AH signal is full on modulated, and tries to rise at the period boundary where the self-restart occurs for the channel. However, since the low-side output of the channel was only recently removed due to a trip, the rise edge on PWM_AH is delayed until the emergency dead-time period is over. PWMTRIP1 is enabled on channel B as a fault trip. Channel B works with the PWM_CHANCFG.POLAH bit =0. PWMTRIP1 stays low for an extended time period. The first processor write to reenable the channel output fails. The second processor write passes since the fault condition has gone away.

NOTE: Dead time is ensured on re-enabling the channel outputs after trip.

NOTE: Programs must not allow changes in the configuration or enable bits of PWM_TRIPCFG register within ± 10 clock cycles of when the external trip pulse toggles. (The configuration or enable bits of PWM_TRIPCFG register select between trip enable and disable). If this time frame is not followed, then unexpected behavior occurs.

Programming Model

The following sections provide general (and some application-specific) programming steps for configuring and using the PWM module.

- Programming Model for Three-Phase AC Motor Control

Programming Model for Three-Phase AC Motor Control

The ***PWM Module and Interaction with System*** figure shows how the PWM unit (green) interfaces to both software (blue) and hardware (yellow). The software configures the unit, calculates duty cycles (Duty A, Duty B, Duty C), and services the interrupts generated by the module (PWM SYNC IRQ, TRIP IRQ). The hardware applies the gate signals (AH, AL, BH, BL, CH, CL) to the inverter and provides an over-current trip signal back to the unit (TRIP0).

The typical three-phase AC motor configuration shown in the ***PWM Module and Interaction with System*** figure applies for both permanent magnet and induction motor types.

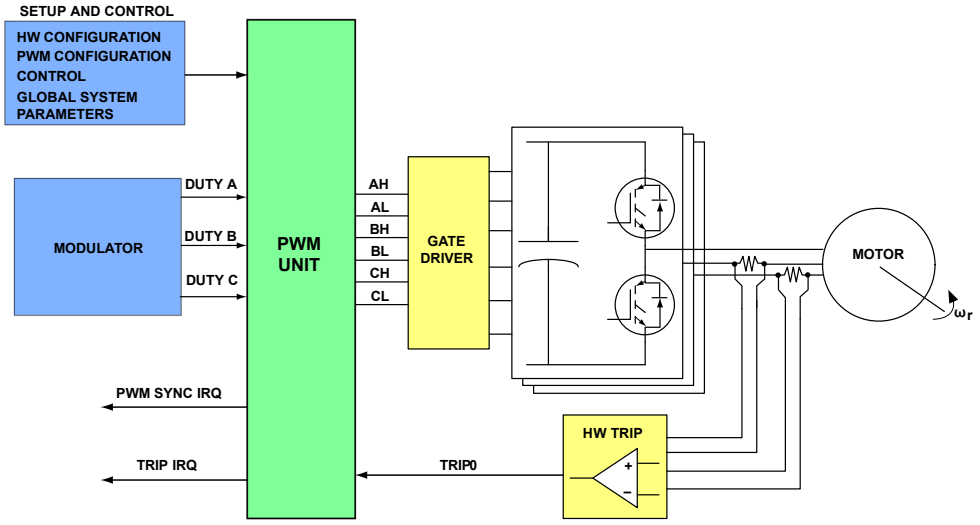

Figure 24-21: PWM Module and Interaction with System

System Parameters

The following system parameters (characteristics) influence the module configuration for this application. This example system features:

- One three-phase AC machine
- B6 inverter
- SVPWM, including both linear- and over-modulation
- Switching frequency of 20 kHz
- Dead time of 1us
- Trip signal generated by hardware
- Active high-level gate drive
- Core frequency of 200 MHz
- Peripheral clock of 100 MHz

System State Sequencing

Managing the system state and sequence of states is critically important when programming the PWM module. The ***PWM System States*** figure provides an overview of these states.

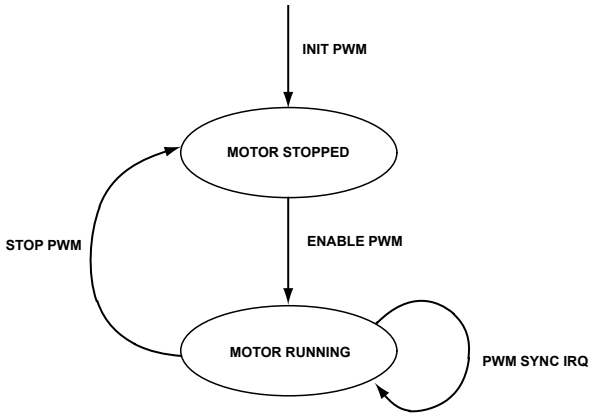

Figure 24-22: PWM System States

As shown in the state diagram, the module configuration is updated on state transitions (indicated by the arrows). The transitions are initialization, motor start, PWM sync interrupt request (on each), and motor stop. The following sections discuss the transitions in detail.

- PWM Initialization for Motor Control
- PWM Enable for Motor Control
- PWM Response to Sync Interrupt for Motor Control
- PWM Disable (and Stop the Motor) for Motor Control

PWM Initialization for Motor Control

The processor must program the PWM at power-up as follows and repeat this programming to bring the PWM and the system into a known (safe) state.

