The phase requester ASRC device transmits its SRCx_FS_OP/SRCx_FS_IP ratio through the data output pin (SRCx_DAT_OP_O) to the completer's ASRC's data input pins (SRCx_TDM_OP_I). The transmitted data (32-bit subframe) contains 24-bit data and 8-bits matched phase (see the ***ASRC Data Frame Format by Protocol*** figure).

The completer SRCs receive the 8-bit matched phase bits (instead of their own internally-derived ratio) if their SRCx_MPHASE bits are set to 1, respectively. The SRCx_FS_IP and SRCx_FS_OP signals may be asynchronous with respect to each other in this mode. Note that there must be 64 SRCx_CLK_OP cycles per frame in matched-phase mode (two 24-bits data and two 8-bits phase match).

NOTE: By default, matched phased data is sent on the SRCx_DAT_OP_O pin, but only if the SRCx_TDM_OP_I pin is tied low. The completers' simply ignore the matched phased data if their ASRC_CTL01.MPHASE1 through ASRC_CTL23.MPHASE3 bits are cleared (= 0).

Bypass Mode

When the ASRC_CTL01.BYP0, ASRC_CTL01.BYP1, ASRC_CTL23.BYP2 and ASRC_CTL23.BYP3 bits are set (=1), the input data bypasses the sample rate converter and is sent directly to the serial output port. Dithering is disabled. This mode is ideal when the input and output sample rates are the same and the SRCx_FS_IP_I and SRCx_FS_OP_I signals are synchronous with respect to each other. In matched phase bypass mode, the SRCx_FS_OP_I signal should come at least one SRCx_CLK_xx_I period before SRCx_FS_IP_I. Cases where this is not met could result in data loss. For example, if internal SPORTS are used then the SRCx_FS_OP_I and SRCx_FS_IP_I signals could be driven by different SPORTs so that the timing of these signals can be controlled by enabling them at different times. This mode can also be used for passing through non-audio data since no processing is performed on the input data.

De-Emphasis Mode

The ASRC_CTL01.DEEMPHASIS0, ASRC_CTL01.DEEMPHASIS1, ASRC_CTL23.DEEMPHASIS2 and ASRC_CTL23.DEEMPHASIS3 bits choose the type of de-emphasis filter based on the input sample rate for 32, 44.1 or 48 kHz sampling rates.

Dithering Mode

The ASRC_CTL01.DITHER0, ASRC_CTL01.DITHER1, ASRC_CTL23.DITHER2, and ASRC_CTL23.DITHER3 control this mode of operation. Serial output data is dithered down to 20, 18, or 16 bits when 20-, 18-, or 16-bit output data is selected. In the case of 20-, 18-, and 16-bit word lengths, the least significant bits of the 24-bit word coming from the SRC into the serial output port are truncated. The DITHER_EN signal (not user configurable) automatically adds dithering to the 24-bit word before truncating to the appropriate output word length. The 21BIT_DITHER signal is used for the consumer version of the SRC to reduce the dynamic range performance to approximately 128 dB.

NOTE: The ASRC can be programmed to add the triangular Probability Distribution Function (PDF) dither to the digital audio samples. It is advisable to add dither when the input word width exceeds the output word width, for example the input word is 20 bits, and the output word is 16 bits. A triangular PDF is considered to create the most favorable noise shaping of the residual quantization noise.

Muting Modes

The mute feature of the ASRC can be controlled automatically in hardware using the MUTE_IN signal by connecting it to the MUTE_OUT signal. Automatic muting can be disabled by setting (=1) the ASRC_MUTE.MUTE0 through ASRC_MUTE.MUTE3 bits.

NOTE: Note that by default, the ASRC_MUTE register connects the MUTE_IN signal to the MUTE_OUT signal, but not conversely.

Soft Mute

When the ASRC_CTL01.SOFTMUTE0, ASRC_CTL01.SOFTMUTE1, ASRC_CTL23.SOFTMUTE2 and ASRC_CTL23.SOFTMUTE3 bits are set, the MUTE_IN signal is asserted, and the ASRC performs a soft mute by linearly decreasing the input data to the ASRC FIFO to zero, (-144 dB) attenuation as described for automatic hardware muting.

A 12-bit counter, clocked by SRCx_FS_IP_I, is used to control the mute attenuation. Therefore, the time it takes from the assertion of the MUTE_IN signal to -144 dB, full mute attenuation is 4096 FS cycles. Likewise, the time it takes to reach 0 dB mute attenuation from the deassertion of the MUTE_IN signal is 4096 FS cycles.

Hard Mute

When the ASRC_CTL01.HARDMUTE0, ASRC_CTL01.HARDMUTE1, ASRC_CTL23.HARDMUTE2 and ASRC_CTL23.HARDMUTE3 bits are set, the ASRC immediately mutes the input data to the ASRC FIFO to zero, (-144 dB) attenuation.

Auto Mute

When the ASRC_CTL01.AUTOMUTE0, ASRC_CTL01.AUTOMUTE1, ASRC_CTL23.AUTOMUTE2 and ASRC_CTL23.AUTOMUTE3 bits are set, the ASRC communicates with the S/PDIF receiver peripheral to determine when the input should mute.

This mode is useful for automatic detection of non-PCM audio data received from the S/PDIF receiver.

Interrupts

The following sections provide information about interrupt sources, masking, and servicing.

Sources

Each ASRC module drives one interrupt signal (mute out asserted). All these signals are connected into the DAI_IRPTL_H or DAI_IRPTL_L latch registers. The ASRC ports generate interrupts as described below.

SRC Mute Out

The SRC mute out signal can be used to generate interrupts on their rising edge, falling edge, or both, depending on how the DAI interrupt mask registers (DAI_IMSK_RE/DAI_IMSK_FE) are programmed. This programming allows the generation of DAI_IRPTL_H/DAI_IRPTL_L interrupts either entering mute, exiting muting or both. The SRCx_MUTE_OUT interrupt is generated only once when the SRC is locked (after 4096 FS input samples) and after changes to the sample ratio. Hard mute, soft mute, and auto mute only control the muting of the input data to the SRC.

Masking

The DAI_IMSK_FE, DAI_IMSK_RE, and DAI_IMSK_PRI registers must be unmasked accordingly. The DAI_IRQH and DAI_IRQL signals are routed to the system event controller (SEC) and general interrupt controller (GIC).

Service

The ISR reads the DAI_IRPTL_H and DAI_IRPTL_L registers to clear the interrupt request.

Programming Model

The following is basic information on programming the ASRC module.

1. Program the ASRC_CTL01 and ASRC_CTL23 registers and keep the ASRC_CTL01.EN0 through ASRC_CTL23.EN3 bits cleared.
2. Set the ASRC_CTL01.EN0 through ASRC_CTL23.EN3 bits. After 4096 input port FS cycles the ASRC has un-muted.

Debug Features

The asynchronous sample rate converter allow the bypass mode. When the ASRC_CTL01.BYP0 through ASRC_CTL23.BYP3 bits are set (=1), the input data bypasses the sample rate converter and is sent directly to the serial output port. This mode can be used for testing both ports when the input and output sample rates are at the same frequency, therefore both input and output ports can be routed to the same serial clock and frame sync.

ADSP-2184x ASRC Register Descriptions

Sample Rate Converter Module (ASRC) contains the following registers.

Table 32-3: ADSP-2184x ASRC Register List

Name	Description
ASRC_CTL01	Control Register for ASRC 0 and 1
ASRC_CTL23	Control Register for ASRC 2 and 3

Table 32-3: ADSP-2184x ASRC Register List (Continued)

Name	Description
ASRC_CTL45	Control Register For ASRC 4 And 5
ASRC_CTL67	Control Register for ASRC 6 and 7
ASRC_MUTE	Mute Register
ASRC_RAT01	Ratio Register for ASRC 0 and 1
ASRC_RAT23	Ratio Register for ASRC 2 and 3
ASRC_RAT45	Ratio Register For ASRC 4 and 5
ASRC_RAT67	Ratio Register for ASRC 6 and 7

Control Register for ASRC 0 and 1

The ASRC_CTL01 register (read/write) controls the operating modes, filters, and data formats used in the ASRC modules 0 and 1.

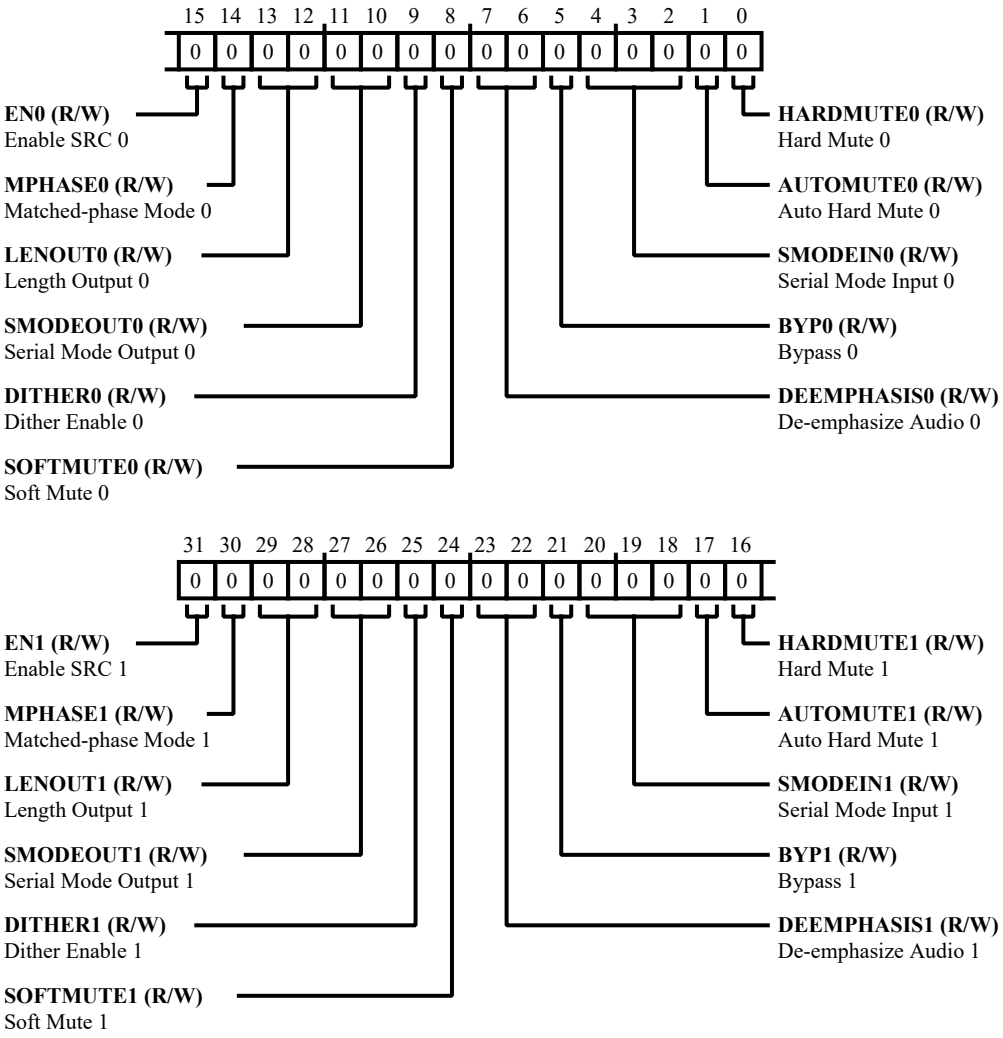

Figure 32-7: ASRC_CTL01 Register Diagram

Table 32-4: ASRC_CTL01 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	EN1	Enable SRC 1. The ASRC_CTL01.EN1 bit enables SRC 1. When (set = 1), or when the sample rate (frame sync) between the input and output changes, the SRC begins its initialization routine where; 1) MUTE_OUT is asserted, 2) soft mute control counter for input samples is set to maximum attenuation (-144 dB). Note that SRC power-up completion is finished by clearing the ASRC_RAT01.MUTEOUT1 bit. Writes to the ASRC_CTL01 register should be at least one cycle before setting the ASRC_CTL01.EN1 bit. When setting and clearing this bit, it should be held low for a minimum of 5 SCLK cycles.	
30 (R/W)	MPHASE1	Matched-phase Mode 1. The ASRC_CTL01.MPHASE1 bit configures SRC1 to not use its own internally-generated sample rate ratio but use an externally-generated ratio. Used with TDM data.	
		0	Matched phase completer disabled
		1	Matched phase completer enabled
29:28 (R/W)	LENOUT1	Length Output 1. The ASRC_CTL01.LENOUT1 bit field selects the serial output word length on SRC1.	
		0	24 bits
		1	20 bits
		2	18 bits
		3	16 bits
27:26 (R/W)	SMODEOUT1	Serial Mode Output 1. The ASRC_CTL01.SMODEOUT1 bit field selects the serial output format on SRC1.	
		0	Left-justified
		1	I2S
		2	TDM
		3	Right-justified
25 (R/W)	DITHER1	Dither Enable 1. The ASRC_CTL01.DITHER1 bit enables dithering before truncation on SRC1 when a word length less than 24 bits is selected.	
		0	Truncation only
		1	Dithering before truncation

Table 32-4: ASRC_CTL01 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
24 (R/W)	SOFTMUTE1	Soft Mute 1. The `ASRC_CTL01.SOFTMUTE1` bit enables soft mute on SRC1.	
		0	Unmute
		1	Mute
23:22 (R/W)	DEEMPHASIS1	De-emphasize Audio 1. The `ASRC_CTL01.DEEMPHASIS1` bits are used to de-emphasize audio data that has been emphasized. The type of de-emphasis filter is based on the input sample rate (SRCx_FS_IP_I signal).	
		0	No de-emphasis
		1	32 kHz
		2	44.1 kHz
		3	48 kHz
21 (R/W)	BYP1	Bypass 1. The `ASRC_CTL01.BYP1` bit makes the output of SRC1 the same as the input.	
20:18 (R/W)	SMODEIN1	Serial Mode Input 1. The `ASRC_CTL01.SMODEIN1` bit field selects the serial input format for SRC1.	
		0	left-justified
		1	I2S
		2	TDM
		4	24-bit right-justified
		5	20-bit right-justified
		6	18-bit right-justified
		7	16-bit right-justified
17 (R/W)	AUTOMUTE1	Auto Hard Mute 1. The `ASRC_CTL01.AUTOMUTE1` bit auto hard mutes SRC1 when non audio is asserted by the SPDIF receiver.	
		0	Unmute
		1	Mute
16 (R/W)	HARDMUTE1	Hard Mute 1. The `ASRC_CTL01.HARDMUTE1` bit hard mutes SRC1.	
		0	Unmute
		1	Mute

Table 32-4: ASRC_CTL01 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	EN0	Enable SRC 0. The ASRC_CTL01.EN0 bit enables SRC 0. When (set =1), or when the sample rate (frame sync) between the input and output changes, the SRC begins its initialization routine where; 1) MUTE_OUT is asserted, 2) soft mute control counter for input samples is set to maximum attenuation (-144 dB). Note that SRC power-up completion is finished by clearing the ASRC_RAT01.MUTEOUT0 bit. Writes to the ASRC_CTL01 register should be at least one cycle before setting the ASRC_CTL01.EN0 bit. When setting and clearing this bit, it should be held low for a minimum of 5 CLK cycles.	
14 (R/W)	MPHASE0	Matched-phase Mode 0. The ASRC_CTL01.MPHASE0 bit configures SRC0 to not use its own internally-generated sample rate ratio but use an externally-generated ratio. Used with TDM data.	
		0	Matched phase completer disabled
		1	Matched phase completer enabled
13:12 (R/W)	LENOUT0	Length Output 0. The ASRC_CTL01.LENOUT0 bit field selects the serial output word length on SRC0.	
		0	24 bits
		1	20 bits
		2	18 bits
		3	16 bits
11:10 (R/W)	SMODEOUT0	Serial Mode Output 0. The ASRC_CTL01.SMODEOUT0 bit field selects the serial output format on SRC0.	
		0	Left-justified
		1	I2S
		2	TDM
		3	Right-justified
9 (R/W)	DITHER0	Dither Enable 0. The ASRC_CTL01.DITHER0 bit enables dithering before truncation on SRC0 when a word length less than 24 bits is selected.	
		0	Truncation only
		1	Dithering before truncation

Table 32-4: ASRC_CTL01 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	SOFTMUTE0	Soft Mute 0. The `ASRC_CTL01.SOFTMUTE0` bit enables soft mute on SRC0.	
		0	Unmute
		1	Mute
7:6 (R/W)	DEEMPHASIS0	De-emphasize Audio 0. The `ASRC_CTL01.DEEMPHASIS0` bits are used to de-emphasize audio data that has been emphasized. The type of de-emphasis filter is based on the input sample rate (SRCx_FS_IP_I signal).	
		0	No de-emphasis
		1	32 kHz
		2	44.1 kHz
		3	48 kHz
5 (R/W)	BYP0	Bypass 0. The `ASRC_CTL01.BYP0` bit makes the output of SRC0 the same as the input.	
4:2 (R/W)	SMODEIN0	Serial Mode Input 0. The `ASRC_CTL01.SMODEIN0` bit field selects the serial input format for SRC0.	
		0	left-justified
		1	I2S
		2	TDM
		4	24-bit right-justified
		5	20-bit right-justified
		6	18-bit right-justified
		7	16-bit right-justified
1 (R/W)	AUTOMUTE0	Auto Hard Mute 0. The `ASRC_CTL01.AUTOMUTE0` bit auto hard mutes SRC0 when non audio is asserted by the SPDIF receiver.	
		0	Unmute
		1	Mute
0 (R/W)	HARDMUTE0	Hard Mute 0. The `ASRC_CTL01.HARDMUTE0` bit hard mutes SRC0.	
		0	Unmute
		1	Mute (default)

Control Register for ASRC 2 and 3

The ASRC_CTL23 register (read/write) controls the operating modes, filters, and data formats used in the sample rate converter modules 2 and 3.

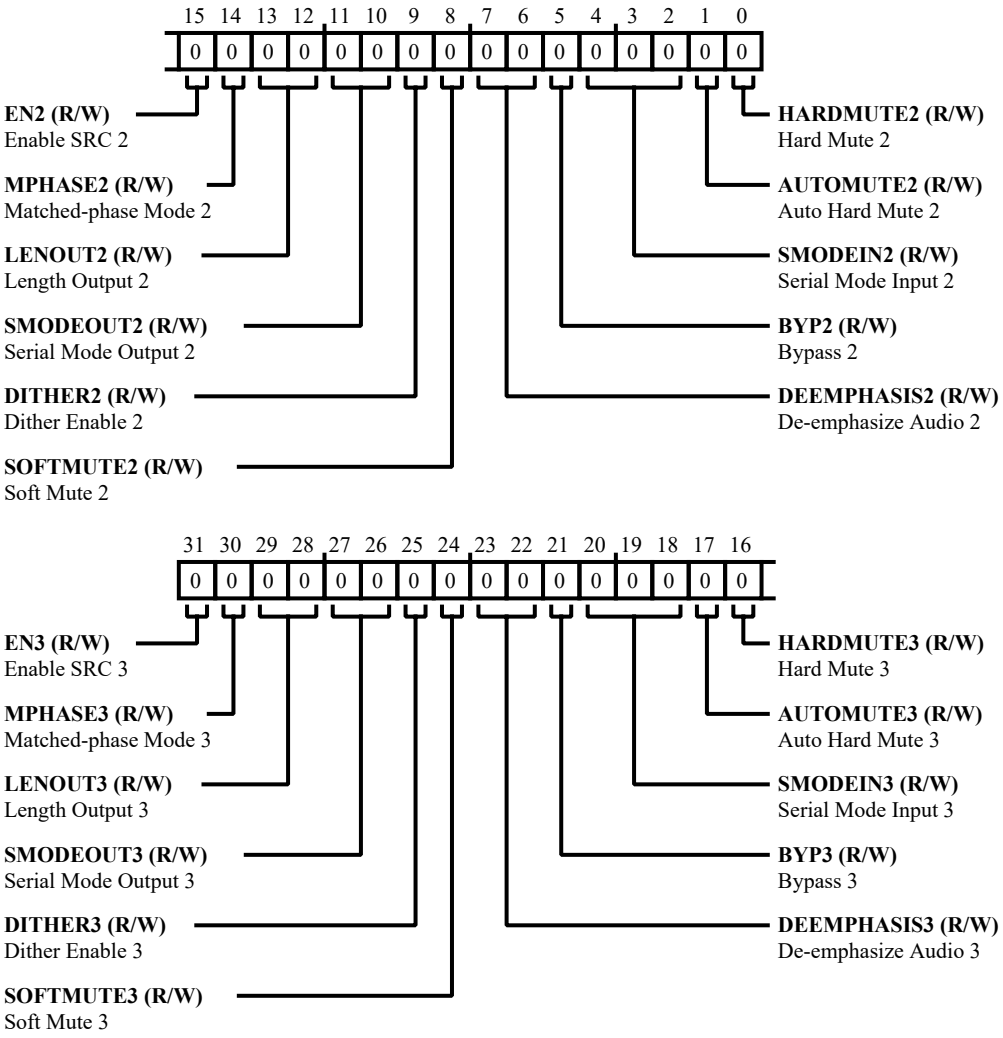

Figure 32-8: ASRC_CTL23 Register Diagram

Table 32-5: ASRC_CTL23 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	EN3	Enable SRC 3. The ASRC_CTL23.EN3 bit enables SRC 3. When (set =1), or when the sample rate (frame sync) between the input and output changes, the SRC begins its initialization routine where; 1) MUTE_OUT is asserted, 2) soft mute control counter for input samples is set to maximum attenuation (-144 dB). Note that SRC power-up completion is finished by clearing the ASRC_RAT23.MUTEOUT3 bit. Writes to the ASRC_CTL23 register should be at least one cycle before setting the ASRC_CTL23.EN3 bit. When setting and clearing this bit, it should be held low for a minimum of 5 CLK cycles.	
30 (R/W)	MPHASE3	Matched-phase Mode 3. The ASRC_CTL23.MPHASE3 bit configures SRC3 to not use its own internally-generated sample rate ratio but use an externally-generated ratio. Used with TDM data.	
		0	Matched phase completer disabled
		1	Matched phase completer enabled
29:28 (R/W)	LENOUT3	Length Output 3. The ASRC_CTL23.LENOUT3 bit field selects the serial output word length on SRC3.	
		0	24 bits
		1	20 bits
		2	18 bits
		3	16 bits
27:26 (R/W)	SMODEOUT3	Serial Mode Output 3. The ASRC_CTL23.SMODEOUT3 bit field selects the serial output format on SRC3.	
		0	Left-justified
		1	I2S
		2	TDM
		3	Right-justified
25 (R/W)	DITHER3	Dither Enable 3. The ASRC_CTL23.DITHER3 bit enables dithering before truncation on SRC3 when a word length less than 24 bits is selected.	
		0	Truncation only
		1	Dithering before truncation

Table 32-5: ASRC_CTL23 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
24 (R/W)	SOFTMUTE3	Soft Mute 3. The ASRC_CTL23.SOFTMUTE3 bit enables soft mute on SRC3.	
		0	Unmute
		1	Mute
23:22 (R/W)	DEEMPHASIS3	De-emphasize Audio 3. The ASRC_CTL23.DEEMPHASIS3 bits are used to de-emphasize audio data that has been emphasized. The type of de-emphasis filter is based on the input sample rate (SRCx_FS_IP_I signal).	
		0	No de-emphasis
		1	32 kHz
		2	44.1 kHz
		3	48 kHz
21 (R/W)	BYP3	Bypass 3. The ASRC_CTL23.BYP3 bit makes the output of SRC3 the same as the input.	
20:18 (R/W)	SMODEIN3	Serial Mode Input 3. The ASRC_CTL23.SMODEIN3 bit field selects the serial input format for SRC3.	
		0	left-justified
		1	I2S
		2	TDM
		4	24-bit right-justified
		5	20-bit right-justified
		6	18-bit right-justified
		7	16-bit right-justified
17 (R/W)	AUTOMUTE3	Auto Hard Mute 3. The ASRC_CTL23.AUTOMUTE3 bit auto hard mutes SRC3 when non audio is asserted by the SPDIF receiver.	
		0	Unmute
		1	Mute
16 (R/W)	HARDMUTE3	Hard Mute 3. The ASRC_CTL23.HARDMUTE3 bit hard mutes SRC3.	
		0	Unmute
		1	Mute

Table 32-5: ASRC_CTL23 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	EN2	Enable SRC 2. The ASRC_CTL23.EN2 bit enables SRC 2. When (set =1), or when the sample rate (frame sync) between the input and output changes, the SRC begins its initialization routine where; 1) MUTE_OUT is asserted, 2) soft mute control counter for input samples is set to maximum attenuation (-144 dB). Note that SRC power-up completion is finished by clearing the ASRC_RAT23.MUTEOUT2 bit. Writes to the ASRC_CTL23 register should be at least one cycle before setting the ASRC_CTL23.EN2 bit. When setting and clearing this bit, it should be held low for a minimum of 5 CLK cycles.	
14 (R/W)	MPHASE2	Matched-phase Mode 2. The ASRC_CTL23.MPHASE2 bit configures SRC2 to not use its own internally-generated sample rate ratio but use an externally-generated ratio. Used with TDM data.	
		0	Matched phase completer disabled
		1	Matched phase completer enabled
13:12 (R/W)	LENOUT2	Length Output 2. The ASRC_CTL23.LENOUT2 bit field selects the serial output word length on SRC2.	
		0	24 bits
		1	20 bits
		2	18 bits
		3	16 bits
11:10 (R/W)	SMODEOUT2	Serial Mode Output 2. The ASRC_CTL23.SMODEOUT2 bit field selects the serial output format on SRC2.	
		0	Left-justified
		1	I2S
		2	TDM
		3	Right-justified
9 (R/W)	DITHER2	Dither Enable 2. The ASRC_CTL23.DITHER2 bit enables dithering before truncation on SRC2 when a word length less than 24 bits is selected.	
		0	Truncation only
		1	Dithering before truncation

Table 32-5: ASRC_CTL23 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	SOFTMUTE2	Soft Mute 2. The ASRC_CTL23.SOFTMUTE2 bit enables soft mute on SRC2.	
		0	Unmute
		1	Mute
7:6 (R/W)	DEEMPHASIS2	De-emphasize Audio 2. The ASRC_CTL23.DEEMPHASIS2 bits are used to de-emphasize audio data that has been emphasized. The type of de-emphasis filter is based on the input sample rate (SRCx_FS_IP_I signal).	
		0	No de-emphasis
		1	32 kHz
		2	44.1 kHz
		3	48 kHz
5 (R/W)	BYP2	Bypass 2. The ASRC_CTL23.BYP2 bit makes the output of SRC2 the same as the input.	
4:2 (R/W)	SMODEIN2	Serial Mode Input 2. The ASRC_CTL23.SMODEIN2 bit field selects the serial input format for SRC2.	
		0	left-justified
		1	I2S
		2	TDM
		4	24-bit right-justified
		5	20-bit right-justified

1 (R/W)	AUTOMUTE2	Auto Hard Mute 2. The ASRC_CTL23.AUTOMUTE2 bit auto hard mutes SRC2 when non audio is asserted by the SPDIF receiver.	
		0	Unmute
		1	Mute
0 (R/W)	HARDMUTE2	Hard Mute 2. The ASRC_CTL23.HARDMUTE2 bit hard mutes SRC2.	
		0	Unmute
		1	Mute

Control Register For ASRC 4 And 5

The ASRC_CTL45 register (read/write) controls the operating modes, filters, and data formats used in the sample rate converter modules 4 and 5.

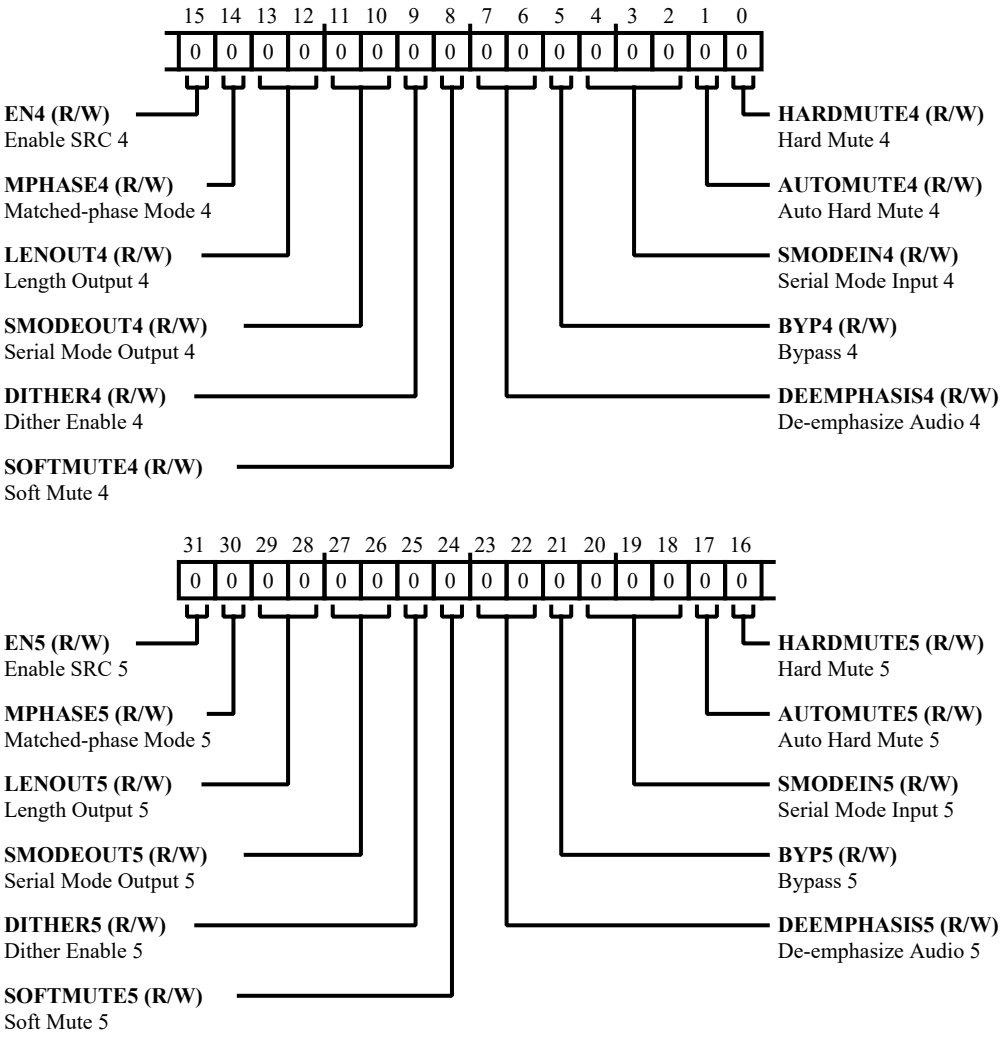

Figure 32-9: ASRC_CTL45 Register Diagram

Table 32-6: ASRC_CTL45 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	EN5	Enable SRC 5. The ASRC_CTL45.EN5 bit enables SRC 5. When (set =1), or when the sample rate (frame sync) between the input and output changes, the SRC begins its initialization routine where; 1) MUTE_OUT is asserted, 2) soft mute control counter for input samples is set to maximum attenuation (-144 dB). Note that SRC power-up completion is finished by clearing the ASRC_RAT45.MUTEOUT5 bit. Writes to the ASRC_CTL45 register should be at least one cycle before setting the ASRC_CTL45.EN5 bit. When setting and clearing this bit, it should be held low for a minimum of 5 CLK cycles.	
30 (R/W)	MPHASE5	Matched-phase Mode 5. The ASRC_CTL45.MPHASE5 bit configures SRC5 to not use its own internally-generated sample rate ratio but use an externally-generated ratio. Used with TDM data.	
		0	Matched phase completer disabled
		1	Matched phase completer enabled
29:28 (R/W)	LENOUT5	Length Output 5. The ASRC_CTL45.LENOUT5 bit field selects the serial output word length on SRC5.	
		0	24 bits
		1	20 bits
		2	18 bits
		3	16 bits
27:26 (R/W)	SMODEOUT5	Serial Mode Output 5. The ASRC_CTL45.SMODEOUT5 bit field selects the serial output format on SRC5.	
		0	Left-justified
		1	I2S
		2	TDM
		3	Right-justified
25 (R/W)	DITHER5	Dither Enable 5. The ASRC_CTL45.DITHER5 bit enables dithering before truncation on SRC3 when a word length less than 24 bits is selected.	
		0	Truncation only
		1	Dithering before truncation

Table 32-6: ASRC_CTL45 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
24 (R/W)	SOFTMUTE5	Soft Mute 5. The `ASRC_CTL45.SOFTMUTE5` bit enables soft mute on SRC5.	
		0	Unmute
		1	Mute
23:22 (R/W)	DEEMPHASIS5	De-emphasize Audio 5. The `ASRC_CTL45.DEEMPHASIS5` bits are used to de-emphasize audio data that has been emphasized. The type of de-emphasis filter is based on the input sample rate (SRCx_FS_IP_I signal).	
		0	No de-emphasis
		1	32 kHz
		2	44.1 kHz
		3	48 kHz
21 (R/W)	BYP5	Bypass 5. The `ASRC_CTL45.BYP5` bit makes the output of SRC5 the same as the input.

Control Register for ASRC 6 and 7

The ASRC_CTL67 register (read/write) controls the operating modes, filters, and data formats used in the sample rate converter modules 6 and 7.

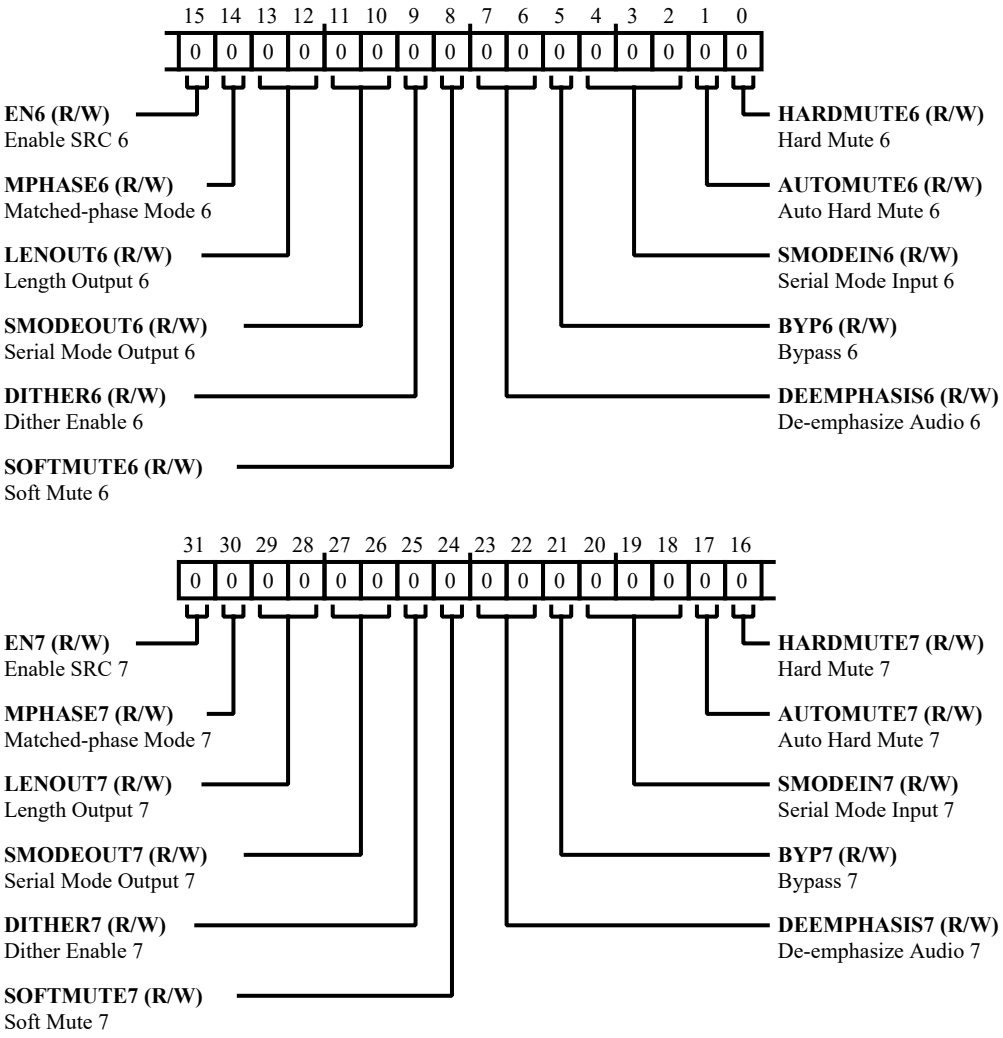

Figure 32-10: ASRC_CTL67 Register Diagram

Table 32-7: ASRC_CTL67 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	EN7	Enable SRC 7. The ASRC_CTL67.EN7 bit enables SRC 7. When (set =1), or when the sample rate (frame sync) between the input and output changes, the SRC begins its initialization routine where; 1) MUTE_OUT is asserted, 2) soft mute control counter for input samples is set to maximum attenuation (-144 dB). Note that SRC power-up completion is finished by clearing the ASRC_RAT67.MUTEOUT7 bit. Writes to the ASRC_CTL67 register should be at least one cycle before setting the ASRC_CTL67.EN7 bit. When setting and clearing this bit, it should be held low for a minimum of 5 CLK cycles.	
30 (R/W)	MPHASE7	Matched-phase Mode 7. The ASRC_CTL67.MPHASE7 bit configures SRC7 to not use its own internally-generated sample rate ratio but use an externally-generated ratio. Used with TDM data.	
		0	Matched phase completer disabled
		1	Matched phase completer enabled
29:28 (R/W)	LENOUT7	Length Output 7. The ASRC_CTL67.LENOUT7 bit field selects the serial output word length on SRC7.	
		0	24 bits
		1	20 bits
		2	18 bits
		3	16 bits
27:26 (R/W)	SMODEOUT7	Serial Mode Output 7. The ASRC_CTL67.SMODEOUT7 bit field selects the serial output format on SRC7.	
		0	Left-justified
		1	I2S
		2	TDM
		3	Right-justified
25 (R/W)	DITHER7	Dither Enable 7. The ASRC_CTL67.DITHER7 bit enables dithering before truncation on SRC7 when a word length less than 24 bits is selected.	
		0	Truncation only
		1	Dithering before truncation

Table 32-7: ASRC_CTL67 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
24 (R/W)	SOFTMUTE7	Soft Mute 7. The ASRC_CTL67.SOFTMUTE7 bit enables soft mute on SRC7.	
		0	Unmute
		1	Mute
23:22 (R/W)	DEEMPHASIS7	De-emphasize Audio 7. The ASRC_CTL67.DEEMPHASIS7 bits are used to de-emphasize audio data that has been emphasized. The type of de-emphasis filter is based on the input sample rate (SRCx_FS_IP_I signal).	
		0	No de-emphasis
		1	32 kHz
		2	44.1 kHz
		3	48 kHz
21 (R/W)	BYP7	Bypass 7. The ASRC_CTL67.BYP7 bit makes the output of SRC7 the same as the input.	
20:18 (R/W)	SMODEIN7	Serial Mode Input 7. The ASRC_CTL67.SMODEIN7 bit field selects the serial input format for SRC7.

Mute Register

This register connects an ASRCx mute input and output when the mute bit is cleared (=0). This allows ASRCx to automatically mute input while the ASRC is initializing (0 = automatic muting and 1 = manual muting). Bit 0 controls ASRC0, bit 1 controls ASRC1, bit 2 controls ASRC2, and bit 3 controls ASRC3.

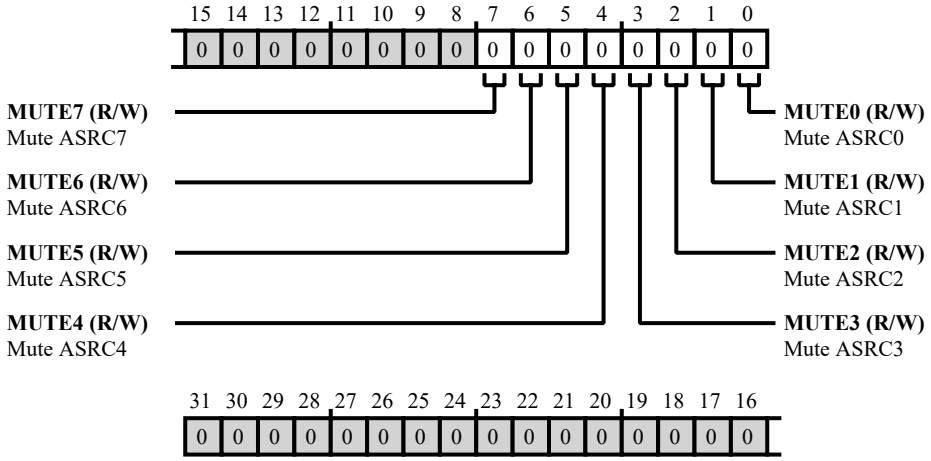

Figure 32-11: ASRC_MUTE Register Diagram

Table 32-8: ASRC_MUTE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7 (R/W)	MUTE7	Mute ASRC7. The `ASRC_MUTE.MUTE7` bit automatically mutes ASCR7 output when cleared (=0).
6 (R/W)	MUTE6	Mute ASRC6. The `ASRC_MUTE.MUTE6` bit automatically mutes ASCR6 output when cleared (=0).
5 (R/W)	MUTE5	Mute ASRC5. The `ASRC_MUTE.MUTE5` bit automatically mutes ASCR5 output when cleared (=0).
4 (R/W)	MUTE4	Mute ASRC4. The `ASRC_MUTE.MUTE4` bit automatically mutes ASCR4 output when cleared (=0).
3 (R/W)	MUTE3	Mute ASRC3. The `ASRC_MUTE.MUTE3` bit automatically mutes ASCR3 output when cleared (=0).

Table 32-8: ASRC_MUTE Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
2 (R/W)	MUTE2	Mute ASRC2. The `ASRC_MUTE.MUTE2` bit automatically mutes ASCR2 output when cleared (=0).
1 (R/W)	MUTE1	Mute ASRC1. The `ASRC_MUTE.MUTE1` bit automatically mutes ASCR1 output when cleared (=0).
0 (R/W)	MUTE0	Mute ASRC0. The `ASRC_MUTE.MUTE0` bit automatically mutes ASCR0 output when cleared (=0).

Ratio Register for ASRC 0 and 1

The ASRC_RAT01 register report the mute and I/O sample ratio for ASRC0 and ASRC1.