1. Place the PWM module in a safe state and set up synchronization of the module using the following bitwise operations on the `PWM_CTL` and `PWM_CHANCFG` registers:

```
PWM_CTL &= 0xFFE0FF08
PWM_CTL |= 0x20000
PWM_CHANCFG &= 0x80808080
PWM_CHANCFG |= 0x24242424
```

   These operations result in the following bit settings:

   - Disable PWM (`PWM_CTL.GLOBEN` =0)
   - Disable delay for channels A, B, C, D (`PWM_CTL.DLYAEN` through `PWM_CTL.DLYDEN` =0). All phases must run with same phase.
   - Use internal synchronization by timer TMR0 (`PWM_CTL.EXTSYNC` =0, `PWM_CTL.EXTSYNCSEL` =1)
   - The same timer, TMR0 (`PWM_CTL.INTSYNCREF` = b#000) synchronizes all phases.

- Low-side is always the inverse of high-side (PWM_CHANCFG.POLAL through PWM_CHANCFG.POLDL = 1).
- System uses active high gate driver (PWM_CHANCFG.ENCHOPAH through PWM_CHANCFG.ENCHOPDH =1).
- Disable gate chopping (PWM_CHANCFG.ENCHOPAL through PWM_CHANCFG.ENCHOPDL =0). PWM does not use the pulse transformer.

2. Set up the trip and associated interrupt requests using the following bitwise operations on the PWM_TRIPCFG and PWM_ILAT registers:

```
PWM_TRIPCFG &= 0xF0F0F0F0
PWM_TRIPCFG |= 0x1010101
PWM_ILAT &= 0xFFE0FFFC
PWM_ILAT |= 0x1
```

These operations result in the following bit settings:

- All phases must shut down simultaneously in case of fault: (PWM_TRIPCFG.EN0A through PWM_TRIPCFG.EN0D =0, PWM_TRIPCFG.MODE0A through PWM_TRIPCFG.MODE0D =0, PWM_TRIPCFG.EN1A through PWM_TRIPCFG.EN1D =0, PWM_TRIPCFG.MODE1A through PWM_TRIPCFG.MODE1D =0)
- Enable TRIP0 as fault trigger for all channels (PWM_TRIPCFG.EN0A through PWM_TRIPCFG.MODE1D =1).
- For thermal control and synchronization, SW intervention is needed at trip. Do not use automatic restart of any channels.
- Generate an interrupt at trip on TRIP0 (PWM_ILAT.TMR0PER = 1).

3. Configure the PWM channels using the following bitwise operations on the PWM_TRIPCFG and PWM_ILAT registers:

```
PWM_CHA_DT=0x32 PWM_CHB_DT=0x32 PWM_CHC_DT=0x32
PWM_TM0 = 0x9C4
PWM_ACTL = 0xFFFFF0000
PWM_BCTL = 0xFFFFF0000
PWM_CCTL = 0xFFFFF0000
PWM_AH0 = 0x0
PWM_BH0 = 0x0
PWM_CH0 = 0x0
```

These operations result in the following bit settings:

- Configure a dead time of 1 µs (DT =0x32 =0x32)
- Configure a PWM frequency of 20 kHz (assuming a system clock frequency of 100Mhz, so a clock divisor of 5000:1) (PWM_TM0 =0x9C4)

- Disable all outputs (PWM_ACTL.DISHI through PWM_CCTL.DISHI =0, PWM_ACTL.DISLO through PWM_CCTL.DISLO =0)
- Use conventional PWM, disable crossover (PWM_ACTL.XOVR through PWM_CCTL.XOVR =0)
- Use symmetrical pulse position on all outputs (PWM_ACTL.PULSEMODEHI through PWM_CCTL.PULSEMODEHI =0, PWM_ACTL.PULSEMODELO through PWM_CCTL.PULSEMODELO =0)
- Set an initial duty-cycle of 50% (PWM_AH0 through PWM_CH0 =0x0)

PWM Enable for Motor Control

The processor must do the following programming to enable the PWM before starting the motor.

1. Start the PWM timer TMR0 using the PWM_CTL |=0x1 bitwise operation on the PWM_CTL register.

   ADDITIONAL INFORMATION: This operation has the same effect as setting the PWM_CTL.GLOBEN bit =1.

2. Enable six PWM outputs using the following bitwise operations on the PWM_ACTL through PWM_CCTL registers.

   ```
   PWM_ACTL|=0x3
   PWM_BCTL|=0x3
   PWM_CCTL|=0x3
   ```

   ADDITIONAL INFORMATION: These operations have the same effect as enabling high and low-side channel outputs by setting the PWM_ACTL.DISHI through PWM_CCTL.DISHI bits =1 and the PWM_ACTL.DISLO through PWM_CCTL.DISLO bits =1.

3. Enable the PWM TRIP0 interrupt using the PWM_ILAT |= 0x1 bitwise operation on the PWM_ILAT register.

   ADDITIONAL INFORMATION: This operation has the same effect as setting the PWM_ILAT.TRIP0 bit =1

PWM Response to Sync Interrupt for Motor Control

When the PWM sync interrupt occurs, the processor could need to update to the PWM duty cycle with a value calculated by the motor control algorithm. This application uses symmetric pulses position and uses dependent high and low-side output. So, the PWM updates only one register for each phase.

1. Write the new duty cycle value (calculated by motor control algorithm) to the timer when the sync interrupt occurs.

   The following bitwise operations on the PWM_AH0 through PWM_CH0 registers accomplish this task:

```
PWM_AH0 = Duty_A_mc_algorithm_current_value
PWM_BH0 = Duty_B_mc_algorithm_current_value
PWM_CH0 = Duty_C_mc_algorithm_current_value
```

PWM Disable (and Stop the Motor) for Motor Control

The processor must program the PWM as follows to stop the motor, disable the PWM, and disable PWM interrupts. These actions place the PWM and system in a safe, passive state.

1. Disable the PWM timer using the `PWM_CTL &= 0xFFFFFFFE` bitwise operation on the `PWM_CTL` register.

   ADDITIONAL INFORMATION: This operation has the same effect as clearing the `PWM_CTL.GLOBEN` bit =0.

2. Disable all PWM outputs using the following bitwise operations on the `PWM_ACTL` through `PWM_CCTL` registers.

   ```
   PWM_ACTL &= 0xFFFFFFFC
   PWM_BCTL &= 0xFFFFFFFC
   PWM_CCTL &= 0xFFFFFFFC
   ```

   These operations disable PWM outputs where the `PWM_ACTL.DISHI` through `PWM_CCTL.DISHI` bits =1 and the `PWM_ACTL.DISLO` through `PWM_CCTL.DISLO` bits =0)

3. Set the PWM duty-cycle to 50% using the following bitwise operations on the `PWM_AH0` through `PWM_CH0` registers.

   ```
   PWM_AH0 =0x0
   PWM_BH0 =0x0
   PWM_CH0 =0x0
   ```

   These operations have the same effect as clearing the `PWM_AH0.DUTY` through `PWM_CH0.DUTY` bit =0.

4. Disable the PWM TRIP0 interrupt request using the `PWM_ILAT &= 0xFFFFFFFE` bitwise operation on the `PWM_ILAT` register.

   ADDITIONAL INFORMATION: This operation has the same effect as clearing the PWM TRIP0 interrupt request `PWM_ILAT.TRIP0` =0.

ADSP-2184x PWM Register Descriptions

Pulse-Width Modulator (PWM) contains the following registers.

Table 24-5: ADSP-2184x PWM Register List

Name	Description
`PWM_ACTL`	Channel A Control Register

Table 24-5: ADSP-2184x PWM Register List (Continued)

Channel A Control Register

The PWM_ACTL register selects the low and high side output pulse mode, enables low and high side output, and enables low/high side output crossover.

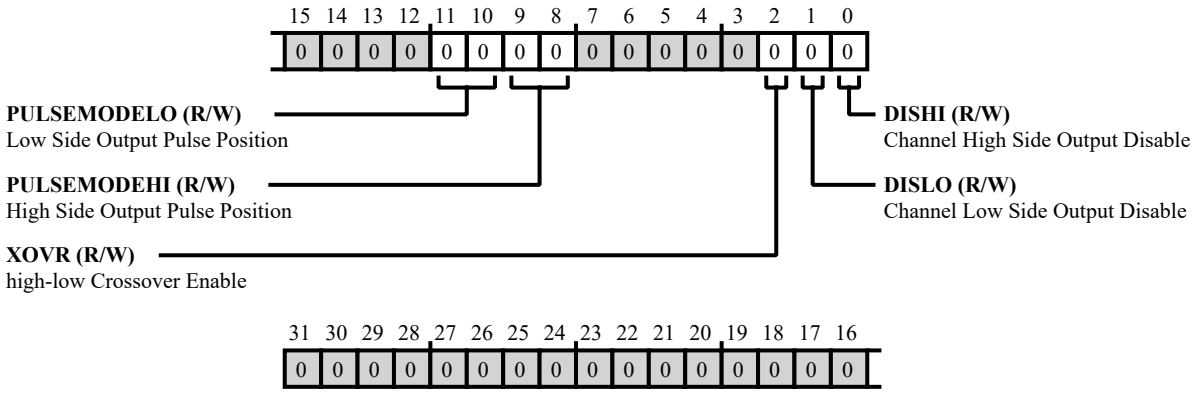

Figure 24-23: PWM_ACTL Register Diagram

Table 24-6: PWM_ACTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11:10 (R/W)	PULSEMODELO	Low Side Output Pulse Position. The PWM_ACTL.PULSEMODELO bits select the pulse position for Channel A low side output. In symmetrical mode, the channel forms a symmetrical pulse waveform around the center of the PWM period. Only one of the duty cycle registers is used for an output in symmetrical mode. Note that in this mode, the values in the PWM_AL0 register is scaled, such that a value of 0 produces 50% duty. In asymmetrical mode, the channel forms an asymmetrical pulse waveform around the center of the PWM period. This mode uses both the duty cycle registers (PWM_AL0 and PWM_AL1). In left half or right half mode, the channel forms the pulse waveforms on either the first half (left) or the second half (right) of the PWM period. This mode uses both the duty cycle registers (PWM_AL0 and PWM_AL1).	
		0	Symmetrical
		1	Asymmetrical
		2	Left Half
		3	Right Half