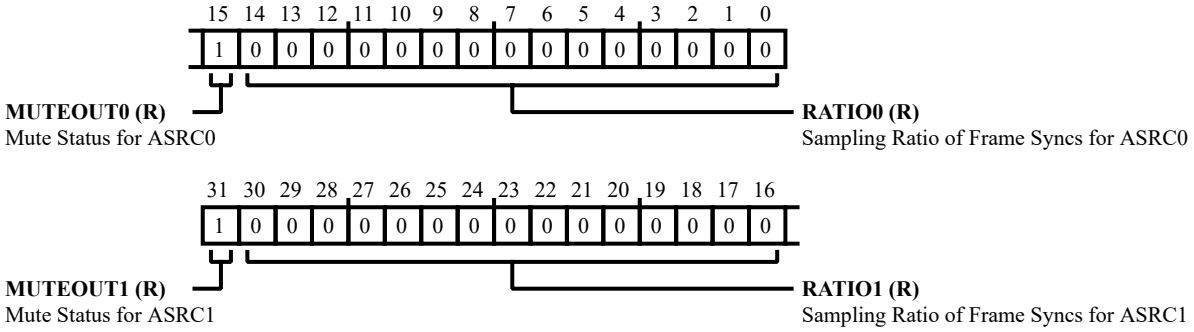

Figure 32-12: ASRC_RAT01 Register Diagram

Table 32-9: ASRC_RAT01 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/NW)	MUTEOUT1	Mute Status for ASRC1. The ASRC_RAT01.MUTEOUT1 bit field reports the status of the MUTE_OUT signal. Once the SRCx_MUTEOUT signal is cleared, the ratio can be read. When ASRC1 is enabled or there is a change in the sample ratio, the MUTE_OUT signal is asserted. The MUTE_OUT signal remains asserted until the digital servo loop's internal fast settling mode is complete. When the digital servo loop has switched to slow settling mode, the MUTE_OUT signal is deasserted.
30:16 (R/NW)	RATIO1	Sampling Ratio of Frame Syncs for ASRC1. The ASRC_RAT01.RATIO1 bit field is read to find the ratio of output to input sampling frequency for ASRC1 (SRCx_FS_OP_I/SRCx_FS_IP_I). This ratio is reported in 4.11 (integer.fraction) format where the 15-bit value of the normal binary number is comprised of 4 bits for the integer and 11 bits for the fraction.
15 (R/NW)	MUTEOUT0	Mute Status for ASRC0. The ASRC_RAT01.MUTEOUT0 bit field reports the status of the MUTE_OUT signal. Once the SRCx_MUTEOUT signal is cleared, the ratio can be read. When ASRC0 is enabled or there is a change in the sample ratio, the MUTE_OUT signal is asserted. The MUTE_OUT signal remains asserted until the digital servo loop's internal fast settling mode is complete. When the digital servo loop has switched to slow settling mode, the MUTE_OUT signal is deasserted.

Table 32-9: ASRC_RAT01 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
14:0 (R/NW)	RATIO0	Sampling Ratio of Frame Syncs for ASRC0. The `ASRC_RAT01.RATIO0` bit field is read to find the ratio of output to input sampling frequency for ASRC0 (SRCx_FS_OP_I/SRCx_FS_IP_I). This ratio is reported in 4.11 (integer.fraction) format where the 15-bit value of the normal binary number is comprised of 4 bits for the integer and 11 bits for the fraction.

Ratio Register for ASRC 2 and 3

The ASRC_RAT23 register report the mute and I/O sample ratio for ASRC0 and ASRC1.

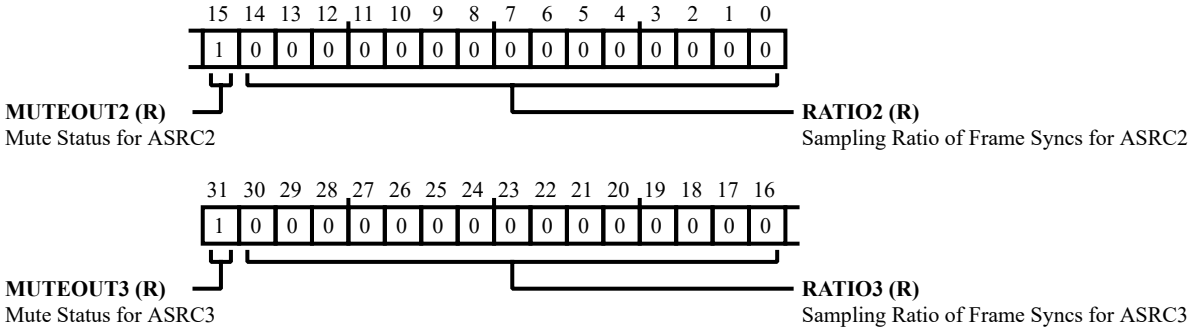

Figure 32-13: ASRC_RAT23 Register Diagram

Table 32-10: ASRC_RAT23 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/NW)	MUTEOUT3	Mute Status for ASRC3. The ASRC_RAT23.MUTEOUT3 bit field reports the status of the MUTE_OUT signal. Once the SRCx_MUTEOUT signal is cleared, the ratio can be read. When ASRC3 is enabled or there is a change in the sample ratio, the MUTE_OUT signal is asserted. The MUTE_OUT signal remains asserted until the digital servo loop's internal fast settling mode is complete. When the digital servo loop has switched to slow settling mode, the MUTE_OUT signal is deasserted.
30:16 (R/NW)	RATIO3	Sampling Ratio of Frame Syncs for ASRC3. The ASRC_RAT23.RATIO3 bit field is read to find the ratio of output to input sampling frequency for ASRC3 (SRCx_FS_OP_I/SRCx_FS_IP_I). This ratio is reported in 4.11 (integer.fraction) format where the 15-bit value of the normal binary number is comprised of 4 bits for the integer and 11 bits for the fraction.
15 (R/NW)	MUTEOUT2	Mute Status for ASRC2. The ASRC_RAT23.MUTEOUT2 bit field reports the status of the MUTE_OUT signal. Once the SRCx_MUTEOUT signal is cleared, the ratio can be read. When ASRC2 is enabled or there is a change in the sample ratio, the MUTE_OUT signal is asserted. The MUTE_OUT signal remains asserted until the digital servo loop's internal fast settling mode is complete. When the digital servo loop has switched to slow settling mode, the MUTE_OUT signal is deasserted.

Table 32-10: ASRC_RAT23 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
14:0 (R/NW)	RATIO2	Sampling Ratio of Frame Syncs for ASRC2. The `ASRC_RAT23.RATIO2` bit field is read to find the ratio of output to input sampling frequency for ASRC2 (SRCx_FS_OP_I/SRCx_FS_IP_I). This ratio is reported in 4.11 (integer.fraction) format where the 15-bit value of the normal binary number is comprised of 4 bits for the integer and 11 bits for the fraction.

Ratio Register For ASRC 4 and 5

The ASRC_RAT45 register report the mute and I/O sample ratio for ASRC4 and ASRC5.

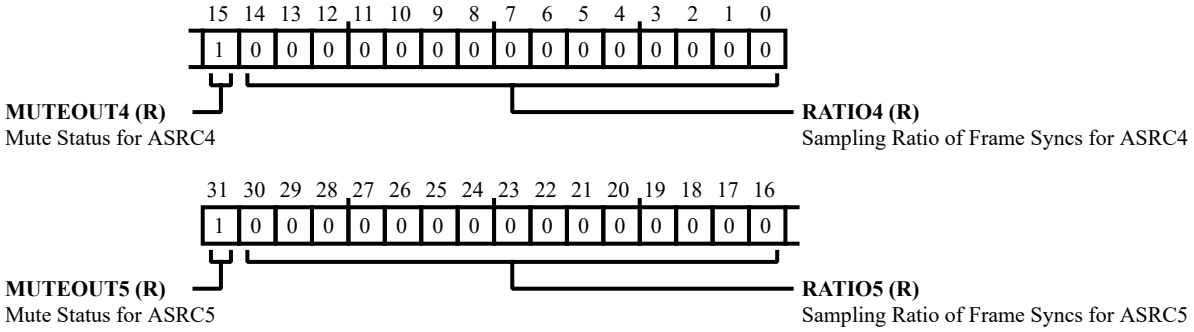

Figure 32-14: ASRC_RAT45 Register Diagram

Table 32-11: ASRC_RAT45 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/NW)	MUTEOUT5	Mute Status for ASRC5. The ASRC_RAT45.MUTEOUT5 bit field reports the status of the MUTE_OUT signal. Once the SRCx_MUTEOUT signal is cleared, the ratio can be read. When ASRC5 is enabled or there is a change in the sample ratio, the MUTE_OUT signal is asserted. The MUTE_OUT signal remains asserted until the digital servo loop's internal fast settling mode is complete. When the digital servo loop has switched to slow settling mode, the MUTE_OUT signal is deasserted.
30:16 (R/NW)	RATIO5	Sampling Ratio of Frame Syncs for ASRC5. The ASRC_RAT45.RATIO5 bit field is read to find the ratio of output to input sampling frequency for ASRC5 (SRCx_FS_OP_I/SRCx_FS_IP_I). This ratio is reported in 4.11 (integer.fraction) format where the 15-bit value of the normal binary number is comprised of 4 bits for the integer and 11 bits for the fraction.
15 (R/NW)	MUTEOUT4	Mute Status for ASRC4. The ASRC_RAT45.MUTEOUT4 bit field reports the status of the MUTE_OUT signal. Once the SRCx_MUTEOUT signal is cleared, the ratio can be read. When ASRC4 is enabled or there is a change in the sample ratio, the MUTE_OUT signal is asserted. The MUTE_OUT signal remains asserted until the digital servo loop's internal fast settling mode is complete. When the digital servo loop has switched to slow settling mode, the MUTE_OUT signal is deasserted.

Table 32-11: ASRC_RAT45 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
14:0 (R/NW)	RATIO4	Sampling Ratio of Frame Syncs for ASRC4. The `ASRC_RAT45.RATIO4` bit field is read to find the ratio of output to input sampling frequency for ASRC4 (SRCx_FS_OP_I/SRCx_FS_IP_I). This ratio is reported in 4.11 (integer.fraction) format where the 15-bit value of the normal binary number is comprised of 4 bits for the integer and 11 bits for the fraction.

Ratio Register for ASRC 6 and 7

The ASRC_RAT67 register report the mute and I/O sample ratio for ASRC6 and ASRC7.

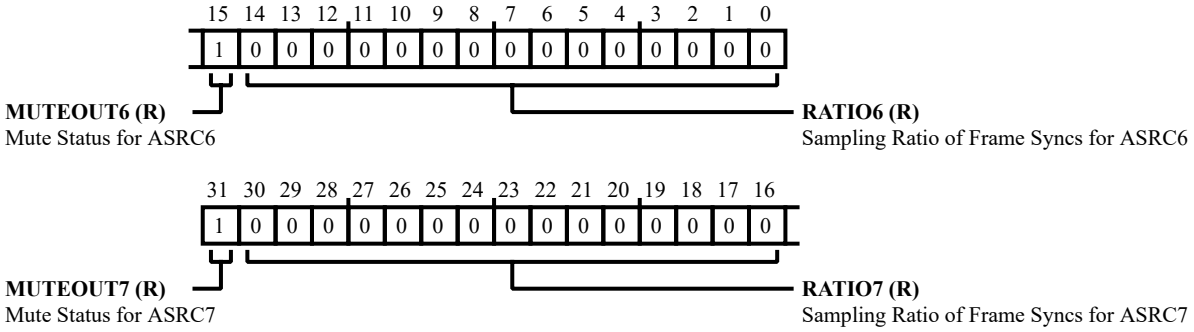

Figure 32-15: ASRC_RAT67 Register Diagram

Table 32-12: ASRC_RAT67 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/NW)	MUTEOUT7	Mute Status for ASRC7. The ASRC_RAT67.MUTEOUT7 bit field reports the status of the MUTE_OUT signal. Once the SRCx_MUTEOUT signal is cleared, the ratio can be read. When ASRC7 is enabled or there is a change in the sample ratio, the MUTE_OUT signal is asserted. The MUTE_OUT signal remains asserted until the digital servo loop's internal fast settling mode is complete. When the digital servo loop has switched to slow settling mode, the MUTE_OUT signal is deasserted.
30:16 (R/NW)	RATIO7	Sampling Ratio of Frame Syncs for ASRC7. The ASRC_RAT67.RATIO7 bit field is read to find the ratio of output to input sampling frequency for ASRC7 (SRCx_FS_OP_I/SRCx_FS_IP_I). This ratio is reported in 4.11 (integer.fraction) format where the 15-bit value of the normal binary number is comprised of 4 bits for the integer and 11 bits for the fraction.
15 (R/NW)	MUTEOUT6	Mute Status for ASRC6. The ASRC_RAT67.MUTEOUT6 bit field reports the status of the MUTE_OUT signal. Once the SRCx_MUTEOUT signal is cleared, the ratio can be read. When ASRC6 is enabled or there is a change in the sample ratio, the MUTE_OUT signal is asserted. The MUTE_OUT signal remains asserted until the digital servo loop's internal fast settling mode is complete. When the digital servo loop has switched to slow settling mode, the MUTE_OUT signal is deasserted.

Table 32-12: ASRC_RAT67 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
14:0 (R/NW)	RATIO6	Sampling Ratio of Frame Syncs for ASRC6. The `ASRC_RAT67.RATIO6` bit field is read to find the ratio of output to input sampling frequency for ASRC6 (SRCx_FS_OP_I/SRCx_FS_IP_I). This ratio is reported in 4.11 (integer.fraction) format where the 15-bit value of the normal binary number is comprised of 4 bits for the integer and 11 bits for the fraction.

33 Sony/Philips Digital Interface (S/PDIF)

The Sony/Philips Digital Interface (S/PDIF) is a standard audio data transfer format that allows the transfer of digital audio signals from one device to another without having to convert them to an analog signal. The digital audio interface carries three types of information; audio data, non-audio data (compressed data), and timing information.

Features

The S/PDIF interface has the following features.

- Supports one stereo channel or compressed audio streams.
- AES3-compatible S/PDIF transmitter and receiver.
- Transmitting a biphase mark encoded signal that may contain any number of audio channels (compressed or linear pulse code modulation) or non-audio data.
- S/PDIF receiver managing clock recovery with separate S/PDIF on-chip PLL.
- S/PDIF receiver supports the detection of DTS frames of 256, 512, 1024, 2048, and 4096.
- Manage user status information and provide error-handling capabilities in both the transmitter and receiver.
- DAI allows interactions over DAI by serial ports and the external DAI pins to interface to other S/PDIF devices. This includes using the receiver to decode incoming biphase encoded audio streams and passing them via the SPORTs to internal memory for processing-or using the transmitter to encode audio or digital data and transfer it to another S/PDIF receiver in the audio system.

It is important to be familiar with serial digital audio interface standards IEC-60958, EIAJ CP-340, AES3 and AES11.

ADSP-2184x SPDIF Register List

The S/PDIF module is a standard audio data transfer format that allows the transfer of digital audio signals from one device to another without having to convert them to an analog signal. A set of registers govern S/PDIF operations. For more information on S/PDIF functionality, see the S/PDIF register descriptions.

Table 33-1: ADSP-2184x SPDIF Register List

Name	Description
SPDIF_RX_CTL	Receive Control
SPDIF_RX_STAT	Receive Status Register
SPDIF_RX_STAT0_A	Receive Status A0 Register
SPDIF_RX_STAT0_B	Receive Status B0 Register
SPDIF_RX_STAT1_A	Receive Status A1 Register
SPDIF_RX_STAT1_B	Receive Status B1 Register

Table 33-1: ADSP-2184x SPDIF Register List (Continued)

Name	Description
SPDIF_TX_USRUPDT	User Bit Update Register

SRU Programming

The SRU (signal routing unit) is used to connect the S/PDIF transmitter biphase data out to the output pins or to the S/PDIF receiver. The serial clock, frame sync, data, and external sync (if external synchronization is required) inputs also need to be routed through the SRU. For details of the routing, see DAI Routing Capabilities in the *Digital Audio Interface (DAI)* chapter.

The SRU needs to be programmed in order to connect the S/PDIF receiver to the output pins or any other peripherals and also for the connection to the input biphase stream.

Program the corresponding SRU registers to connect the outputs to the required destinations (see DAI Routing Capabilities inputs to the receiver are routed through the SRU. The extracted clock, frame sync, and data are also routed through the SRU.

S/PDIF Interrupt List

The S/PDIF interrupts are controlled through the DAI.

Table 33-2: S/PDIF Interrupt List

Interrupt Name	Interrupt Condition	Return DAI Register	Interrupt ID
DAI0_IRQH	Block Start	DAIx_IRPTL	64
DAI0_IRQL	Non Audio		66

Clocking

The fundamental timing clock of the S/PDIF receiver is SCLK1_0 from the CDU. When SCLK1_0 is configured, it supports sampling frequencies of 32 kHz to 192 kHz. The fundamental timing clock of the S/PDIF transmitter is *SCLK0*/4.

For information on clock programming, see CDU Programming Model.

S/PDIF Transmitter

The following sections provide information on the S/PDIF transmitter.

Functional Description

The S/PDIF transmitter, shown in the ***S/PDIF Transmitter Block Diagram***, resides within the DAI, and its inputs and outputs can be routed via the SRU. It receives audio data in serial format, encloses the specified user status

information, and converts it into the biphase encoded signal. The serial data input to the transmitter can be formatted as left-justified, I^{2}S, or right-justified with word widths of 16, 18, 20 or 24 bits. ***AES3 Output Block*** shows the detail of the AES block.

The serial data, clock, and frame sync inputs to the S/PDIF transmitter are routed through the signal routing unit (SRU).

The S/PDIF transmitter output may be routed to an output pin via the SRU and then routed to another S/PDIF receiver or to components for off-board connections to other S/PDIF receivers. The output is also available to the S/PDIF receiver for loop-back testing through SRU.

In addition to encoding the audio data in the bi-phase format, the transmitter also provides a way to easily add the channel status information to the outgoing bi-phase stream. There are status/user registers for a frame (192-bits/24 bytes) in the transmitter that correspond to each channel or subframe.

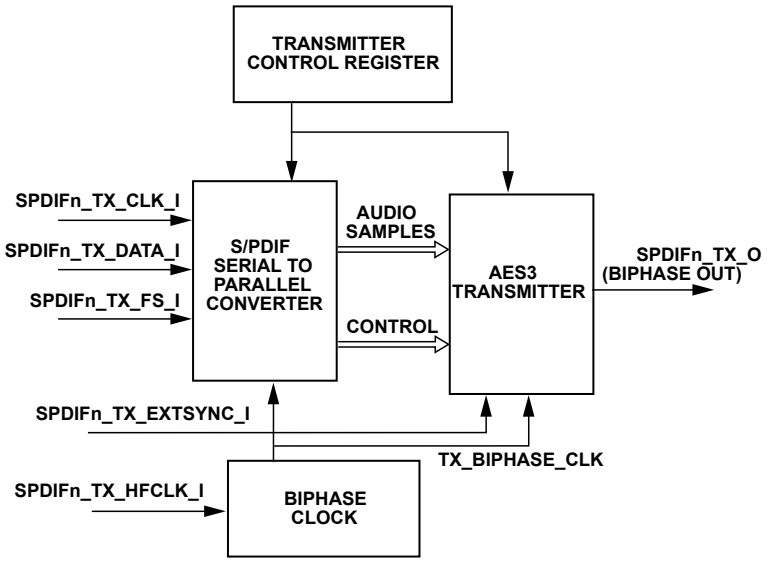

Figure 33-1: S/PDIF Transmitter Block Diagram

Validity bits for both channels may also be controlled by the transmitter control register. Optionally, the user bit, validity bit, and channel status bit are sent to the transmitter with each left/right sample. For each subframe the parity bit is automatically generated and inserted into the biphase encoded data.

A mute control and support for double-frequency single-channel mode are also provided. The serial data input format may be selected as left-justified, I^{2}S, or right-justified with 16-, 18-, 20-, or 24-bit word widths. The over sampling clock is also selected by the transmitter control register.

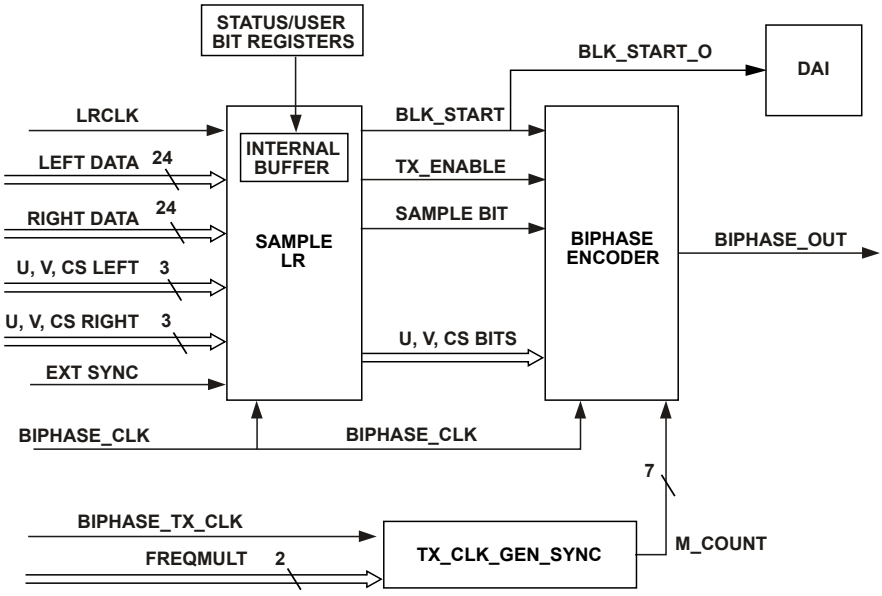

Figure 33-2: AES3 Output Block

Input Data Formats

The *I2S and Left-Justified Formats* and *Right-Justified Formats* figures show the format of data that is sent to the S/PDIF transmitter using a variety of protocol standards.

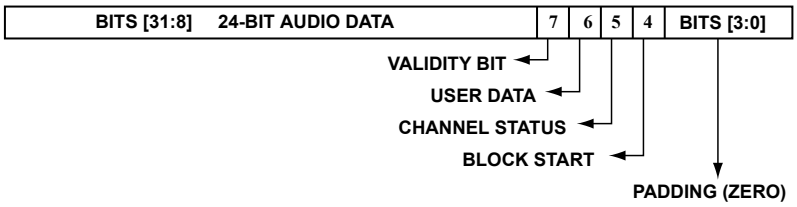

Figure 33-3: I^2S and Left-Justified Formats

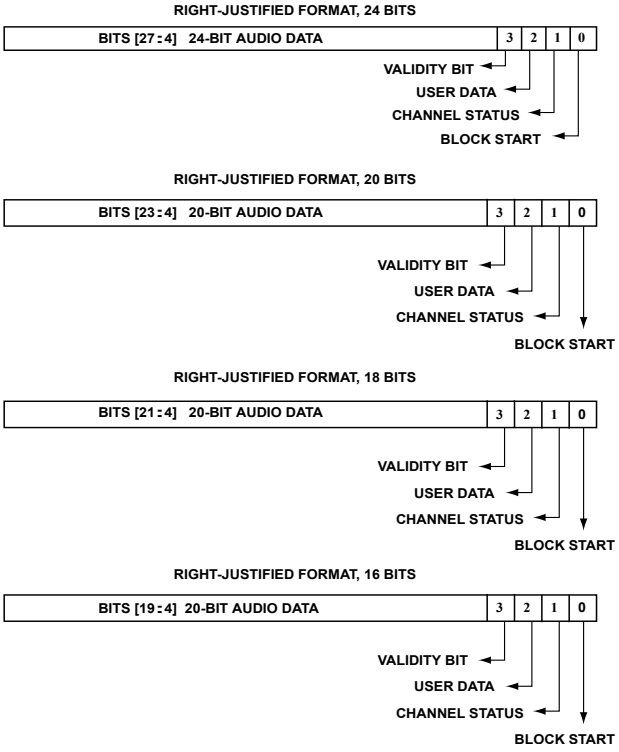

Figure 33-4: Right-Justified Formats

Operating Modes

The S/PDIF transmitter can operate in standalone and full serial modes. The following sections describe these modes in detail.

Full Serial Mode

This mode is selected by clearing the `SPDIF_TX_CTL.AUTO` bit. In this mode all the status bits, audio data and the block start bit (indicating start of a frame), come through the serial data stream (`SPDIF_TX_DATA_I`) pin. The transmitter should be enabled after or at the same time as all of the other control bits.

Standalone Mode

This mode is selected by setting the `SPDIF_TX_CTL.AUTO` bit. In this mode, the block start bit (indicating the start of a frame) is generated internally. The channel status bits come from the channel status buffer registers. The user status bits come from the user bits buffers as shown in the ***AES3 Output Block*** figure.

The validity bits are the `SPDIF_TX_CTL.VALIDR` and `SPDIF_TX_CTL.VALIDL`. In this mode only audio data comes from the `SPDIF_TX_DATA_I` pin. All other data, including the status bit and block start bit is either generated internally or taken from the internal register.

Once the user bits buffer registers (`SPDIF_TX_UBUFF_A0` - `SPDIF_TX_UBUFF_B5`) are programmed, they are used only for the next block of data. This allows programs to change the user bit information in every block of data.

To allow user bit updates, write a 0x1 to the SPDIF_TX_USRUPDT register that is used for further processing. If the SPDIF_TX_CTL.AUTO bit is set:

- and if SPDIF_TX_USRUPDT =1, at every 192nd frame end the user status bits are taken from user bits buffers and transmitted. Simultaneously, the SPDIF_TX_USRUPDT register is cleared automatically by hardware.
- and if SPDIF_TX_USRUPDT =0, at every 192nd frame end the user status bits are updated as zeros and transmitted. The SPDIF_TX_USRUPDT register remains low.

In general, for the next block, programs can update user bits buffers at any time during the transfer of the current block (1 block = 192 frames). There are internal buffers to store the user status bits of the current block of transfer. In other words, at the beginning of every new block, the user status bit (SPDIF_TX_CTL.USRPEND bit) from user bits buffers are copied to internal buffers and transmitted in each frame during the transfer.

Note that since a frame contains 192 bits/8 = 24 bytes, six status/user registers are required to store each four bytes.

Data Output Mode

Two output data formats are supported by the transmitter; *two channel mode* and *single-channel double-frequency* (SCDF) mode. The output format is determined by the transmitter control register (SPDIF_TX_CTL).

In two channel mode, the left channel (channel A) is transmitted when the SPDIF_TX_FS_I is high, and the right channel (channel B) is transmitted when the SPDIF_TX_FS_I is low.

In SCDF mode, the transmitter sends successive audio samples of the same signal across both sub frames, instead of channel A and B. The transmitter transmits at half the sample rate of the input bit stream. The SPDIF_TX_CTL.SCDF bit selects SCDF mode. When in SCDF mode, the SPDIF_TX_CTL.SCDFLR bit determines whether left or right channel data is transmitted.

S/PDIF Receiver

The S/PDIF receiver (***S/PDIF Receiver Block Diagram***) is compliant with all common serial digital audio interface standards including IEC-60958, IEC-61937, AES3, and AES11. For the IEC-60958 standard, all the user-data and channel-status bits (as outlined in this document) are not decoded by the S/PDIF receiver. The interface does make all 192 user-data and channel-status pairs available as an output of the block, for post-decoding.

For the IEC-61937 standard, the S/PDIF only detects compressed AC-3 and DTS formats. No decompression is performed.

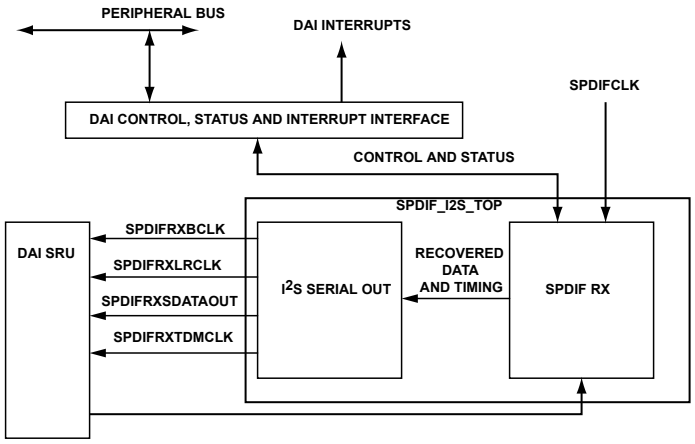

Figure 33-5: S/PDIF Receiver Block Diagram

Functional Description

If the receiver is used, programs need to enable it using the `SPDIF_RX_CTL` register. After the SRU programming is complete, write to the register with control values. At this point, the receiver attempts to lock.

NOTE: The S/PDIF receiver is disabled at default. If the receiver is used in an application, programs should enable the receiver.

The input to the receiver (SPDIFn_RX_I) is a biphase encoded signal that may contain two audio channels (compressed or linear PCM) or non-audio data. The receiver decodes the single biphase encoded stream, producing an I^2S compatible serial data output that consists of a serial clock, a left-right frame sync, and data (channel A/B). It provides the programmer with several methods of managing the incoming status bit information.

The S/PDIF receiver receives any S/PDIF stream with a sampling frequency range of 24 kHz to 192 kHz. Refer to Clocking for more details.

The channel status bits are collected into memory-mapped registers, while other channel status and user bytes must be handled manually. The block start bit, which replaces the parity bit in the serial I^2S stream, indicates the reception of the Z preamble and the start of a new block of channel status and data bits.

Clock Recovery

The S/PDIF receiver recovers the clock that generated the AES3/SPDIF biphase encoded stream from the incoming S/PDIF stream.

This clock is used by the receiver to clock in the biphase encoded data stream and also to provide clocks for either the SPORTs, sample rate converter, or the AES3 and S/PDIF transmitter. The recovered clock may also be used externally to the chip for clocking D/A and A/D converters.

In order to maintain performance, jitter on the clock is sourced to several peripherals.

To comply with the AES11 standard, the recovered left or right clock must be aligned with the preambles within a + or - 5% of the frame period. Since the PLL clock generates a clock 512 times the frame rate clock (512 f_{SCLK}), this clock can be used and divided down to create the phase aligned jitter-free left or right clock.

Output Data Format

The extracted 24-bit audio data, V, U, C, and block start bits are sent on the SPDIF_RX_DAT pin in 32-bit I^2S format as shown in ***I2S and Left-Justified Formats***. The frame sync is transmitted on the SPDIF_RX_FS pin and serial clock is transmitted on the SPDIF_RX_CLK pin. All three pins are routed through the SRU.

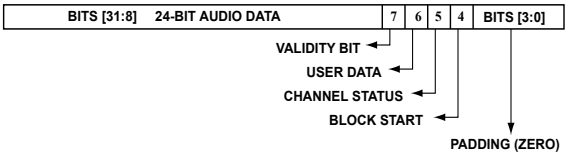

Figure 33-6: I^2S Format

Channel Status

The channel status for the first bytes 4-0 (consumer mode) are collected into memory-mapped registers (SPDIF_RX_STAT0_A, SPDIF_RX_STAT0_B, SPDIF_RX_STAT1_A and SPDIF_RX_STAT1_B). All other channel status bytes 23-5 (professional mode) must be manually extracted from the receiver data stream.

NOTE: Only the first 5 channel status bytes (40-bit) for consumer mode of a frame are stored into the S/PDIF receiver status registers.

Operating Modes

This section describes the receiver channel status for the different modes.

Compressed or Non-linear Audio Data

The S/PDIF receiver processes compressed as well as non-linear audio data according to the supported standards. The following sections describe how this peripheral handles different data.

MPEG-2, AC-3, DTS, and AAC compressed data may be transmitted without setting either the SPDIF_RX_STAT.VALID bit or bit 1 of byte 0. To detect this data, the IEC61937 and SPMTE 337M standards dictate that there be a 96-bit sync code in the 16-, 20- or 24-bit audio data stream. This sync code consists of four words of zeros followed by a word consisting of 0xF872 and another word consisting of 0x4E1F. When this sync code is detected, the SPDIF_RX_STAT.COMPMODE bits hold the information regarding type of compression.

The last two words of the sync code, 0xF872 and 0x4E1F, are called the preamble-A and preamble-B of the burst preamble. Preamble-C of the burst preamble contains burst information and is captured and stored by the receiver. Preamble-D of the burst preamble contains the length code and is captured by the receiver. Even if the validity bit or bit 1 of byte 0 has been set, the receiver still looks for the sync code in order to record the preamble-C and D values. Once the sync code has not been detected in 4096 frames, the preamble-C and D registers are set to zero.

Emphasized Audio Data

Determination as to whether the received audio data is emphasized or not is done in software using the channel status bits as detailed below.

- In professional mode, (bit 0 of byte 0 = 1), channel status bits 2-4 of byte 0 indicate the audio data is emphasized if they are equal to 110 or 111.
- In consumer mode, (bit 0 of byte 0 = 0), channel status bits 3-5 indicate the audio data is emphasized if they are equal to 100, 010 or 110.

Single-Channel Double-Frequency Mode

Unlike previous processors, support for single-channel, double-frequency mode (SCDF) is not supported through specific bits within the `SPDIF_RX_CTL` register, but must be implemented in software using the information provided by the CS (channel status) bits.

- 0111–single channel double frequency mode
- 1000–single channel double frequency mode-stereo left
- 1001–single channel double frequency mode-stereo right

Clock Recovery Modes

The S/PDIF receiver extracts audio data, channel status, and user bits from the biphase encoded AES3 and S/PDIF stream. In addition, a 50% duty cycle reference clock running at the sampling rate of the audio input data is generated for the receiver to recover the oversampling clock.

Number Controlled Oscillator

The receiver can recover the clock from the biphase encoded stream using an on-chip NCO shown in the following figure. The dedicated NCO is separate from the PLL that supplies the clock to the processor core, which is the default operation of the receiver.

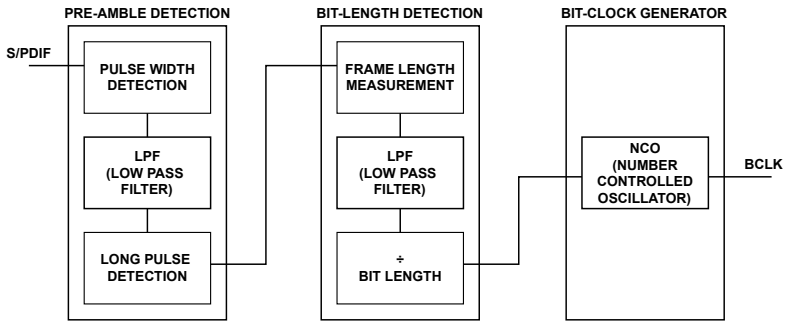

Figure 33-7: S/PDIF Clock Recovery Mechanism

The left/right frame reference clock for the NCO is generated using the preambles. The recovered low jitter left/right frame clock from the NCO attempts to align with the reference clock. However, this recovered left/right clock, like the reference clock, is not phase aligned with the preambles.

Interrupts

The following sections provide information about interrupt sources, masking, and servicing.

Sources

The S/PDIF module of each DAI drives five interrupt signals. Four are status signals driven from SPDIFn_RX and one signal is driven from SPDIFn_TX (block start). These signals are connected into the DAI_IRPTL_L/ DAI_IRPTL_H latch register.

Transmit Block Start

The SPDIFn_TX_BLKSTART output signal, if routed to any miscellaneous interrupt bits (DAIn_INT_31-22 in the DAI_MISC0/DAI_MISC1 registers), triggers a block start interrupt during the last frame of current block.

Receiver Status

The following receiver status bits generate an interrupt.

- Validity (SPDIF_RX_STAT.VALID)
- Receiver locked (SPDIF_RX_STAT.LOCK)
- No audio (SPDIF_RX_STAT.AUDIOTYPE)

Receiver Error

The loss of lock (SPDIF_RX_STAT.LOCKLOSS) bit generates an interrupt.

Masking

For the S/PDIF receiver the DAI_IMSK_RE register must be unmasked accordingly. For the S/PDIF transmit the DAIn_IMASK_x register must be unmasked accordingly.

The INTR_DAI_IRQH and INTR_DAI_IRQL signals are routed to the SEC.

Service

The ISR reads the DAI_IRPTL_H and DAI_IRPTL_L registers to clear the interrupt request.

Programming Model

The following sections provide information on programming the transmitter and receiver.

Programming the Transmitter

Since the S/PDIF transmitter data input is not available to the core, programming the transmitter is as simple as: 1) connecting the SRU to the on-chip (serial ports or input data port) or off-chip (DAI pins) serial devices that provide the clock and data to be encoded, and 2) selecting the desired mode in the transmitter control register. This setup can be accomplished in three steps.

1. Connect the transmitter's four required input signals and one biphase encoded output in the SRU. The four input signals are the serial clock (SPDIF_TX_CLK_I), the serial frame sync (SPDIF_TX_FS_I), the serial data (SPDIF_TX_DAT_I), and the high frequency clock (SPDIF_TX_HFCLK_I) used for the encoding. The only output of the transmitter is SPDIF_TX_O.
2. If user bits are required, write 0x1 to the SPDIF_TX_USRUPDT register for the first block of transfer. Also route the SPDIF_TX_BLK_START_O signal to the DAI_INT_31-22 (DAI_IRPTLx register). This generates interrupts during the last frame of the block (192), allowing changes of user bits for the next block.
3. Initialize the SPDIF_TX_CTL register to enable the data encoding.
4. Manually set the block start bit in the data stream once per block (every 384 words). This is necessary if automatic generation of block start information is not enabled using the SPDIF_TX_CTL.AUTO bit = 0.

NOTE: For more information, see the "DAI Routing Capabilities" section of the *Digital Audio Interface (DAI)* chapter.

Programming the Receiver

Since the S/PDIF receiver data output is not available to the core, programming the peripheral is as simple as connecting the SRU to the on-chip (serial ports) or off-chip (DAI pins) serial devices that provide the clock and data to be decoded, and selecting the desired mode in the receiver control register. This setup can be accomplished in two steps.

1. Connect the input signal and three output signals in the SRU. The only input of the receiver is the biphase encoded stream, SPDIFn_RX_I. The three required output signals are the serial clock (SPDIFn_RX_CLK), the serial frame sync (SPDIFn_RX_FS), and the serial data (SPDIFn_RX_DAT). The high frequency clock (SPDIFn_RX_TDMCLK) derived from the encoded stream is also available if the system requires it.
2. Initialize the SPDIF_RX_CTL register to enable the data decoding. Note that this peripheral is disabled by default.

NOTE: For more information, see the "DAI Routing Capabilities" section of the *Digital Audio Interface (DAI)* chapter.

Interrupted Data Streams on the Receiver

When using the S/PDIF receiver with data streams that are likely to be interrupted, (in other words unplugged and reconnected), it is necessary to take some extra steps to ensure that the S/PDIF receiver's digital PLL will relock to the stream. The steps to accomplish this are described below.

1. Set up interrupts within the DAI so that the S/PDIF receiver can generate an interrupt when the stream is reconnected.
2. Within the interrupt service routine (ISR), stop and restart the NCO. This is accomplished by setting and then clearing the SPDIF_RX_CTL.RST bit.
3. Return from the ISR and continue normal operation.

This method of resetting the NCO has been shown to provide extremely reliable performance when the S/PDIF inputs are interrupted or unplugged momentarily.

Debug Features

The following feature supports S/PDIF debugging.

Loopback Routing

The S/PDIF supports an internal loopback mode by using the SRU. For more information about loopback, see "Loopback Routing" in the *Digital Audio Interface (DAI)* chapter.

ADSP-2184x SPDIF Register Descriptions

The S/PDIF module (SPDIF) contains the following registers.

Table 33-3: ADSP-2184x SPDIF Register List

Name	Description
SPDIF_RX_CTL	Receive Control
SPDIF_RX_STAT	Receive Status Register
SPDIF_RX_STAT0_A	Receive Status A0 Register
SPDIF_RX_STAT0_B	Receive Status B0 Register
SPDIF_RX_STAT1_A	Receive Status A1 Register
SPDIF_RX_STAT1_B	Receive Status B1 Register
SPDIF_TX_CTL	Transmit Control Register
SPDIF_TX_STAT_A0	Transmit Status A0 Register
SPDIF_TX_STAT_A1	Transmit Status A1 Register
SPDIF_TX_STAT_A2	Transmit Status A2 Register
SPDIF_TX_STAT_A3	Transmit Status A3 Register
SPDIF_TX_STAT_A4	Transmit Status A4 Register
SPDIF_TX_STAT_A5	Transmit Status A5 Register
SPDIF_TX_STAT_B0	Transmit Status B0 Register
SPDIF_TX_STAT_B1	Transmit Status B1 Register
SPDIF_TX_STAT_B2	Transmit Status B2 Register
SPDIF_TX_STAT_B3	Transmit Status B3 Register
SPDIF_TX_STAT_B4	Transmit Status B4 Register
SPDIF_TX_STAT_B5	Transmit Status B5 Register

Table 33-3: ADSP-2184x SPDIF Register List (Continued)

Name	Description
SPDIF_TX_UBUFF_A0	Transmit User Buffer A0 Register
SPDIF_TX_UBUFF_A1	Transmit User Buffer A1 Register
SPDIF_TX_UBUFF_A2	Transmit User Buffer A2 Register
SPDIF_TX_UBUFF_A3	Transmit User Buffer A3 Register
SPDIF_TX_UBUFF_A4	Transmit User Buffer A4 Register
SPDIF_TX_UBUFF_A5	Transmit User Buffer A5 Register
SPDIF_TX_UBUFF_B0	Transmit User Buffer B0 Register
SPDIF_TX_UBUFF_B1	Transmit User Buffer B1 Register
SPDIF_TX_UBUFF_B2	Transmit User Buffer B2 Register
SPDIF_TX_UBUFF_B3	Transmit User Buffer B3 Register
SPDIF_TX_UBUFF_B4	Transmit User Buffer B4 Register
SPDIF_TX_UBUFF_B5	Transmit User Buffer B5 Register
SPDIF_TX_USRUPDT	User Bit Update Register

Receive Control

The SPDIF_RX_CTL register is used to enable and control the S/PDIF receiver.

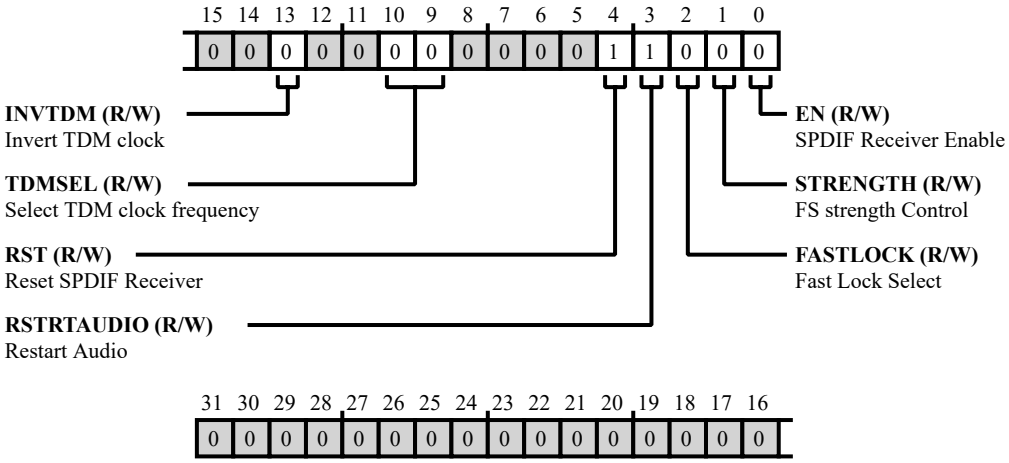

Figure 33-8: SPDIF_RX_CTL Register Diagram

Table 33-4: SPDIF_RX_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W)	INVTDM	Invert TDM clock. When set to 0, inverted TDM clock or non-inverted Bit clock is selected. When set to 1, non-inverted TDM clock or inverted Blit clock is selected.	
12:9 (R/W)	TDMSEL	Select TDM clock frequency. Select TDM clock frequency	
4 (R/W)	RST	Reset SPDIF Receiver. The SPDIF_RX_CTL.RST bit resets the receiver.	
		0	Takes the receiver out of reset
		1	Resets the SPDIF receiver
3 (R/W)	RSTRTAUDIO	Restart Audio. The SPDIF_RX_CTL.RSTRTAUDIO bit restarts the audio once a re-lock has occurred. When the S/PDIF receiver loses lock the audio output is set to 0. This bit determines the behavior of the audio once lock is re-established. Audio can be manually restarted by toggling this bit high and then low.	
		0	Manually restart audio
		1	Automatically restart audio

Table 33-4: SPDIF_RX_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	FASTLOCK	Fast Lock Select. The `SPDIF_RX_CTL.FASTLOCK` bit allows the lock mechanism to lock at normal speed or at faster speed. This has the advantage of recovering very quickly whenever the S/PDIF receiver looses lock due to glitches in the signal. In normal mode the S/PDIF receiver locks after 64 consecutive valid samples, in fast mode the S/PDIF receiver locks after 8 consecutive valid samples	
		0	Enable normal mode
		1	Enable fast mode
1 (R/W)	STRENGTH	FS strength Control. The `SPDIF_RX_CTL.STRENGTH` bit controls the strength of the bit clock and Frame sync outputs from the SPDIF receiver. In strong mode these output signals are continued (as best possible) when the receiver notices a loss-of-lock condition. Note that 'as best possible' refers to the fact that this recovered signal may not be accurate, given the loss-of-lock condition. In weak mode these output signals are interrupted as soon as the receiver notices a loss-of-lock condition.	
		0	Enable strong mode
		1	Enable weak mode
0 (R/W)	EN	SPDIF Receiver Enable. When the `SPDIF_RX_CTL.EN` bit =0 the clock to SPDIF is switched off for power savings.	
		0	Disable receiver
		1	Enable receiver

Receive Status Register

The SPDIF_RX_STAT register consists of bits that indicate the status of various functions supported by S/PDIF receiver.

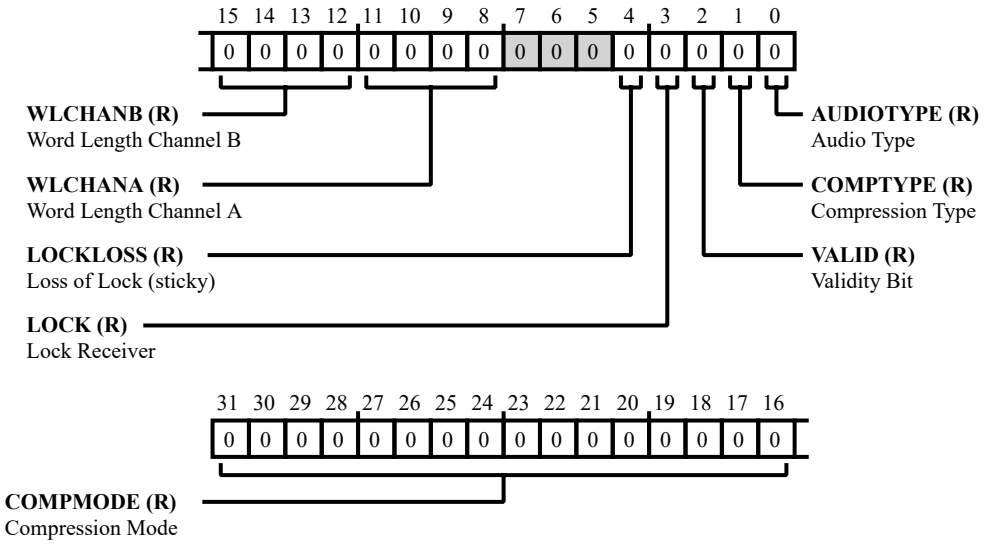

Figure 33-9: SPDIF_RX_STAT Register Diagram

Table 33-5: SPDIF_RX_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:16 (R/NW)	COMPMODE	Compression Mode. The SPDIF_RX_STAT.COMPMODE bit field indicates the type of compression mode used in the Digital audio stream. The value in this field indicates the 16-bit burst information as specified by the IEC 62937-2 standard. Use this document to decode the value in this bit field.	
15:12 (R/NW)	WLCHANB	Word Length Channel B. The SPDIF_RX_STAT.WLCHANB bit field indicates the S/PDIF word length for channel B. May be decoded as follows (from the S/PDIF standard).	
		0	Reserved
		1	Reserved
		2	SPDIF_LENGTH_16
		3	Reserved
		4	SPDIF_LENGTH_18
		5	SPDIF_LENGTH_22
		6	Reserved

Table 33-5: SPDIF_RX_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		7	Reserved
		8	SPDIF_LENGTH_19
		9	SPDIF_LENGTH_23
		10	SPDIF_LENGTH_20
		11	SPDIF_LENGTH_24
		12	SPDIF_LENGTH_17
		13	SPDIF_LENGTH_21
		14	Reserved
		15	Reserved
11:8 (R/NW)	WLCHANA	Word Length Channel A. The `SPDIF_RX_STAT.WLCHANA` bit indicates the S/PDIF word length for channel A. May be decoded as follows (from the S/PDIF standard).	
		0	Reserved
		1	Reserved
		2	SPDIF_LENGTH_16
		3	Reserved
		4	SPDIF_LENGTH_18
		5	SPDIF_LENGTH_22
		6	Reserved
		7	Reserved
		8	SPDIF_LENGTH_19
		9	SPDIF_LENGTH_23
		10	SPDIF_LENGTH_20
		11	SPDIF_LENGTH_24
		12	SPDIF_LENGTH_17
		13	SPDIF_LENGTH_21
		14	Reserved
		15	Reserved

Table 33-5: SPDIF_RX_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/NW)	LOCKLOSS	Loss of Lock (sticky). The SPDIF_RX_STAT.LOCKLOSS bit indicates that the system has lost lock. This is different to the lock register, as it is sticky it goes high when system looses lock, but returns to low once SPDIF_RX_CTL.RSTRTAUDIO bit is toggled. This is to allow the programs to poll the lock status.	
		0	SPDIF receiver locked
		1	SPDIF Receiver lost lock
3 (R/NW)	LOCK	Lock Receiver. The SPDIF_RX_STAT.LOCK bit indicates the S/PDIF receiver has successfully locked to the S/PDIF stream and is outputting valid data.	
		0	Receiver not locked
		1	Receiver locked
2 (R/NW)	VALID	Validity Bit. The SPDIF_RX_STAT.VALID bit indicates the ORed bits of channel A and B.	
		0	Linear PCM data
		1	Non-linear audio data
1 (R/NW)	COMPTYPE	Compression Type. The SPDIF_RX_STAT.COMPTYPE bit indicates AC3 or DTS compression. Valid only if SPDIF_RX_STAT.AUDIOTYPE indicates compressed data.	
		0	AC3 compressed data
		1	DTS compressed data
0 (R/NW)	AUDIOTYPE	Audio Type. The SPDIF_RX_STAT.AUDIOTYPE bit indicates PCM or compressed data.	
		0	PCM data
		1	Compressed Data

Receive Status A0 Register

The SPDIF_RX_STAT0_A register holds the receive channel 0 status for bytes 0-3 for sub frame A.

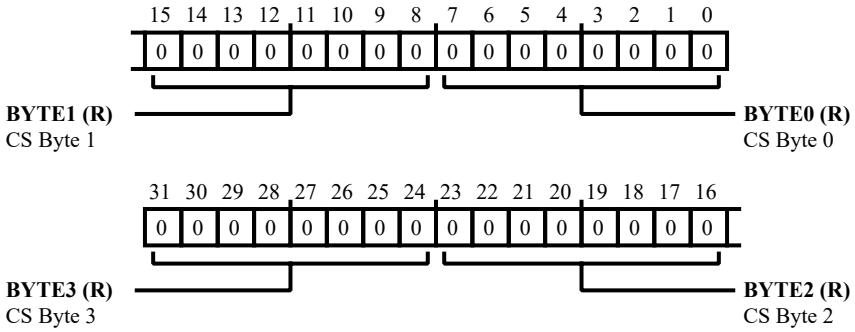

Figure 33-10: SPDIF_RX_STAT0_A Register Diagram

Table 33-6: SPDIF_RX_STAT0_A Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/NW)	BYTE3	CS Byte 3. The SPDIF_RX_STAT0_A.BYTE3 bit field contains byte 3 of received channel A status.
23:16 (R/NW)	BYTE2	CS Byte 2. The SPDIF_RX_STAT0_A.BYTE2 bit field contains byte 2 of received channel A status.
15:8 (R/NW)	BYTE1	CS Byte 1. The SPDIF_RX_STAT0_A.BYTE1 bit field contains byte 1 of received channel A status.
7:0 (R/NW)	BYTE0	CS Byte 0. The SPDIF_RX_STAT0_A.BYTE0 bit field contains the status of byte 0-3 of received channel A.

Receive Status B0 Register

The SPDIF_RX_STAT0_B register holds the receive channel 0 status for bytes 0-3 for sub frame B.

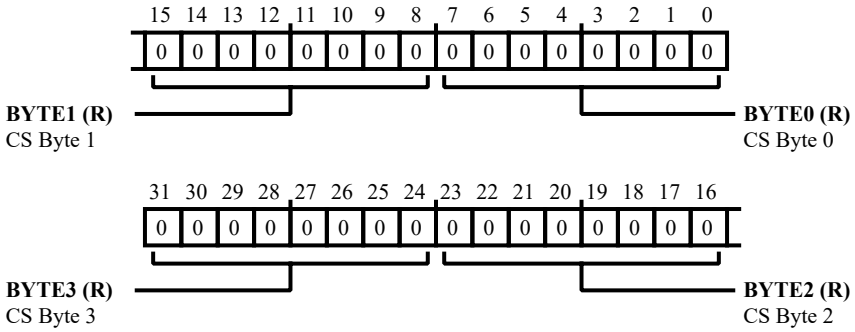

Figure 33-11: SPDIF_RX_STAT0_B Register Diagram

Table 33-7: SPDIF_RX_STAT0_B Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/NW)	BYTE3	CS Byte 3. The SPDIF_RX_STAT0_B.BYTE3 bit field contains byte 3 of received channel B status.
23:16 (R/NW)	BYTE2	CS Byte 2. The SPDIF_RX_STAT0_B.BYTE2 bit field contains byte 2 of received channel B status.
15:8 (R/NW)	BYTE1	CS Byte 1. The SPDIF_RX_STAT0_B.BYTE1 bit field contains byte 1 of received channel B status.
7:0 (R/NW)	BYTE0	CS Byte 0. The SPDIF_RX_STAT0_B.BYTE0 bit field contains byte 0 of received channel B status.

Receive Status A1 Register

The SPDIF_RX_STAT1_A register holds the receive channel 1 status for byte 4 for sub frame A.

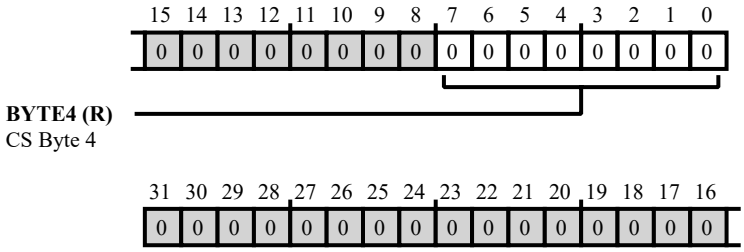

Figure 33-12: SPDIF_RX_STAT1_A Register Diagram

Table 33-8: SPDIF_RX_STAT1_A Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/NW)	BYTE4	CS Byte 4. The SPDIF_RX_STAT1_A.BYTE4 bit field contains byte 4 of received channel A status.

Receive Status B1 Register

The SPDIF_RX_STAT1_B register holds the receive channel 1 status for byte 4 for sub frame B.

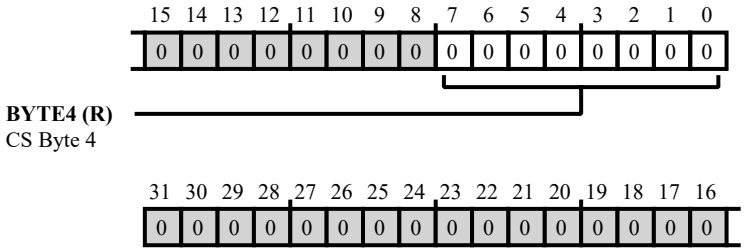

Figure 33-13: SPDIF_RX_STAT1_B Register Diagram

Table 33-9: SPDIF_RX_STAT1_B Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/NW)	BYTE4	CS Byte 4. The SPDIF_RX_STAT1_B.BYTE4 bit field contains byte 4 of received channel B status.

Transmit Control Register

The SPDIF_TX_CTL register provides bits the enable/disable the transmitter and configure several options related to data transmission.

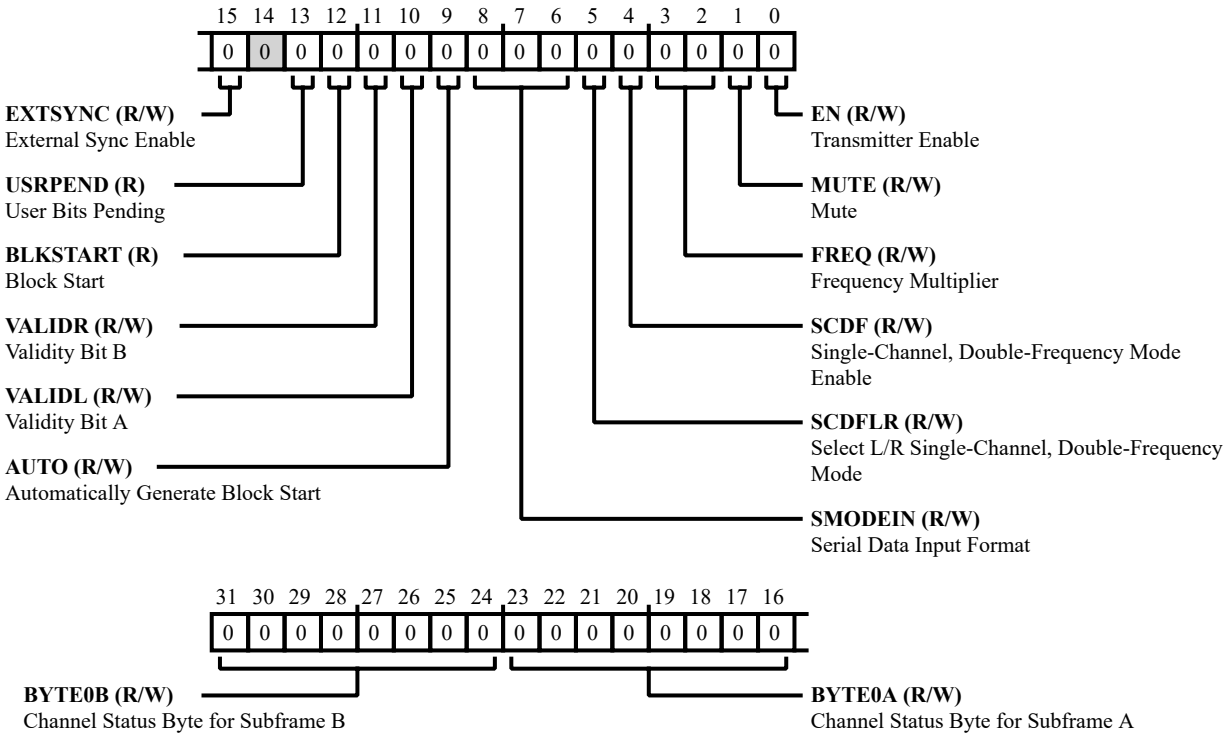

Figure 33-14: SPDIF_TX_CTL Register Diagram

Table 33-10: SPDIF_TX_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	BYTE0B	Channel Status Byte for Subframe B. The SPDIF_TX_CTL.BYTE0B bit field contains the channel status for the second bytes 9-5.
23:16 (R/W)	BYTE0A	Channel Status Byte for Subframe A. The SPDIF_TX_CTL.BYTE0A bit field contains the channel status for the first bytes 4-0.
15 (R/W)	EXTSYNC	External Sync Enable. When the SPDIF_TX_CTL.EXTSYNC bit is set (regardless of the SPDIF_TX_CTL.AUTO bit setting) the internal frame counter is set to zero at an internal LRCLK rising edge followed by an EXTSYNC_I rising edge.

Table 33-10: SPDIF_TX_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/NW)	USRPEND	User Bits Pending. The SPDIF_TX_CTL.USRPEND bit is set if the update of the internal buffer from the Transmit User Bits Buffer registers has not yet completed.	
12 (R/NW)	BLKSTART	Block Start. The SPDIF_TX_CTL.BLKSTART bit is a status bit that indicates block start (when the SPDIF_TX_CTL.AUTO bit = 1).	
		0	Current word is not block start
		1	Current word is block start
11 (R/W)	VALIDR	Validity Bit B. Use the SPDIF_TX_CTL.VALIDR bit with the channel status buffer.	
10 (R/W)	VALIDL	Validity Bit A. The SPDIF_TX_CTL.VALIDL bit either manually start block transfer according to input stream status bits or automatically start block transfer. Use the SPDIF_TX_CTL.VALIDL bit with the channel status buffer.	
		0	Manually start block transfer
		1	Automatically start block transfer
9 (R/W)	AUTO	Automatically Generate Block Start. When enabled, the transmitter is in standalone mode where it inserts block start, channel status, and validity bits on its own. If the channel status or validity buffer needs to be enabled (after the DAI programming is complete), first write to the buffers with the required data and then enable the buffers by setting the SPDIF_TX_CTL.AUTO bit.	
8:6 (R/W)	SMODEIN	Serial Data Input Format. The SPDIF_TX_CTL.SMODEIN bit selects the data input format.	
		0	Left-justified
		1	I2S
		2	Reserved
		3	Reserved
		4	Right-justified, 24 bits
		5	Right-justified, 20 bits
		6	Right-justified, 18 bits
		7	Right-justified, 16 bits

Table 33-10: SPDIF_TX_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W)	SCDFLR	Select L/R Single-Channel, Double-Frequency Mode. The SPDIF_TX_CTL.SCDFLR bit selects the left or right channel in SCDF mode.	
		0	Left channel
		1	Right channel
4 (R/W)	SCDF	Single-Channel, Double-Frequency Mode Enable. The SPDIF_TX_CTL.SCDF bit enables single-channel, double-frequency mode.	
		0	Two-channel mode
		1	SCDF mode
3:2 (R/W)	FREQ	Frequency Multiplier. The SPDIF_TX_CTL.FREQ bit field sets the oversampling ratio.	
		0	256 x frame sync oversampling
		1	384 x frame sync oversampling
		2-3	Reserved
1 (R/W)	MUTE	Mute. The SPDIF_TX_CTL.MUTE bit mutes the serial data output.	
		0	Disable Mute
		1	Enable Mute
0 (R/W)	EN	Transmitter Enable. The SPDIF_TX_CTL.EN bit enables the transmitter and resets the control registers to their defaults.	
		0	Transmitter disabled
		1	Transmitter enabled

Transmit Status A0 Register

The SPDIF_TX_STAT_A0 register holds the transmit channel 0 status for bytes 1-4 for sub frame A.

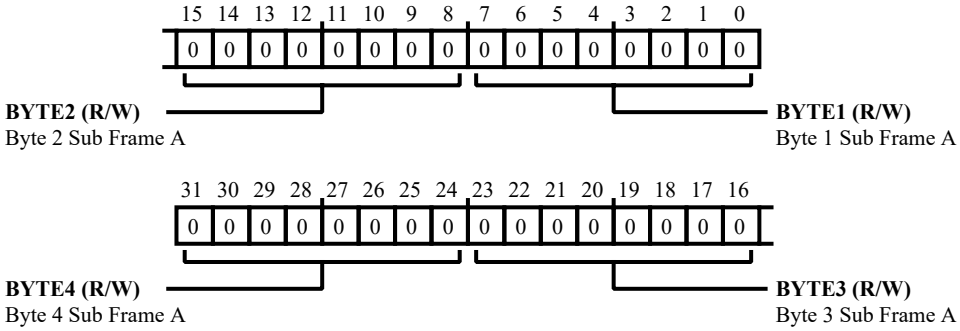

Figure 33-15: SPDIF_TX_STAT_A0 Register Diagram

Table 33-11: SPDIF_TX_STAT_A0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	BYTE4	Byte 4 Sub Frame A. The SPDIF_TX_STAT_A0.BYTE4 bit field holds the transmit channel 0 status for byte 4 for sub frame A.
23:16 (R/W)	BYTE3	Byte 3 Sub Frame A. The SPDIF_TX_STAT_A0.BYTE3 bit field holds the transmit channel 0 status for byte 3 for sub frame A.
15:8 (R/W)	BYTE2	Byte 2 Sub Frame A. The SPDIF_TX_STAT_A0.BYTE2 bit field holds the transmit channel 0 status for byte 2 for sub frame A.
7:0 (R/W)	BYTE1	Byte 1 Sub Frame A. The SPDIF_TX_STAT_A0.BYTE1 bit field holds the transmit channel 0 status for byte 1 for sub frame A.

Transmit Status A1 Register

The SPDIF_TX_STAT_A1 register holds the transmit status for bytes 5-8 for sub frame A.

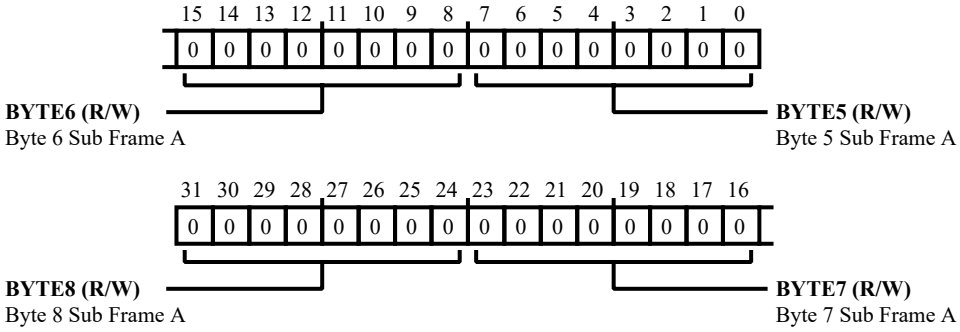

Figure 33-16: SPDIF_TX_STAT_A1 Register Diagram

Table 33-12: SPDIF_TX_STAT_A1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	BYTE8	Byte 8 Sub Frame A. The SPDIF_TX_STAT_A1.BYTE8 bit field contains transmit status for byte 8 of sub frame A.
23:16 (R/W)	BYTE7	Byte 7 Sub Frame A. The SPDIF_TX_STAT_A1.BYTE7 bit field contains transmit status for byte 7 of sub frame A.
15:8 (R/W)	BYTE6	Byte 6 Sub Frame A. The SPDIF_TX_STAT_A1.BYTE6 bit field contains transmit status for byte 6 of sub frame A.
7:0 (R/W)	BYTE5	Byte 5 Sub Frame A. The SPDIF_TX_STAT_A1.BYTE5 bit field contains transmit status for byte 5 of sub frame A.

Transmit Status A2 Register

The SPDIF_TX_STAT_A2 register holds the transmit status for bytes 9-12 for sub frame A.

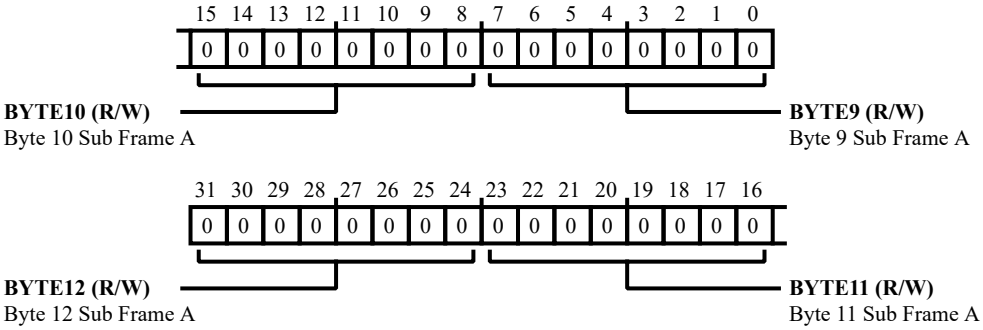

Figure 33-17: SPDIF_TX_STAT_A2 Register Diagram

Table 33-13: SPDIF_TX_STAT_A2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	BYTE12	Byte 12 Sub Frame A. The SPDIF_TX_STAT_A2.BYTE12 bit field contains transmit status for byte 12 of sub frame A.
23:16 (R/W)	BYTE11	Byte 11 Sub Frame A. The SPDIF_TX_STAT_A2.BYTE11 bit field contains transmit status for byte 11 of sub frame A.
15:8 (R/W)	BYTE10	Byte 10 Sub Frame A. The SPDIF_TX_STAT_A2.BYTE10 bit field contains transmit status for byte 10 of sub frame A.
7:0 (R/W)	BYTE9	Byte 9 Sub Frame A. The SPDIF_TX_STAT_A2.BYTE9 bit field contains transmit status for byte 9 of sub frame A.

Transmit Status A3 Register

The SPDIF_TX_STAT_A3 register holds the transmit status for bytes 13-16 for sub frame A.

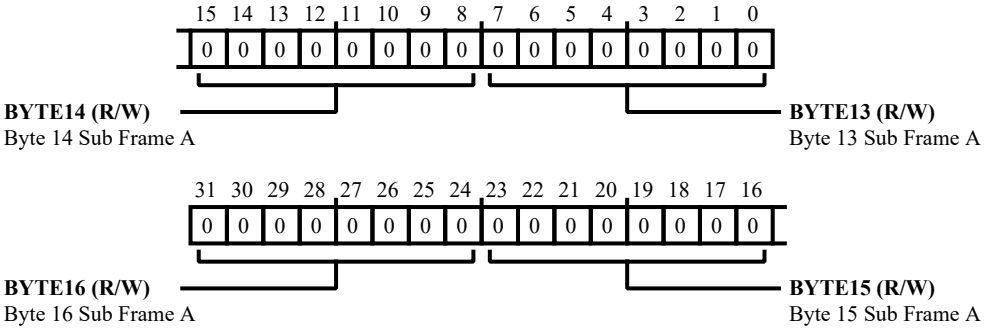

Figure 33-18: SPDIF_TX_STAT_A3 Register Diagram

Table 33-14: SPDIF_TX_STAT_A3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	BYTE16	Byte 16 Sub Frame A. The SPDIF_TX_STAT_A3.BYTE16 bit field contains transmit status for byte 16 of sub frame A.
23:16 (R/W)	BYTE15	Byte 15 Sub Frame A. The SPDIF_TX_STAT_A3.BYTE15 bit field contains transmit status for byte 15 of sub frame A.
15:8 (R/W)	BYTE14	Byte 14 Sub Frame A. The SPDIF_TX_STAT_A3.BYTE14 bit field contains transmit status for byte 14 of sub frame A.
7:0 (R/W)	BYTE13	Byte 13 Sub Frame A. The SPDIF_TX_STAT_A3.BYTE13 bit field contains transmit status for byte 13 of sub frame A.

Transmit Status A4 Register

The SPDIF_TX_STAT_A4 register holds the transmit status for bytes 17-20 for sub frame A.

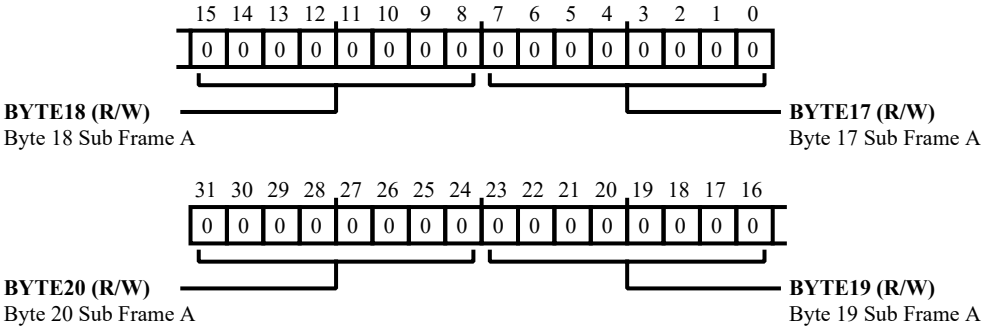

Figure 33-19: SPDIF_TX_STAT_A4 Register Diagram

Table 33-15: SPDIF_TX_STAT_A4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	BYTE20	Byte 20 Sub Frame A. The SPDIF_TX_STAT_A4.BYTE20 bit field contains transmit status for byte 20 of sub frame A.
23:16 (R/W)	BYTE19	Byte 19 Sub Frame A. The SPDIF_TX_STAT_A4.BYTE19 bit field contains transmit status for byte 19 of sub frame A.
15:8 (R/W)	BYTE18	Byte 18 Sub Frame A. The SPDIF_TX_STAT_A4.BYTE18 bit field contains transmit status for byte 18 of sub frame A.
7:0 (R/W)	BYTE17	Byte 17 Sub Frame A. The SPDIF_TX_STAT_A4.BYTE17 bit field contains transmit status for byte 17 of sub frame A.

Transmit Status A5 Register

The SPDIF_TX_STAT_A5 register holds the transmit status for bytes 21-23 for sub frame A.

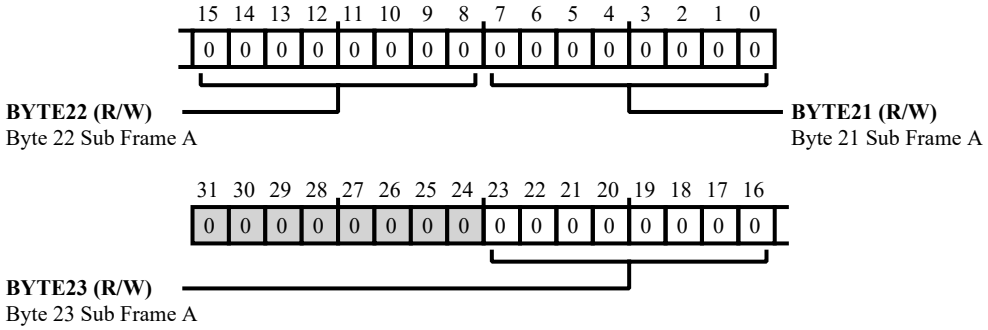

Figure 33-20: SPDIF_TX_STAT_A5 Register Diagram

Table 33-16: SPDIF_TX_STAT_A5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:16 (R/W)	BYTE23	Byte 23 Sub Frame A. The SPDIF_TX_STAT_A5.BYTE23 bit field contains transmit status for byte 23 of sub frame A.
15:8 (R/W)	BYTE22	Byte 22 Sub Frame A. The SPDIF_TX_STAT_A5.BYTE22 bit field contains transmit status for byte 22 of sub frame A.
7:0 (R/W)	BYTE21	Byte 21 Sub Frame A. The SPDIF_TX_STAT_A5.BYTE21 bit field contains transmit status for byte 21 of sub frame A.

Transmit Status B0 Register

The SPDIF_TX_STAT_B0 register holds the transmit channel 0 status for bytes 1-4 for sub frame B.

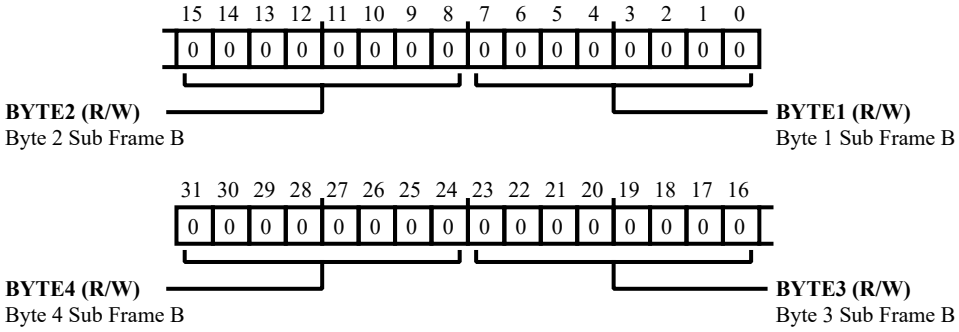

Figure 33-21: SPDIF_TX_STAT_B0 Register Diagram

Table 33-17: SPDIF_TX_STAT_B0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	BYTE4	Byte 4 Sub Frame B. The SPDIF_TX_STAT_B0.BYTE4 bit field holds the transmit channel 0 status for byte 4 for sub frame B.
23:16 (R/W)	BYTE3	Byte 3 Sub Frame B. The SPDIF_TX_STAT_B0.BYTE3 bit field holds the transmit channel 0 status for byte 3 for sub frame B.
15:8 (R/W)	BYTE2	Byte 2 Sub Frame B. The SPDIF_TX_STAT_B0.BYTE2 bit field holds the transmit channel 0 status for byte 2 for sub frame B.
7:0 (R/W)	BYTE1	Byte 1 Sub Frame B. The SPDIF_TX_STAT_B0.BYTE1 bit field holds the transmit channel 0 status for byte 1 for sub frame B.

Transmit Status B1 Register

The SPDIF_TX_STAT_B1 register holds the transmit status for bytes 5-8 for sub frame B.

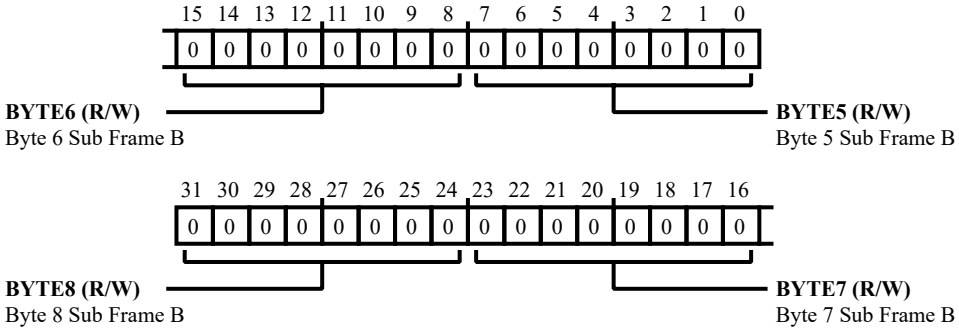

Figure 33-22: SPDIF_TX_STAT_B1 Register Diagram

Table 33-18: SPDIF_TX_STAT_B1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	BYTE8	Byte 8 Sub Frame B. The SPDIF_TX_STAT_B1.BYTE8 bit field contains transmit status for byte 8 of sub frame B.
23:16 (R/W)	BYTE7	Byte 7 Sub Frame B. The SPDIF_TX_STAT_B1.BYTE7 bit field contains transmit status for byte 7 of sub frame B.
15:8 (R/W)	BYTE6	Byte 6 Sub Frame B. The SPDIF_TX_STAT_B1.BYTE6 bit field contains transmit status for byte 6 of sub frame B.
7:0 (R/W)	BYTE5	Byte 5 Sub Frame B. The SPDIF_TX_STAT_B1.BYTE5 bit field contains transmit status for byte 5 of sub frame B.

Transmit Status B2 Register

The SPDIF_TX_STAT_B2 register holds the transmit status for bytes 9-12 for sub frame B.

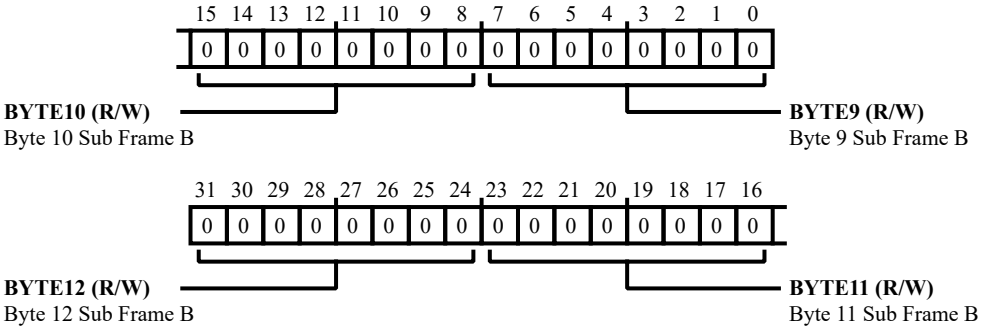

Figure 33-23: SPDIF_TX_STAT_B2 Register Diagram

Table 33-19: SPDIF_TX_STAT_B2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	BYTE12	Byte 12 Sub Frame B. The SPDIF_TX_STAT_B2.BYTE12 bit field contains transmit status for byte 12 of sub frame B.
23:16 (R/W)	BYTE11	Byte 11 Sub Frame B. The SPDIF_TX_STAT_B2.BYTE11 bit field contains transmit status for byte 11 of sub frame B.
15:8 (R/W)	BYTE10	Byte 10 Sub Frame B. The SPDIF_TX_STAT_B2.BYTE10 bit field contains transmit status for byte 10 of sub frame B.
7:0 (R/W)	BYTE9	Byte 9 Sub Frame B. The SPDIF_TX_STAT_B2.BYTE9 bit field contains transmit status for byte 9 of sub frame B.

Transmit Status B3 Register

The SPDIF_TX_STAT_B3 register holds the transmit status for bytes 13-16 for sub frame B.

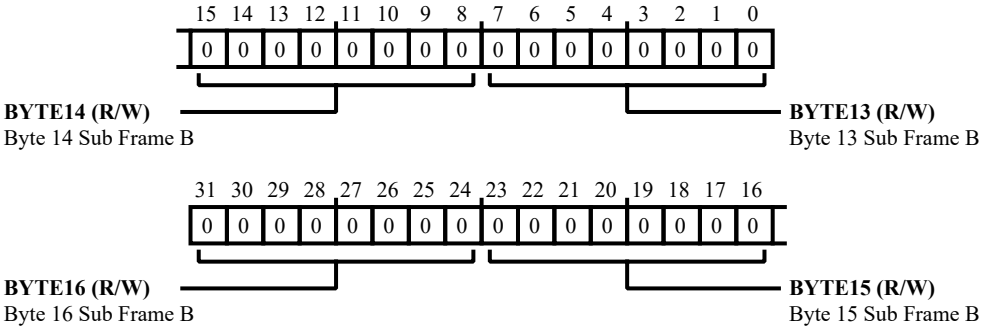

Figure 33-24: SPDIF_TX_STAT_B3 Register Diagram

Table 33-20: SPDIF_TX_STAT_B3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	BYTE16	Byte 16 Sub Frame B. The SPDIF_TX_STAT_B3.BYTE16 bit field contains transmit status for byte 16 of sub frame B.
23:16 (R/W)	BYTE15	Byte 15 Sub Frame B. The SPDIF_TX_STAT_B3.BYTE15 bit field contains transmit status for byte 15 of sub frame B.
15:8 (R/W)	BYTE14	Byte 14 Sub Frame B. The SPDIF_TX_STAT_B3.BYTE14 bit field contains transmit status for byte 14 of sub frame B.
7:0 (R/W)	BYTE13	Byte 13 Sub Frame B. The SPDIF_TX_STAT_B3.BYTE13 bit field contains transmit status for byte 13 of sub frame B.

Transmit Status B4 Register

The SPDIF_TX_STAT_B4 register holds the transmit status for bytes 17-20 for sub frame B.

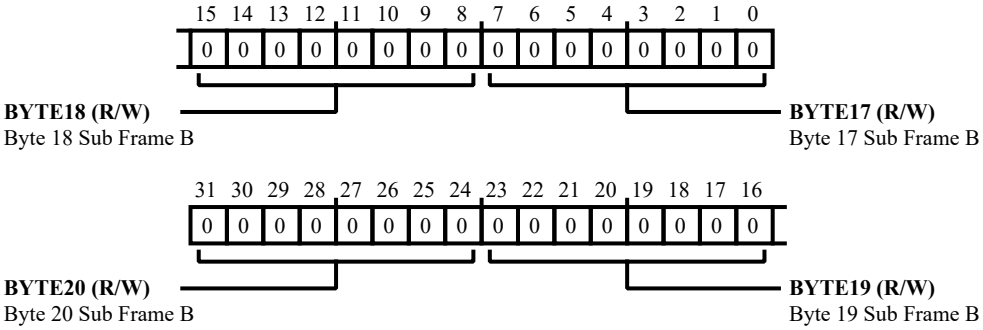

Figure 33-25: SPDIF_TX_STAT_B4 Register Diagram

Table 33-21: SPDIF_TX_STAT_B4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	BYTE20	Byte 20 Sub Frame B. The SPDIF_TX_STAT_B4.BYTE20 bit field contains transmit status for byte 20 of sub frame B.
23:16 (R/W)	BYTE19	Byte 19 Sub Frame B. The SPDIF_TX_STAT_B4.BYTE19 bit field contains transmit status for byte 19 of sub frame B.
15:8 (R/W)	BYTE18	Byte 18 Sub Frame B. The SPDIF_TX_STAT_B4.BYTE18 bit field contains transmit status for byte 18 of sub frame B.
7:0 (R/W)	BYTE17	Byte 17 Sub Frame B. The SPDIF_TX_STAT_B4.BYTE17 bit field contains transmit status for byte 17 of sub frame B.

Transmit Status B5 Register

The SPDIF_TX_STAT_B5 register holds the transmit status for bytes 21-23 for sub frame B.

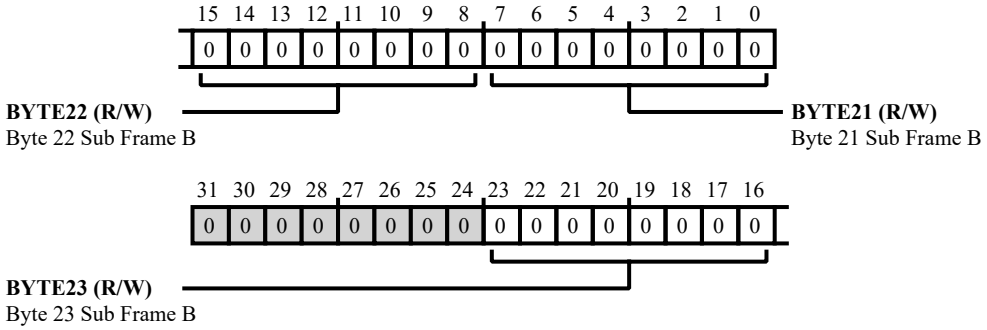

Figure 33-26: SPDIF_TX_STAT_B5 Register Diagram

Table 33-22: SPDIF_TX_STAT_B5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:16 (R/W)	BYTE23	Byte 23 Sub Frame B. The SPDIF_TX_STAT_B5.BYTE23 bit field contains transmit status for byte 23 of sub frame B.
15:8 (R/W)	BYTE22	Byte 22 Sub Frame B. The SPDIF_TX_STAT_B5.BYTE22 bit field contains transmit status for byte 22 of sub frame B.
7:0 (R/W)	BYTE21	Byte 21 Sub Frame B. The SPDIF_TX_STAT_B5.BYTE21 bit field contains transmit status for byte 21 of sub frame B.

Transmit User Buffer A0 Register

The SPDIF_TX_UBUFF_A0 register holds the transmit user buffer data for bytes 0-3 for sub frame A.

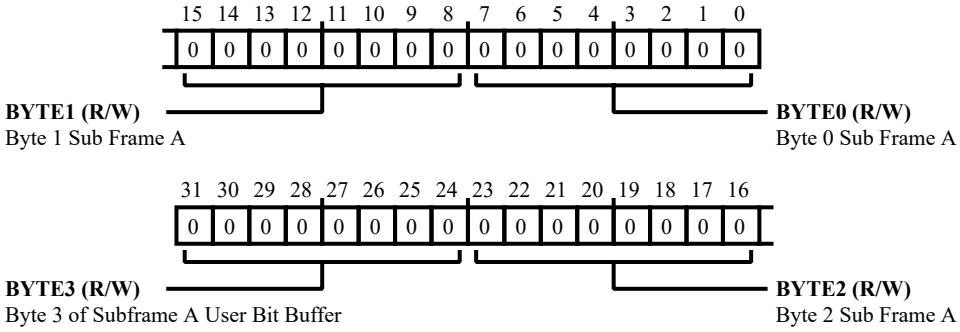

Figure 33-27: SPDIF_TX_UBUFF_A0 Register Diagram

Table 33-23: SPDIF_TX_UBUFF_A0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	BYTE3	Byte 3 of Subframe A User Bit Buffer. The SPDIF_TX_UBUFF_A0.BYTE3 bit field contains user bit data for byte 0 of sub frame A.
23:16 (R/W)	BYTE2	Byte 2 Sub Frame A. The SPDIF_TX_UBUFF_A0.BYTE2 bit field contains user bit data for byte 2 of sub frame A.
15:8 (R/W)	BYTE1	Byte 1 Sub Frame A. The SPDIF_TX_UBUFF_A0.BYTE1 bit field contains user bit data for byte 1 of sub frame A.
7:0 (R/W)	BYTE0	Byte 0 Sub Frame A. The SPDIF_TX_UBUFF_A0.BYTE0 bit field contains user bit data for byte 0 of sub frame A.