Table 24-6: PWM_ACTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9:8 (R/W)	PULSEMODEHI	High Side Output Pulse Position. The PWM_ACTL.PULSEMODEHI bits select the pulse position for Channel A high side output. In symmetrical mode, the channel forms a symmetrical pulse waveform around the center of the PWM period. Only one of the duty cycle registers is used for an output in symmetrical mode. Note that in this mode, the values in the PWM_AH0 register is scaled, such that a value of 0 produces 50% duty. In asymmetrical mode, the channel forms an asymmetrical pulse waveform around the center of the PWM period. This mode uses both the duty cycle registers (PWM_AH0 and PWM_AH1). In left half or right half mode, the channel forms the pulse waveforms on either the first half (left) or the second half (right) of the PWM period. This mode uses both the duty cycle registers (PWM_AH0 and PWM_AH1).	
		0	Symmetrical
		1	Asymmetrical
		2	Left Half
		3	Right Half
2 (R/W)	XOVR	high-low Crossover Enable. The PWM_ACTL.XOVR bit enables crossover between the channels high and low side outputs. When enabled, this bit directs the PWM to send the low-side output through the high-side output pin and the high-side output through the low side output pin.	
		0	Disable Crossover
		1	Enable Crossover
1 (R/W)	DISLO	Channel Low Side Output Disable. The PWM_ACTL.DISLO bit enables the channels low side output.	
		0	Enable Low Side Output
		1	Disable Low Side Output
0 (R/W)	DISHI	Channel High Side Output Disable. The PWM_ACTL.DISHI bit enables the channels high side output.	
		0	Enable High Side Output
		1	Disable High Side Output

Channel A-High Duty-0 Register

The PWM_AH0 and PWM_AH1 registers determine the width for the high side output pulses. The values in these registers select the assertion count (in terms of t_{CK}) of the high side output pulses for the channel A duty cycle.

The operation of the duty-cycle registers varies, depending on the pulse mode selected with the PWM_ACTL.PULSEMODEHI bits. When the pulse mode is symmetrical, the PWM uses the value in the PWM_AH0 register to determine the assertion and deassertion count for the high side output pulses. When the pulse mode is asymmetrical, left half, or right half, the PWM asserts channel A high pulse output for a count less than PWM_AH0 and deasserts this output for a count greater than PWM_AH1.

The value range for the PWM_AH0 and PWM_AH1 registers depends on the period of the timer being used by the channel. For example, if PWM_TM0 is used, the duty cycle values may be between -PWM_TM0/2 (two's complement) and +PWM_TM0/2, when dead time (PWM_CHA_DT) is not considered.

When dead time is considered for symmetrical and asymmetrical pulse modes, the value range for PWM_AH0 and PWM_AH1 depends on the period of the time being used by the channel and the amount of dead time applied to the channel. For example, if PWM_TM0 is used, the duty cycle values may be between -PWM_TM0/2 + PWM_CHA_DT (two's complement) and +PWM_TM0/2 + PWM_CHA_DT.

When dead time is considered for left half or right half pulse modes, if PWM_TM0 is used, the duty cycle values may be between PWM_TM0/2 + PWM_CHA_DT (two's complement) and -PWM_TM0/2 - PWM_CHA_DT .

Note that using values in the PWM_AH0 or PWM_AH1 registers that fall outside these limits causes PWM over or under modulation.

For more information about pulse modes and duty cycle selection, see the Functional Description section.

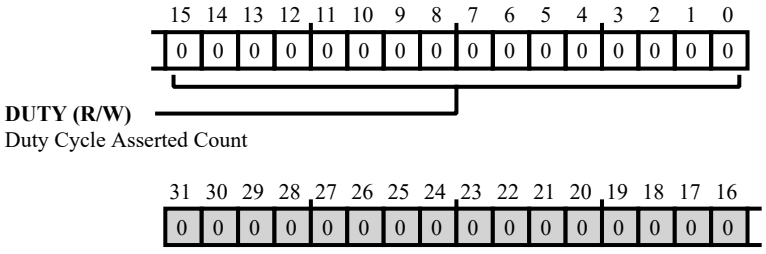

Figure 24-24: PWM_AH0 Register Diagram

Table 24-7: PWM_AH0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	DUTY	Duty Cycle Asserted Count. The PWM_AH0.DUTY bits select the duty cycle asserted count for Channel A high side output.

Channel A-High Duty-1 Register

The PWM_AH0 and PWM_AH1 registers determine the width for the high side output pulses. For more information, see the PWM_AH0 register description.

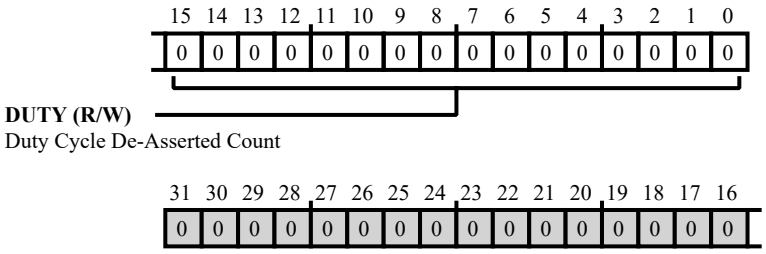

Figure 24-25: PWM_AH1 Register Diagram

Table 24-8: PWM_AH1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	DUTY	Duty Cycle De-Asserted Count. The PWM_AH1.DUTY bits select the duty cycle de-asserted count for Channel A high side output.