Transmit User Buffer A1 Register

The SPDIF_TX_UBUFF_A1 register holds the transmit user buffer data for bytes 4-7 for sub frame A.

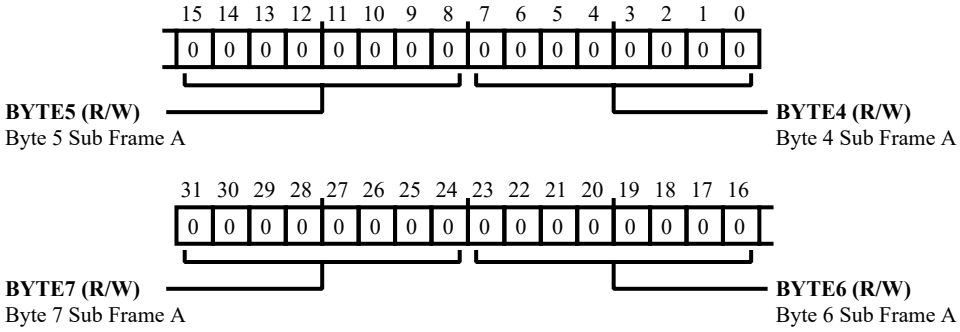

Figure 33-28: SPDIF_TX_UBUFF_A1 Register Diagram

Table 33-24: SPDIF_TX_UBUFF_A1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	BYTE7	Byte 7 Sub Frame A. The SPDIF_TX_UBUFF_A1.BYTE7 bit field contains user bit data for byte 7 of sub frame A.
23:16 (R/W)	BYTE6	Byte 6 Sub Frame A. The SPDIF_TX_UBUFF_A1.BYTE6 bit field contains user bit data for byte 6 of sub frame A.
15:8 (R/W)	BYTE5	Byte 5 Sub Frame A. The SPDIF_TX_UBUFF_A1.BYTE5 bit field contains user bit data for byte 5 of sub frame A.
7:0 (R/W)	BYTE4	Byte 4 Sub Frame A. The SPDIF_TX_UBUFF_A1.BYTE4 bit field contains user bit data for byte 0 of sub frame A.

Transmit User Buffer A2 Register

The SPDIF_TX_UBUFF_A2 register holds the transmit user buffer data for bytes 8-11 for sub frame A.

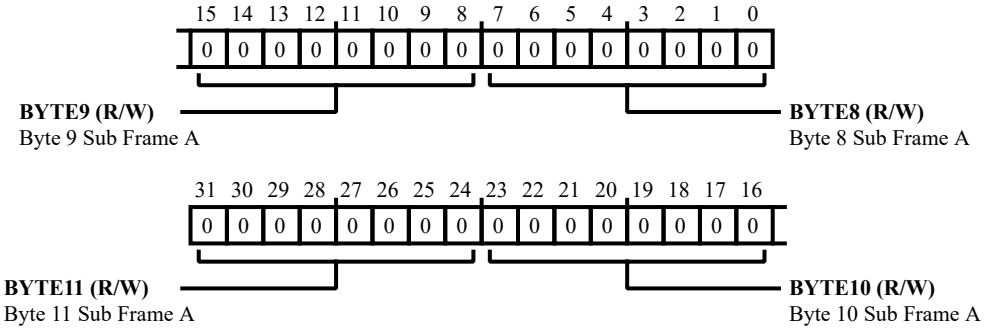

Figure 33-29: SPDIF_TX_UBUFF_A2 Register Diagram

Table 33-25: SPDIF_TX_UBUFF_A2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	BYTE11	Byte 11 Sub Frame A. The SPDIF_TX_UBUFF_A2.BYTE11 bit field contains user bit data for byte 11 of sub frame A.
23:16 (R/W)	BYTE10	Byte 10 Sub Frame A. The SPDIF_TX_UBUFF_A2.BYTE10 bit field contains user bit data for byte 10 of sub frame A.
15:8 (R/W)	BYTE9	Byte 9 Sub Frame A. The SPDIF_TX_UBUFF_A2.BYTE9 bit field contains user bit data for byte 9 of sub frame A.
7:0 (R/W)	BYTE8	Byte 8 Sub Frame A. The SPDIF_TX_UBUFF_A2.BYTE8 bit field contains user bit data for byte 8 of sub frame A.

Transmit User Buffer A3 Register

The SPDIF_TX_UBUFF_A3 register holds the transmit user buffer data for bytes 12-15 for sub frame A.

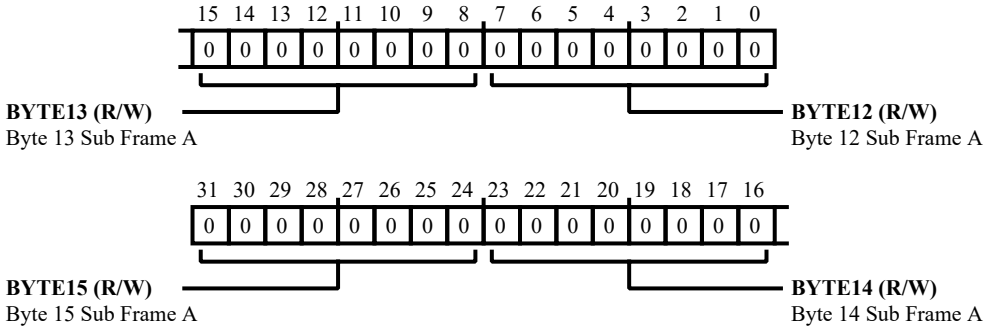

Figure 33-30: SPDIF_TX_UBUFF_A3 Register Diagram

Table 33-26: SPDIF_TX_UBUFF_A3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	BYTE15	Byte 15 Sub Frame A. The SPDIF_TX_UBUFF_A3.BYTE15 bit field contains user bit data for byte 15 of sub frame A.
23:16 (R/W)	BYTE14	Byte 14 Sub Frame A. The SPDIF_TX_UBUFF_A3.BYTE14 bit field contains user bit data for byte 14 of sub frame A.
15:8 (R/W)	BYTE13	Byte 13 Sub Frame A. The SPDIF_TX_UBUFF_A3.BYTE13 bit field contains user bit data for byte 13 of sub frame A.
7:0 (R/W)	BYTE12	Byte 12 Sub Frame A. The SPDIF_TX_UBUFF_A3.BYTE12 bit field contains user bit data for byte 12 of sub frame A.

Transmit User Buffer A4 Register

The SPDIF_TX_UBUFF_A4 register holds the transmit user buffer data for bytes 16-19 for sub frame A.

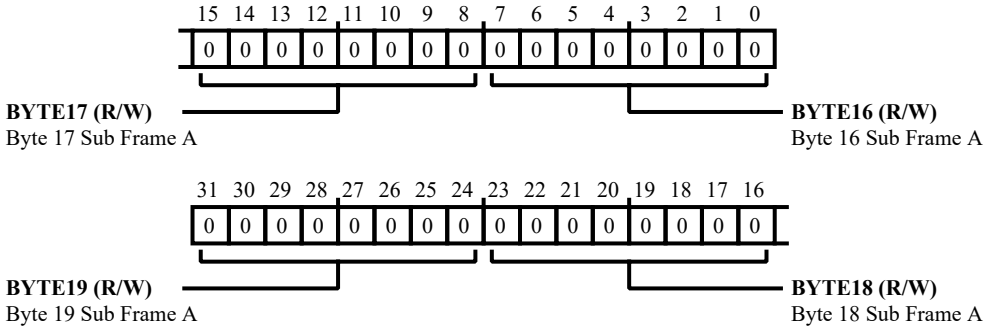

Figure 33-31: SPDIF_TX_UBUFF_A4 Register Diagram

Table 33-27: SPDIF_TX_UBUFF_A4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	BYTE19	Byte 19 Sub Frame A. The SPDIF_TX_UBUFF_A4.BYTE19 bit field contains user bit data for byte 19 of sub frame A.
23:16 (R/W)	BYTE18	Byte 18 Sub Frame A. The SPDIF_TX_UBUFF_A4.BYTE18 bit field contains user bit data for byte 18 of sub frame A.
15:8 (R/W)	BYTE17	Byte 17 Sub Frame A. The SPDIF_TX_UBUFF_A4.BYTE17 bit field contains user bit data for byte 17 of sub frame A.
7:0 (R/W)	BYTE16	Byte 16 Sub Frame A. The SPDIF_TX_UBUFF_A4.BYTE16 bit field contains user bit data for byte 16 of sub frame A.

Transmit User Buffer A5 Register

The SPDIF_TX_UBUFF_A5 register holds the transmit user buffer data for bytes 20-23 for sub frame A.

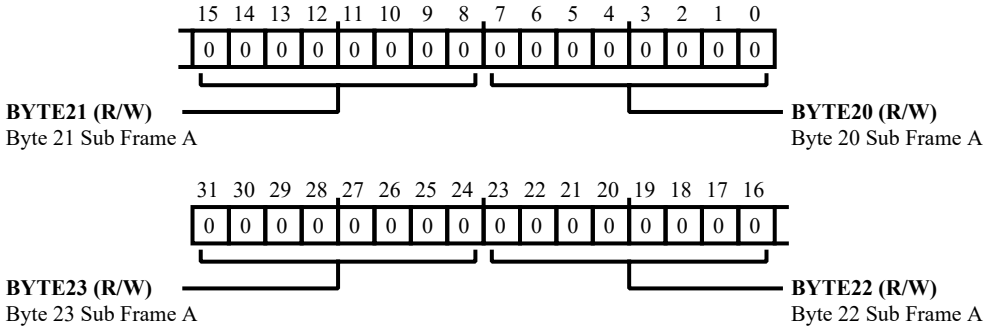

Figure 33-32: SPDIF_TX_UBUFF_A5 Register Diagram

Table 33-28: SPDIF_TX_UBUFF_A5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	BYTE23	Byte 23 Sub Frame A. The SPDIF_TX_UBUFF_A5.BYTE23 bit field contains user bit data for byte 23 of sub frame A.
23:16 (R/W)	BYTE22	Byte 22 Sub Frame A. The SPDIF_TX_UBUFF_A5.BYTE22 bit field contains user bit data for byte 22 of sub frame A.
15:8 (R/W)	BYTE21	Byte 21 Sub Frame A. The SPDIF_TX_UBUFF_A5.BYTE21 bit field contains user bit data for byte 21 of sub frame A.
7:0 (R/W)	BYTE20	Byte 20 Sub Frame A. The SPDIF_TX_UBUFF_A5.BYTE20 bit field contains user bit data for byte 20 of sub frame A.

Transmit User Buffer B0 Register

The SPDIF_TX_UBUFF_B0 register holds the transmit user buffer data for bytes 0-3 for sub frame B.

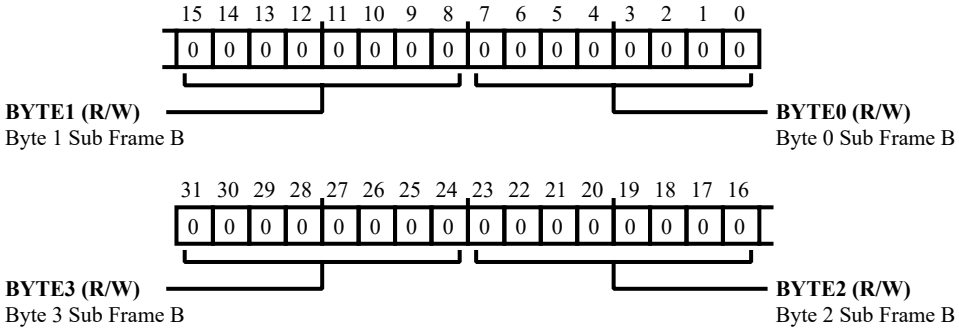

Figure 33-33: SPDIF_TX_UBUFF_B0 Register Diagram

Table 33-29: SPDIF_TX_UBUFF_B0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	BYTE3	Byte 3 Sub Frame B. The SPDIF_TX_UBUFF_B0.BYTE3 bit field contains user bit data for byte 3 of sub frame B.
23:16 (R/W)	BYTE2	Byte 2 Sub Frame B. The SPDIF_TX_UBUFF_B0.BYTE2 bit field contains user bit data for byte 2 of sub frame B.
15:8 (R/W)	BYTE1	Byte 1 Sub Frame B. The SPDIF_TX_UBUFF_B0.BYTE1 bit field contains user bit data for byte 1 of sub frame B.
7:0 (R/W)	BYTE0	Byte 0 Sub Frame B. The SPDIF_TX_UBUFF_B0.BYTE0 bit field contains user bit data for byte 0 of sub frame B.

Transmit User Buffer B1 Register

The SPDIF_TX_UBUFF_B1 register holds the transmit user buffer data for bytes 4-7 for sub frame B.

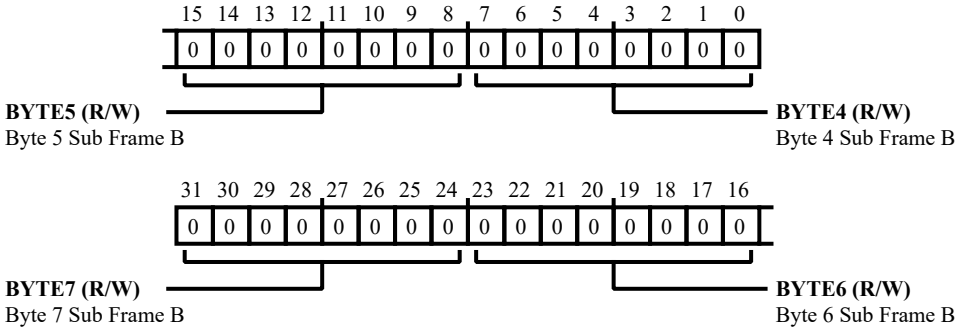

Figure 33-34: SPDIF_TX_UBUFF_B1 Register Diagram

Table 33-30: SPDIF_TX_UBUFF_B1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	BYTE7	Byte 7 Sub Frame B. The SPDIF_TX_UBUFF_B1.BYTE7 bit field contains user bit data for byte 7 of sub frame B.
23:16 (R/W)	BYTE6	Byte 6 Sub Frame B. The SPDIF_TX_UBUFF_B1.BYTE6 bit field contains user bit data for byte 6 of sub frame B.
15:8 (R/W)	BYTE5	Byte 5 Sub Frame B. The SPDIF_TX_UBUFF_B1.BYTE5 bit field contains user bit data for byte 5 of sub frame B.
7:0 (R/W)	BYTE4	Byte 4 Sub Frame B. The SPDIF_TX_UBUFF_B1.BYTE4 bit field contains user bit data for byte 4 of sub frame B.

Transmit User Buffer B2 Register

The SPDIF_TX_UBUFF_B2 register holds the transmit user buffer data for bytes 8-11 for sub frame B.

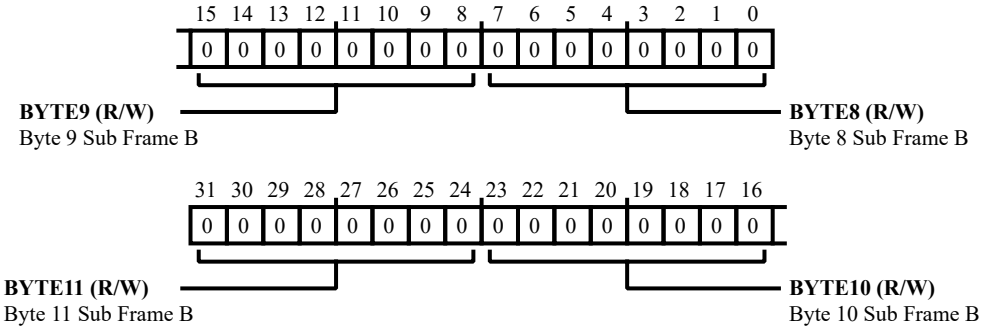

Figure 33-35: SPDIF_TX_UBUFF_B2 Register Diagram

Table 33-31: SPDIF_TX_UBUFF_B2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	BYTE11	Byte 11 Sub Frame B. The SPDIF_TX_UBUFF_B2.BYTE11 bit field contains user bit data for byte 11 of sub frame B.
23:16 (R/W)	BYTE10	Byte 10 Sub Frame B. The SPDIF_TX_UBUFF_B2.BYTE10 bit field contains user bit data for byte 10 of sub frame B.
15:8 (R/W)	BYTE9	Byte 9 Sub Frame B. The SPDIF_TX_UBUFF_B2.BYTE9 bit field contains user bit data for byte 9 of sub frame B.
7:0 (R/W)	BYTE8	Byte 8 Sub Frame B. The SPDIF_TX_UBUFF_B2.BYTE8 bit field contains user bit data for byte 8 of sub frame B.

Transmit User Buffer B3 Register

The SPDIF_TX_UBUFF_B3 register holds the transmit user buffer data for bytes 12-15 for sub frame B.

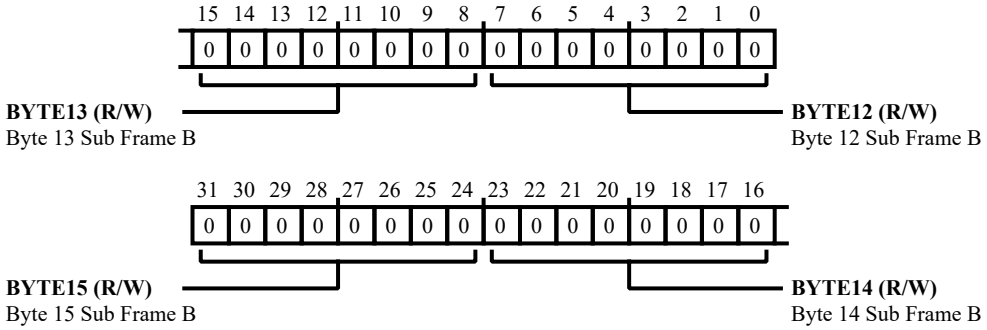

Figure 33-36: SPDIF_TX_UBUFF_B3 Register Diagram

Table 33-32: SPDIF_TX_UBUFF_B3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	BYTE15	Byte 15 Sub Frame B. The SPDIF_TX_UBUFF_B3.BYTE15 bit field contains user bit data for byte 15 of sub frame B.
23:16 (R/W)	BYTE14	Byte 14 Sub Frame B. The SPDIF_TX_UBUFF_B3.BYTE14 bit field contains user bit data for byte 14 of sub frame B.
15:8 (R/W)	BYTE13	Byte 13 Sub Frame B. The SPDIF_TX_UBUFF_B3.BYTE13 bit field contains user bit data for byte 13 of sub frame B.
7:0 (R/W)	BYTE12	Byte 12 Sub Frame B. The SPDIF_TX_UBUFF_B3.BYTE12 bit field contains user bit data for byte 12 of sub frame B.

Transmit User Buffer B4 Register

The SPDIF_TX_UBUFF_B4 register holds the transmit user buffer data for bytes 16-19 for sub frame B.

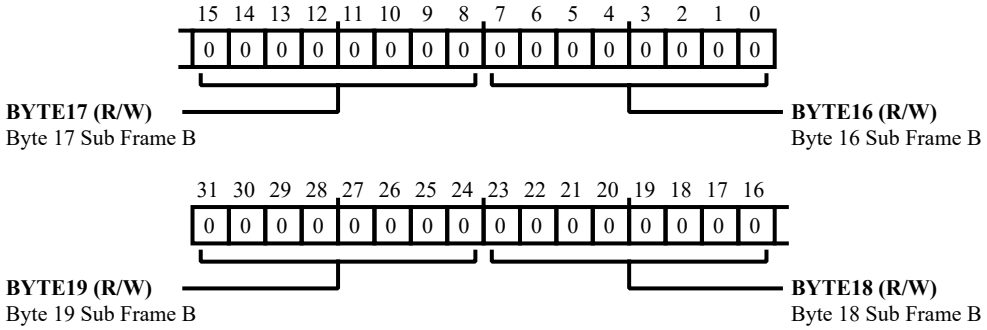

Figure 33-37: SPDIF_TX_UBUFF_B4 Register Diagram

Table 33-33: SPDIF_TX_UBUFF_B4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	BYTE19	Byte 19 Sub Frame B. The SPDIF_TX_UBUFF_B4.BYTE19 bit field contains user bit data for byte 19 of sub frame B.
23:16 (R/W)	BYTE18	Byte 18 Sub Frame B. The SPDIF_TX_UBUFF_B4.BYTE18 bit field contains user bit data for byte 18 of sub frame B.
15:8 (R/W)	BYTE17	Byte 17 Sub Frame B. The SPDIF_TX_UBUFF_B4.BYTE17 bit field contains user bit data for byte 17 of sub frame B.
7:0 (R/W)	BYTE16	Byte 16 Sub Frame B. The SPDIF_TX_UBUFF_B4.BYTE16 bit field contains user bit data for byte 16 of sub frame B.

Transmit User Buffer B5 Register

The SPDIF_TX_UBUFF_B5 register holds the transmit user buffer data for bytes 20-23 for sub frame B.

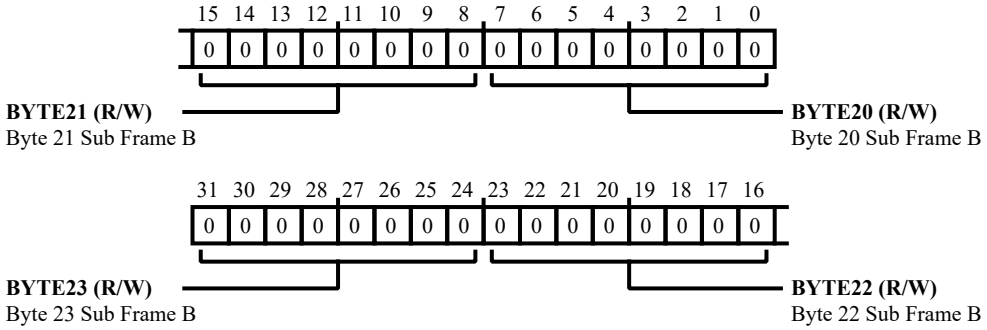

Figure 33-38: SPDIF_TX_UBUFF_B5 Register Diagram

Table 33-34: SPDIF_TX_UBUFF_B5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	BYTE23	Byte 23 Sub Frame B. The SPDIF_TX_UBUFF_B5.BYTE23 bit field contains user bit data for byte 23 of sub frame B.
23:16 (R/W)	BYTE22	Byte 22 Sub Frame B. The SPDIF_TX_UBUFF_B5.BYTE22 bit field contains user bit data for byte 22 of sub frame B.
15:8 (R/W)	BYTE21	Byte 21 Sub Frame B. The SPDIF_TX_UBUFF_B5.BYTE21 bit field contains user bit data for byte 21 of sub frame B.
7:0 (R/W)	BYTE20	Byte 20 Sub Frame B. The SPDIF_TX_UBUFF_B5.BYTE20 bit field contains user bit data for byte 20 of sub frame B.

User Bit Update Register

After writing to the transmit user buffer registers, a value of 0x1 must be written into the SPDIF_TX_USRUPDT register to enable the use of these user buffer bits in the next transfer block.

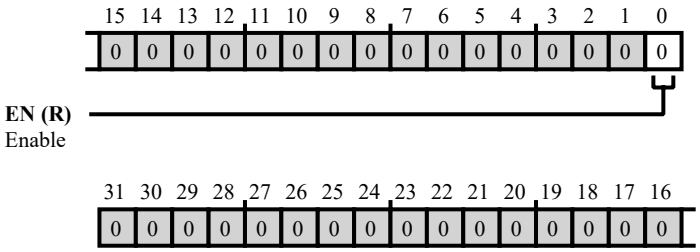

Figure 33-39: SPDIF_TX_USRUPDT Register Diagram

Table 33-35: SPDIF_TX_USRUPDT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/NW)	EN	Enable. After writing to the transmit user buffer registers, a value of 0x1 must be written into the SPDIF_TX_USRUPDT register to enable the use of these SPDIF_TX_USRUPDT.EN bits in the next transfer block.

34 Direct Memory Access (DMA)

The processor architecture distributes the DMA channels throughout the infrastructure. Often, the channels cluster together through system crossbars (SCB), sharing a single interface with the main system crossbar.

The DMA channels can perform transfers between memory and a peripheral or between one memory and another memory. Memory-to-memory DMA transfers (MDMA) require two DMA channels. One channel is the source channel, and the second, the destination channel.

All DMA channels can transport data to and from virtually all on-chip and off-chip memories.

DMA transfers on the processor use either a descriptor-based method or register-based method. Register-based DMA allows the processor directly to program DMA controller registers to initiate a DMA transfer. On completion, the controller registers can automatically update with their original setup values for continuous transfer, if needed. Descriptor-based DMA transfers require a set of parameters stored within memory to initiate a DMA sequence. Descriptor-based transfers allow the chaining together of multiple DMA sequences. In descriptor-based DMA operations, DMA channel programming can automatically set up and start another DMA transfer after the current sequence completes.

The DMA channel does not connect external memories and devices directly. Rather, data passes through an external-memory interface port. DMA operations can access any device the external memory interface supports. These interfaces typically include:

- Flash memory
- SRAM
- FIFOs
- Memory-mapped peripheral devices
- Dynamic Memory (if present)

DMA Channel Features

The processor uses Direct Memory Access (DMA) to transfer data within memory spaces or between a memory space and a peripheral. The processor can specify data transfer operations and return to normal processing while the fully integrated DMA channel carries out the data transfers independent of processor activity. The DMA channels are dispersed throughout the infrastructure and interface with the system crossbar unit (SCB).

The following is a list of DMA interface features.

- Supports integer byte strides including byte strides of 0 and negative byte strides
- Register-based configuration
  - Core writes DMA configuration
  - Supports automatic reloading for continuous operation
- Flexible descriptor-based configuration
  - DMA descriptors are fetched from memory
  - Support for variable descriptor sizes
- Flexible flow control – Transitions between the various descriptor-based modes and for DMA termination
- Orthogonal transfers
  - Support for three transfer dimensions
  - One and two dimensional (1D and 2D) transfers supported per descriptor set
  - Three dimensional (3D) support provided by chained descriptor sets
- Configurable memory and peripheral-transfer word sizes
  - Memory interface supports 8-bit, 16-bit, 32-bit, 64-bit, and 128-bit transfers
  - Peripheral interface supports for 8-bit, 16-bit, and 32-bit transfers
- Interrupt notification
  - Row or work unit completion
  - Error conditions
- Incoming and outgoing trigger support
  - Trigger generation for row or work unit completion
  - Work unit can wait for incoming trigger
- MMR access bus – Provides access to memory-mapped registers for configuration, monitoring, and debug
- SCB crossbar interface connects the DMA channel to the system crossbar
- Peripheral DMA bus – Interfaces the DMA channel to a peripheral or another DMA channel
- Peripheral data-request interrupt support
- Bandwidth monitoring and limiting for MDMA channels

DMA Channel Functional Description

This section provides a functional description of the DMA channel interface.

NOTE: There are two types of peripherals that use DMA. The first have dedicated DMA channels controlled by the Dedicated DMA Engine (DDE) and are described in this chapter. The second type is not controlled by the DDE. These peripherals have their own operating modes and programming models (see the peripheral chapter for this information). The complete list of DMA supported peripherals are shown in .

ADSP-2184x DMA Register List

The DMA channel controller (DMA) supports data transfers within memory spaces or between a memory space and a peripheral. The processor can specify data transfer operations and return to normal processing while the fully integrated DMA channel carries out the data transfers independent of processor activity. The DMA channels are dispersed throughout the infrastructure, as DMAn's. A set of registers governs DMA operations. For more information on DMA functionality, see the DMA register descriptions.

Table 34-1: ADSP-2184x DMA Register List

Name	Description
DMA_ADDRSTART	Start Address of Current Buffer Register
DMA_ADDR_CUR	Current Address Register
DMA_BWLCNT	Bandwidth Limit Count Register
DMA_BWLCNT_CUR	Bandwidth Limit Count Current Register
DMA_BWMCNT	Bandwidth Monitor Count Register
DMA_BWMCNT_CUR	Bandwidth Monitor Count Current Register
DMA_CFG	Configuration Register
DMA_DSCPTR_CUR	Current Descriptor Pointer Register
DMA_DSCPTR_NXT	Pointer to Next Initial Descriptor Register
DMA_DSCPTR_PRV	Previous Initial Descriptor Pointer Register
DMA_STAT	Status Register
DMA_XCNT	Inner Loop Count Start Value Register
DMA_XCNT_CUR	Current Count (1D) or Intra-row XCNT (2D) Register
DMA_XMOD	Inner Loop Address Increment Register
DMA_YCNT	Outer Loop Count Start Value (2D only) Register
DMA_YCNT_CUR	Current Row Count (2D only) Register
DMA_YMOD	Outer Loop Address Increment (2D only) Register

ADSP-2184x DMA Channel List

Table 34-2: ADSP-2184x DMA Channel List

DMA ID	DMA Channel Name	Description
DMA0	SPORT0_A_DMA	SPORT0 Channel A DMA
DMA1	SPORT0_B_DMA	SPORT0 Channel B DMA
DMA2	SPORT1_A_DMA	SPORT1 Channel A DMA
DMA3	SPORT1_B_DMA	SPORT1 Channel B DMA
DMA4	SPORT2_A_DMA	SPORT2 Channel A DMA
DMA5	SPORT2_B_DMA	SPORT2 Channel B DMA
DMA6	SPORT3_A_DMA	SPORT3 Channel A DMA
DMA7	SPORT3_B_DMA	SPORT3 Channel B DMA
DMA8	MDMA0_SRC	Memory DMA Stream 0 Source Channel
DMA9	MDMA0_DST	Memory DMA Stream 0 Destination Channel
DMA10	SPORT4_A_DMA	SPORT4 Channel A DMA
DMA11	SPORT4_B_DMA	SPORT4 Channel B DMA
DMA12	SPORT5_A_DMA	SPORT5 Channel A DMA
DMA13	SPORT5_B_DMA	SPORT5 Channel B DMA
DMA14	SPORT6_A_DMA	SPORT6 Channel A DMA
DMA15	SPORT6_B_DMA	SPORT6 Channel B DMA
DMA16	SPORT7_A_DMA	SPORT7 Channel A DMA
DMA17	SPORT7_B_DMA	SPORT7 Channel B DMA
DMA18	MDMA1_SRC	Memory DMA Stream 1 Source Channel
DMA19	MDMA1_DST	Memory DMA Stream 1 Destination Channel
DMA20	UART0_TXDMA	UART0 Transmit DMA
DMA21	UART0_RXDMA	UART0 Receive DMA
DMA22	SPI0_TXDMA	SPI0 TX DMA Channel
DMA23	SPI0_RXDMA	SPI0 RX DMA Channel
DMA24	SPI1_TXDMA	SPI1 TX DMA Channel
DMA25	SPI1_RXDMA	SPI1 RX DMA Channel
DMA26	SPI2_TXDMA	SPI2 TX DMA Channel

Table 34-2: ADSP-2184x DMA Channel List (Continued)

DMA ID	DMA Channel Name	Description
DMA27	SPI2_RXDMA	SPI2 RX DMA Channel
DMA30	LP0_DMA	LP0 DMA Channel
DMA34	UART1_TXDMA	UART1 Transmit DMA
DMA35	UART1_RXDMA	UART1 Receive DMA
DMA36	LP1_DMA	LP1 DMA Channel
DMA37	UART2_TXDMA	UART2 Transmit DMA
DMA38	UART2_RXDMA	UART2 Receive DMA
DMA39	MDMA2_SRC	Memory DMA Stream 2 Source Channel
DMA40	MDMA2_DST	Memory DMA Stream 2 Destination Channel
DMA43	MDMA3_SRC	Memory DMA Stream 3 Source Channel
DMA44	MDMA3_DST	Memory DMA Stream 3 Destination Channel
DMA45	MDMA4_SRC	Memory DMA Stream 4 Source Channel
DMA46	MDMA4_DST	Memory DMA Stream 4 Destination Channel
DMA47	MDMA5_SRC	Memory DMA Stream 5 Source Channel
DMA48	MDMA5_DST	Memory DMA Stream 5 Destination Channel
DMA49	MDMA6_SRC	Memory DMA Stream 6 Source Channel
DMA50	MDMA6_DST	Memory DMA Stream 6 Destination Channel
DMA51	MDMA7_SRC	Memory DMA Stream 7 Source Channel
DMA52	MDMA7_DST	Memory DMA Stream 7 Destination Channel
DMA59	SPI5_TXDMA	SPI5 TX DMA Channel
DMA60	SPI5_RXDMA	SPI5 RX DMA Channel

DMA Definitions

To make the best use of the DMA controller, it is useful to understand the following terms.

Descriptor

A single element of a descriptor set that maps to a specific register of a DMA channel.

Descriptor Fetch

The action of retrieving descriptors from memory through memory read operations and loading then into the DMA channel registers upon their read return.

Descriptor Set

An array of descriptors associated with a single work unit. The user can configure the size of the descriptor set. See Descriptor-Based Flow Modes .

Disabled State

The channel is disabled because the enable bit = 0 or because of an error.

DMAC

An acronym used for a DMA cluster.

DMA Channel

A single DMA engine that has all the capabilities and registers as defined for a given processor. A DMA channel or engine is connected to a single peripheral.

DMA Cluster

A grouping of multiple DMA channels with a shared SCB crossbar interface, controller, and arbiter. Also known as a DMAC.

Initial Descriptor

The first descriptor in the descriptor set.

MDMA

Memory-to-Memory DMA data transfer. Two DMA channels are paired to perform a memory read from one address location and a memory write of that data to another address location.

Stop State

A time where the channel is enabled but not currently programmed to perform a data transfer. Programming the flow to STOP causes the channel to enter the stop state at the end of the work unit.

User

Any person, debug, emulator, software routine, or action taken by the core that accesses the MMR registers of the DMA channel or peripherals, or sets up data and descriptors in memory.

Wait State

If instructed to wait for a trigger, the channel enters this state once it has completed a work unit. The channel remains in this state until a trigger occurs. If a trigger came in before reaching the wait state, the channel skips over the wait state upon completion of the work unit.

Work Unit

A single data transaction or series of data transactions performed based on the configuration of the DMA channel. For autobuffer mode, a new work unit is defined at the time all current count registers are initialized to start values. Once all the current count registers count down to zero, the work unit has completed.

Work Unit Chain

A single work unit or a series of work units separated by a `STOP` or disabled state. The work units in the chain (except the last one) are programmed to the required descriptor flow. The last work unit in the chain is programmed to a flow of `STOP` or `AUTO`. `STOP` terminates the state at the end of that work unit. `AUTO` must be terminated by disabling the DMA channel. A work unit chain is also known as a descriptor chain.

Block Diagram

The ***DMA Channel Block Diagram*** shows the functional blocks within the DMA interface.

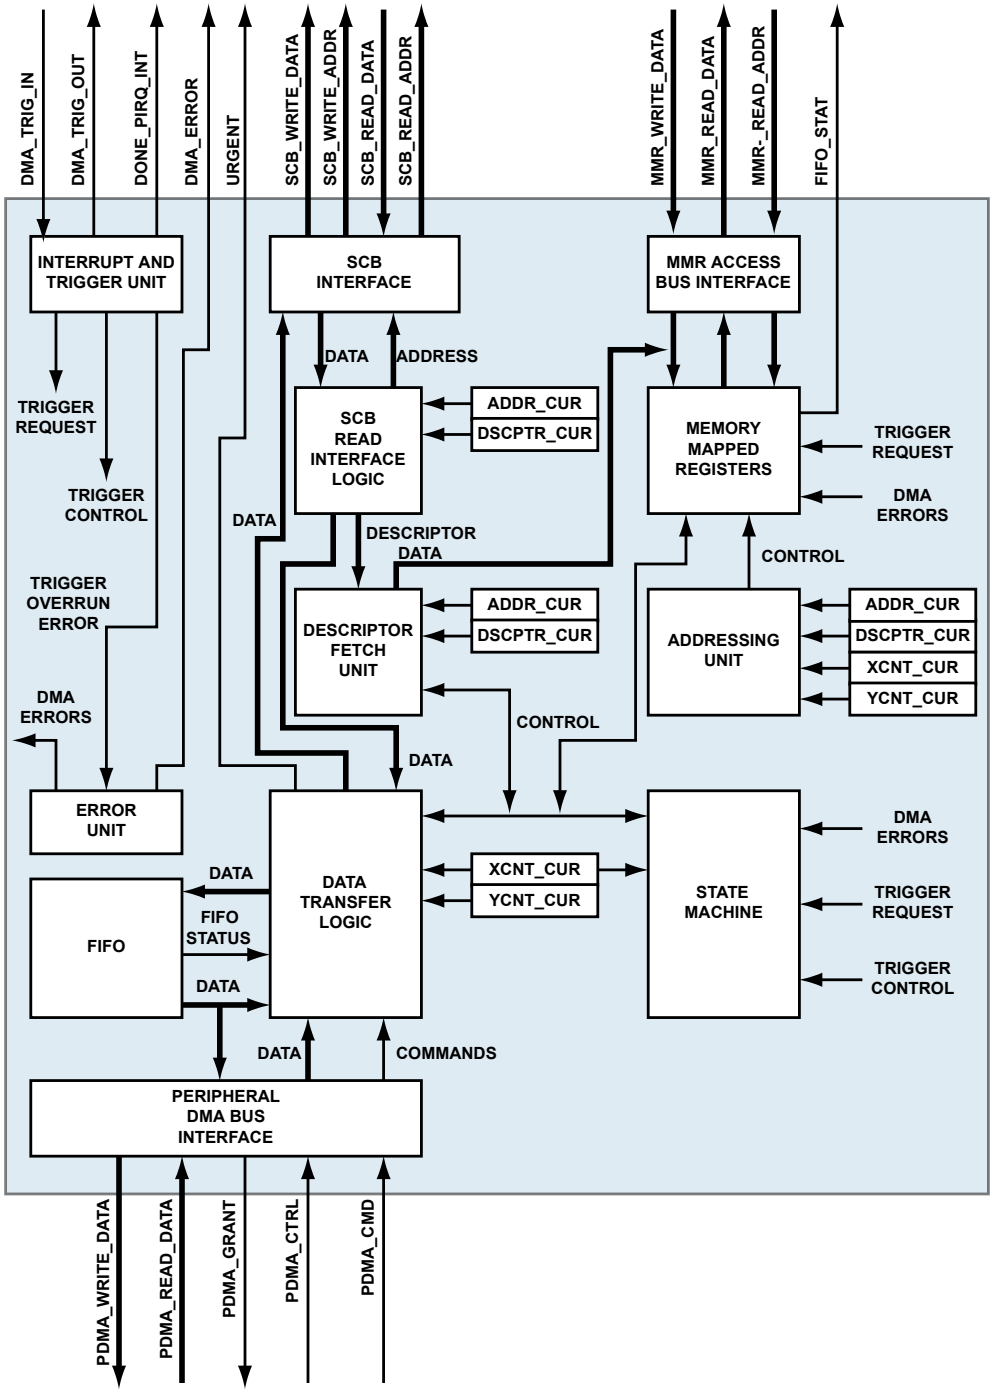

Figure 34-1: DMA Channel Block Diagram

For more information on the interfaces, see:

- DMA Channel Peripheral DMA Bus

- DMA Channel Event Control

- DMA Channel SCB Interface

Architectural Concepts

The DMA channel provides a method to transfer data between memory spaces or between memory and a peripheral using a number of system interfaces. The DMA channel provides an efficient method of distributing data throughout the system, freeing up the processor core for other operations. Each peripheral that supports DMA transfers has its own dedicated DMA channel or channels with its own register set. The register set configures and controls the operating modes of the DMA transfers.

DMA Channel SCB Interface

The SCB interface connects the DMA channel to the SCB crossbar allowing for transfers to and from the processors internal memory and other suitable system resources.

The DMA channel connects to the system interconnect through the SCB interface. This connection lets the DMA channel perform work-unit data transfers with memories such as L1, L2 (internal), and L3 (external). In addition to work unit data transfers, the SCB interface also is used for fetching descriptor sets for all the descriptor-based transfer modes.

The DMA channel can support data bus widths of 16, 32, 64, or 128 bits. The data bus widths for a given DMA channel on a specific processor can vary and are not configurable. Read the `DMA_STAT.MBWID` field to determine the assigned bus widths.

SCB Interface Signals

The DMA channel operates at *SYSCLK* frequencies. The SCB crossbar handles the internal arbitration of the transfer requests of all the controllers interfaced to the SCB crossbar instance as shown in the ***SCB Interface Signals*** table.

Table 34-3: SCB Interface Signals

Signal	Width (bits)	Description
SCB_WRITE_DATA	16, 32, 64, or 128	Data bus used for write operations. The width of the bus can be determined from `DMA_STAT.MBWID`.
SCB_WRITE_ADDRESS	32	Write address bus. Provides the address of the first transfer in a burst transaction.
SCB_READ_DATA	16, 32, 64, or 128	Data bus used for read operations. The width of the bus can be determined from `DMA_STAT.MBWID`.
SCB_READ_ADDRESS	32	Read address bus. Provides the address of the first transfer in a burst transaction.

SCB Burst Transfers

The SCB interface supports burst transfers for memory read and write operations. The burst length is a function of the configurable memory size of the DMA channel for the work unit and the fixed bus width of the SCB data bus of the DMA channel.

- If the DMA channel configuration selects a memory transfer size less than or equal to the DMA channels bus width, the burst length is always 1.
- If the configured memory size is greater than the SCB interface bus width, the burst length is sufficient to transfer a transaction as specified by the configured memory size.

Table 34-4: DMA Channel SCB Burst Lengths

Configured Memory Size	Burst Length			
	16-bit Bus	*32-bit Bus*	*64-Bit Bus*	*128-bit Bus*
1 Byte	1	1	1	1
2 Bytes	1	1	1	1
4 Bytes	2	1	1	1
8 Bytes	4	2	1	1
16 Bytes	8	4	2	1
32 Bytes	16	8	4	2

Data Address Alignment

To prevent addressing errors and to maximize bandwidth of the SCB interface to the DMA channel, data addresses align with a multiple of the programmable memory size of the DMA channels configuration. These configuration options appear in the Descriptor Set Address Alignment table.

There are situations in which entire work units may not transfer at the maximum configurable memory size. In this case, the entire work unit can transfer by reducing the configured memory size at the expense of bus bandwidth using descriptor sets as follows:

- The first descriptor set can be configured to transfer data until the larger memory size alignments are met.
- A second descriptor set with a larger memory size configuration then can be used to transfer the bulk of the data in the work unit.
- Finally, a third descriptor set can be used with a smaller memory size to complete any final data transfers that cannot meet the alignment requirements of the previous descriptor set configuration.

Table 34-5: DMA Channel Address Alignment Requirements

Configured Memory Size	Address Restriction
1 Byte	No restriction
2 Bytes	ADDR[0] == 0
4 Bytes	ADDR[1:0] == 0
8 Bytes	ADDR[2:0] == 0
16 Bytes	ADDR[3:0] == 0
32 Bytes	ADDR[4:0] == 0

Descriptor Set Address Alignment

All descriptor set addresses and descriptors within a descriptor set must align to a 32-bit address. For descriptor set fetches, the DMA engine ignores the memory-size configuration of the DMA channel. This feature avoids the need to align descriptor sets based on the memory width configuration of the previous descriptor set.

For descriptor sets containing only a single descriptor, the transfer takes place as a single 32-bit transfer. For descriptor sets containing multiple descriptors, the DMA engine fetches each 32-bit descriptor individually and treats it as multiple 32-bit transfers.

Peripheral Control Commands

The peripheral DMA bus of the DMA channel provides a means for peripherals on the processor to issue commands to the DMA channel. These commands provide greater control over the DMA channel operation. This control improves real-time performance and relieves control and interrupt demands on the core. Peripherals can send commands to the DMA controller over the 3-bit PERI_CMD bus. The DMA control commands extend the set of operations available to the peripheral beyond the simple “request data” command used by peripherals in general. Refer to the appropriate peripheral chapter for a description on how that peripheral uses DMA control commands.

These DMA control commands (see the ***PDMA_CMD Peripheral DMA Control Commands*** table) are not visible to or controlled by the program. But, their use by a peripheral has implications for the structure of the DMA transfers that the peripheral can support. It is important to write application software such that it complies with certain restrictions, regarding work units and descriptor chains. Complying with this guideline makes the peripheral operate properly whenever it issues DMA control commands.

The ***PDMA_CMD Peripheral DMA Control Commands*** table describes the commands the DMA controller issues. The following sections describe these commands in more detail.

Table 34-6: PDMA_CMD Peripheral DMA Control Commands

Command	Name	Description
b#000	NOP	No operation
b#001	Restart	Restarts the current work unit from the beginning
b#010	Finish	Finishes the current work unit and starts the next
b#011	Interrupt	Immediately sets the DMA completion interrupt in the DMA channel
b#100	Request Data	Typical DMA data request
b#101	Request Data Urgent	Urgent DMA data request
b#110	Reserved	Reserved
b#111	Reserved	Reserved

Idle Command

The DMA channel drives this command when the enabled peripheral has no data requests required.

Request-Data Command

The request data command is a request for data transfers between the DMA channel and the peripheral. The request is held by the peripheral until granted or acknowledged by the DMA channel.

Request-Data Urgent Command

The request-data urgent command behaves identically to the request data command, except that---during the commands assertion---the DMA channel performs its memory accesses with urgent priority. This priority includes both data and descriptor fetch memory accesses. For example, a DMA management capable peripheral can use this control command if an internal FIFO approaches a critical condition.

The request is held by the peripheral until granted or acknowledged by the DMA channel.

Peripheral-Control Command Restrictions

The proper operation of the DMA channel FIFO leads to certain restrictions in the sequence of DMA peripheral control commands issued by a peripheral. The following sections describe these restrictions.

DMA Channel Peripheral DMA Bus

The DMA channel connects to peripherals or other DMA channels through the peripheral DMA bus. This bus is a dedicated point-to-point interface supporting data bus widths of 8, 16, 32, or 64 bits. The data bus widths for a given DMA channel on a particular processor can vary and are not configurable. Reading the `DMA_STAT.PBWID` field permits determining the assigned bus width.

The DMA channel operates at the SYSCLK frequencies, as does the peripheral DMA bus. The ***Peripheral DMA Bus Signals*** table provides descriptions of the peripheral DMA bus signals.

Table 34-7: Peripheral DMA Bus Signals

Signal	Width (bits)	Description
PDMA_WRITE_DATA	8, 16, 32, or 64	Data bus used for write operations. The width of the bus can be determined from `DMA_STAT.PBWID`.
PDMA_READ_DATA	8, 16, 32, or 64	Data bus used for read operations. The width of the bus can be determined from `DMA_STAT.PBWID`.
PDMA_DMA_GRANT		Control signals to indicate that data is valid for DMA channel read operations (peripheral transmit). These signals indicate that the DMA channel is ready to receive data for write operations (peripheral receive).
PDMA_CMD	3	The peripheral uses the signal for issuing DMA channel control commands.
PDMA_CTRL		The peripheral uses the control signals to send various commands to the DMA channel and control the direction of flow.

Memory DMA and Triggering

A memory DMA (MDMA) channel provides a means of doing memory-to-memory DMA transfers among the various memory spaces that have DMA support.

The DMA controller implements memory DMA (MDMA) channels by interfacing two DMA channels through the peripheral DMA bus interface. One DMA channel serves for memory read operations, and the second channel servers for memory writes. Depending on the processor, a memory DMA channel can have an additional peripheral, such as a CRC peripheral. The additional peripheral is inserted into the peripheral DMA bus that optionally can be enabled.

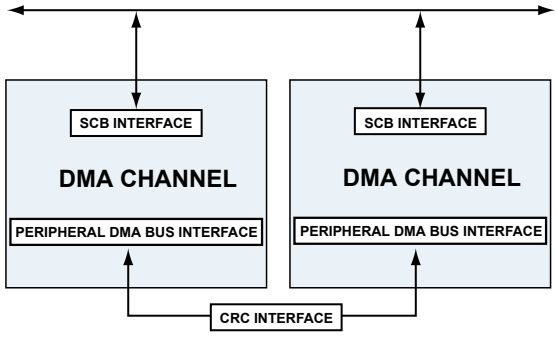

Figure 34-2: MDMA Channel Dedicated Pair

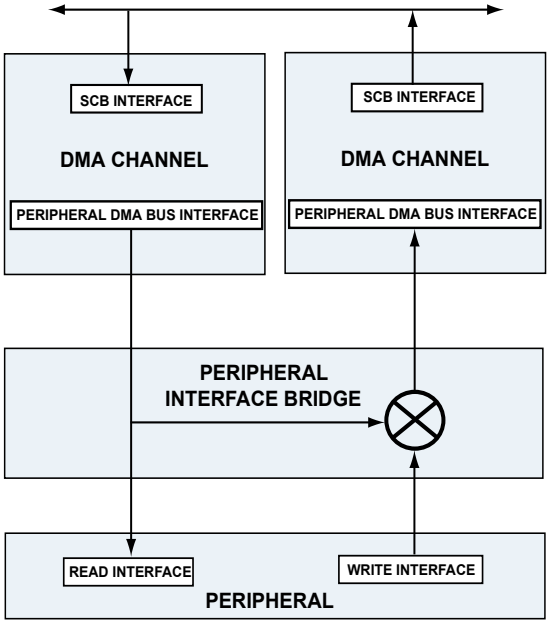

Figure 34-3: MDMA Channel Pair with Peripheral

A memory-to-memory transfer always requires enabled source and destination channels. Because the channels interface through the peripheral DMA bus and can have an additional peripheral inserted into the peripheral DMA bus, programs must make sure to set the same values in the `DMA_CFG.PSIZE` of both the source and destination channels.

The memory DMA channels support the full range of the `DMA_CFG.MSIZE` options for the DMA transfers to and from the memories.

Because the MDMA channel consists of two DMA channels, the entire MDMA channel has two sets of FIFOs, one in the read channel and one in the write channel. This FIFO usage allows for more efficient bursting of both read and write transactions using the available bandwidth. While the DMA_CFG.PSIZE configuration must be identical for both source and destination DMA channels, this restriction does not apply for the DMA_CFG.MSIZE configuration.

Configure the DMA_CFG.PSIZE bits to a value no larger than the supported bus width of the peripheral DMA bus. From a performance perspective, use the largest possible DMA_CFG.PSIZE value (for example, equal to the supported peripheral bus width (DMA_STAT.PBWID)). However, ensure that the number of bytes in the work unit is a multiple of the PSIZE value used.

NOTE: This is applicable for all of the DMA channels, except the MDMA channels 2 and 3. For the MDMA 2 and 3, the minimum *PSIZE* and *MSIZE* is 4 bytes (32 bits).

The independent source and destination DMA channels also have their own dedicated interrupt and trigger events. While it is normal practice to have only event generation performed at destination DMA completion, programs also can use other means of interrupt generation.

Configuration of an MDMA transfer is done in a similar manner to peripheral DMA transfers, except for writing two DMA channel registers instead of one.

To control the pace of data transfers, use triggers on either the memory read or the memory write channel pair used in an MDMA operation. Setting the DMA_CFG.TWAIT bit in the memory read channel prevents both channels from transferring data before the system is ready. However, only configuring the memory write channel to wait for a trigger allows for data fetch from the memory in anticipation of the memory write operation.

The processor supports these categories of MDMA channels:

Enhanced Bandwidth MDMA. The channels run in SYSCLK domain and support 32-bit memory and peripheral bus width. The maximum theoretical bandwidth of this MDMA stream is up to 4 × 500 = 2000 MB/s.

Maximum Bandwidth MDMA. The channels run in SYSCLK domain and support 64-bit memory and peripheral bus width. The maximum theoretical bandwidth of these MDMA streams is up to 8 × 500 = 4000 MB/s.

Table 34-8: MDMA Streams

MDMA Stream	Source Channel	Destination Channel	CRC Support	Other Names	Operating Clock	Bus Width (bits)	Maximum Theoretical BW (Mbytes/ second)
0	8	9	Yes	CRC0	SYSCLK (500 MHz max)	32	2000
1	18	19	Yes	CRC1			
2	39	40	No	MSMDMA			
3	43	44	No	HSMDMA		64	4000

Table 34-8: MDMA Streams (Continued)

MDMA Stream	Source Channel	Destination Channel	CRC Support	Other Names	Operating Clock	Bus Width (bits)	Maximum Theoretical BW (Mbytes/ second)
4	45	46	Yes	CRC2		32	2000
5	47	48	Yes	CRC3			
6	49	50	No	MSMDMA1			
7	51	52	No	HSMDMA1		64	4000

Medium Band Width DMA Channel MMR Access Bus

The MMR access bus provides access to all the DMA channels memory-mapped registers for DMA channel configuration, monitoring, and debug. The interface has a fixed 32-bit data bus for read and write accesses.

The ***MMR Access Bus Signals*** table provides descriptions of the MMR access bus signals.

Table 34-9: MMR Access Bus Signals

Signal	Width (bits)	Description
MMR_WRITE_DATA	32	Data bus used for write operations to the MMRs from the core
MMR_READ_DATA	32	Data bus used to return read data from the MMRs
MMR_READ_ADDR	7	Address used to select the MMR to access

DMA Channel Operation Flow

A detailed description of the flow of operation of the DMA channel appears in the following topics:

- Startup Flow
- Refresh Flow
- DMA Operating Modes
- Stop Mode
- DMA Channel Errors

Startup Flow

Enabling a DMA operation on a given channel first requires directly writing some or all of the DMA parameter registers. The minimum set of register required to be initialized depends on the desired mode of operation as described in the following sections.

Startup Minimum-Enable Requirements

To start a DMA operation on a given channel, some or all of the DMA parameter registers must first be initialized and configured to the desired DMA channels operating mode.

- For descriptor-array-based flow modes, at minimum, write the DMA_DSCPTR_CUR register prior to writing to the DMA_CFG register, which is the special action required to start the DMA channel.
- For descriptor-list-based flow modes, at minimum, write the DMA_DSCPTR_NXT register prior to writing to the DMA_CFG register, which is the special action required to start the DMA channel.
- For non-descriptor-based flow modes, write the DMA_ADDRSTART, DMA_XCNT, and DMA_XMOD registers prior to writing the DMA_CFG register.

Programs can write other registers that can remain static throughout the course of the DMA activity. The write to the DMA_CFG register begins the DMA operation.

ATTENTION: When software directly writes the DMA_CFG register, the DMA controller recognizes this action as the special startup condition. This condition occurs when starting the DMA controller for the first time on this channel or occurs after the DMA channel stops. It is possible for the channel to flag a DMA error condition regardless of the DMA_CFG.EN bit setting.

Startup Operation

The startup operation is initiated by software directly writing the DMA_CFG register when starting DMA for the first time on a channel or after the channel has entered to the stop state.

When the descriptor fetch is complete and the DMA channel is enabled, the DMA_CFG descriptor element replaces the DMA_CFG register content and assumes control. Before this point, the direct write to the DMA_CFG register had control.

At startup, the selected flow mode and the descriptor size determine the course of the DMA initialization process. The DMA_CFG.FLOW field determines whether to load more current registers from descriptor sets in memory. The DMA_CFG.NDSIZE field details how many descriptor elements to fetch before starting the DMA operation. This process does not affect DMA registers that are not in the descriptor; no modifications are made to their prior values.

For descriptor-list flow modes, the channel copies the DMA_DSCPTR_NXT register value into the DMA_DSCPTR_CUR register. Then, the channel fetches new descriptor elements from memory. The DMA_DSCPTR_CUR register indexes each fetch, and the channel increments the index after each fetch. After completion of the descriptor fetch, the DMA_DSCPTR_CUR register points to the next 32-bit word in memory past the end of the descriptor.

If the descriptor fetch is for a descriptor-array mode transfer, the channel does *not* copy the DMA_DSCPTR_NXT register into the DMA_DSCPTR_CUR register. *Instead*, the descriptor fetch indexing begins with the value in the DMA_DSCPTR_CUR register.

If DMA_CFG is not part of the fetched descriptor set, the previous value (originally as written on startup) controls the work unit operation. If the DMA_CFG register is part of the fetched descriptor set, the value programmed by the MMR access controls only the loading of the first descriptor set fetched from memory. The configuration of the DMA_CFG register controls the subsequent DMA work units of the fetched descriptor set.

After the descriptor fetch is complete or if the flow configuration was originally for one of the register-based flow modes, the DMA operation begins. The DMA channel immediately fills its FIFO. For a memory-write operation,

the DMA channel begins accepting data from the peripheral. For a memory-read operation, the DMA channel begins memory reads when the SCB bus grants access to the DMA channel.

When the DMA channel performs its first data-memory access, its address and count computations take their input operands from the start registers. These registers can include DMA_ADDRSTART, DMA_XCNT, and DMA_YCNT, if necessary. The channel writes results back to the current registers. These registers include DMA_ADDR_CUR, DMA_XCNT_CUR, and DMA_YCNT_CUR. Note that the current registers are not valid until the channel performs the first memory access, which can be some time after the write to the DMA_CFG register starts the channel. Once started, the channel automatically loads the current registers from the appropriate descriptor elements, overwriting their previous contents. These automatic-load operations include:

- The channel copies the DMA_ADDRSTART value to DMA_ADDR_CUR.
- The channel copies the DMA_XCNT value to DMA_XCNT_CUR.
- The channel copies the DMA_YCNT to DMA_YCNT_CUR.

Refresh Flow

When the channel completes processing of a work unit, the DMA channel performs the following operations:

- Completes the transfer of all data between memory and the DMA channel.
- Performs a synchronized transition (if the DMA channel configuration is a memory read operation with the DMA_CFG.SYNC bit enabled) *and* transfers all data to the peripheral before continuing.
- Forwards the signals from the DMA channel (if interrupts or triggers are enabled) *and* updates the DMA_STAT register to indicate the interrupt request or trigger events.
- Clears the DMA_STAT.RUN bit field to stop DMA operation (if the flow was set to stop mode) *and* transfers any remaining data in the FIFO of the DMA channel to the peripheral.
- Loads a new descriptor from memory into the DMA registers by way of the contents of the DMA_DSCPTR_CUR register (for descriptor-array mode) *and* increments the DMA_DSCPTR_CUR register

  The channel takes the descriptor size from the DMA_CFG.NDSIZE value before the fetch.
- Copies the DMA_DSCPTR_NXT register into the DMA_DSCPTR_CUR register (for descriptor-list mode), fetches the descriptor from the new contents of the DMA_DSCPTR_CUR register, *and* places these contents into the DMA registers while incrementing the DMA_DSCPTR_CUR register.
- Checks for detection of an incoming trigger event (for descriptor-on-demand array mode):
  - If the channel detects a trigger event, the DMA channel loads a new descriptor from memory into the DMA registers from the contents of the DMA_DSCPTR_CUR register, while incrementing the DMA_DSCPTR_CUR register. The channel takes the descriptor size from the DMA_CFG.NDSIZE value before the fetch.
  - If the channel detects no trigger event, the DMA channel begins the next work unit by reloading the current registers.

- Checks for detection of an incoming trigger event (for descriptor-on-demand list mode):
  - If the channel detects a trigger event, the DMA channel copies the DMA_DSCPTR_NXT register value to the DMA_DSCPTR_CUR register, fetches the descriptor memory from the DMA_DSCPTR_CUR register, *and* places the contents into the DMA registers while incrementing the DMA_DSCPTR_CUR register.
  - If the channel detects no trigger event, the DMA channel begins the next work unit by reloading the current registers as described in the next step.
- Begins the next work unit (if flow configuration is anything other than stop mode) by reloading the current registers (DMA_ADDR_CUR, DMA_XCNT_CUR, and DMA_YCNT_CUR) from their descriptor registers (DMA_ADDRSTART, DMA_XCNT, and DMA_YCNT)

Work Unit Transition Flow

The DMA_CFG.SYNC bit controls transitions from one work unit to the next work unit. In general, continuous transitions have lower latency at the cost of restrictions on changes of data format or addressed memory space in the two work units. These latency gains and data restrictions arise from the way the channel handles the DMA FIFO while fetching the next descriptor.

In continuous transitions, with disabled synchronization, the DMA FIFO pipeline continues to transfer data to and from the peripheral or destination memory. These transfers continue during the descriptor fetch and during the DMA channel pause between descriptor chains. By comparison, synchronized transitions provide better real-time synchronization of interrupts and triggers with a given peripheral state. Synchronized transitions also provide greater flexibility in the data formats and memory spaces of the two work units. This flexibility comes at the cost of higher latency in the transition. In synchronized transitions, the DMA FIFO pipeline drains to the destination or flushes (received data discarded) between work units.

NOTE: The DMA_CFG.SYNC bit of the MDMA source channel controls work unit transitions for MDMA streams. Clear this reserved bit of the MDMA destination channel, placing it in the disabled state. In transmit (memory read) channels, the DMA_CFG.SYNC bit of the last descriptor before the transition controls the transition behavior. In contrast, in receive channels, the DMA_CFG.SYNC bit of the first descriptor of the next descriptor chain controls the transition.

Work Unit Transmit and MDMA Source Transitions

In DMA transmit (memory read) and MDMA source channels, the DMA_CFG.SYNC bit controls the interrupt timing at the end of the work unit. This bit also controls the handling of the DMA FIFO between the current and the next work unit.

If the DMA_CFG.SYNC bit configuration disables synchronization, the DMA channel operates in continuous transition. In a continuous transition, just after reading the last data item from memory, the DMA channel starts all of the following operations parallel:

- Signals the interrupt request or trigger
- Updates the DMA_STAT register to indicate DMA completion status
- Begins fetching the next descriptor

- Delivers the final data items from the DMA FIFO to the destination memory or peripheral

This process lets the DMA channel provide data from the FIFO to the peripheral continuously during the descriptor fetch latency period.

If the configuration disables synchronization, the final interrupt request or trigger (if enabled) occurs when the channel reads the last data from memory. This event occurs at the earliest time that the channel safely can modify the output memory buffer without affecting the previous data transmission. There can be a number of data items remaining in the FIFO and not yet at the peripheral. This number depends on the FIFO depth of the DMA channel. In this configuration, do not use the DMA interrupt request as the sole means of synchronizing the shutdown or reconfiguration of the peripheral following a transmission.

NOTE: If the configuration selects continuous transition on a transmit (memory read) descriptor, the next descriptor must have the same:

- Peripheral transfer size (`DMA_CFG.PSIZE`)
- Read or write direction
- Source memory (internal versus external) as the current descriptor

It is possible to disable synchronization by selecting continuous transition on a work unit with configuration for stop-flow mode and with enabled interrupts or triggers. This approach can result in the execution of the event service routine while draining of the final data is ongoing from the FIFO to the peripheral. If data transfers are in-progress, the FIFO is not yet empty. The `DMA_STAT.RUN` bits of the DMA channels indicate this status. Do not start a new work unit with a different peripheral transfer size or direction while data transfers are in-progress.

CAUTION: Disabling the channel with the `DMA_CFG.EN` bit while data transfers are in-progress causes the loss of the data in the FIFO.

A synchronized transition configuration directs the channel to drain the DMA FIFO to the destination memory or peripheral. This FIFO operation occurs before the channel signals any interrupt and before the channel fetches any subsequent descriptor or data. This operation incurs greater latency, but provides direct synchronization between the DMA interrupt and the state of the data at the peripheral.

If the configuration enables synchronization and enables interrupts, on the last descriptor in a work unit, the interrupt occurs when the channel transfers the final data to the peripheral. This event allows the service routine to switch properly to non-DMA transmit operation. When the event vectors to the interrupt service routine, the DMA channel FIFO is empty, and the DMA channel is no longer running (indicated by the `DMA_STAT.RUN` bits).

A synchronized transition also allows greater flexibility in the format of the DMA descriptor chain. When enabled, the next descriptor can have any `DMA_CFG.PSIZE` configuration or read/write direction supported by the peripheral and can come from either memory space (internal or external). This feature can be useful in managing MDMA work unit queues, since it is no longer necessary to interrupt the queue between dissimilar work units.

Work Unit Receive and MDMA Destination Transitions

In DMA receive channels (memory write operations), the `DMA_CFG.SYNC` bit controls the handling of the DMA FIFO between descriptor chains (not individual descriptor sets), during the DMA channel pause. The

DMA channel pauses after the descriptor sets configured with stop flow mode are complete. Restart the channel (for example, after an interrupt) by writing the DMA_CFG register of the channel with a value that enables the DMA channel. If the configuration disables synchronization in the DMA_CFG value of the new work unit, the configuration selects a continuous transition. In this mode, the DMA FIFO retains any data items received during the channel pause, and they are the first items written to memory in the new work unit. This mode of operation provides lower latency at work unit transitions and ensures no dropping of data items during a DMA pause. The channel provides this operation at the cost of certain restrictions on the DMA descriptors.

NOTE: If the DMA_CFG.SYNC bit disables synchronization on the first descriptor of a chain after a DMA pause, do not change the configuration of the DMA_CFG.PSIZE field of the new chain from the previous descriptor chain (active before the pause). This restriction applies unless the DMA channel is reset between chains by disabling and then re-enabling the DMA channel.

If the DMA_CFG.SYNC bit configuration enables synchronization, the channel uses a synchronized transition. In this mode, only the data that the DMA channel receives from the peripheral after the write to the DMA_CFG register gets to memory. The channel discards any prior data items transferred from the peripheral to the DMA FIFO before this register write occurs. This operation provides direct synchronization between the data stream received from the peripheral and the timing of the channel restart, which occurs on the write to the DMA_CFG register.

For receive DMA operations, the synchronization has no effect in transitions between work units in the same descriptor chain. When the flow mode of previous descriptor was not stopped, the DMA channel did not pause.

If a descriptor chain begins with synchronization enabled, there is no restriction on the DMA_CFG.PSIZE of the new chain in comparison with the previous chain.

NOTE: The peripheral transfer size (DMA_CFG.PSIZE) must not change between one descriptor and the next in any DMA receive (memory write) channel within a single descriptor chain, regardless of the DMA_CFG.SYNC bit setting. In other words, all memory write descriptor sets in a descriptor chain must have the same DMA_CFG.PSIZE value. For any DMA receive channel (memory write operation), there is no restriction on changes of peripheral transfer size (internal versus external) between descriptors or descriptor chains.

Transfer Termination and Shutdown Flow

This section describes channel transfer termination and shutdown in stop flow mode and in autobuffer flow mode.

Stop Flow Mode

In stop flow mode, the DMA channel stops automatically after the work unit is complete. If using a list or array of descriptors to control DMA transfers and if every descriptor contains a DMA_CFG descriptor element, configure the flow of the final DMA_CFG descriptor element to stop mode, stopping the channel gracefully. After completion, the DMA channel remains in the stop state. Do not confuse this state with the disabled state, which either occurs due to a DMA error or occurs through disabling the DMA channel by configuring the DMA_CFG.EN bit.

The intention of disabling the DMA channel through a write to the DMA_CFG.EN bit is to shut down the DMA channel and to enter the disabled state. All memory and peripheral data transfers cease, and only peripheral interrupts pass through the DMA channels interrupt signals. However, the DMA channel maintains the

DMA_STAT.RUN bits. For a write to memory, the outstanding memory-transaction counter tracks returning memory write acknowledgments and updates as required.

For memory reads, the outstanding memory-transaction count also tracks returning memory reads. The channel does not write the memory reads into the FIFO. The channel updates the counter to reflect the completion of the transaction, but the channel ignores the data. The DMA_STAT.RUN bits remain in the *waiting for write ACK or FIFO drain to peripheral* state and do not change to *stop or idle state* until the return of all outstanding transactions.

When the DMA_CFG.EN bit again enables the DMA channel, the channel performs a full reset and clears all counters. If an outstanding memory transaction returns an acknowledgment or read data after this event, a memory transaction error occurred, which generates an error event. Programs must ensure that all outstanding memory transactions complete before reconfiguring the DMA channel. For example, programs can poll the DMA_STAT.RUN bits to return to the stop or idle state before proceeding.

Autobuffer Flow Mode

In this mode, the flow does not use any descriptors in stored memory. Instead, the channel performs DMA in a continuous circular buffer fashion, based on user-programmed DMA register settings. On completion of the work unit, the channel reloads the parameter registers into the current registers, and the DMA controller resumes immediately with zero overhead. Consider this mode as a succession of automatically restarted work units.

For autobuffer-flow modes, the only way to cease operations is to disable the DMA channel through the DMA_CFG.EN bit. One method of changing to a new work unit is:

- Disable the DMA channel
- Set up all the registers (and descriptors in memory, if used) except for DMA_CFG
- Poll DMA_STAT.RUN to wait for the status to reflect stop or idle state, and
- Write DMA_CFG to the new configuration to begin the next work unit

In autobuffer-flow mode or for a list or array of descriptor sets without DMA_CFG descriptors, use an MMR write to the DMA_CFG register to terminate the DMA transfer process. Configure the value of the DMA_CFG.EN bit in this register to disable the DMA channel.

CAUTION: When the configuration disables a DMA channel, the DMA controller disables interrupt logic that is based on work unit transitions. Be aware of the system environment and current actions, so that additional interrupts are not required from the DMA channel.

CAUTION: If disabled through DMA_CFG.EN in the middle of a transaction, the DMA channel completes any transactions that have begun and avoids generating bus errors. However, the channel considers the action of re-enabling the DMA as a hard reset for all internal DMA channel components. Therefore, pay attention to that particular action to avoid unexpected results.

DMA Channel Errors

When an error occurs, the DMA channel maintains all the state and register values that allow programs to diagnose error causes more thoroughly. The greatest benefit to the programmer is to know exactly what operational state the DMA channel was in at the exact moment the error occurred.

Take care to address the root cause of the error, whether or not the problem originated in the DMA channel. If not properly resolved, the error can result in an additional error shortly after operations resume. The problem can cause other errors elsewhere in the DMA channel or associated modules and circuitry. So, take care also to address those potential problems. Ensure that all outstanding memory reads and writes are complete or cleared before resuming DMA channel operation.

After addressing all issues and neutralizing all side effects of any errors, clear the DMA_STAT.ERRC status field and restart the DMA channel by disabling then re-enabling the DMA channel through the DMA_CFG.EN bit.

The following sections describe the error types.

Status and Debug Errors

DMA channel error conditions can cause the DMA process to end abnormally. The DMA channel provides error detection as a tool for system development and debug, helping to identify DMA-related programming errors. When the DMA channel detects an error, the channel immediately stops and discards any returned memory-read transactions. The DMA_STAT.RUN field of the DMA channel indicates the idle state after acknowledging all outstanding memory transactions. In addition, the channel asserts an error interrupt request and updates the DMA_STAT.IRQERR field. Also, the channel updates the DMA_STAT.ERRC field, indicating the error cause of the first detected error. Unless the error occurs at the exact moment that modification of register values occurs, the registers contain the error values.

All the DMA error interrupt requests are combined into a single shared interrupt request output. Combined error signals require reading the DMA_STAT register of each DMA channel associated with a combined error interrupt request to determine the DMA channel responsible for the generation of the interrupt.

The DMA channel error interrupt handler performs the following actions:

- Read the DMA_STAT register of each DMA channel, seeking a channel with the DMA_STAT.IRQERR set to indicate an error.
- Read the DMA_STAT.ERRC field of each DMA channel, determining the cause of the error.
- Clear the problem with the DMA channel. For example, fix the register values.
- Clear the error in the DMA channel through a write-1-to-clear operation to the DMA_STAT.IRQERR bit.

If the channel flags any uncleared error other than a bandwidth monitor error, the channel reports no other error. If the channel reports an uncleared bandwidth monitor error, the channel reports any newly detected error through updating the DMA_STAT.ERRC field.

DMA Configuration Register Errors

The channel only flags these configuration errors when the DMA_CFG.EN bit enables the DMA channel. Error flagging occurs when the configuration:

- Uses a reserved setting
- Enables DMA_CFG.TWAIT in descriptor on-demand flow mode
- Uses an illegal DMA_CFG.NDSIZE
- Uses an illegal DMA_CFG.MSIZE
- Configures DMA_XCNT = 0 or, when DMA_YCNT = 0 in 2D DMA mode
- Uses non-zero value in DMA_CFG.NDSIZE when DMA is configured in stop mode or auto mode
- Enables interrupt or outgoing triggers on DMA_YCNT when DMA is configured in 1D mode
- Use a DMA_CFG.MSIZE that exceeds the FIFO size of the DMA channel
- Uses an illegal DMA_CFG.PSIZE
- Uses a DMA_CFG.PSIZE that exceeds the FIFO size
- Uses a DMA_CFG.PSIZE that exceeds the bus width
- Attempts to change from a transmit operation (memory read) to a receive operation without properly synching in the previous work unit or when it is the first work unit in a new chain
- Attempts to change DMA_CFG.PSIZE of a transmit operation (memory read) without properly synching in previous work unit or when it is the first work unit in a new chain
- Attempts to change from receive operation (memory write) to a transmit operation during a descriptor chain.

  The channel only can change from receive to transmit if the new transmit is synchronized and is the first work unit.
- Attempts to change DMA_CFG.PSIZE of a receive operation (memory write) when the operation was not the first work unit (with DMA_CFG.SYNC enabled)

Illegal Register Write During Run

The channel generates an error when a write occurs to writable registers of an enabled, running DMA channel. The channel blocks the write. The DMA_STAT, DMA_BWLCNT, and DMA_BWMCNT registers are exempt from this behavior.

Address Alignment Error

The channel generates an address alignment error when any of the following apply:

- Alignment of a descriptor address is not on a 32-bit boundary.
- The current DMA_CFG.MSIZE configuration contains an unaligned transfer address. The DMA_ADDRSTART register is not aligned according to the DMA_CFG.MSIZE field.

Memory Access Error

The channel generates a memory access error when the DMA process:

- attempts to access an unpopulated address,

- attempts to access a location that provokes a security violation

The error returned from the memory triggers the memory access error.

Trigger Overrun Error

A trigger overrun error is generated when a new trigger input occurred while an outstanding trigger is waiting. This error is only generated if `DMA_CFG.TOVEN` is enabled.

Bandwidth-Monitor Error

The channel generates this error when the bandwidth-monitor count expires. This error is not fatal, and the DMA channel continues operation.

Control Interface Error

The channel reports control-interface errors as bus errors to the bus controller. This error can result from:

- An address error
- A register write error (write to a read-only register)

DMA Operating Modes

The DMA channel supports a number of different flow modes that control how the DMA channel progresses from one work unit to the next.

The flow mode of a DMA channel is not a global setting. A DMA descriptor set can include the descriptor responsible for configuring the flow of the work unit. There is no restriction, limiting the flow configuration to be the same for the entire descriptor chain. If the descriptor chain is not endless, the last descriptor set configures the flow to stop mode, which results in termination of the descriptor chain after the work unit completes. Another example for mixing flow modes is to create an endless descriptor-array. The configuration of the last descriptor set in the array selects the descriptor-list mode. The next descriptor pointer in this set of descriptors points to the first descriptor in the array.

Register-Based Flow Modes

Register-based DMA operations require configuration by directly writing to the memory-mapped registers of the DMA channel.

Register-based DMA is the traditional method of DMA operation. Software writes all of the configuration of the DMA channel into the memory-mapped registers. This configuration includes information such as the source or destination address and length of the data in the transfer. The DMA controller then starts channel operation. The DMA channel supports the following register-based flow modes.

- Stop Mode
- Autobuffer Mode

The DMA channel supports variable descriptor set sizes within the configuration. The size of a descriptor set can contain as little as a single descriptor. The supported descriptor set sizes can differ between the various

descriptor-based flow modes. In addition to the descriptor set size being configurable, descriptor-based DMA also allows altering the flow mode of the next descriptor set. This feature allows for the transition from descriptor-array mode to descriptor-list mode and permits configuring the flow to stop or autobuffer mode.

Stop Mode

In stop mode, the DMA operation executes only once. If started, the DMA channel transfers the desired number of data words and stops itself again when finished. If the DMA channel is no longer used, software configures the enable bit to disable a paused channel. The channel also can generate interrupts and triggers for each row or work unit completion, depending on the desired operation.

Autobuffer Mode

In autobuffer mode, the DMA operates repeatedly in a circular manner. If the transfer of all data words completes, the channel reloads the address pointer (`DMA_ADDR_CUR`) automatically with the `DMA_ADDRSTART` value. The channel also can generate an interrupt.

The `DMA_CFG.FLOW` field enables autobuffer mode. The configuration must load the `DMA_CFG.NDSIZE` field value, such that the next descriptor size is zero.

Descriptor-Based Flow Modes

Descriptor-based DMA operations fetch descriptor sets from memory allowing for autonomous loading of work units on other work units. Software does not need to set up the DMA sequences directly by writing into the DMA controller registers. Rather, software keeps DMA descriptor sets in memory.

Descriptor-based DMA operations have the following additional attributes.

- The DMA controller autonomously loads the descriptor set from memory to the affected DMA controller registers on demand.
- The channel can fetch descriptor sets from any memory space that supports DMA read operations.
- The descriptor set describes the next operation that the DMA controller performs.
- The descriptor set can include information such as the DMA configuration word as well as data source or destination address, transfer count, and address modify values.

A descriptor set describes a single work unit. The next work unit can reuse some values from the previous one descriptor set. But, this reusage is possible only if they are not overwritten in the subsequent descriptor set fetches and only if the work unit requires the use of this descriptor.

The DMA channel supports the following flow modes with descriptor-based operations.

- Descriptor-Array Mode
- Descriptor-List Mode
- Descriptor-On-Demand Modes

The DMA channel supports variable descriptor set sizes within the configuration. The size of a descriptor set can contain as little as a single descriptor and the supported descriptor set sizes can differ between the various descriptor-based flow modes. In addition to configurable descriptor set size, descriptor-based DMA also allows for altering of the flow mode of the next descriptor set. Programs can transition from one descriptor-based mode to another descriptor-based mode and can also transition to any of the register-based flow modes.

Descriptor-Array Mode

When configured in this mode, the descriptor sets do not contain further descriptor pointers. Software writes the initial descriptor-pointer value, which points to an array of descriptors. This operation assumes that the individual descriptors reside next to each other and assumes that their addresses are known.

The ***Offsets for Descriptor-Array Mode Parameters and Descriptors*** table illustrates how to structure a descriptor set in memory. The descriptor sets must reside in a contiguous block or memory in the format shown in the table. Locate the first descriptor of the next descriptor set in the memory location immediately following the last descriptor of the current descriptor set. The values have the same order as the corresponding offset addresses of the memory-mapped register.

Table 34-10: Offsets for Descriptor -Array Mode Parameters and Descriptors

Descriptor Offset	Parameter Register
0x00	DMA_ADDRSTART
0x04	DMA_CFG
0x08	DMA_XCNT
0x0C	DMA_XMOD
0x10	DMA_YCNT
0x14	DMA_YMOD

All other DMA channel registers that were not loaded as a result of the descriptor set fetch, retain their previous values. The channel reloads all of the current registers between the descriptor set fetch and the start of the DMA operation for the work unit.

NOTE: At a minimum, write the DMA_DSCPTR_CUR register prior to writing to the DMA_CFG register, which is the special action required to start the DMA channel.

Descriptor-List Mode

In this flow mode, multiple descriptors form a chained list in which each descriptor set contains a pointer to the next descriptor set, allowing greater flexibility in memory layout options. When the channel fetches the descriptor set, the operation loads this pointer value into the next descriptor pointer register of the DMA channel.

Descriptor Sets

The ***Offsets for Descriptor-List Mode Parameters and Descriptors*** table shows how to structure a descriptor set in memory. Disperse the placement of the descriptor sets throughout memory, having sets reside in different memory

blocks. But, each descriptor of the descriptor set must reside in a contiguous section of memory in the format shown in the table. The values have the same order as the corresponding offset addresses of the memory-mapped registers.

Table 34-11: Offsets for Descriptor-List Mode Parameters and Descriptors

Descriptor Offset	Parameter Register
0x00	DMA_DSCPTR_NXT
0x04	DMA_ADDRSTART
0x08	DMA_CFG
0x0C	DMA_XCNT
0x10	DMA_XMOD
0x14	DMA_YCNT
0x18	DMA_YMOD

All other DMA channel registers that were not loaded as a result of the descriptor set fetch, retain their previous values. The channel reloads all of the current values of the registers between the descriptor set fetch and the start of the DMA operation for the work unit.

Minimum Startup Requirements

At a minimum, write the `DMA_DSCPTR_NXT` register prior to write to the `DMA_CFG` register, which is the special action required to start the DMA channel.

Descriptor-On-Demand Modes

The Descriptor-Array Mode and Descriptor-List Mode each have an on-demand mode of operation.

In on-demand mode, at the end of the work unit, if the DMA channel has not detected an incoming trigger event, the channel repeats the current work unit. If the DMA channel receives an incoming trigger before completion of the work unit, the channel fetches a new descriptor set.

The ***Offsets for Descriptor-Array Mode Parameters and Descriptors*** and ***Offsets for Descriptor-List Mode Parameters and Descriptors*** tables illustrate how to structure each descriptor set in memory.

Table 34-12: Offsets for Descriptor-Array Mode Parameters and Descriptors

Descriptor Offset	Parameter Register
0x00	DMA_ADDRSTART
0x04	DMA_CFG
0x08	DMA_XCNT
0x0C	DMA_XMOD
0x10	DMA_YCNT

Table 34-12: Offsets for Descriptor-Array Mode Parameters and Descriptors (Continued)

Descriptor Offset	Parameter Register
0x14	DMA_YMOD

NOTE: For descriptor-array mode, at a minimum, write the DMA_DSCPTR_CUR register prior to writing to the DMA_CFG register, which is the special action required to start the DMA channel.

Table 34-13: Offsets for Descriptor-List Mode Parameters and Descriptors

Descriptor Offset	Parameter Register
0x00	DMA_DSCPTR_NXT
0x04	DMA_ADDRSTART
0x08	DMA_CFG
0x0C	DMA_XCNT
0x10	DMA_XMOD
0x14	DMA_YCNT
0x18	DMA_YMOD

NOTE: For descriptor-list mode, at a minimum, write the DMA_DSCPTR_NXT register prior to write to the DMA_CFG register, which is the special action required to start the DMA channel.

Data Transfer Modes

In addition to supporting basic one-dimensional DMA transfers, the DMA channel also supports two-dimensional functionality.

Two-Dimensional DMA

Register-based flow modes and descriptor-based flow modes support two-dimensional data transfers.

In two-dimensional (2D) mode, the X-direction count (DMA_XCNT), the X-direction modifier (DMA_XMOD), the Y-direction count (DMA_YCNT), and the Y-direction modifier (DMA_YMOD) support arbitrary row and column sizes. Also, the modify values can be negative, allowing implementation of interleaved data streams. The DMA_XCNT value specifies the row size, and the DMA_YCNT value specifies the column size; where the DMA_XCNT value must be 2 or greater.

The DMA start address (DMA_ADDRSTART), the X-direction modifier (DMA_XMOD), and the Y-direction modifier (DMA_YMOD) specifications all are in bytes. The alignment must be a multiple of the DMA transfer word size; configured using the DMA_CFG.MSIZE bit. Misalignment results in a DMA channel error.

The DMA_XMOD register value is the byte-address increment that the channel applies after each transfer, decrementing the DMA_XCNT register. The channel does not apply the DMA_XCNT when the inner loop count ends with the DMA_XCNT_CUR register decrementing to 0 from 1. Except, the channel does apply the DMA_XCNT on the final transfer, when the DMA_YCNT register is 1 and the DMA_XCNT register decrements from 1 to 0.

The DMA_YMOD register value is the byte-address increment that the channel applies after each decrement of the value in DMA_YCNT_CUR. However, the channel does not apply the DMA_YMOD value to the last item in the array on which the outer loop count (DMA_YCNT_CUR) also expires by decrementing from 1 to 0.

After the last transfer completes, DMA_YCNT_CUR is 1 and the DMA_XCNT_CUR register is 0. The DMA channels current address points to the last items address plus the DMA_XMOD register value. If the DMA channel programming selects automatic refresh (such as in autobuffer mode), the channel reloads the DMA_XCNT_CUR, DMA_YCNT_CUR, and DMA_ADDR_CUR for the first data transfer of the next work unit.

Interrupt notification is configurable for end-of-row or end-of-work unit completion.

For example, two-dimensional DMA can be used to extract interleaved data (such as RGB values for a video frame) by modifying both DMA_XMOD and DMA_YMOD values. The ***Capturing a Video Data Stream 2D DMA Example*** depicts the process of receiving a stream of the R, G, B values from an N*M frame. The inner loop of the 2D DMA configuration has three values (DMA_XCNT = 3) and a stride (DMA_XMOD) of N*M, chosen such that successive elements in each row are 1-2-3, 4-5-6 and so forth. The outer loop of the 2D DMA configuration has N*M values (DMA_YCNT = N*M) and a negative stride (DMA_YMOD) of 1-2*N*M chosen to instruct the DMA controller to jump from element 3 to 4, 6 to 7 and so forth at the end of each inner loop.

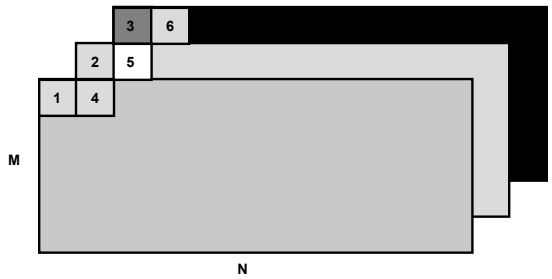

Figure 34-4: Capturing a Video Data Stream 2D DMA Example

DMA Channel Event Control

The DMA channel supports a number of events that provide notification of work unit state, peripheral data request, peripheral interrupt request and completion events, and DMA channel error conditions. In addition to flexible interrupt configuration, the DMA channel also supports incoming and outgoing triggers which are useful in synchronizing the DMA channel with other system resources.

The DMA channel has two interrupt signals for support of a number of events such as work-unit state events, peripheral interrupt request (PIRQ) events, peripheral data request (PDR) events, and DMA channel errors. The channel reports DMA channel errors on a dedicated interrupt signal. All other interrupt sources share an interrupt signal. In addition to flexible interrupt configuration, the DMA channel also supports incoming and outgoing triggers which are useful in synchronizing the DMA channel with other system resources.

The channel can signal the processor on DMA channel events using status information and optional interrupt requests. Programs can use these events to update the progress of data transfers and to request intervention from the processor core. Configure most DMA channel interrupts using bits in the DMA_CFG register. Dedicated bits in

the DMA_STAT register report the occurrence of various events. Use write-one-to-clear (W1C) operations to clear interrupt requests from the status register.

NOTE: Hardware does not clear the interrupt status bits automatically, even when programs disable then reenable the DMA channel. In this situation, the channel deasserts the interrupt signal, after the program disables the DMA channel. But, the status bit remains set until software either re-enables the DMA channel or clears the status bit.

The DMA channel supports the following categories of events on the interrupt signals:

- Work-unit state events generate interrupts on row or on work unit DMA completion.
- A peripheral uses peripheral interrupt request (PIRQ) events to signal when it has completed the transfer of all data.
- A peripheral uses peripheral data request (PDR) events to request data from a disabled or idle DMA channel.
- Error events signal a failure in the work unit.

ATTENTION: While in an error state, the DMA channel does not generate an interrupt to the processor for a work-unit state event or a PIRQ event, nor does the channel forward a PDR event.

Event Signals

The ***Event Signals*** table provides descriptions of DMA channel events.