Channel A-High Full Duty0 Register

The PWM_AH_DUTY0 register contains the PWM_AH_DUTY0.DUTY bit field from the PWM_AH0 register.

Note that the PWM_AH_DUTY0 register reads the PWM_AH0 register values and visa-versa.

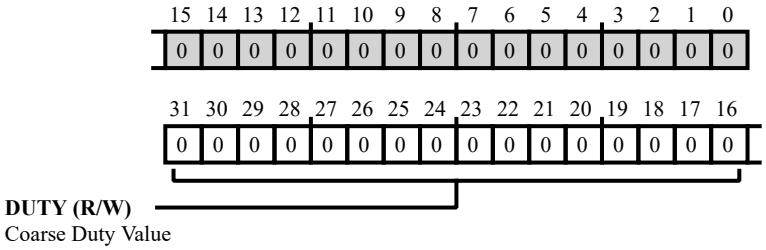

Figure 24-26: PWM_AH_DUTY0 Register Diagram

Table 24-9: PWM_AH_DUTY0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	DUTY	Coarse Duty Value. The PWM_AH_DUTY0.DUTY bits determine the output pulse-widths in the normal PWM operation.

Channel A-High Full Duty1 Register

The PWM_AH_DUTY1 register contains the PWM_AH_DUTY1.DUTY bit field from the PWM_AH1 register.

Note that the PWM_AH_DUTY1 register reads the PWM_AH1 register values and visa-versa.

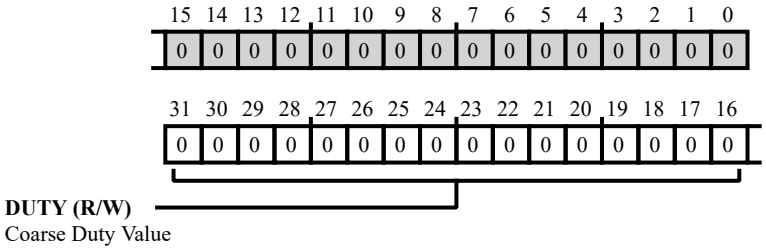

Figure 24-27: PWM_AH_DUTY1 Register Diagram

Table 24-10: PWM_AH_DUTY1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	DUTY	Coarse Duty Value. The PWM_AH_DUTY1.DUTY bits determine the output pulse-widths in the normal PWM operation.

Channel A-Low Duty-0 Register

The PWM_AL0 and PWM_AL1 registers determine the width for the low side output pulses. The values in these registers select the assertion count (in terms of t_{CK}) of the low side output pulses for the channel A duty cycle.

The operation of the duty-cycle registers varies, depending on the pulse mode selected with the PWM_ACTL.PULSEMODELO bits. When the pulse mode is symmetrical, the PWM uses the value in the PWM_AL0 register to determine the assertion and deassertion count for the low side output pulses. When the pulse mode is asymmetrical, left half, or right half, the PWM asserts channel A low pulse output for count less than PWM_AL0 and deasserts this output for count greater than PWM_AL1.

The value range for the PWM_AL0 and PWM_AL1 registers depends on the period of the timer being used by the channel. For example, if PWM_TM0 is used, the duty cycle values may be between -PWM_TM0/2 (two's complement) and +PWM_TM0/2, when dead time (PWM_CHA_DT) is not considered.

When dead time is considered for symmetrical and asymmetrical pulse modes, the value range for PWM_AL0 and PWM_AL1 depends on the period of the time being used by the channel and the amount of dead time applied to the channel. For example, if PWM_TM0 is used, the duty cycle values may be between -PWM_TM0/2 + PWM_CHA_DT (two's complement) and +PWM_TM0/2 + PWM_CHA_DT.

When dead time is considered for left half or right half pulse modes, if PWM_TM0 is used, the duty cycle values may be between PWM_TM0/2 + PWM_CHA_DT (two's complement) and -PWM_TM0/2 - PWM_CHA_DT.

Note that using values in the PWM_AL0 or PWM_AL1 registers that fall outside these limits causes PWM over or under modulation.

For more information about pulse modes and duty cycle selection, see the Functional Description section.

Channel B Control Register

The PWM_BCTL register selects the low and high side output pulse mode, enables low and high side output, and enables low/high side output crossover.