Table 34-14: Event Signals

Signal	Width (bits)	Description
DMA_ERROR	1	Used to signal an error condition in the DMA channel. The source of the error can be determined by reading the DMA_STAT.ERRC bit.
DONE_PIRQ_INT	1	Signal used to indicate DMA completions events, PIRQ events and also for forwarding PDR events based on configuration. Read the corresponding fields in DMA_STAT to determine the source of the event.
DMA_TRIG_OUT	1	Trigger output that gets routed to the TRU and can be configured to provide notification on row or work unit completion.
DMA_TRIG_IN	1	Trigger input from the TRU that can be used to control the start of a work unit.

Work Unit State Events

Completing a row or a work unit generates a work-unit state event. For either of these events to generate an interrupt request, the configuration of the interrupt of the DMA channel must select one of the available work-unit completion modes.

- Current X count reaching 0 for row completion or 1D DMA work unit completion
- Current Y count reaching 0 for work unit completion of 2D DMA

NOTE: For 1D DMA, a DMA channel configuration error results if the configuration generates the interrupt request when the current Y counter reaches 0.

The DMA channel issues the last memory read or write transaction for the row or work unit, then pauses until the return of the read or write acknowledge. After successful acknowledge of the transfer, the DMA channel issues the interrupt request and continues to process the next row or work unit.

Waiting for acknowledgement of the memory access results in a delay. However, programs can read or modify data in the memory without adversely affecting or being affected by the DMA transfer.

NOTE: While the DMA channel pauses waiting for acknowledgement of the memory transfer, the DMA channel is still capable of fetching the next descriptor set. This fetch gets the channel ready to process the next work unit as soon as the memory access completes.

The channel configuration of the synchronization feature also affects interrupt timing. For memory-read operations with synchronization enabled, the channel delays the interrupt request until the completion of the last transfer from the DMA channel FIFO to the peripheral. The synchronization feature does not affect interrupt timing for memory write operations.

Peripheral Interrupt Request Events

For peripheral-transmit operations, a peripheral connected to the DMA channel can use peripheral interrupt request (PIRQ) events to indicate that data has left the channel FIFO and to indicate transfer completion.

In order to support PIRQ interrupts, correctly configure the interrupt of the DMA channel. This configuration disables the generation of interrupt requests based on the work unit state and, instead, results in generating an interrupt request when the DMA channel receives the command from the peripheral.

The channel only generates the interrupt request under the following conditions:

- The configuration enables the DMA channel
- The DMA channel is in the stop state
- The configuration of the DMA channel interrupt selects PIRQ operation

Peripheral Data Request Events

Peripheral data request (PDR) events occur when an interfaced peripheral requests data from the DMA channel and the DMA channel (either disabled or enabled) is in the stop state.

When a peripheral sends a data request command to a disabled DMA channel, the DMA channel generates an interrupt to the System Event Controller (SEC). There is no status information reported about this event in the status register of the DMA channel. Instead, the channel identifies the PDR event from the fact that the DMA channel generated an interrupt while disabled. It is possible to further confirm event status by verifying the status of the peripheral interfaced to the DMA channel.

This operation forwards data requests as interrupts when the DMA channel is in the disabled state. The DMA channel can forward PDR events as an interrupt request when the DMA channel is in the stop state after the

completion of a work unit. The forwarding of this interrupt when the DMA channel is in the stop state is optional and configured by the program during DMA channel configuration.

DMA Channel Triggers

DMA channel triggers are useful for synchronizing the DMA channel with other events in the system. One usage is to combine channel triggers with each other to create ping-pong buffers. Another usage is to combine the triggers with interrupt requests to notify the processor on reaching a particular milestone that requires service. The channel also can use triggers to enforce a handshake DMA operation in which the trigger acts as a signal for a DMA request.

NOTE: Using the trigger to control the pace of data transfers, such as for handshake DMA, requires that all the data for the entire work unit is ready for transfer.

The DMA channel has a single incoming trigger that can control the pace of the data transfers performed by the DMA channel. The configuration can direct the DMA channel to wait for the incoming trigger before starting the work unit transfer or fetching a descriptor set from memory.

The DMA channel also has a single outgoing trigger signal. This configuration can direct this trigger to signal the end of row or an entire work unit. The DMA channel issues the last memory read or memory write transaction for the row or work unit, then pauses until return of the transfer acknowledge. After acknowledgement of the transfer, the DMA channel issues the trigger before processing the next row or work unit.

NOTE: The peripheral interrupt (PIRQ) and trigger out are independent functions. PIRQ is asserted when the respective peripheral completes the transaction. Trigger out is asserted when the DMA module completes the transaction.

Issuing Triggers

The DMA channel configuration can direct the channel to generate an outgoing trigger signal at the end of row or the end of a work unit. The DMA channel issues the last memory read or memory write transaction for the row or work unit, then pauses until the return of the transfer acknowledge. After acknowledgement of the transfer, the DMA channel issues the trigger before processing the next row or work unit.

NOTE: While the DMA channel pauses waiting for acknowledgement of the memory transfer, the DMA channel is still capable of fetching the next descriptor set. This fetch gets the channel ready to process the next work unit as soon as the memory access completes.

Waiting For Triggers

Programs can use triggering to control the pace of data transfers performed by the DMA channel. The DMA channel enters a wait state before beginning the next work unit if the configuration enables `DMA_CFG.TWAIT` and either of the following apply:

- The channel receives a trigger since the last time the DMA channel left the wait state.
- The channel receives a trigger since its transition from disable to enable.

In the wait state, the DMA channel also does not perform a descriptor fetch. After receiving a trigger, the DMA channel leaves the wait state and begins the next work unit or fetches the next descriptor if configured for a descriptor-based mode of operation.

If a memory-mapped register write operation programs the channel with stop flow mode enabled (DMA_CFG.TWAIT bit) and the channel has not already received a trigger, the DMA channel enters a wait state before performing the data transfer. On receiving the trigger, the DMA channel begins the data transfer portion of the work unit. Once the data transfer is complete, the DMA channel enters the stop state.

If a memory-mapped register write operation programs the DMA channel with the flow mode configured to one of the descriptor-based modes, the DMA channel enters the wait state before performing the descriptor fetch. After completing the descriptor fetch, the DMA channel immediately proceeds to the data transfer, regardless of the value of the DMA_CFG.TWAIT bit. If another (next) descriptor fetch follows the descriptor fetch, the DMA channel enters a wait state before fetching the next descriptor.

If the descriptor fetch returns a descriptor with stop flow mode, the DMA_CFG.TWAIT value for that descriptor does not affect the DMA as the channel enters the stop state after completing the data transfer. The DMA channel only enters the wait state based on DMA_CFG.TWAIT before the next work unit or descriptor fetch.

If the descriptor fetch returns a descriptor configured for autobuffer flow mode, the DMA_CFG.TWAIT for that descriptor does not affect the DMA for the first work unit of the autobuffer transfer. After completing the first work unit and not receiving another trigger, the DMA channel enters the wait state before reinitializing its counters and address registers (if not configured for current addressing). The channel performs the next work unit after receiving the trigger.

The incoming trigger can occur when the DMA channel has not entered the wait state. The trigger can occur while the DMA channel is executing a work unit, is performing descriptor fetch, or is in the stop state. The trigger is held internally. After the work unit is complete, the DMA channel skips the wait state and proceeds directly to executing the following work unit. If the DMA_CFG.TWAIT bit is not enabled, the DMA channel also skips the wait state. However, the trigger is held internally and is used the next time the configuration enables DMA_CFG.TWAIT. This trigger retention allows programs to enable the DMA_CFG.TWAIT functionality several work units apart without concern for losing a trigger. The DMA channels trigger-overrun enable functionality can be enabled in all work units to ensure that multiple triggers do not occur between the work units with the DMA_CFG.TWAIT bit enabled.

DMA Channel Programming Model

Several synchronization and control methods are available for use in development of software tasks which manage peripheral DMA and memory DMA. Software must accept requests for new DMA transfers from other software tasks, integrate these transfers into existing transfer queues, and reliably notify other tasks when the transfers are complete.

In the processor, it is possible to manage each peripheral DMA and memory DMA stream with a separate task or to manage them together with any other stream. Each DMA channel has independent, orthogonal control registers, resources, and interrupts. So, the selection of the control scheme for one channel does not affect the choice of control scheme on other channels. For example, one peripheral can use a linked-descriptor-list, interrupt-driven

scheme while another peripheral can simultaneously use a demand-driven, buffer-at-a-time scheme synchronized by polling DMA events.

The topics that follow describe the steps required to configure the DMA channel for the various modes in addition to the programming concepts required for software synchronization.

Mode Configuration

Use the step-by-step directions that follow to set up the DMA channel for operating modes.

Register-Based Linear-Buffer Stop Flow Mode

This procedure configures the DMA channel of a peripheral to read data from internal memory and to send it to the peripheral for transmission. Upon DMA completion, the DMA channel enters the idle state until either disabled or reconfigured for a new transfer.

Assume that the peripheral is in a state where it is ready to transmit data received from the DMA channel.

The task involves writing to a number of DMA channel MMR registers to configure a DMA channel to:

- Read data from internal memory, and
- Send it to a peripheral connected to the peripheral DMA bus.

1. Write the DMA_ADDRSTART register.

   ADDITIONAL INFORMATION: Software can use the address to calculate the most optimum possible DMA_CFG.MSIZE.

2. Calculate the optimum DMA_CFG.MSIZE based on the DMA_ADDRSTART register and number of bytes in work unit.

   ADDITIONAL INFORMATION: The number of bytes in the work unit must be a multiple of the selected DMA_CFG.MSIZE, and the calculation also must consider the start address alignment.

3. Write the DMA_XCNT register based on the calculated DMA_CFG.MSIZE.

   ADDITIONAL INFORMATION: The DMA_XCNT value is the number of DMA_CFG.MSIZE transfers to make up the entire work unit.

4. Write the DMA_XMOD register.

   ADDITIONAL INFORMATION: For a linear buffer transfer, determine the value in DMA_XMOD from the selected DMA_CFG.MSIZE. Always specify this register as a number of bytes.

5. Write the DMA_CFG register with DMA_CFG.EN configured to enable the DMA channel.

   ADDITIONAL INFORMATION: Set the DMA_CFG.FLOW bit for STOP mode. Configure the DMA_CFG.WNR bit for memory read operation. Configure the DMA_CFG.PSIZE bits to a value no larger than the supported bus width of the peripheral DMA bus. From performance perspective, it is recommended

to use the largest possible DMA_CFG.PSIZE value (for example, equal to the supported peripheral bus width (DMA_STAT.PBWID)). However, ensure that the number of bytes in the work unit is a multiple of the DMA_CFG.PSIZE value used.

- The DMA_CFG.SYNC bit can be configured to control DMA completion notification timing.
- Interrupts and triggers also can be configured at this step depending on requirements.

Now, the DMA channel is enabled, and the buffer is transferred. The DMA channel enters the IDLE state upon completion of the work unit.

Register-Based Autobuffer Flow Mode

This procedure configures the DMA channel of a peripheral to read data from internal memory and send it to the peripheral for transmission. The transmission of the buffer repeats endlessly. Upon DMA completion, the DMA channel restarts the DMA operation, creating an endless circular buffer transfer.

Assume the peripheral is in a state where it is ready to transmit data received from the DMA channel.

The task involves writing to a number of DMA channel MMR registers to configure a DMA channel to:

- Read data from internal memory, and
- Send it to a peripheral connected to the peripheral DMA bus.

1. Write the DMA_ADDRSTART register.

   ADDITIONAL INFORMATION: Use the address to calculate the optimum possible DMA_CFG.MSIZE.

2. Calculate the optimum DMA_CFG.MSIZE based on the DMA_ADDRSTART register and number of bytes in work unit.

   ADDITIONAL INFORMATION: The number of bytes in the work unit must be a multiple of the selected DMA_CFG.MSIZE, and the calculation must consider the start address alignment.

3. Write the DMA_XCNT register based on calculated DMA_CFG.MSIZE.

   ADDITIONAL INFORMATION: The DMA_XCNT register value is the number of DMA_CFG.MSIZE transfers to make up the entire work unit.

4. Write the DMA_XMOD register.

   ADDITIONAL INFORMATION: For a linear buffer transfer, determine the value in DMA_XMOD from the selected DMA_CFG.MSIZE. Always specify this register as a number of bytes.

5. Write the DMA_CFG register with the DMA_CFG.EN bit configured to enable the DMA channel.

   ADDITIONAL INFORMATION: Set the DMA_CFG.FLOW bit for autobuffer mode. Configure the DMA_CFG.WNR bit for memory read operation. Configure the DMA_CFG.PSIZE bit to a value no larger than the supported bus width of the peripheral DMA bus. From performance perspective, it is recommended

to use the largest possible DMA_CFG.PSIZE value (for example, equal to the supported peripheral bus width (DMA_STAT.PBWID)). However, ensure that the number of bytes in the work unit is a multiple of the DMA_CFG.PSIZE value used.

- The DMA_CFG.SYNC bit can be configured to control DMA completion notification timing.
- Interrupts and triggers also can be configured at this step depending on requirements.

Now, the DMA channel is enabled, and the buffer transfers until the DMA channel is disabled.

Descriptor-Array Flow Mode

This procedure configures the DMA channel of a peripheral to:

- Read data from memory as described by the descriptor sets in the array, and
- Send the data to the peripheral for transmission.

Descriptor sets are read from an array in memory to configure the individual work units.

Assume the peripheral is in a state where it is ready to transmit data received from the DMA channel. Assume that the array of descriptors is to be initialized with the last descriptor set configured for STOP flow mode.

The task involves writing to a number of DMA channel MMR registers to:

- Configure a DMA channel to read the array in memory, containing the first descriptor set that configured the DMA channel to retrieve, and
- Send the data to a peripheral connected to the peripheral DMA bus.

On DMA completion, the DMA channel enters the idle state until either disabled or reconfigured for a new transfer.

1. Write the DMA_DSCPTR_CUR register with the address of the array in which the descriptor sets are stored.

   ADDITIONAL INFORMATION: The array address must meet any processor alignments restrictions imposed by descriptor fetches.

2. Write the DMA_CFG register with the DMA_CFG.EN bit configured to enable the DMA channel.

   ADDITIONAL INFORMATION: Configure the DMA_CFG.PSIZE bits to a value no larger than the supported bus width of the peripheral DMA bus. From performance perspective, it is recommended to use the largest possible DMA_CFG.PSIZE value (for example, equal to the supported peripheral bus width (DMA_STAT.PBWID)). However, ensure that the number of bytes in the work unit is a multiple of the DMA_CFG.PSIZE value used. Set the DMA_CFG.FLOW bit for descriptor-array mode. Configure the DMA_CFG.NDSIZE bits to describe the number of descriptor elements contained within the first descriptor set. Configure the DMA_CFG.WNR bit for memory read operation.

   - The descriptor set that is fetched controls the DMA_CFG.SYNC configuration and the interrupt or trigger configurations.

The first descriptor set is fetched from memory location provided by the DMA_DSCPTR_CUR register and loaded to the MMR registers of the DMA channel.

Now, the DMA channel is processing all the work units provided in the descriptor array. The DMA channel enters the IDLE state on completion of the final work unit that was configured for STOP flow mode.

Descriptor-List Flow Mode

This procedure configures the DMA channel of a peripheral to:

- Read data from memory as described by the descriptor sets in the list, and
- Send it to the peripheral for transmission.

The DMA controller reads the descriptor sets from a list of descriptors. With the list, each descriptor set has a descriptor that points to the next descriptor set location in memory.

Assume the peripheral must be in a state where it is ready to transmit data received from the DMA channel. Assume that the list of descriptors must be initialized with the last descriptor set in the list configured for Stop flow mode.

The task involves writing to a number of DMA channel MMR registers to:

- Configure a DMA channel to read the list in memory, containing the first descriptor set that configured the DMA channel to retrieve, and
- Send the data to a peripheral connected to the peripheral DMA bus.

On DMA completion, the DMA channel enters the idle state until either disabled or reconfigured for a new transfer.

1. Write the DMA_DSCPTR_NXT register with the address of the first descriptor in the list to be processed.

   ADDITIONAL INFORMATION: The array address must meet any processor alignments restrictions imposed by descriptor fetches.

2. Write the DMA_CFG register with the DMA_CFG.EN configured to enable the DMA channel.

   ADDITIONAL INFORMATION: Set the DMA_CFG.FLOW for descriptor-list mode. Configure the DMA_CFG.NDSIZE bit to describe the number of descriptor elements contained within the first descriptor set. Configure the DMA_CFG.WNR bit for memory read operation. Configure the DMA_CFG.PSIZE bit to a value no larger than the supported bus width of the peripheral DMA bus. From performance perspective, it is recommended to use the largest possible DMA_CFG.PSIZE value (for example, equal to the supported peripheral bus width (DMA_STAT.PBWID)). However, ensure that the number of bytes in the work unit is a multiple of the DMA_CFG.PSIZE value used.

   - The descriptor set that is fetched controls the DMA_CFG.SYNC configuration and controls the interrupt or trigger configurations.

The first descriptor set is fetched from the memory location provided by DMA_DSCPTR_NXT and is loaded to the MMR registers of the DMA channel.

Now, the DMA channel is processing all the work units provided in the descriptor list. The DMA channel enters the idle state when the final work unit that was configured for stop-flow mode is complete.

Register-Based Memory-to-Memory Transfer in Stop Flow Mode

This procedure configures a memory DMA channel pair in stop flow mode. One DMA channel is configured for memory read operations, while the other DMA channel is configured for memory write.

The task involves writing to a number of DMA channels on two DMA channels that create a memory DMA pair. On DMA completion, the DMA channel enters the idle state, until either the DMA channel is disabled or is reconfigured for a new transfer.

1. Write the DMA_ADDRSTART register of the source DMA channel.

   ADDITIONAL INFORMATION: The address can be used to calculate the optimum DMA_CFG.MSIZE possible.

2. Calculate the optimum DMA_CFG.MSIZE based on the DMA_ADDRSTART register and number of bytes in work unit.

   ADDITIONAL INFORMATION: The number of bytes in the work unit must be a multiple of the selected DMA_CFG.MSIZE and the start address alignment must also be considered.

3. Write the DMA_XCNT register of the source DMA channel based on calculated DMA_CFG.MSIZE.

   ADDITIONAL INFORMATION: DMA_XCNT is the number of DMA_CFG.MSIZE transfers to make up the entire work unit.

4. Write the DMA_XMOD register of the source DMA channel.

   ADDITIONAL INFORMATION: For a linear buffer transfer, determine the value in DMA_XMOD from the selected DMA_CFG.MSIZE. This register is always specified in the number of bytes.

5. Write the DMA_ADDRSTART register of the destination DMA channel.

   ADDITIONAL INFORMATION: The address can be used to calculate the most optimum DMA_CFG.MSIZE possible.

6. Calculate the optimum DMA_CFG.MSIZE based on the DMA_ADDRSTART register and number of bytes in work unit.

   ADDITIONAL INFORMATION: The number of bytes in the work unit must be a multiple of the selected DMA_CFG.MSIZE and the start address alignment must also be considered.

7. Write the DMA_XCNT register of the destination DMA channel based on the calculated DMA_CFG.MSIZE.

ADDITIONAL INFORMATION: DMA_XCNT is the number of DMA_CFG.MSIZE transfers to make up the entire work unit.

8. Write the DMA_XMOD register of the destination DMA channel.

   ADDITIONAL INFORMATION: For a linear buffer transfer, determine the value in DMA_XMOD from the selected DMA_CFG.MSIZE. This register is always specified in the number of bytes.

9. Write the DMA_CFG register of the source DMA channel with DMA_CFG.EN configured to enable the DMA channel.

   ADDITIONAL INFORMATION: The DMA_CFG.FLOW bit field must be configured for stop mode. The DMA_CFG.WNR bit must be cleared for memory read operation. The DMA_CFG.PSIZE bits must be configured to a value no larger than the supported bus width of the peripheral DMA bus. From performance perspective, it is recommended to use the largest possible DMA_CFG.PSIZE value (for example, equal to the supported peripheral bus width (DMA_STAT.PBWID)). However, ensure that the number of bytes in the work unit is a multiple of the DMA_CFG.PSIZE value used.

   - The DMA_CFG.SYNC bit can be configured to control DMA completion notification timing.
   - Interrupts and triggers also can be configured at this step, depending on requirements. The interrupts and triggers are enabled within the destination DMA channel configuration.

   The memory read DMA transfer begins.

10. Write the DMA_CFG register of the destination DMA channel with DMA_CFG.EN configured to enable the DMA channel.

    ADDITIONAL INFORMATION: The DMA_CFG.FLOW bit field must be configured for stop mode. The DMA_CFG.WNR bit must be set for memory write operation. The DMA_CFG.PSIZE bits must be configured to a value no larger than the supported bus width of the peripheral DMA bus. This value must also match the value written for the source DMA channel configuration.

    - Interrupts and triggers also can be configured at this step depending on requirements.

    The memory write DMA transfer begins.

Both memory DMA channels are now running and the data is transferred from the source address to the destination address. The DMA channel enters the IDLE state upon completion of the work unit.

Programming Concepts

Using the features, operating modes, and event control for the DMA channel to their greatest potential requires an understanding of some DMA channel-related concepts.

Synchronization of Software and DMA

A critical element of software DMA management is the synchronization of DMA work unit completion with software. This synchronization can be achieved using DMA channel interrupt request and trigger events and using a poll of the status bits of these events within the DMA channel registers, or combining these techniques.

Processor polling of DMA address/count/status for completion is not a recommended programming practice. The requirements and limitations of processor polling place significant responsibility onto the code developer to be deeply aware of the underlying hardware. The interrupt requests and triggers are designed for efficient code development and reuse.

Interrupt and Trigger Event-Based Synchronization

Interrupt and trigger based synchronization methods must avoid overrun. An overrun occurs when some events fail to invoke the event handler of a DMA channel for every event due to excessive latency in processing of events. The system design must ensure to either:

- Schedule only one event per channel (for example, at the end of a descriptor list), or
- Space the generated events sufficiently far apart in time that system processing budgets can guarantee service of every event.

The DMA channel issues status information through an interrupt request or trigger event or changes event status bits in the DMA_STAT register. This status guarantees that the last memory operation of the work unit is complete. For memory read DMA transactions, this status means that the FIFO of the DMA channel safely receives the final memory read data. For DMA transactions writing to memory, this status indicates that the DMA channel received an acknowledge of completion of the last write transfer of the work unit.

Register Polling Based Synchronization

Do not poll the DMA channel registers (DMA_ADDR_CUR, DMA_DSCPTR_CUR, DMA_XCNT_CUR, or DMA_YCNT_CUR) as a method of precisely synchronizing DMA with data processing. This approach is inaccurate due to the operation of the DMA channel FIFOs and DMA or memory pipelining. The current address, pointer, and count registers change several cycles in advance of the completion of the corresponding memory operation. This timing is measurable from the time at which the results of the operation are first visible to the core by memory read or write instructions.

For example, in a DMA channel memory write operation to external memory, assume DMA channel *A* initiates a DMA channel write operation. For memories with access latency, this operation requires many system-clock cycles. Meanwhile, DMA channel *B* (which does not in itself incur latency) initiates a transfer, which stalls behind the slow operation of channel *A*. Software monitoring channel *B* could not safely conclude whether the memory location pointed to by the DMA_ADDR_CUR of channel *B*. Also, the software cannot conclude whether the register has been written based solely on the contents of this register.

Polling of the current address, pointer, and count registers can permit loose synchronization of DMA with software. But, the software must allow for the lengths of the DMA or memory pipeline. Also, software must consider the length of the DMA FIFO for a particular peripheral. If the FIFOs are filled with incomplete work, the DMA channel does not advance current address, pointer, or count registers. The incomplete work includes reads that have been started but have not yet finished.

Additionally, software must consider the length of the pipelines to the destination memory. If the DMA FIFO length and channel memory-pipeline length are added, software can estimate the maximum number of incomplete memory operations in progress.

NOTE: The estimate would be a maximum, as the DMA or memory pipeline can include traffic from other DMA channels.

Descriptor Queues

A system designer may want to write a DMA manager facility which accepts DMA requests from other software. The DMA manager software does not know in advance when new work requests are received or what these requests contain. The software could manage these transfers using a circular linked list of DMA descriptors. In such a list, each descriptor sets the DMA_DSCPTR_NXT descriptor, which points to the next descriptor set. And the last descriptor set in the list points to the first descriptor set.

The code that writes into this descriptor list could use the circular addressing modes of the processor. This approach does not need to use comparison and conditional instructions to manage the circular structure. In this case, the DMA_DSCPTR_NXT descriptor of each descriptor set can be written once at startup, and skipped over as new contents are written for each descriptor.

The recommended method for synchronization of a descriptor queue is to use an interrupt or trigger. The descriptor queue is structured, such that (at least) the final valid descriptor set is always programmed to generate an interrupt or trigger event upon completion. More detail is provided in the following sections.

- Queues Using Event Generation for Every Descriptor Set
- Queues Using Minimal Events

Queues Using Event Generation for Every Descriptor Set

In this system, the DMA manager software synchronizes with the DMA channel by enabling an interrupt request or trigger on every descriptor set. Only use this method if the system design can guarantee that each work unit completion event is serviced separately (no interrupt or trigger overrun).

To maintain synchronization of the descriptor set queue, the non-interrupt software maintains a count of descriptor sets added to the queue. The event handler (either interrupt or trigger) maintains a count of completed descriptor sets removed from the queue. The counts are equal only when the DMA channel is paused after having processed all the descriptor sets.

When each new work unit event is received, the DMA manager software initializes a new descriptor set, taking care to set the flow to stop mode. Next, the software compares the descriptor set counts to determine whether the DMA channel is running. If the DMA channel is paused (counts equal), the software increments its count. Then, the software starts the DMA channel by writing the DMA_CFG of the new descriptor set.

If the counts are unequal, the software instead modifies the DMA_CFG of the next-to-last descriptor set, such that it now describes the newly queued descriptor set. This operation does not disrupt the DMA channel provided the rest of the descriptors of the set are initialized in advance. It is necessary to synchronize the software to the DMA to determine whether the DMA channel read the new or the old DMA_CFG value.

The event handler performs the synchronization operation. When an event is detected, the handler reads the DMA_STAT register of the DMA channel. If the DMA_STAT.RUN bit indicates that the DMA channel is running, the channel has moved on to processing another descriptor. The event handler can increment its count and exit. If the DMA_STAT.RUN bit indicates that the channel is not running, the channel is paused because either:

- There are no more descriptor sets to process, or
- The last descriptor set was queued too late

Where *too late* means that the modification of the DMA_CFG of the next-to-last descriptor set occurred *after* that descriptor was read into the DMA channel. In this case, the event handler does the following:

- Writes the DMA_CFG value appropriate for the last descriptor set to DMA_CFG register of the DMA channel,
- Increments the completed descriptor count, and
- Exits

If the event latencies of the system are large enough to cause any of the events to be dropped, this system can fail. An event handler capable of safely synchronizing multiple descriptor set interrupt requests is complex, performing several MMR accesses to ensure robust operation. In such a system environment, a minimal event synchronization method is preferred.

Queues Using Minimal Events

In this system, only one DMA interrupt request or trigger event is generated in the queue at any time. The DMA event handler for this system can also be extremely short. Here, the descriptor queue is organized into an *active* and a *waiting* portion, where events are enabled only on the last descriptor set in each portion.

When each new DMA request is processed, the software fills in the content of a new descriptor set and adds it to the waiting portion of the queue. The DMA_CFG descriptor of the descriptor set must have the flow set to stop mode. If more than one request is received before the DMA queue completion event occurs, the non-interrupt code queues later descriptor sets. It forms a waiting portion of the queue separate from the active portion of the queue that the DMA channel is processing. In other words, all but the last active descriptor sets contain flow values for a descriptor-based mode and have no event enable set.

The last active descriptor set has the stop flow mode and an event generation enabled. Also, all but the last waiting descriptor sets are configured for descriptor-based flow modes with no event generation. Only the last waiting descriptor set is configured for stop flow mode and event generation enabled. This configuration ensures that the DMA channel can automatically process the whole active queue before then issuing one event. Also, this arrangement makes it easy to start the waiting queue within the event handler by a single DMA_CFG register write.

After queuing a new waiting descriptor, the non-interrupt software leaves a message for its interrupt handler in a memory mailbox location. The location contains the desired DMA_CFG value for starting the first waiting descriptor set in the waiting queue (or 0, indicating no waiting descriptors).

The software must not modify the contents of the active descriptor set queue directly once processing by the DMA channel has started, unless careful synchronization measures are taken. In the most straightforward implementation of a descriptor set queue, the DMA manager software never modifies descriptors on the active queue. Instead, the DMA manager waits until the DMA queue completion event indicates that the processing of the entire active queue is complete.

When a DMA queue completion event is received, the event handler reads the mailbox from the non-interrupt software and writes the value to the DMA_CFG register of the DMA channel. This write to a register restarts the

queue, effectively transforming the waiting queue to an active queue. The event handler then passes a message back to the non-interrupt software indicating the location of the last descriptor set accepted into the active queue.

However, the event handler can read its mailbox and find a DMA_CFG value of zero, indicating there is no more work to perform. It then passes an appropriate message back to the non-interrupt software indicating that the queue has stopped.

The non-interrupt software which accepts new DMA work unit requests must synchronize the activation of a new work unit with the interrupt handler. If the queue has stopped (the mailbox from the event handler is zero), the non-interrupt software must start the queue. (The queue starts by writing the first descriptor sets DMA_CFG value to the DMA_CFG register of the channel). If the queue is not stopped, the non-interrupt software must not write the DMA_CFG register. (This write causes a DMA error). Instead, it must queue the descriptor onto the waiting queue and update its mailbox directed to the event handler.

ADSP-2184x DMA Register Descriptions

The Direct Memory Access module (DMA) contains the following registers.

Table 34-15: ADSP-2184x DMA Register List

Name	Description
DMA_ADDRSTART	Start Address of Current Buffer Register
DMA_ADDR_CUR	Current Address Register
DMA_BWLCNT	Bandwidth Limit Count Register
DMA_BWLCNT_CUR	Bandwidth Limit Count Current Register
DMA_BWMCNT	Bandwidth Monitor Count Register
DMA_BWMCNT_CUR	Bandwidth Monitor Count Current Register
DMA_CFG	Configuration Register
DMA_DSCPTR_CUR	Current Descriptor Pointer Register
DMA_DSCPTR_NXT	Pointer to Next Initial Descriptor Register
DMA_DSCPTR_PRV	Previous Initial Descriptor Pointer Register
DMA_STAT	Status Register
DMA_XCNT	Inner Loop Count Start Value Register
DMA_XCNT_CUR	Current Count (1D) or Intra-row XCNT (2D) Register
DMA_XMOD	Inner Loop Address Increment Register
DMA_YCNT	Outer Loop Count Start Value (2D only) Register
DMA_YCNT_CUR	Current Row Count (2D only) Register
DMA_YMOD	Outer Loop Address Increment (2D only) Register

Start Address of Current Buffer Register

The DMA_ADDRSTART register contains the start address of the work unit currently targeted for DMA. This register is read/write prior to enabling the channel, but is read-only after enabling channel.

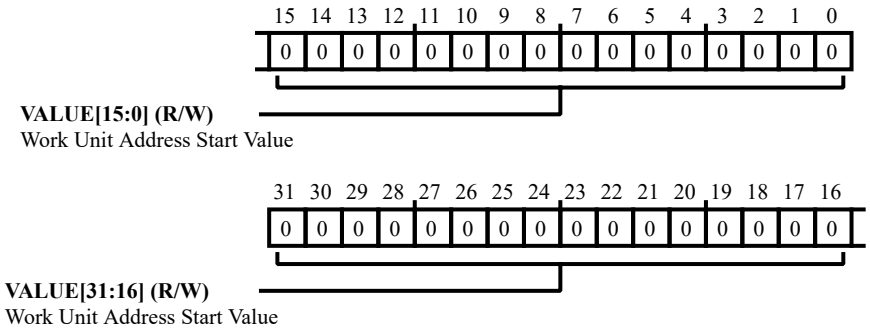

Figure 34-5: DMA_ADDRSTART Register Diagram

Table 34-16: DMA_ADDRSTART Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Work Unit Address Start Value. The DMA_ADDRSTART.VALUE bit field contains the start address of the work unit currently targeted for DMA.

Current Address Register

The DMA_ADDR_CUR register contains the present memory transfer address for a given work unit. At the start of a work unit, the DMA_ADDR_CUR register is loaded from the DMA_ADDRSTART register, and the DMA_ADDR_CUR register is incremented as each transfer occurs. The DMA_ADDR_CUR register is read/write prior to enabling the channel, but is read-only after enabling the channel.

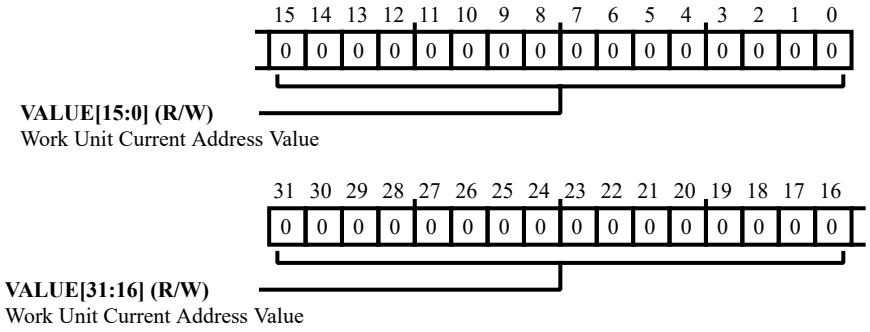

Figure 34-6: DMA_ADDR_CUR Register Diagram

Table 34-17: DMA_ADDR_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Work Unit Current Address Value. The DMA_ADDR_CUR.VALUE bit field contains the present memory transfer address for a given work unit.

Bandwidth Limit Count Register

The DMA_BWLCNT register contains a count that determines how often the DMA issues memory transactions. The DMA loads the value from the DMA_BWLCNT register into the DMA_BWLCNT_CUR register and decrements the current value each SCLK cycle. When DMA_BWLCNT_CUR reaches 0x0000, the next request is issued, and the DMA reloads DMA_BWLCNT_CUR. This bandwidth limit functionality is not applied to descriptor fetch requests. Programming 0x0000 allows the DMA to request as often as possible. 0xFFFF is a special case and causes requests to stop.

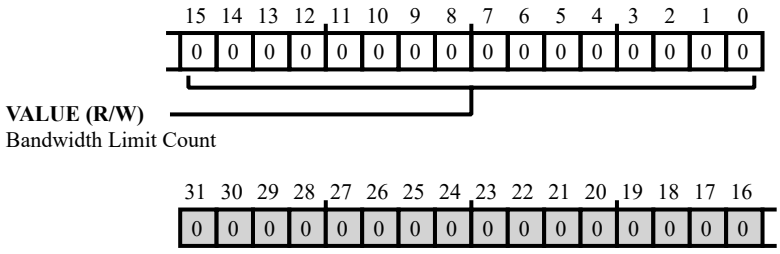

Figure 34-7: DMA_BWLCNT Register Diagram

Table 34-18: DMA_BWLCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Bandwidth Limit Count. The DMA_BWLCNT.VALUE bit field contains a count that determines how often the DMA issues memory transactions.

Bandwidth Limit Count Current Register

The DMA_BWLCNT_CUR register contains the number of SCLK count cycles remaining before the next request is issued.

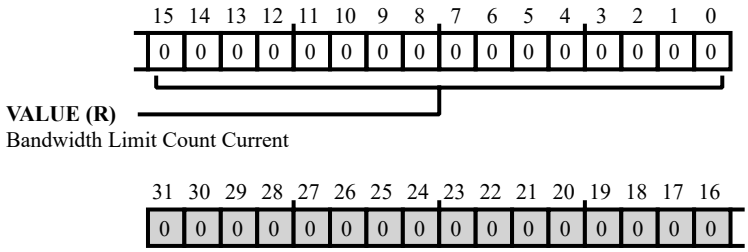

Figure 34-8: DMA_BWLCNT_CUR Register Diagram

Table 34-19: DMA_BWLCNT_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/NW)	VALUE	Bandwidth Limit Count Current. The DMA_BWLCNT_CUR.VALUE bit field contains the number of SCLK count cycles remaining before the next request is issued.

Bandwidth Monitor Count Register

The DMA_BWMCNT register contains the maximum number of SCLK cycles allowed for a work unit to complete. Each time the DMA_CFG register is written (MMR access only), a work unit ends or an autobuffer wraps. The DMA loads the value in this register into the DMA_BWMCNT_CUR register.

The DMA decrements DMA_BWMCNT_CUR every SCLK a work unit is active. If the DMA_BWMCNT_CUR register reaches 0x0000_0000, the DMA_STAT.IRQERR bit is set, and the DMA_STAT.ERRC bit field is set to 0x6. The DMA_BWMCNT_CUR remains at 0x0000_0000 until it is reloaded when the work unit completes.

Unlike other errors, a bandwidth monitor error does not stop work unit processing. Programming 0x0000_0000 disables bandwidth monitor functionality.

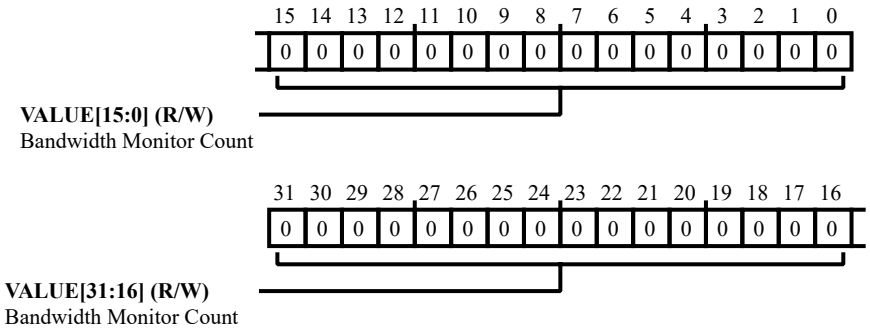

Figure 34-9: DMA_BWMCNT Register Diagram

Table 34-20: DMA_BWMCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Bandwidth Monitor Count. The DMA_BWMCNT.VALUE bit field contains the maximum number of SCLK cycles allowed for a work unit to complete.

Bandwidth Monitor Count Current Register

The DMA_BWMCNT_CUR register contains the number of cycles remaining for the current descriptor to complete.

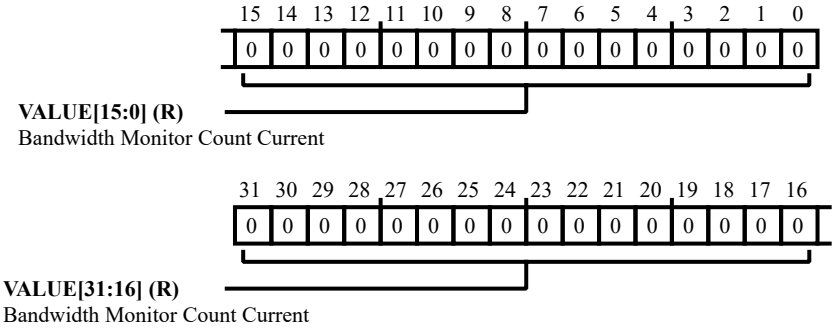

Figure 34-10: DMA_BWMCNT_CUR Register Diagram

Table 34-21: DMA_BWMCNT_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Bandwidth Monitor Count Current. The DMA_BWMCNT_CUR.VALUE bit field contains the number of cycles remaining for the current descriptor to complete.

Configuration Register

The DMA_CFG register sets up DMA parameters and operation modes. Writing to the DMA_CFG register while a DMA process is already running causes a DMA error (except when clearing the DMA_CFG.EN bit).

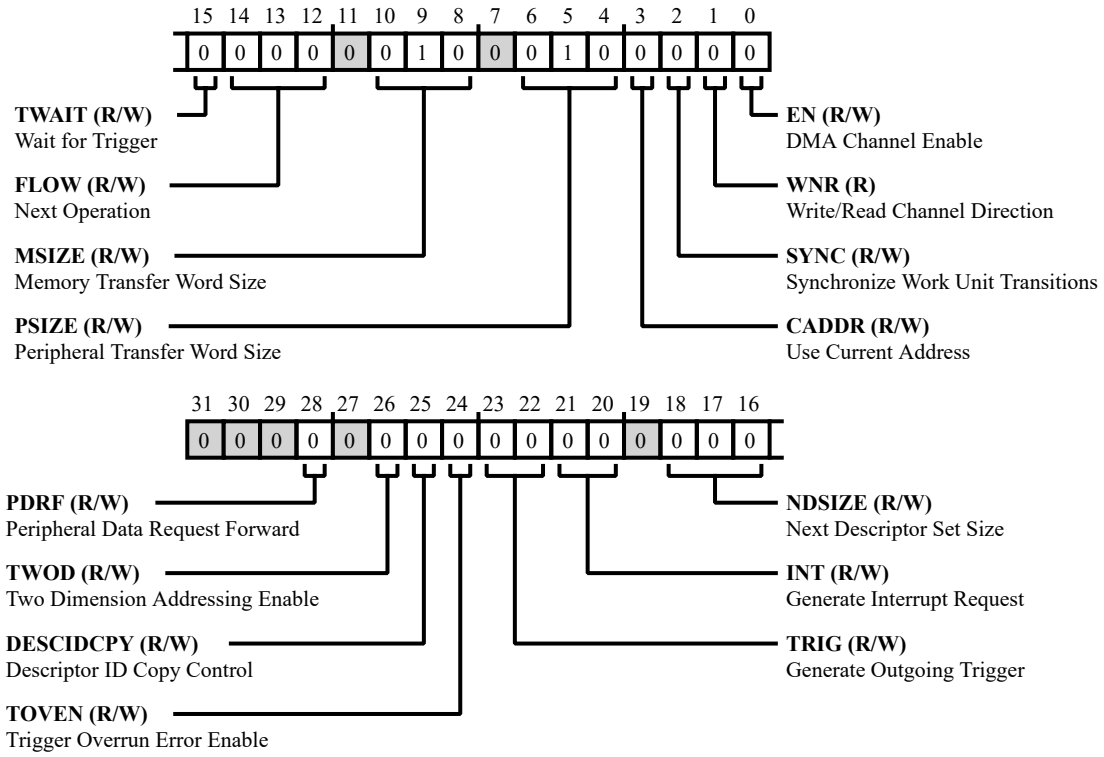

Figure 34-11: DMA_CFG Register Diagram

Table 34-22: DMA_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
28 (R/W)	PDRF	Peripheral Data Request Forward. The DMA_CFG.PDRF bit defines how the DMA handles data requests from the peripheral while in idle state after a stop mode or memory read work unit. If set, the DMA forwards the peripheral data request as an interrupt. This bit applies only to the DMA_CFG.FLOW bits configured for stop and DMA_CFG.WNR bits configured for memory read.	
		0	Peripheral Data Request Not Forwarded
		1	Peripheral Data Request Forwarded

Table 34-22: DMA_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
26 (R/W)	TWOD	Two Dimension Addressing Enable. The DMA_CFG.TWOD bit selects whether the DMA addressing involves only DMA_XCNT and DMA_XMOD (one-dimensional DMA) or also involves DMA_YCNT and DMA_YMOD (two-dimensional DMA).	
		0	One-Dimensional Addressing
		1	Two-Dimensional Addressing
25 (R/W)	DESCIDCPY	Descriptor ID Copy Control. The DMA_CFG.DESCIDCPY bit specifies when to copy the initial descriptor pointer to the DMA_DSCPTR_PRV register. A bus write to the DMA_CFG register to clear the DMA_CFG.EN bit causes the DMA to immediately use the new value of the DMA_CFG.DESCIDCPY bit. To preserve consistency (if required by application), match the new value of this bit to the previous value.	
		0	Never Copy
		1	Copy on Work Unit Complete
24 (R/W)	TOVEN	Trigger Overrun Error Enable. A trigger overrun occurs if more than one trigger was received before the DMA reached the trigger wait state. If DMA_CFG.TOVEN is set, a trigger overrun causes the DMA to flag an error. In cases where a trigger overrun is not a problem, clearing DMA_CFG.TOVEN prevents the overrun from causing an error and halting the DMA. The DMA_CFG.TOVEN operates independently of the DMA_CFG.TWAIT bit selection.	
		0	Ignore Trigger Overrun
		1	Error on Trigger Overrun

Table 34-22: DMA_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
23:22 (R/W)	TRIG	Generate Outgoing Trigger. The DMA_CFG.TRIG selects whether the DMA issues an outgoing trigger, based on the work unit counter values. In one-dimensional mode, the only options are to trigger at the end of the whole work unit (trigger when DMA_XCNT_CUR reaches 0) or not to trigger at all. If in one-dimensional addressing mode, programming the DMA_CFG.TRIG bit field to trigger when DMA_YCNT_CUR reaches 0 (or to reserved) causes the DMA to flag a configuration error. In two-dimensional addressing mode, the trigger options are: at the end of each row of the inner loop (when DMA_XCNT_CUR reaches 0), only after completing the whole work unit (when DMA_YCNT_CUR reaches 0), or no trigger. If in two-dimensional mode and set to trigger when DMA_XCNT_CUR reaches 0, the DMA also issues a trigger at the end of the work unit. If in two-dimensional addressing mode, programming DMA_CFG.TRIG to reserved causes the DMA to flag a configuration error. If DMA_CFG.TRIG is non-zero and the peripheral issues a finish command, the DMA issues a trigger after the finish procedure is complete. For more information about trigger generation timing, see the trigger section of the DMA functional description.	
		0	Never Assert Trigger
		1	Trigger When XCNTCUR Reaches 0
		2	Trigger When YCNTCUR Reaches 0
		3	Reserved

Table 34-22: DMA_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
21:20 (R/W)	INT	Generate Interrupt Request. The DMA_CFG.INT bit field selects whether an interrupt request goes to the core based on work unit status or a peripheral interrupt request. For one-dimensional mode, setting the DMA_CFG.INT bits to generate an interrupt request when the DMA_YCNT_CUR register reaches 0 causes the DMA to flag a configuration error. The peripheral interrupt setting lets the DMA generate the last grant indication and to accept and or forward the peripheral interrupt command. The peripheral interrupt selection applies only to the DMA_CFG.FLOW bits set for stop and the DMA_CFG.WNR bits set for memory read. If the DMA_CFG.INT is set for interrupt request on count completion (DMA_XCNT_CUR or DMA_YCNT_CUR reach 0) and the peripheral issues a finish command, the DMA issues an interrupt request after the finish procedure is complete. For more information, see the sections on interrupt generation and peripheral control in the DMA functional description.	
		0	Never Assert Interrupt
		1	Interrupt When X Count Expires
		2	Interrupt When Y Count Expires
		3	Peripheral Interrupt request
18:16 (R/W)	NDSIZE	Next Descriptor Set Size. The DMA_CFG.NDSIZE bit field specifies the number of descriptor elements in memory to load during the next descriptor fetch. The DMA loads the descriptors in a specific order. The descriptor set contains the next descriptor pointer when it is a descriptor list. The descriptor set does not contain the next descriptor pointer when it is a descriptor array.	
		0	Fetch One Descriptor Element
		1	Fetch Two Descriptor Elements
		2	Fetch Three Descriptor Elements
		3	Fetch Four Descriptor Elements
		4	Fetch Five Descriptor Elements
		5	Fetch Six Descriptor Elements
		6	Fetch Seven Descriptor Elements
		7	Reserved

Table 34-22: DMA_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	TWAIT	Wait for Trigger. The DMA_CFG.TWAIT bit controls whether the DMA waits for an incoming trigger from another channel or user. If the DMA_CFG.TWAIT bit is set, the DMA enters the wait state before starting the next work unit, including descriptor fetch when in descriptor mode. Do not use the wait for trigger control for descriptor-on-demand mode which causes an error. For more information, see the trigger section of the DMA functional description.	
		0	Begin Work Unit Automatically (No Wait)
		1	Wait for Trigger (Halt before Work Unit)
14:12 (R/W)	FLOW	Next Operation. The DMA_CFG.FLOW bit field selects the descriptor handling options.	
		0	STOP. See the Stop Flow Mode section.
		1	AUTO. See the Autobuffer Flow Mode section.
		2	Reserved
		3	Reserved
		4	DSCL. See the Descriptor List Mode section.
		5	DSCA. See the Descriptor Array Mode section.
		6	Descriptor On-Demand List. See the Descriptor List Mode section.
		7	Descriptor On Demand Array. See the Descriptor On Demand section.
10:8 (R/W)	MSIZE	Memory Transfer Word Size. The DMA_CFG.MSIZE bits select memory transfer sizes of 8-, 16-, 32-, 64-, 128-, or 256-bit words. The transfer start address (DMA_ADDRSTART) and transfer increment values (DMA_XMOD, and, if needed, DMA_YMOD) must be a multiple of the memory transfer unit size.	
		2	4 Bytes
		3	8 Bytes
		4	16 Bytes
		5	32 Bytes

Table 34-22: DMA_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
6:4 (R/W)	PSIZE	Peripheral Transfer Word Size. The DMA_CFG.PSIZE bits select peripheral transfer sizes as 8, 16, 32, or 64 bits wide. Each request and grant results in a single peripheral access. There are no bursts on the peripheral bus, so the DMA_CFG.PSIZE selection must be less than or equal to the width of the bus. If the selection is greater than the bus width, a configuration error occurs. The peripheral bus of the processor is dedicated to DMA and peripheral accesses.	
		2	4 Bytes
		3	8 Bytes
3 (R/W)	CADDR	Use Current Address. When the DMA_CFG.CADDR bit is cleared, the DMA loads the DMA_ADDRSTART register on the first access of the work unit. When the DMA_CFG.CADDR bit is set, the DMA uses the DMA_ADDR_CUR register value for the starting address for the work unit and writes the same value to the DMA_ADDRSTART register. This operation permits continuation of a previous work unit. When DMA uses this mode, the fetched start address value (as part of the descriptor set at the end of a descriptor list or array) is ignored.	
		0	Load Starting Address
		1	Use Current Address

Table 34-22: DMA_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	SYNC	Synchronize Work Unit Transitions. Setting the DMA_CFG.SYNC bit clears the DMA FIFO and pointers before starting the first work unit of a work unit chain. When the transfer direction is memory read/transmit (DMA_CFG.WNR =0), the DMA waits until all data transmits to a peripheral before moving on to the next work unit, clearing the FIFO and pointers. When the transfer direction is memory write/receive (DMA_CFG.WNR =1), the DMA ignores the DMA_CFG.SYNC bit value after processing the first work unit of a work unit chain. As a channel can receive data when turned on but idle, data from the peripheral can still be in the FIFO even though the channel was not programmed. When the DMA_CFG.SYNC bit field is set at the beginning of a work unit chain (during the first work unit), the DMA clears the FIFO, erasing the data put into the FIFO while the channel was idle. Syncing lets programs change the DMA_CFG.PSIZE between individual work units and (in some cases) work unit chains. The sync resets the pointers in the FIFO, preventing misaligned FIFO access. Programs can change the DMA_CFG.MSIZE field between consecutive work units, independent of the DMA_CFG.SYNC bit setting. Syncing also permits changes to transfer direction. Because the data in the FIFO is eliminated, the data that went into the FIFO from one direction (transmit or receive) is not sent back in the other direction after the direction change.	
		0	No Synchronization
		1	Synchronize Channel
1 (R/NW)	WNR	Write/Read Channel Direction. The DMA_CFG.WNR selects receive (write to memory) or transmit (read from memory) channel direction.	
		0	Transmit (Read from memory)
		1	Receive (Write to memory)

Table 34-22: DMA_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	EN	DMA Channel Enable. The DMA_CFG.EN bit enables the selected DMA channel. When a peripheral DMA channel is enabled, data requests from the peripheral denote DMA requests. When a channel is disabled, the DMA unit ignores the peripheral data request and passes it directly to the system event controller. To avoid unexpected results, enable the DMA channel before enabling the peripheral, and disable the peripheral before disabling the DMA channel. A transition of the DMA_CFG.EN bit from 0 to 1 creates a hard reset of all internal counters and states, including the DMA_STAT register. (All other register values remain unaffected.) A transition from 1 to 0 maintains all counters and registers for reading and analysis. Note that if a descriptor loads when this bit is cleared (see the DMA_CFG.FLOW field), the DMA transitions to the off or idle state after the descriptor load is complete.	
		0	Disable
		1	Enable

Current Descriptor Pointer Register

The DMA_DSCPTR_CUR register contains the memory address for the next descriptor to be loaded. The DMA_DSCPTR_CUR register is read/write prior to enabling the channel, but is read-only after enabling the channel. For DMA_CFG.FLOW mode settings that involve descriptor fetches, this register is used to read descriptors into appropriate MMRs before a work unit begins. For descriptor list mode, the DMA_DSCPTR_CUR register is initialized from the DMA_DSCPTR_NXT register before fetching each descriptor set. Then, the address in the DMA_DSCPTR_CUR register increments as each descriptor is read.

When the entire descriptor set has been read, the DMA_DSCPTR_CUR register contains this value:

DMA_DSCPTR_CUR = Descriptor Start Address + Descriptor Size (# of elements)

For descriptor array mode, the DMA_DSCPTR_CUR register, and not the DMA_DSCPTR_NXT register, must be programmed by a MMR access before starting DMA operation.

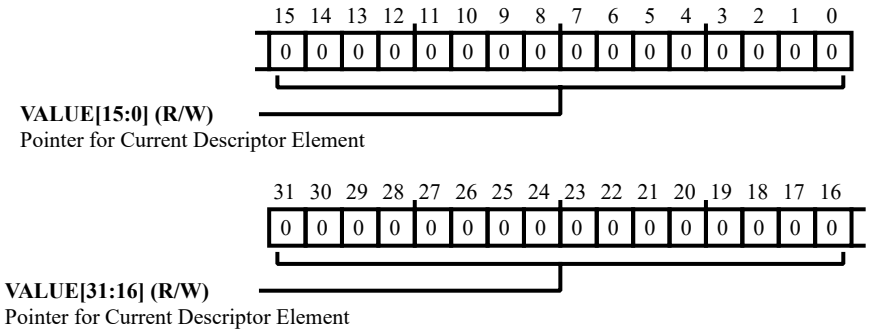

Figure 34-12: DMA_DSCPTR_CUR Register Diagram

Table 34-23: DMA_DSCPTR_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Pointer for Current Descriptor Element. The DMA_DSCPTR_CUR.VALUE bit field contains the memory address for the next descriptor to be loaded.

Pointer to Next Initial Descriptor Register

The DMA_DSCPTR_NXT register specifies the start location of the next descriptor set, which begins when the DMA activity specified by the current descriptor set completes. This register is read/write prior to enabling the channel, but is read-only after enabling channel.

The DMA_DSCPTR_NXT register is only used in descriptor list mode. At the start of a descriptor fetch in this mode, the DMA_DSCPTR_NXT register is copied into the DMA_DSCPTR_CUR register. During descriptor fetch, the DMA increments the DMA_DSCPTR_CUR register value after reading each element of the descriptor set.

In descriptor list mode, the DMA_DSCPTR_NXT register (not the DMA_DSCPTR_CUR register) must be programmed directly through MMR access, before the DMA operation is started. In descriptor array mode, the DMA disregards the DMA_DSCPTR_NXT register and uses the DMA_DSCPTR_CUR register to control descriptor fetch.

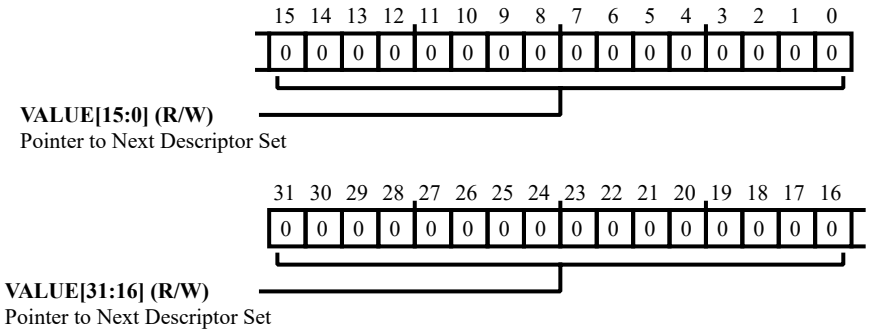

Figure 34-13: DMA_DSCPTR_NXT Register Diagram

Table 34-24: DMA_DSCPTR_NXT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Pointer to Next Descriptor Set. The DMA_DSCPTR_NXT.VALUE bit field specifies the start location of the next descriptor set.

Previous Initial Descriptor Pointer Register

The DMA_DSCPTR_PRV register contains the initial descriptor pointer for the previous work unit. If DMA_CFG.DESCIDCPYis set, the DMA copies the initial descriptor pointer to DMA_DSCPTR_PRV after the work unit completes. Otherwise, the value is not updated.

To indicate an overrun, bit 0 of the DMA_DSCPTR_PRV register is used as a previous descriptor pointer overrun (PDPO) status bit. Due to aligned addressing combined with all descriptors being 32 bits in width, bits 0 and 1 of all descriptor pointers must be zero. Otherwise, an alignment error occurs when used for descriptor fetches. As a result, bit 1 and 0 of the DMA_DSCPTR_PRV register can be used for status. For more information, see the section on descriptor pointer capture in the DMA functional description.

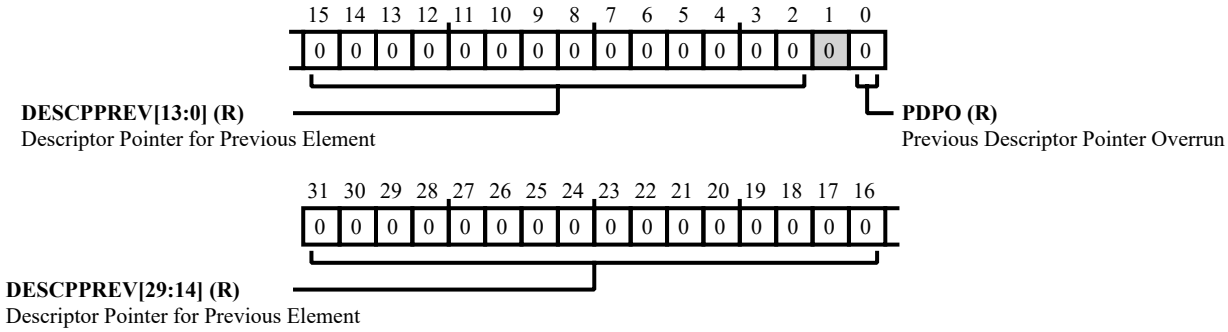

Figure 34-14: DMA_DSCPTR_PRV Register Diagram

Table 34-25: DMA_DSCPTR_PRV Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:2 (R/NW)	DESCPPREV	Descriptor Pointer for Previous Element. The DMA_DSCPTR_PRV.DESCPPREV bit field contains the initial descriptor pointer for the previous work unit.	
0 (R/NW)	PDPO	Previous Descriptor Pointer Overrun. The DMA_DSCPTR_PRV.PDPO bit signifies an alignment error. Due to aligned addressing combined with all descriptors being 32 bits in width, bits 0 and 1 of all descriptor pointers must be zero. Otherwise, an alignment error would occur when used for descriptor fetches.	
		0	No Error Occurred
		1	Error Occurred

Status Register

The DMA_STAT register indicates the status of DMA work units, the FIFO, errors, interrupts, and triggers.

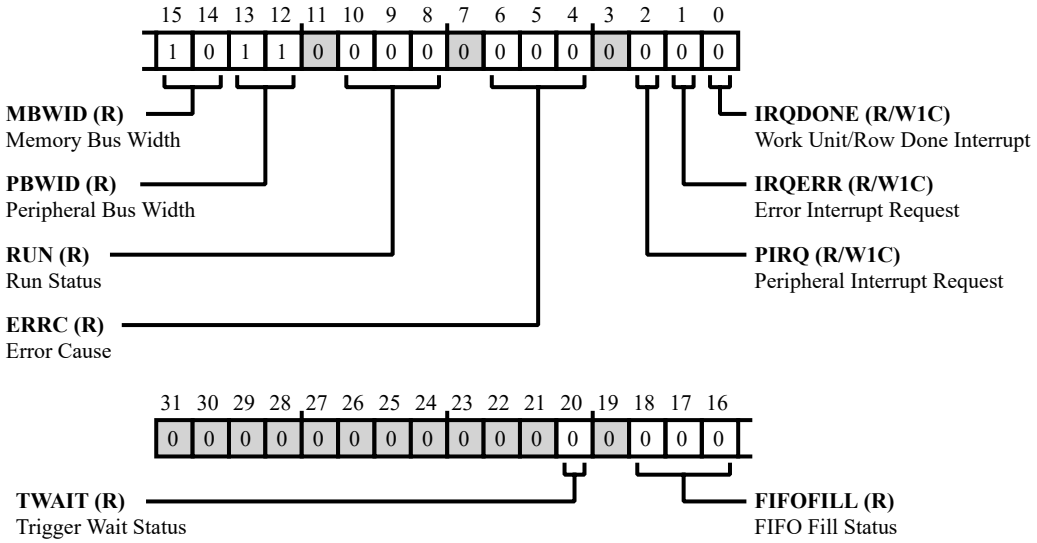

Figure 34-15: DMA_STAT Register Diagram

Table 34-26: DMA_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
20 (R/NW)	TWAIT	Trigger Wait Status. The DMA_STAT.TWAIT bit indicates whether the DMA has or has not received a trigger. This bit is set until it reaches the next wait state. At that point, the bit is cleared, the DMA stops processing that work unit, and the following work unit processes. The DMA does not distinguish between one or more triggers received.	
		0	No Trigger Received
		1	Trigger Received
18:16 (R/NW)	FIFOFILL	FIFO Fill Status. The DMA_STAT.FIFOFILL bit field reports the quantity of data in the FIFO relative to available space.	
		0	Empty
		1	Empty < FIFO = 1/4 Full
		2	1/4 Full < FIFO = 1/2 Full
		3	1/2 Full < FIFO = 3/4 Full
		4	3/4 Full < FIFO = Full
		5	Reserved

Table 34-26: DMA_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		6	Reserved
		7	Full
15:14 (R/NW)	MBWID	Memory Bus Width. The DMA_STAT.MBWID bit field indicates the width of the memory bus connected to this DMA.	
		0	2 Bytes
		1	4 Bytes
		2	8 Bytes
		3	16 Bytes
13:12 (R/NW)	PBWID	Peripheral Bus Width. The DMA_STAT.PBWID bit field indicates the width of the peripheral bus connected to this DMA.	
		0	1 Byte
		1	2 Bytes
		2	4 Bytes
		3	8 Bytes
10:8 (R/NW)	RUN	Run Status. The DMA_STAT.RUN bit field reports the DMA's current operational state. If the DMA is in idle or stop state, the DMA_CFG.EN bit is either 0 or 1. This bit field does not clear when a transition of the DMA_CFG.EN bit from 0 to 1 occurs. The DMA_STAT.RUN clears automatically when the DMA completes.	
		0	Idle/Stop State
		1	Descriptor Fetch
		2	Data Transfer
		3	Waiting for Trigger
		4	Waiting for Write ACK/FIFO Drain to Peripheral
		5	Reserved
		6	Reserved
		7	Reserved
6:4 (R/NW)	ERRC	Error Cause. When an interrupt request error occurs (DMA_STAT.IRQERR), the DMA updates the DMA_STAT.ERRC bit field to identify the type of error. For more information, see the errors section of the DMA functional description.	

Table 34-26: DMA_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		0	Configuration Error
		1	Illegal Write Occurred While Channel Running
		2	Address Alignment Error
		3	Memory Access or Fabric Error
		4	Reserved
		5	Trigger Overrun
		6	Bandwidth Monitor Error
		7	Reserved
2 (R/W1C)	PIRQ	Peripheral Interrupt Request. The DMA_STAT.PIRQ bit indicates a peripheral interrupt request. Programs can use the DMA_STAT.PIRQ bit status to help determine which DMA asserted the interrupt request. This bit also helps to distinguish between an interrupt request caused by the state of the work unit and an interrupt request caused by the peripheral.	
		0	No Interrupt request
		1	Interrupt Request signaled by peripheral
1 (R/W1C)	IRQERR	Error Interrupt Request. The DMA_STAT.IRQERR bit indicates that the DMA has detected a documented rule violation during DMA programming or operation. The DMA cannot, however, flag all possible programming or operation issues to indicate errors. Programmers can use the DMA_STAT.IRQERR bit to help determine which DMA issued the error interrupt request. The DMA_STAT.IRQERR does not clear a transition of the DMA_CFG.EN bit from 0 to 1. Clear the DMA_STAT.IRQERR bit with a write-1-to-clear operation prior to the DMA_CFG.EN transition for the fields to be reset.	
		0	No Error
		1	Error Occurred
0 (R/W1C)	IRQDONE	Work Unit/Row Done Interrupt. The DMA_STAT.IRQDONE bit indicates that the DMA has detected the completion of a work unit or row (inner loop count) and has issued an interrupt request. Programs can use the DMA_STAT.IRQDONE status to help determine which DMA asserted the interrupt request. Programs can also use these bits to help distinguish between an interrupt request based on the state of the work unit and an interrupt request made by the peripheral. For more information, see the interrupts section of the DMA functional description.	
		0	Inactive
		1	Active

Inner Loop Count Start Value Register

For 2D DMA, the DMA_XCNT register contains the inner loop count. This value selects the number of DMA_CFG.MSIZE size data transfers that make up the length of a row. For 1D DMA, the DMA_XCNT register specifies the number of DMA_CFG.MSIZE size data transfers for the entire work unit. The DMA_XCNT register is read/write prior to enabling the channel, but is read-only after enabling channel. Note that the DMA generates a configuration error if this register is 0x0 when a work unit begins.

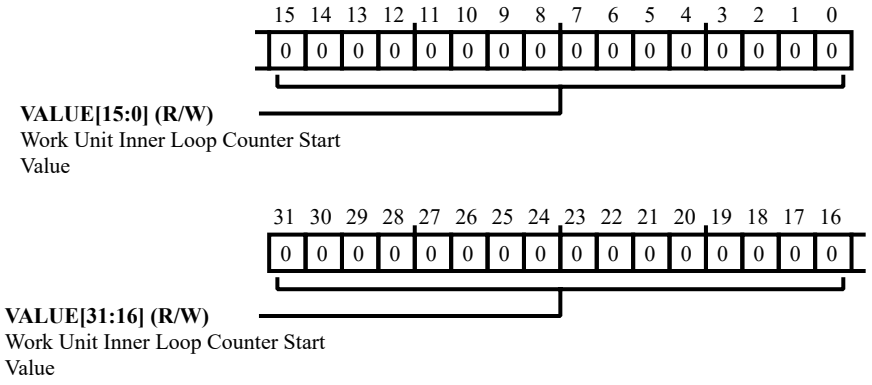

Figure 34-16: DMA_XCNT Register Diagram

Table 34-27: DMA_XCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Work Unit Inner Loop Counter Start Value. For 2D DMA, the DMA_XCNT.VALUE bit field contains the inner loop count. For 1D DMA, DMA_XCNT.VALUE specifies the number of DMA_CFG.MSIZE size data transfers for the entire work unit.

Current Count (1D) or Intra-row XCNT (2D) Register

For 1D DMA, the DMA loads the DMA_XCNT_CUR register from the DMA_XCNT register at the beginning of each work unit. For 2D DMA, the DMA loads the DMA_XCNT_CUR register from the DMA_XCNT register after the end of each row. The DMA decrements the value in DMA_XCNT_CUR register each time a DMA_CFG.MSIZE size data transfer occurs. When the count in DMA_XCNT_CUR register expires, the work unit is complete. In 2D DMA, the DMA_XCNT_CUR value is 0 only when the entire transfer is complete.

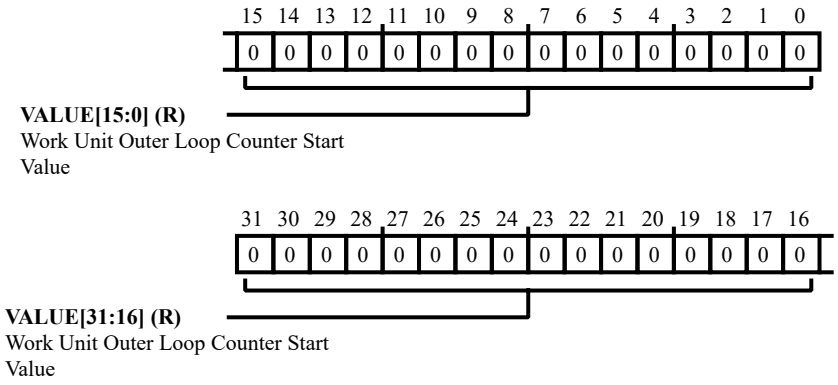

Figure 34-17: DMA_XCNT_CUR Register Diagram

Table 34-28: DMA_XCNT_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Work Unit Outer Loop Counter Start Value. For 1D DMA, the DMA_XCNT_CUR.VALUE bit field holds the DMA_XCNT value at the beginning of each work unit. For 2D DMA, the DMA_XCNT_CUR.VALUE bit field holds the DMA_XCNT value after the end of each row.

Inner Loop Address Increment Register

The DMA_XMOD register contains a signed, two's-complement byte address increment. In 1D DMA, this increment is the stride that is applied after each DMA_CFG.MSIZE size data transfer. The DMA_XMOD register is read/write prior to enabling the channel, but is read-only after enabling the channel.

The DMA_XMOD register value is specified in bytes, regardless of the work unit size. In 2D DMA, this increment is applied after each DMA_CFG.MSIZE size data transfer in the inner loop, up to but not including the last DMA_CFG.MSIZE size data transfer in each inner loop. After the last DMA_CFG.MSIZE size data transfer in each inner loop, the DMA_YMOD register is applied instead, including the last DMA_CFG.MSIZE size data transfer of a work unit.

The DMA_XMOD field can be set to 0. In this case, DMA is performed repeatedly to or from the same address. This approach can be useful for transferring data between a data register and an external memory-mapped peripheral.

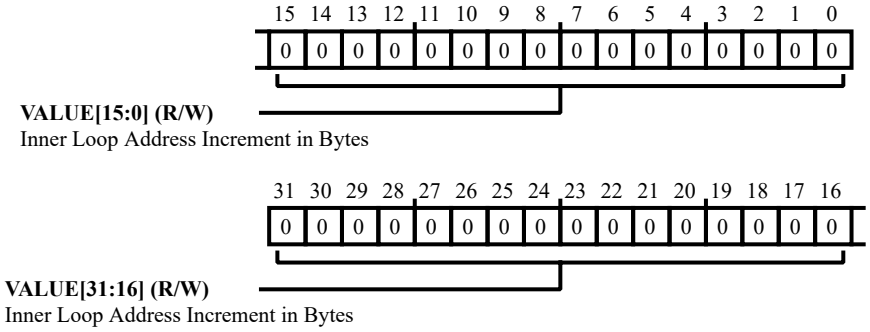

Figure 34-18: DMA_XMOD Register Diagram

Table 34-29: DMA_XMOD Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Inner Loop Address Increment in Bytes. The DMA_XMOD.VALUE bit field contains a signed, two's-complement byte address increment.

Outer Loop Count Start Value (2D only) Register

For 2D DMA, the DMA_YCNT register contains the outer loop count. This register is not used in 1D DMA mode. The DMA_YCNT register specifies the number of rows in the outer loop of a 2D DMA sequence. The DMA_YCNT register is read/write prior to enabling the channel, but is read-only after enabling channel. Note that the DMA generates a configuration error if this register is 0x0 when a work unit begins.

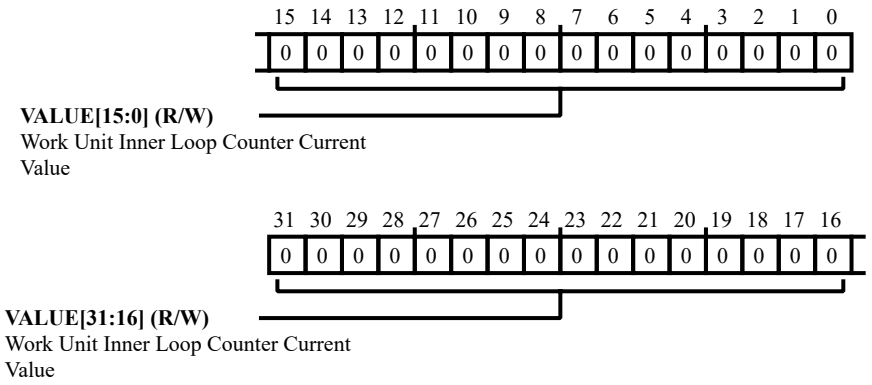

Figure 34-19: DMA_YCNT Register Diagram

Table 34-30: DMA_YCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Work Unit Inner Loop Counter Current Value. For 2D DMA, the DMA_YCNT.VALUE bit field contains the outer loop count.

Current Row Count (2D only) Register

For 2D DMA, the DMA loads the DMA_YCNT_CUR register from the DMA_YCNT register at the beginning of each 2D DMA session. The DMA_YCNT_CUR register is not used for 1D DMA. The DMA decrements the DMA_YCNT_CUR register each time the DMA_XCNT_CUR register expires during 2D DMA operation, signifying the completion of an entire row transfer.

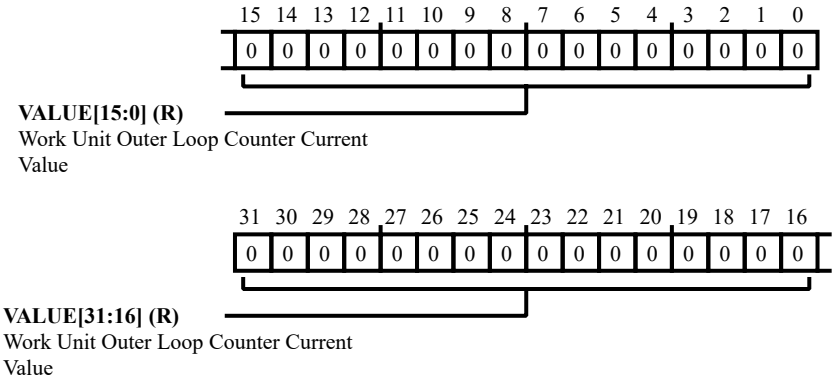

Figure 34-20: DMA_YCNT_CUR Register Diagram

Table 34-31: DMA_YCNT_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Work Unit Outer Loop Counter Current Value. For 2D DMA, the DMA_YCNT_CUR.VALUE bit field holds the value from the DMA_YCNT register at the beginning of each 2D DMA session.

Outer Loop Address Increment (2D only) Register

The DMA_YMOD register contains a signed, two's-complement value. This byte address increment is applied after each decrement of the DMA_YCNT_CUR register. The value is the offset between the last word of one row and the first word of the next row. Note that DMA_YMOD is specified in bytes, regardless of the work unit size. The DMA_YMOD register is read/write prior to enabling the channel, but is read-only after enabling the channel.

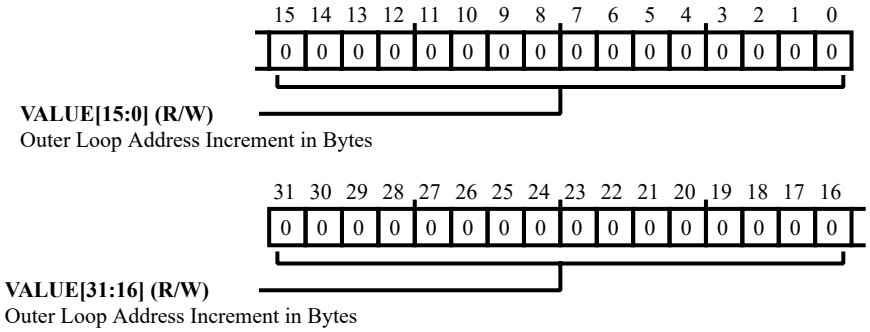

Figure 34-21: DMA_YMOD Register Diagram

Table 34-32: DMA_YMOD Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Outer Loop Address Increment in Bytes. The DMA_YMOD.VALUE bit field contains a signed, two's-complement value.

35 Extended Memory DMA (EMDMA)

The Extended Memory DMA engine can be used in applications that copy data in a non-sequential manner. This includes delay lines, scatter and gather, and circular access types.

NOTE: Previous SHARC processors featured external port DMA. Current SHARC products use EMDMA that can access all memory locations for source and destination DMA operations.

EMDMA Features

EMDMA frees the processor core, allowing it to perform other operations while the data transfers between memories occurs as a background task.

EMDMA has the following features and capabilities.

- Standard mode DMA Transfer
- Chained mode with direction on-the-fly
- Tap list mode (scatter/gather)
- Delay line mode (write to read)
- All the DMA modes can operate in circular fashion
- In circular operation, some modes allow a write back of the index pointer for correct addressing of the next Transfer Control Block (TCB)

EMDMA Functional Description

The following sections provide information on the functional operations and operating modes of EMDMA.

Internal-to-internal DMA

This is accomplished by indexing all external parameter registers with internal addresses.

DMA bursting

DMA supports burst transfers only when the modifier is 1, for any other modifier values, single accesses are performed. The burst size is not user configurable and is chosen by the processor for optimal performance. The maximum burst size is 8 and the minimum is 1.

Transfer control blocks

The structure of a TCB is conceptually the same as that of a traditional linked list. Each TCB has several data values and a pointer to the next TCB. Further, the chain pointer of a TCB may point to itself to continuously re-run the same DMA.

Chain pointer DMA

In chained DMA operations, the processor automatically initializes and then begins another DMA transfer when the current DMA transfer is complete.

ADSP-2184x EMDMA Register List

The EMDMA controllers support a variety of direct memory access operations which can access any system memory and transfer the entire block of data. A set of registers govern EMDMA operations. For more information on EMDMA functionality, see the EMDMA register descriptions.

Table 35-1: ADSP-2184x EMDMA Register List

Name	Description
EMDMA_BASE	External Base Address Register
EMDMA_BUFLEN	Circular Buffer Length Register
EMDMA_CHNPTR	Chain Pointer Register
EMDMA_CNT0	Internal Count Register
EMDMA_CNT1	External Count Register
EMDMA_CTL	External Memory DMA Control Register
EMDMA_INDX0	Internal Index Register
EMDMA_INDX1	External Index Register
EMDMA_MOD0	Internal Modifier Register
EMDMA_MOD1	External Modifier Register
EMDMA_TCNT	Delay Line Tap Count Register
EMDMA_TPTR	Tap List Pointer Register

ADSP-2184x EMDMA Interrupt List

Table 35-2: ADSP-2184x EMDMA Interrupt List

Interrupt ID	Name	Description	Sensitivity	DMA Channel
106	EMDMA0_DONE	EMDMA0 Transfer Done	Edge	
107	EMDMA1_DONE	EMDMA1 Transfer Done	Edge

Trigger ID	Name	Description	Sensitivity
None			

DMA Addressing

Besides the traditional internal-to-external addressing type, the DMA module also supports internal-to-internal transfers. This is accomplished by indexing all external parameter registers with internal addresses. The DMA controller recognizes the transfer by addresses and not by an additional control bit setting.

All the DMA addresses given by EMDMA are word-aligned byte addresses. The programming for the index registers is provided in the *Register Descriptions* section.

DMA Burst Transfers

DMA supports burst transfers only when the modifier is 1. For any other modifier values, single accesses are performed.

The burst size is not user-configurable and is chosen by the processor for optimal performance. The maximum burst size is 8 and the minimum is 1.

The EMDMA uses appropriate burst transfer sizes for optimal throughput. For example, if the word count is 15, then 5 bursts are performed with burst sizes of 8+4+1+1+1 transfers.

Transfer Control Block (TCB) Memory Storage

The location of the DMA parameters for the next sequence comes from the chain pointer register that points to the next set of DMA parameters stored in the processor's internal memory. In chained DMA operations, the processor automatically initializes and then begins another DMA transfer when the current DMA transfer is complete. Each new set of parameters is stored in a user-initialized memory buffer or TCB for a chosen peripheral.

Chain Assignment

The structure of a TCB is conceptually the same as that of a traditional linked list. Each TCB has several data values and a pointer to the next TCB. Further, the chain pointer of a TCB may point to itself to continuously rerun the same DMA. The EMDMA reads each word of the TCB and loads it into the corresponding register. The end of the chain (no further TCBs are loaded) is indicated by a TCB with a chain pointer register value of zero.

The address field of the chain pointer registers is only 30 bits wide. If a program writes a symbolic address to bit 30 of the chain pointer there may be a conflict with the `EMDMA_CHNPTR.PCI` bit. Programs should clear the upper bits of the address then AND the `EMDMA_CHNPTR.PCI` bit separately, if needed.

Starting Chain Loading

A DMA sequence is defined as the sum of the DMA transfer from when the parameter registers initialize to when the count register decrements to zero. The EMDMA module has a chaining enable bit (`EMDMA_CTL.CHEN`).

To start the chain, write the internal (channel 0) index address of the first TCB to the chain pointer register (`EMDMA_CHNPTR`). When chaining is enabled, DMA transfers are initiated by writing a memory address to the chain pointer register. This is also an easy way to start a single DMA sequence, with no subsequent chained DMAs.

During TCB chain loading, the EMDMA loads the DMA channel parameter registers with values retrieved from system memory.

The address in the chain pointer register points to the highest address of the TCB. This contains the internal (channel 0) index parameter. This means that if a program declares an array to hold the TCB, the chain pointer register should point to the last location of the array and not to the first TCB location.

Buffered Chain Loading Register

The chain pointer register (`EMDMA_CHNPTR`) is buffered. Before the chain loading starts, the buffer is copied into the chain pointer register and is decremented after each register is loaded.

The chain pointer register can be loaded with a new address at any time during the DMA sequence (`EMDMA_CTL.CHEN` =1). This allows a DMA channel to have chaining status deactivated (chain pointer register = 0x0) until some event occurs that loads the chain pointer register with a non-zero value. Writing all zeros to the address field of the chain pointer register also deactivates chaining for the next TCB.

TCB Storage

The EMDMA supports several types of DMA, resulting in different lengths of TCBs. The TCB size varies from six locations (chained DMA) to 13 locations (delay line DMA). The ***EMDMA TCBs*** table shows the required TCBs for chained DMA.

In the following tables, TCB refers to the start address of the TCB array.

Table 35-5: EMDMA TCBs for Standard DMA

Address	Register
TCB	EMDMA_CHNPTR
TCB + 0x1	EMDMA_MOD1
TCB + 0x2	EMDMA_INDX1
TCB + 0x3	EMDMA_CNT0
TCB + 0x4	EMDMA_MOD0
TCB + 0x5	EMDMA_INDX0

The order the descriptors are fetched with circular buffering enabled is shown in the ***EMDMA TCBs for Standard Circular DMA*** table.

Table 35-6: EMDMA TCBs for Standard Circular DMA

Address	Register
TCB	EMDMA_CHNPTR
TCB + 0x1	EMDMA_BUFLEN
TCB + 0x2	EMDMA_BASE
TCB + 0x3	EMDMA_MOD1
TCB + 0x4	EMDMA_INDX1
TCB + 0x5	EMDMA_CNT0
TCB + 0x6	EMDMA_MOD0
TCB + 0x7	EMDMA_INDX0

For delay line DMA, TCB loading is split into two sequences to improve overall priority. The first TCB loads the write parameters (EMDMA_INDX0 – EMDMA_BUFLEN) and the second loads the read parameters (EMDMA_INDX0 – EMDMA_CHNPTR). This two stage loading is transparent to the application. The order the descriptors are fetched for delay line DMA, as shown in the ***EMDMA TCBs for Delay Line DMA*** table.

Table 35-7: EMDMA TCBs for Delay Line DMA

Address	Register
Delay Line Read	
TCB	EMDMA_CHNPTR
TCB + 0x1	EMDMA_TPTR
TCB + 0x2	EMDMA_TCNT
TCB + 0x3	EMDMA_MOD1
TCB + 0x4	EMDMA_CNT0

Table 35-7: EMDMA TCBs for Delay Line DMA (Continued)

Address	Register
TCB + 0x5	EMDMA_INDX0
Delay Line Write	
TCB + 0x6	EMDMA_BUFLEN
TCB + 0x7	EMDMA_BASE
TCB + 0x8	EMDMA_MOD1
TCB + 0x9	EMDMA_INDX1
TCB + 0xA	EMDMA_CNT0
TCB + 0xB	EMDMA_MOD0
TCB + 0xC	EMDMA_INDX0

The order the descriptors are fetched for scatter/gather DMA with circular buffering disabled is shown in the ***EMDMA TCBs for Scatter/Gather DMA*** table.

Table 35-8: EMDMA TCBs for Scatter/Gather DMA

Address	Register
TCB	EMDMA_CHNPTR
TCB + 0x1	EMDMA_TPTR
TCB + 0x2	EMDMA_TCNT
TCB + 0x3	EMDMA_MOD1
TCB + 0x4	EMDMA_INDX1
TCB + 0x5	EMDMA_CNT0
TCB + 0x6	EMDMA_MOD0
TCB + 0x7	EMDMA_INDX0

The order the descriptors are fetched for scatter/gather DMA with circular buffering enabled is shown in the ***EMDMA TCBs for Circular Scatter/Gather DMA*** table.

Table 35-9: EMDMA TCBs for Circular Scatter/Gather DMA

Address	Register
TCB	EMDMA_CHNPTR
TCB + 0x1	EMDMA_BUFLEN
TCB + 0x2	EMDMA_BASE
TCB + 0x3	EMDMA_TPTR
TCB + 0x4	EMDMA_TCNT

Table 35-9: EMDMA TCBs for Circular Scatter/Gather DMA (Continued)

Address	Register
TCB + 0x5	EMDMA_MOD1
TCB + 0x6	EMDMA_INDX1
TCB + 0x7	EMDMA_CNT0
TCB + 0x8	EMDMA_MOD0
TCB + 0x9	EMDMA_INDX0

EMDMA Operating Modes

This section and the ***EMDMA_CTL Register Bit to Operating Modes*** table show the different DMA modes which can be used. The complete register bit descriptions are in the ***External Memory DMA Control Registers (EMDMA_CTL)***.

Table 35-10: EMDMA_CTL Register Bit to Operating Modes

Bit (Name)	Standard	Chained	Scatter/Gather	Delay Line
Control Bits				
0 (EN)	Valid			
1 (TRAN)	Valid			N/A
2 (CHEN)	Valid			
3 (DLEN)	N/A			Valid
4 (CBEN)	Valid			
5 (DFLSH)	Valid			
6	N/A			
7 (WRBEN)	N/A	Valid	(=0)	(=1)
8 (OFCEN)	Valid			N/A
9 (TLEN)	N/A		Valid	N/A
11–10	N/A			
12 (INTDONE0)	Valid			
15–13	N/A			
Status Bits				
17–16 (DFS)	Valid			
19–18	N/A			
20 (DMAS0)	Valid			
21 (CHS)	N/A	Valid	N/A	Valid

Table 35-10: EMDMA_CTL Register Bit to Operating Modes (Continued)

Bit (Name)	Standard	Chained	Scatter/Gather	Delay Line
22 (TLS)	N/A		Valid	N/A
23 (WBS)	N/A			Valid
24 (DMAS1)	Valid			
25 (DIRS)	Valid			
31–26	N/A			

NOTE: Reading additional bit-field information from N/A (Not applicable) bits does not generate a meaningful result.

A program sets up a DMA channel by writing the transfer's parameters to the DMA parameter registers.

NOTE: The `EMDMA_CNT1` parameter register (read only) is a copy of the `EMDMA_CNT0` register. If `EMDMA_CNT0` is written, the `EMDMA_CNT1` register is updated automatically.