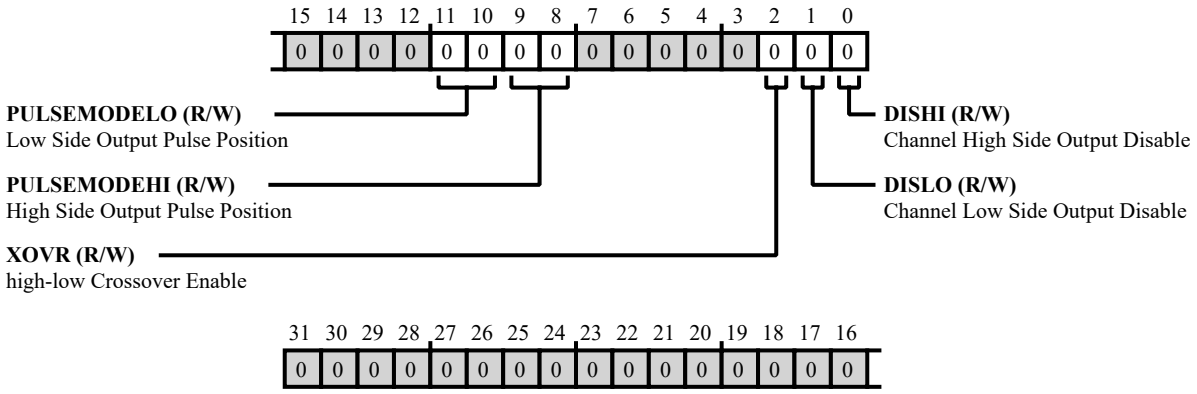

Figure 24-32: PWM_BCTL Register Diagram

Table 24-15: PWM_BCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
11:10 (R/W)	PULSEMODELO	Low Side Output Pulse Position. The PWM_BCTL.PULSEMODELO bits select the pulse position for Channel B low side output. In symmetrical mode, the channel forms a symmetrical pulse waveform around the center of the PWM period. Only one of the duty cycle registers is used for an output in symmetrical mode. Note that in this mode, the values in the PWM_BL0 register is scaled, such that a value of 0 produces 50% duty. In asymmetrical mode, the channel forms an asymmetrical pulse waveform around the center of the PWM period. This mode uses both the duty cycle registers (PWM_BL0 and PWM_BL1). In left half or right half mode, the channel forms the pulse waveforms on either the first half (left) or the second half (right) of the PWM period. This mode uses both the duty cycle registers (PWM_BL0 and PWM_BL1).	
		0	Symmetrical
		1	Asymmetrical
		2	Left Half
		3	Right Half

Bit No. (Access)	Bit Name	Description/Enumeration	
9:8 (R/W)	PULSEMODEHI	High Side Output Pulse Position. The PWM_BCTL.PULSEMODEHI bits select the pulse position for Channel B high side output. In symmetrical mode, the channel forms a symmetrical pulse waveform around the center of the PWM period. Only one of the duty cycle registers is used for an output in symmetrical mode. Note that in this mode, the values in the PWM_BH0 register is scaled, such that a value of 0 produces 50% duty. In asymmetrical mode, the channel forms an asymmetrical pulse waveform around the center of the PWM period. This mode uses both the duty cycle registers (PWM_BH0 and PWM_BH1). In left half or right half mode, the channel forms the pulse waveforms on either the first half (left) or the second half (right) of the PWM period. This mode uses both the duty cycle registers (PWM_BH0 and PWM_BH1).	
		0	Symmetrical
		1	Asymmetrical
		2	Left Half
		3	Right Half
2 (R/W)	XOVR	high-low Crossover Enable. The PWM_BCTL.XOVR bit enables crossover between the channels high and low side outputs. When enabled, this bit directs the PWM to send the low-side output through the high-side output pin and the high-side output through the low side output pin.	
		0	Disable Crossover
		1	Enable Crossover
1 (R/W)	DISLO	Channel Low Side Output Disable. The PWM_BCTL.DISLO bit enables the channels low side output.	
		0	Enable Low Side Output
		1	Disable Low Side Output
0 (R/W)	DISHI	Channel High Side Output Disable. The PWM_BCTL.DISHI bit enables the channels high side output.	
		0	Enable High Side Output
		1	Disable High Side Output

Channel B-High Duty-0 Register

The PWM_BH0 and PWM_BH1 registers determine the width for the high side output pulses. The values in these registers select the assertion count (in terms of t_{CK}) of the high side output pulses for the channel B duty cycle.

The operation of the duty-cycle registers varies, depending on the pulse mode selected with the PWM_BCTL.PULSEMODEHI bits. When the pulse mode is symmetrical, the PWM uses the value in the PWM_BH0 register to determine the assertion and deassertion count for the high side output pulses. When the pulse mode is asymmetrical, left half, or right half, the PWM asserts channel B high pulse output for count less than PWM_BH0 and deasserts this output for count greater than PWM_BH1.

The value range for the PWM_BH0 and PWM_BH1 registers depends on the period of the timer being used by the channel. For example, if PWM_TM0 is used, the duty cycle values may be between -PWM_TM0/2 (two's complement) and +PWM_TM0/2, when dead time (PWM_CHB_DT) is not considered.

When dead time is considered for symmetrical and asymmetrical pulse modes, the value range for PWM_BH0 and PWM_BH1 depends on the period of the time being used by the channel and the amount of dead time applied to the channel. For example, if PWM_TM0 is used, the duty cycle values may be between -PWM_TM0/2 + PWM_CHB_DT (two's complement) and +PWM_TM0/2 + PWM_CHB_DT.

When dead time is considered for left half or right half pulse modes, if PWM_TM0 is used, the duty cycle values may be between PWM_TM0/2 + PWM_CHB_DT (two's complement) and -PWM_TM0/2 - PWM_CHB_DT.

Note that using values in the PWM_BH0 or PWM_BH1 registers that fall outside these limits causes PWM over or under modulation.

For more information about pulse modes and duty cycle selection, see the Functional Description section.

Channel B-Low Duty-0 Register

The PWM_BL0 and PWM_BL1 registers determine the width for the low side output pulses. The values in these registers select the assertion count (in terms of t_{CK}) of the low side output pulses for the channel B duty cycle.

The operation of the duty-cycle registers varies, depending on the pulse mode selected with the PWM_BCTL.PULSEMODELO bits. When the pulse mode is symmetrical, the PWM uses the value in the PWM_BL0 register to determine the assertion and deassertion count for the low side output pulses. When the pulse mode is asymmetrical, left half, or right half, the PWM asserts channel B low pulse output for count less than PWM_BL0 and deasserts this output for count greater than PWM_BL1.

The value range for the PWM_BL0 and PWM_BL1 registers depends on the period of the timer being used by the channel. For example, if PWM_TM0 is used, the duty cycle values may be between -PWM_TM0/2 (two's complement) and +PWM_TM0/2, when dead time (PWM_CHB_DT) is not considered.

When dead time is considered for symmetrical and asymmetrical pulse modes, the value range for PWM_BL0 and PWM_BL1 depends on the period of the time being used by the channel and the amount of dead time applied to the channel. For example, if PWM_TM0 is used, the duty cycle values may be between -PWM_TM0/2 + PWM_CHB_DT (two's complement) and +PWM_TM0/2 + PWM_CHB_DT.

When dead time is considered for left half or right half pulse modes, if PWM_TM0 is used, the duty cycle values may be between PWM_TM0/2 + PWM_CHB_DT (two's complement) and -PWM_TM0/2 - PWM_CHB_DT.

Note that using values in the PWM_BL0 or PWM_BL1 registers that fall outside these limits causes PWM over or under modulation.

For more information about pulse modes and duty cycle selection, see the Functional Description section.

Channel C-High Pulse Duty Register 0

The PWM_CH0 and PWM_CH1 registers determine the width for the high side output pulses. The values in these registers select the assertion count (in terms of t_{CK}) of the high side output pulses for the channel C duty cycle.

The operation of the duty-cycle registers varies, depending on the pulse mode selected with the PWM_CCTL.PULSEMODEHI bits. When the pulse mode is symmetrical, the PWM uses the value in the PWM_CH0 register to determine the assertion and deassertion count for the high side output pulses. When the pulse mode is asymmetrical, left half, or right half, the PWM asserts channel C high pulse output for count less than PWM_CH0 and deasserts this output for count greater than PWM_CH1.

The value range for the PWM_CH0 and PWM_CH1 registers depends on the period of the timer being used by the channel. For example, if PWM_TM0 is used, the duty cycle values may be between -PWM_TM0/2 (two's complement) and +PWM_TM0/2, when dead time (PWM_CHC_DT) is not considered.

When dead time is considered for symmetrical and asymmetrical pulse modes, the value range for PWM_CH0 and PWM_CH1 depends on the period of the time being used by the channel and the amount of dead time applied to the channel. For example, if PWM_TM0 is used, the duty cycle values may be between -PWM_TM0/2 + PWM_CHC_DT (two's complement) and +PWM_TM0/2 + PWM_CHC_DT.

When dead time is considered for left half or right half pulse modes, if PWM_TM0 is used, the duty cycle values may be between PWM_TM0/2 + PWM_CHC_DT (two's complement) and -PWM_TM0/2 - PWM_CHC_DT.

Note that using values in the PWM_CH0 or PWM_CH1 registers that fall outside these limits causes PWM over or under modulation.

For more information about pulse modes and duty cycle selection, see the Functional Description section.

9:0 (R/W)	VALUE	Dead-time value. The PWM_CHC_DT.VALUE bit field contains the dead-time value.

Channel D Dead-time Register

The PWM_CHD_DT register controls the value of dead-time for channel D independently.

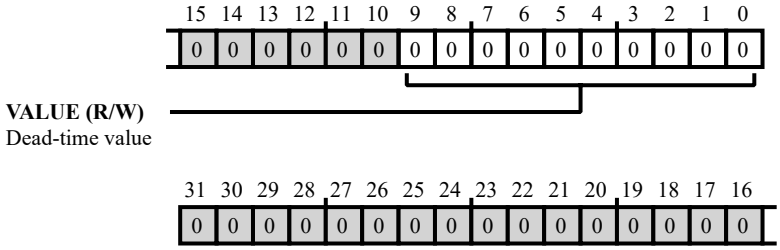

Figure 24-48: PWM_CHD_DT Register Diagram

Table 24-31: PWM_CHD_DT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
9:0 (R/W)	VALUE	Dead-time value. The PWM_CHD_DT.VALUE bit field contains the dead-time value.

Chop Configuration Register

The PWM_CHOPCFG register holds a divisor value that controls the chopping frequency. The PWM permits a mixing of the output signals with a high-frequency chopping signal to aid with interfacing to pulse transformers. Also note that high-frequency chopping may be independently enabled for each channel's high-side and the low-side outputs using channel control bits. (For example, control chopping for Channel A with the PWM_CHANCFG.ENCHOPAH and PWM_CHANCFG.ENCHOPAH bits.)

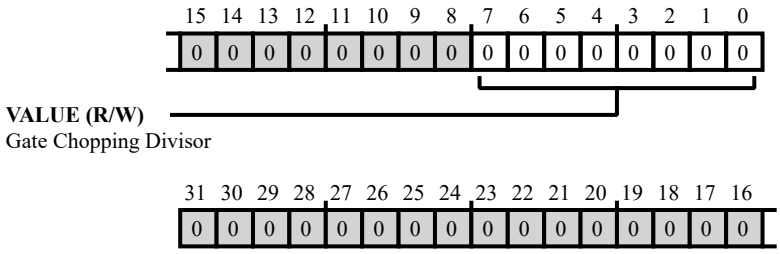

Figure 24-49: PWM_CHOPCFG Register Diagram

Table 24-32: PWM_CHOPCFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	Gate Chopping Divisor. The PWM_CHOPCFG.VALUE bits provide the high frequency chopping divisor. When the divisor value is changed, the new period takes effect from the next edge of the chopping signal. The PWM_CHOPCFG.VALUE value may be calculated using either of the following formulas: CHOPDIV = $[(T_{CHOP}/T_{CK}) / 4] - 1$ CHOPDIV = $[(f_{CK} / f_{CHOP}) / 4] - 1$

Channel C-High Full Duty0 Register

The PWM_CH_DUTY0 register contains the PWM_CH_DUTY0.DUTY bit field from the PWM_CH0 register.

Note that the PWM_CH_DUTY0 register reads the PWM_CH0 register values and visa-versa.

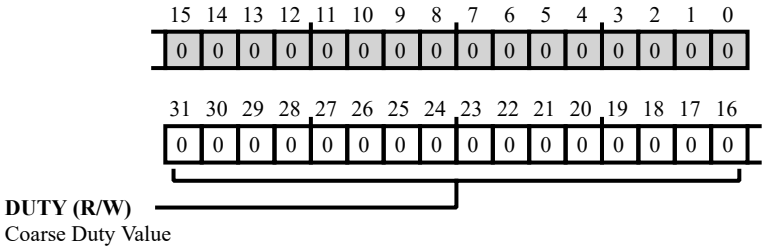

Figure 24-50: PWM_CH_DUTY0 Register Diagram

Table 24-33: PWM_CH_DUTY0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	DUTY	Coarse Duty Value. The PWM_CH_DUTY0.DUTY bits determine the output pulse-widths in the normal PWM operation.

Channel C-High Full Duty1 Register

The PWM_CH_DUTY1 register contains the PWM_CH_DUTY1.DUTY bit field from the PWM_CH1 register.

Note that the PWM_CH_DUTY1 register reads the PWM_CH1 register values and visa-versa.

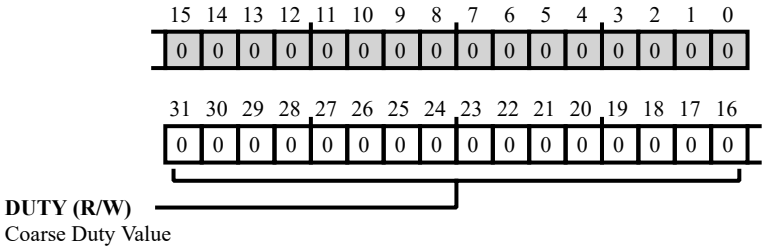

Figure 24-51: PWM_CH_DUTY1 Register Diagram

Table 24-34: PWM_CH_DUTY1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	DUTY	Coarse Duty Value. The PWM_CH_DUTY1.DUTY bits determine the output pulse-widths in the normal PWM operation.

Channel C-Low Pulse Duty Register 0

The PWM_CL0 and PWM_CL1 registers determine the width for the low side output pulses. The values in these registers select the assertion count (in terms of t_{CK}) of the low side output pulses for the channel C duty cycle.

The operation of the duty-cycle registers varies, depending on the pulse mode selected with the PWM_CCTL.PULSEMODELO bits. When the pulse mode is symmetrical, the PWM uses the value in the PWM_CL0 register to determine the assertion and deassertion count for the low side output pulses. When the pulse mode is asymmetrical, left half, or right half, the PWM asserts channel C low pulse output for count less than PWM_CL0 and deasserts this output for count greater than PWM_CL1.

The value range for the PWM_CL0 and PWM_CL1 registers depends on the period of the timer being used by the channel. For example, if PWM_TM0 is used, the duty cycle values may be between -PWM_TM0/2 (two's complement) and +PWM_TM0/2, when dead time (PWM_CHC_DT) is not considered.

When dead time is considered for symmetrical and asymmetrical pulse modes, the value range for PWM_CL0 and PWM_CL1 depends on the period of the time being used by the channel and the amount of dead time applied to the channel. For example, if PWM_TM0 is used, the duty cycle values may be between -PWM_TM0/2 + PWM_CHC_DT (two's complement) and +PWM_TM0/2 + PWM_CHC_DT.