Standard DMA

A standard DMA (once it is configured) transfers data from location A to location B. An interrupt can be used to indicate the end of the transfer. To start a new DMA sequence after the current one is finished, a program must first clear the DMA enable bit (`EMDMA_CTL.EN`), write new parameters to the index, modify, and count registers (parameter registers), then set the DMA enable bit to re-enable DMA.

This DMA type resembles the traditional DMA type to initialize the different internal and external parameters (channel0 and channel1) (index, modify and count) registers and configuration of the DMA control registers.

Circular Buffered DMA

Circular buffered DMA resembles the traditional core DAG circular buffered mode by using registers for circular buffering. In this mode, the DMA needs two additional registers (base and length) to support reads and writes to a circular buffer. The ***Circular Buffering Write DMA*** and ***Circular Buffering Read DMA*** figures illustrate circular buffered DMA, in contrast with the ***Standard Write DMA*** figure.

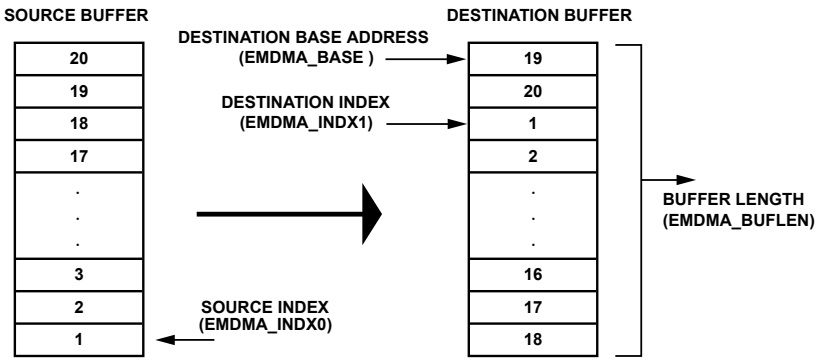

Figure 35-1: Circular Buffering Write DMA

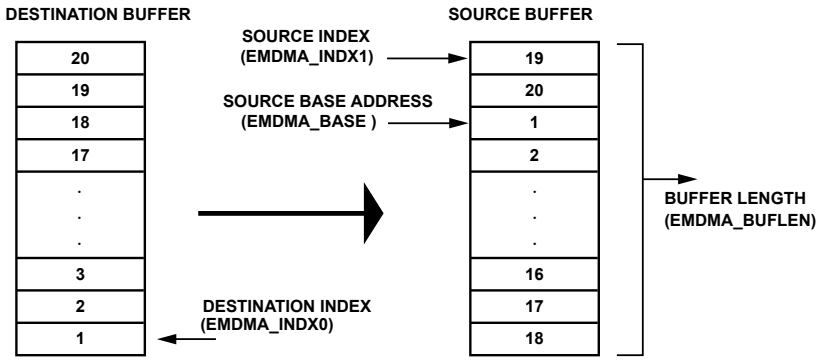

Figure 35-2: Circular Buffering Read DMA

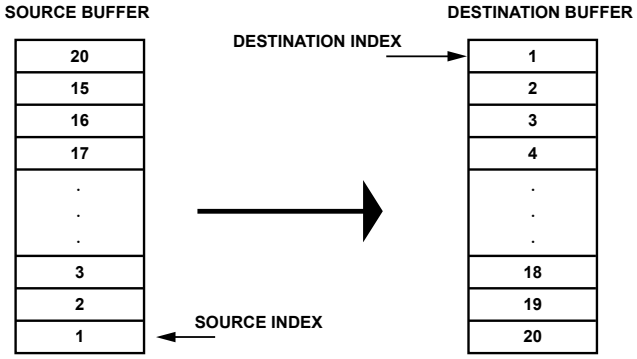

Figure 35-3: Standard Write DMA

NOTE: Circular buffering is available for all operating modes (standard, chained, tap list and delay line DMA).

Chained DMA Mode

Chained DMA sequences are a set of multiple DMA operations, each auto-initializing the next in line. It is used to support automated access by a linked list (repetitive reads and writes to a defined location defined by the individual TCBs). To start a new DMA sequence after the current one is finished, the EMDMA automatically loads new index, modify, and count values pointed to by that channel's `EMDMA_CHNPTR` register. Using chaining, programs can set up consecutive DMA operations and each operation can have different attributes.

DMA data transfers can be set up as continuous or periodic. With chained DMA, the attributes of a specific DMA are stored in internal memory and are referred to as a Transfer Control Block or TCB. Extended Memory DMA loads these attributes in chains for execution. This allows for multiple chains that are finite or infinite.

NOTE: When chaining is enabled, polling should not be used to determine DMA status only because the DMA appears inactive if it is sampled while the next TCB is loading. In such cases where chaining is enabled, along with the polling of DMA status bit, polling of the chaining status bit should also occur to so that the correct status of the DMA is known. For example, the `EMDMA_CTL.CHS` bit should be polled as well as the `EMDMA_CTL.DMAS0` and `EMDMA_CTL.DMAS1` bits when EMDMA is configured in DMA chaining mode.

Data Direction On-the-Fly

A change of external memory data direction for each individual TCB in a chain sequence is allowed.

The EMDMA_CHNPTR.CPDR bit changes the data flow direction. If the EMDMA_CHNPTR.CPDR =0, writes through channel 0 are performed; if EMDMA_CHNPTR.CPDR =1, channel 0 reads are performed. This works similarly to the EMDMA_CHNPTR.PCI bit. The EMDMA_CTL.OFCEN and EMDMA_CTL.CHEN bits must be set (=1) to enable this functionality.

NOTE: If chaining is enabled with the EMDMA_CTL.OFCEN =1, then the EMDMA_CTL.TRAN bit has no effect, and the data direction is determined by the EMDMA_CHNPTR.CPDR bit.

Write Back Circular Index Pointer

Operating the DMA in circular mode requires some special considerations. The index pointer of start address within the buffer may wrap around for the case when IC × IM > EL or it does not finish if IC × IM < EL where:

IC is the value of the EMDMA_INDX0 register

IM is the value of the EMDMA_MOD0 register

EL is the value of the EMDMA_BUFLEN register

In both cases, the TCB start address is no longer valid.

Setting the EMDMA_CTL.WRBEN bit writes (at the end of current TCB block) the current index address + 1 into the TCB memory which is the start address for the next TCB. This bit is only selectable for chained DMA mode. For tap list and delay line modes, this bit is hardwired to 0 or 1.

Scatter/Gather DMA

The purpose of scatter/gather DMA is the transfer of data from/to non-contiguous memory blocks.

The scatter/gather DMA type is a fixed block size scatter/gather DMA that relies on tap list entries in system memory to calculate the (Channel 1 DMA Address) to scatter/gather the DMA. When the DMA direction is Channel 1 write (EMDMA_CTL.TRAN =1) it is a scatter DMA. When (EMDMA_CTL.TRAN =0), it is a gather DMA. This mode also supports chained and circular buffer chained DMAs.

See the ***Scatter DMA (Writes)***, ***Gather DMA (Reads)***, ***Circular Buffering Scatter DMA (Writes)***, and ***Circular Gather DMA (Reads)*** figures.

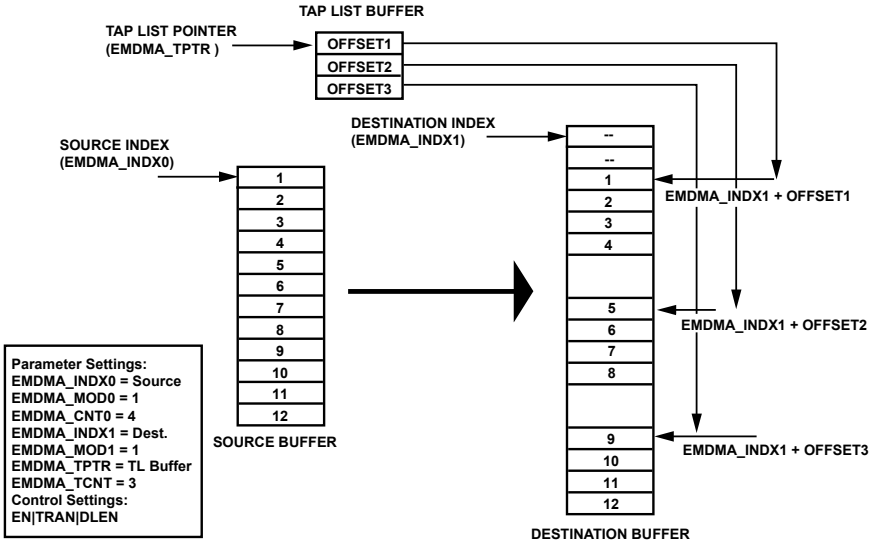

Figure 35-4: Scatter DMA (Writes)

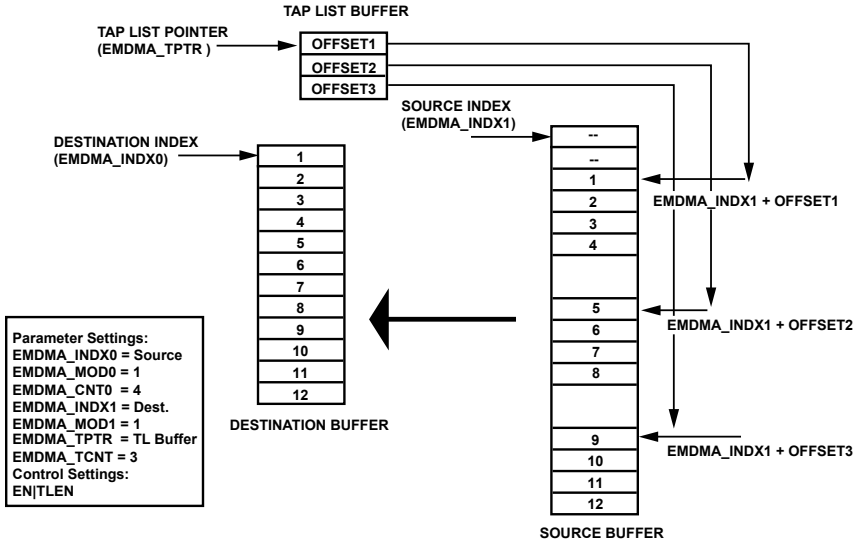

Figure 35-5: Gather DMA (Reads)

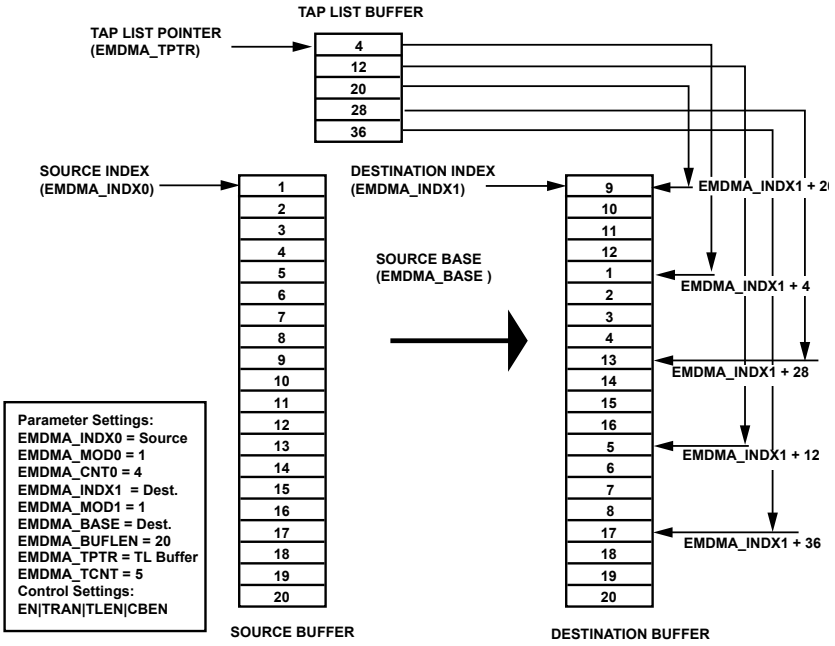

Figure 35-6: Circular Buffering Scatter DMA (Writes)

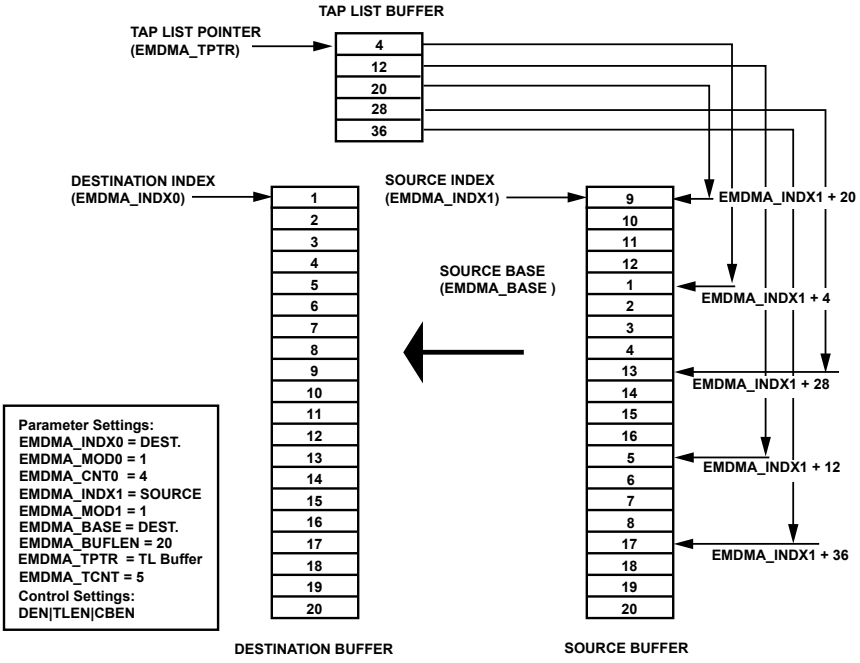

Figure 35-7: Circular Gather DMA (Reads)

For each 32-bit tap read, the Channel 1 read index is shown in the ***Read/Write Index Pre-Modify (Scatter/Gather DMA)*** table. Note that one tap list entry starts multiple reads.

Table 35-11: Read/Write Index Pre-Modify (Scatter/Gather DMA)

Pre-Modify Address Equation **EMDMA_INDX0** + **EMDMA_TPTR** [**EMDMA_TCNT**] + (**EMDMA_MOD1** × **EMDMA_CNT1**)	Result	
	Block Size	Tap
EMDMA_INDX0 + EMDMA_TPTR[0] + EMDMA_MOD1 × 0	N	0
EMDMA_INDX0 + EMDMA_TPTR[0] + EMDMA_MOD1 × 1		
EMDMA_INDX0 + EMDMA_TPTR[0] + EMDMA_MOD1 × 2		
EMDMA_INDX0 + EMDMA_TPTR[0] + EMDMA_MOD1 × N		
EMDMA_INDX0 + EMDMA_TPTR[1] + EMDMA_MOD1 × 0	N	1
EMDMA_INDX0 + EMDMA_TPTR[1] + EMDMA_MOD1 × 1		
EMDMA_INDX0 + EMDMA_TPTR[1] + EMDMA_MOD1 × 2		
EMDMA_INDX0 + EMDMA_TPTR[1] + EMDMA_MOD1 × N		
EMDMA_INDX0 + EMDMA_TPTR[M] + EMDMA_MOD1 × 0	N	M
EMDMA_INDX0 + EMDMA_TPTR[M] + EMDMA_MOD1 × 1		
EMDMA_INDX0 + EMDMA_TPTR[M] + EMDMA_MOD1 × 2		
EMDMA_INDX0 + EMDMA_TPTR[M] + EMDMA_MOD1 × N		

Pre Modified Read/Write Index

For scatter/gather DMA, the tap list modifiers are employed, and the number of taps is determined by the tap list count register (EMDMA_TCNT). The number of sequential reads (block size) from every tap is determined by the internal count register (EMDMA_CNT0), and is the same for every tap. The read/write pointer in external index register (EMDMA_INDX1) serves as the index address for these read/writes.

TL[N] is the first tap list entry in the memory as pointed to by the tap list pointer register (EMDMA_TPTR). The tap list entries are 27-bit signed integers. For each read/write block, the DMA state machine fetches the offset from the tap list. The offset is added to the EMDMA_INDX1 register value to get the start address of the next block. The Channel 1 addresses are circular buffered if circular buffering is enabled (see the ***Circular Buffering Scatter DMA (Writes)*** and ***Circular Buffering Gather DMA (Reads)*** figures in Scatter/Gather DMA).

Once the EMDMA_CNT0 register for the final tap decrements to zero (EMDMA_TCNT and EMDMA_CNT0 are zero), then the tap list DMA access is complete, and the DMA completion interrupt is generated (when chaining is enabled the interrupt depends on the EMDMA_CHNPTR.PCI bit setting).

The write back mode (EMDMA_CTL.WRBEN bit) is hardwired to zero for tap list based DMA (as the addressing is pre-modify, and therefore the EMDMA_INDX1 value coincides with the TCB value even at the end of the DMA).

Delay Line DMA

Delay line DMA is used to support reads and writes to delay line buffers with limited core interaction. In this sense, delay line DMA is a quantity of integrated writes followed by reads from channel 1 (a delay line DMA access). Delay line DMA is described in the following sections.

NOTE: Delay line DMA can only operate by using chained DMA mode (EMDMA_CTL.CHEN bit set). In order to use delay line DMA for a single DMA sequence, initialize the EMDMA_CHNPTR register to zero in the TCB.

NOTE: Delay line DMA can be used in any system memory.

The delay line DMA operation follows these steps:

1. Load the first half of TCB for writing (seven parameters).
2. DMA writes to the delay line buffer until IC = 0.
3. Update the EI index pointer if circular mode is enabled.
4. Load the second half of TCB for reading (six parameters).
5. DMA tap based reads from the delay line buffer until RC = 0.

   Jump to step 1.

Writes to delay line. The number of writes is determined by the EMDMA_CNT0 register. The data is fetched from the EMDMA_INDX0 register and the EMDMA_MOD0 register is used as the internal modifier. The EMDMA_INDX1 register serves as the external index and is incremented by the EMDMA_MOD1 register after each write. These writes are circular buffered if circular buffering is enabled. See the ***Write to Delay Line Buffer*** figure.

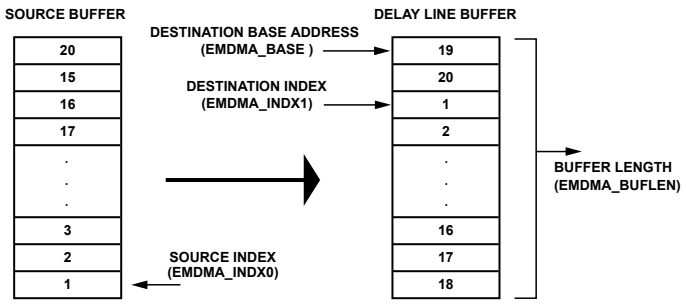

Figure 35-8: Write to Delay Line Buffer

When the writes are complete, (EMDMA_CNT0 =0) the EMDMA_INDX1 register, which serves as the write pointer of the delay line, is written back (EMDMA_CTL.WRBEN is hardwired to 1) to the TCB location from where it was fetched.

Reads from the delay line. For reads, the tap list (TL) modifiers are used, and the number of reads is determined by the EMDMA_CNT0 register. The write pointer in the EMDMA_INDX1 register serves as the index address for these reads (reads start from where writes end). The EMDMA_INDX1 register, along with tap list modifiers, are used in a pre-modify addressing mode to create the external address for the reads. Therefore, for each read, the DMA controller fetches the external modifier (EMDMA_TCNT register) from the tap list and the reads are circular buffered (if enabled). See the ***Read From Delay Line Buffer*** figure.

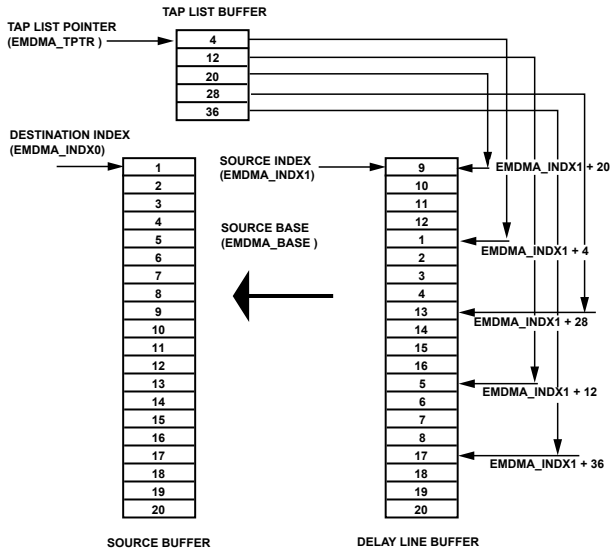

Figure 35-9: Read From Delay Line Buffer

Pre-Modified Read Index

Note that TL[N] is the first tap list entry in memory pointed to by the tap list pointer register (EMDMA_TPTR). Tap list entries are 27-bit signed integers. Therefore, for each read-block, the DMA state machine fetches the offset external modifier from the tap list. The reads are circular buffered if circular buffering is enabled.

NOTE: The channel 1 DMA address generation follows pre-modify addressing for reads in delay line DMA and therefore the EMDMA_INDX1 register values are not updated. Also the EMDMA_MOD1 register does not have any effect during these delay line reads. Once the read count completes, the EMDMA_CNT0 register decrements to zero (both EMDMA_CNT0 and EMDMA_TCNT are zero) for the final tap. Finally, the delay line DMA access completes, and the DMA completion interrupt is generated. When chaining is enabled, the interrupt is dependent on the EMDMA_CHNPTR.PCI bit setting. The delay line DMA can only be initialized using the TCB. To use the delay line DMA for a single DMA sequence, initialize the EMDMA_CHNPTR register to zero in the TCB.

For each 32-bit tap read, the channel 1 read index is shown in the ***Read/Write Index Pre-Modify (Scatter/Gather DMA)*** table. Note that one tap list entry starts multiple reads.

Table 35-12: Read/Write Index Pre-Modify (Scatter/Gather DMA)

Pre-Modify Address Equation	Result	
EMDMA_INDX1 + **EMDMA_TPTR**[**EMDMA_TCNT**] + (**EMDMA_MOD1** × **EMDMA_CNT1**)	Block Size	Tap
EMDMA_INDX1 + EMDMA_TPTR[0] + EMDMA_MOD1 × 0	N	0
EMDMA_INDX1 + EMDMA_TPTR[0] + EMDMA_MOD1 × 1		
EMDMA_INDX1 + EMDMA_TPTR[0] + EMDMA_MOD1 × 2		
EMDMA_INDX1 + EMDMA_TPTR[0] + EMDMA_MOD1 × N		

Table 35-12: Read/Write Index Pre-Modify (Scatter/Gather DMA) (Continued)

Pre-Modify Address Equation **EMDMA_INDX1** + **EMDMA_TPTR**[**EMDMA_TCNT**] + (**EMDMA_MOD1** × **EMDMA_CNT1**)	Result	
	Block Size	Tap
EMDMA_INDX1 + EMDMA_TPTR[1] + EMDMA_MOD1 × 0	N	1
EMDMA_INDX1 + EMDMA_TPTR[1] + EMDMA_MOD1 × 1		
EMDMA_INDX1 + EMDMA_TPTR[1] + EMDMA_MOD1 × 2		
EMDMA_INDX1 + EMDMA_TPTR[1] + EMDMA_MOD1 × N		
EMDMA_INDX1 + EMDMA_TPTR[M] + EMDMA_MOD1 × 0	N	M
EMDMA_INDX1 + EMDMA_TPTR[M] + EMDMA_MOD1 × 1		
EMDMA_INDX1 + EMDMA_TPTR[M] + EMDMA_MOD1 × 2		
EMDMA_INDX1 + EMDMA_TPTR[M] + EMDMA_MOD1 × N		

ADSP-2184x EMDMA Register Descriptions

Extended Memory DMA (EMDMA) contains the following registers.

Table 35-13: ADSP-2184x EMDMA Register List

Name	Description
EMDMA_BASE	External Base Address Register
EMDMA_BUFLEN	Circular Buffer Length Register
EMDMA_CHNPTR	Chain Pointer Register
EMDMA_CNT0	Internal Count Register
EMDMA_CNT1	External Count Register
EMDMA_CTL	External Memory DMA Control Register
EMDMA_INDX0	Internal Index Register
EMDMA_INDX1	External Index Register
EMDMA_MOD0	Internal Modifier Register
EMDMA_MOD1	External Modifier Register
EMDMA_TCNT	Delay Line Tap Count Register
EMDMA_TPTR	Tap List Pointer Register

External Base Address Register

The EMDMA_BASE register contains the external base address of the delay line buffer. This is used for maintaining circular buffered read/writes to the delay line.

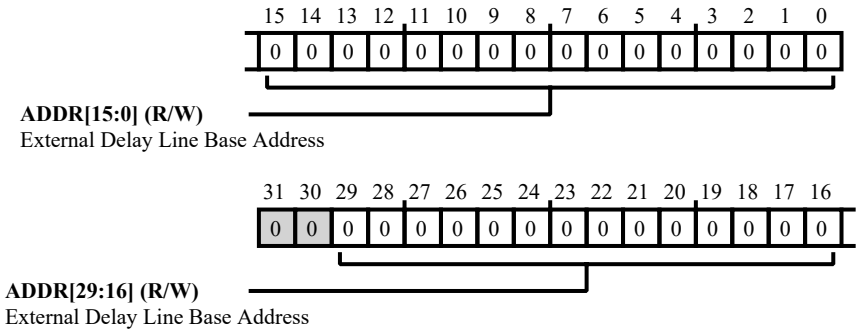

Figure 35-10: EMDMA_BASE Register Diagram

Table 35-14: EMDMA_BASE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:0 (R/W)	ADDR	External Delay Line Base Address. The EMDMA_BASE.ADDR bit field contains the external base address of the delay line buffer.

Circular Buffer Length Register

The EMDMA_BUFLEN register holds the circular buffer length for the delay line DMA.

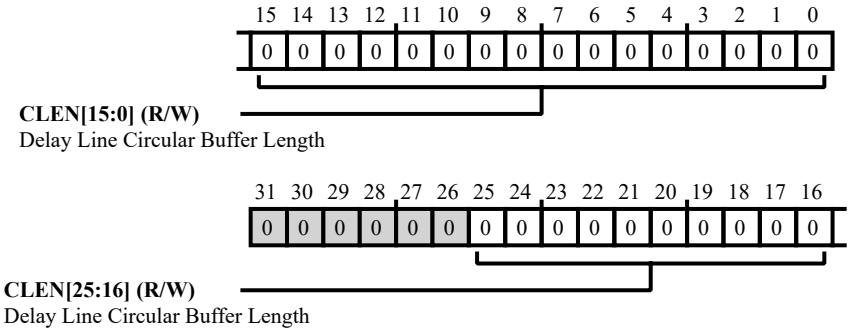

Figure 35-11: EMDMA_BUFLEN Register Diagram

Table 35-15: EMDMA_BUFLEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
25:0 (R/W)	CLEN	Delay Line Circular Buffer Length. The EMDMA_BUFLEN.CLEN bit field holds the circular buffer length for the delay line DMA.

Chain Pointer Register

The EMDMA_CHNPTR register contains the address of the next descriptor in memory when the EMDMA_CTL.CHEN bit =1. This register also has bits to change DMA directions for each descriptor and the PCI bit.

Note that the lower 30-bits of this register are to be written with 30 MSB's of the word-aligned byte addresses of the corresponding next descriptor address.

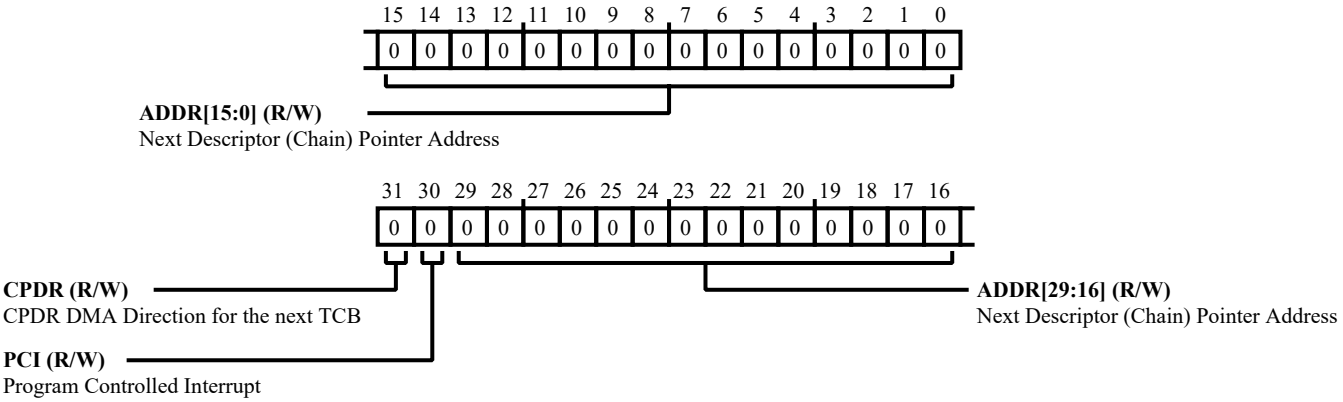

Figure 35-12: EMDMA_CHNPTR Register Diagram

Table 35-16: EMDMA_CHNPTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	CPDR	CPDR DMA Direction for the next TCB. The EMDMA_CHNPTR.CPDR bit configures whether the DMA is a write to internal memory or a read from internal memory. Note: this setting is applicable only if EMDMA_CTL.OFCEN =1 and is not applicable for delay line DMA.	
		0	Write to Channel 0 (Channel 1 reads)
		1	Read from Channel 0 (Channel 1 Writes)
30 (R/W)	PCI	Program Controlled Interrupt. The EMDMA_CHNPTR.PCI bit PCI sets whether an interrupt is generated after the current TCB or if no interrupt is generated. (Only affects DMA if chaining is enabled).	
		0	Enable DMA Channel interrupt to occur at the completion of the entire DMA chained transfer
		1	Enable DMA Channel interrupt to occur at the completion of current DMA sequence

Table 35-16: EMDMA_CHNPTR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
29:0 (R/W)	ADDR	Next Descriptor (Chain) Pointer Address. The `EMDMA_CHNPTR.ADDR` bit field provides the address of the next descriptor in memory.

Internal Count Register

The EMDMA_CNT0 register contains the number of words to be transferred for channel 0 DMA.

Note: If delay line DMA is enabled then the EMDMA_CNT0 register serves as the count register for the delay line writes.

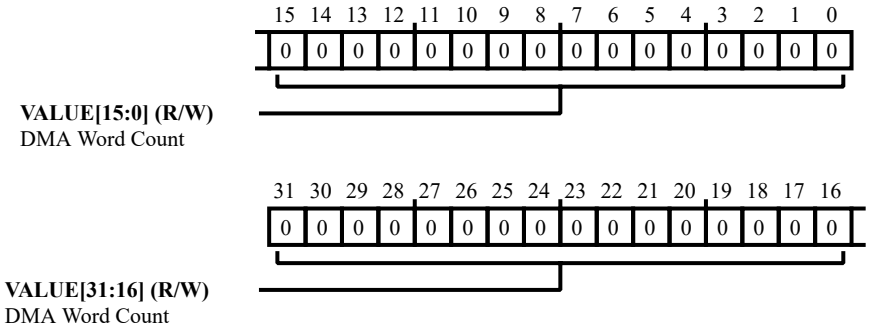

Figure 35-13: EMDMA_CNT0 Register Diagram

Table 35-17: EMDMA_CNT0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	DMA Word Count. The EMDMA_CNT0.VALUE bit field is the DMA word count.

External Count Register

The EMDMA_CNT1 register contains the number of words to be transferred for channel 1 DMA.

Note: If delay line DMA is enabled then the EMDMA_CNT1 register serves as the count register for the delay line writes.

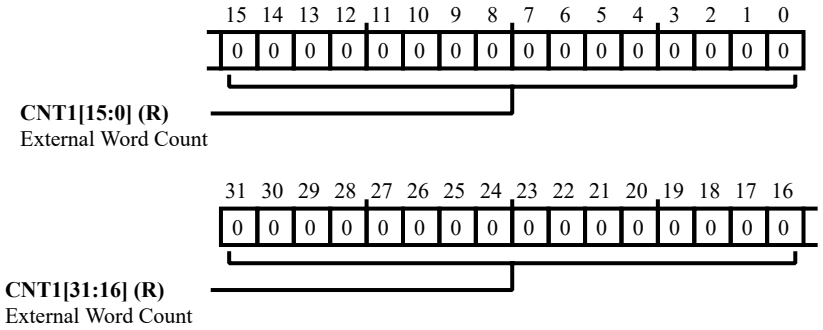

Figure 35-14: EMDMA_CNT1 Register Diagram

Table 35-18: EMDMA_CNT1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNT1	External Word Count. The EMDMA_CNT1.CNT1 bit field is the external word count.

External Memory DMA Control Register

The EMDMA_CTL register contains bits that enable and configure EMDMA and indicate DMA transfer status.

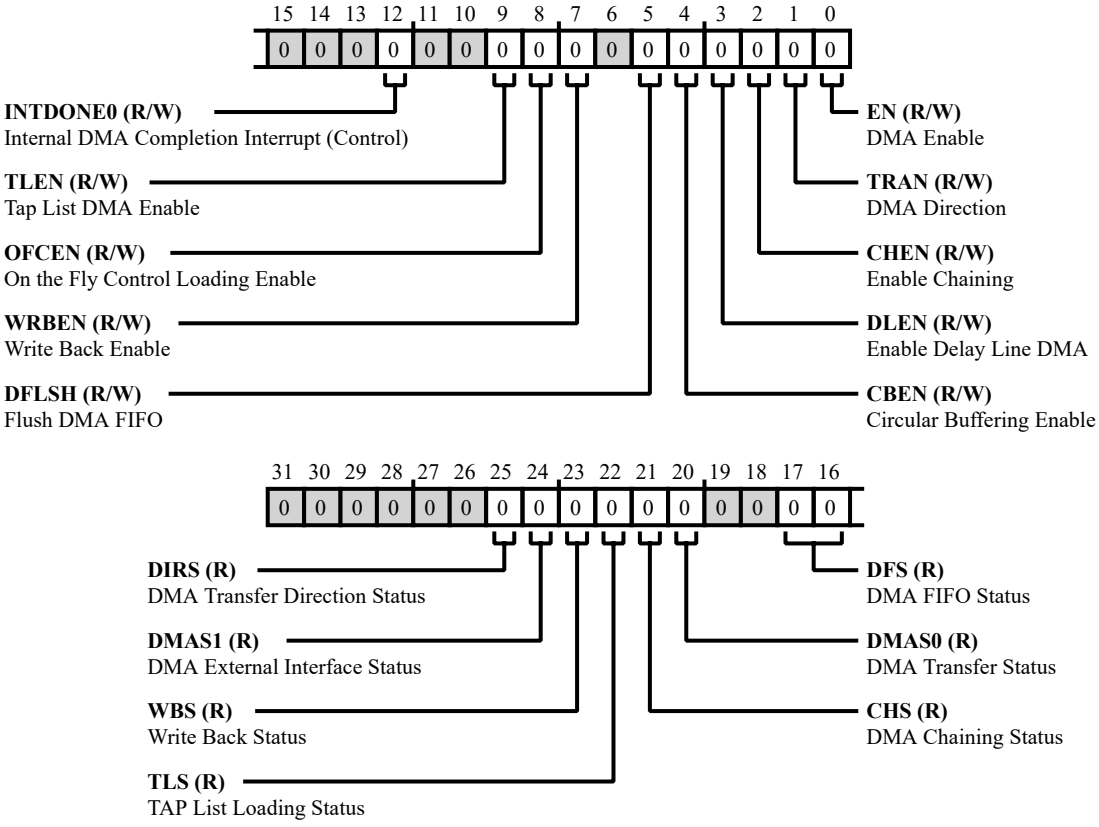

Figure 35-15: EMDMA_CTL Register Diagram

Table 35-19: EMDMA_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
25 (R/NW)	DIRS	DMA Transfer Direction Status. The EMDMA_CTL.DIRS bit provides the DMA transfer status direction. This is useful for delay line DMA where the transfer direction changes with the state of the DMA state machine. For standard DMA, the EMDMA_CTL.DIRS bit reflects the state of the EMDMA_CTL.TRAN bit.	
		0	DMA direction is Channel 1 Reads
		1	DMA direction is Channel 1 Writes

Table 35-19: EMDMA_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
24 (R/NW)	DMAS1	DMA External Interface Status. The EMDMA_CTL.DMAS1 bit provides the DMA channel 1 transfer status.	
		0	Channel 1 DMA does not have any access pending
		1	Channel 1 DMA access are pending
23 (R/NW)	WBS	Write Back Status. The EMDMA_CTL.WBS bit provides the delay line write pointer write back status.	
		0	Write pointer write back is not active
		1	Write pointer write back is active
22 (R/NW)	TLS	TAP List Loading Status. The EMDMA_CTL.TLS bit provides the DMA tap list loading status.	
		0	TAP list loading is not active
		1	TAP list loading is active
21 (R/NW)	CHS	DMA Chaining Status. The EMDMA_CTL.CHS bit provides the DMA chaining status.	
		0	DMA chain loading is not active
		1	DMA chain loading is active
20 (R/NW)	DMAS0	DMA Transfer Status. The EMDMA_CTL.DMAS0 bit provides the DMA channel 0 transfer status.	
		0	DMA idle
		1	DMA in progress
17:16 (R/NW)	DFS	DMA FIFO Status. The EMDMA_CTL.DFS bit field provides the DMA FIFO status.	
		0	FIFO EMPTY
		1	FIFO Partially Full
		2	Reserved
		3	FIFO Full

Table 35-19: EMDMA_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	INTDONE0	Internal DMA Completion Interrupt (Control). The EMDMA_CTL.INTDONE0 bit configures when the DMA complete interrupt is generated. The EMDMA_CTL.INTDONE0 =1 setting is provided for backward compatibility with older SHARC processors.	
		0	Interrupt on access completion (Channel 0 or Channel 1 DMA completion)
		1	Interrupt on Channel 0 DMA completion.
9 (R/W)	TLEN	Tap List DMA Enable. The EMDMA_CTL.TLEN bit enables scatter/gather tap list DMA.	
		0	Disables the tap list based scatter/gather DMA
		1	Enables the tap list based scatter/gather DMA
8 (R/W)	OFCEN	On the Fly Control Loading Enable. The control bits in EMDMA_CHNPTR register are used to describe the next TCB behavior if the EMDMA_CTL.OFCEN bit is set. Therefore, the DMA controls can be changed from TCB to TCB. 0 = disables the control bits in the EMDMA_CHNPTR register. 1 = enables the control bits in the EMDMA_CHNPTR register. If chaining is enabled with EMDMA_CTL.OFCEN bit set, the EMDMA_CTL.TRAN bit has no effect, and direction is determined by the EMDMA_CHNPTR.CPDR bit.	
7 (R/W)	WRBEN	Write Back Enable. The EMDMA_CTL.WRBEN bit enables write back of the EIEP register after reads and or writes. Write back is automatically enabled for delay line DMA. WRBEN is applicable only if chaining is enabled (EMDMA_CTL.CHEN =1).	
5 (R/W)	DFLSH	Flush DMA FIFO. The EMDMA_CTL.DFLSH bit flushes the DMA FIFO. The buffer is only flushed when this bit is set. It can be set with the enable bit. Setting this bit also clears the EMDMA_CTL.DFS bit.	
4 (R/W)	CBEN	Circular Buffering Enable. The EMDMA_CTL.CBEN bit enables circular buffering. Circular buffering can be used with normal DMA as well. If circular buffering is enabled with chaining for normal DMA, then ELEP and EBEP should be part of the TCB.	
		0	Disables circular buffering with delay line DMA
		1	Enables circular buffering with delay line DMA

Table 35-19: EMDMA_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	DLEN	Enable Delay Line DMA. The EMDMA_CTL.DLEN bit enables delay line DMA. This bit is applicable only when the EMDMA_CTL.CHEN bit =1.	
		0	Delay-line DMA disabled
		1	Delay-line DMA enabled
2 (R/W)	CHEN	Enable Chaining. The EMDMA_CTL.CHEN bit enables DMA chaining.	
		0	Chaining disabled
		1	Chaining enabled
1 (R/W)	TRAN	DMA Direction. The EMDMA_CTL.TRAN bit determines the DMA data direction. Note: If the delay line DMA is enabled, this bit does not have any effect. For delay line DMA, transfer direction depends on the state of delay line transfers. For internal-internal or external-external DMA, this bit must be set.	
		0	Write through Channel 0 (Channel 1 reads)
		1	Read from Channel 0(Channel 1 writes)
0 (R/W)	EN	DMA Enable. The EMDMA_CTL.EN bit enables DMA.	
		0	Disable DMA
		1	Enable DMA

Internal Index Register

The EMDMA_INDX0 register contains the start address of the buffer for channel 0 DMA.

Note: For delay line DMA the EMDMA_INDX0 register serves as the delay line write index which is the start address of the channel 0 DMA buffer for the channel 1 write data.

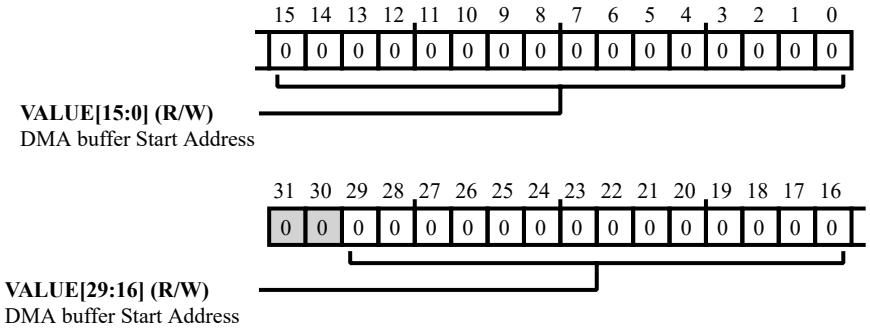

Figure 35-16: EMDMA_INDX0 Register Diagram

Table 35-20: EMDMA_INDX0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:0 (R/W)	VALUE	DMA buffer Start Address. The EMDMA_INDX0.VALUE bit field is written with the 30 MSBs of the word -aligned byte addresses.

External Index Register

The EMDMA_INDX1 register contains the start address of the buffer for channel 1 DMA.

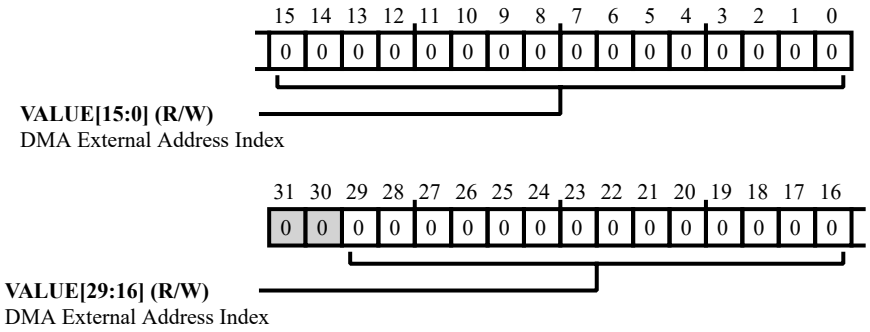

Figure 35-17: EMDMA_INDX1 Register Diagram

Table 35-21: EMDMA_INDX1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:0 (R/W)	VALUE	DMA External Address Index. The EMDMA_INDX1.VALUE bit field is the DMA external address index.

Internal Modifier Register

The EMDMA_MOD0 register contains the channel 0 DMA address modifier.

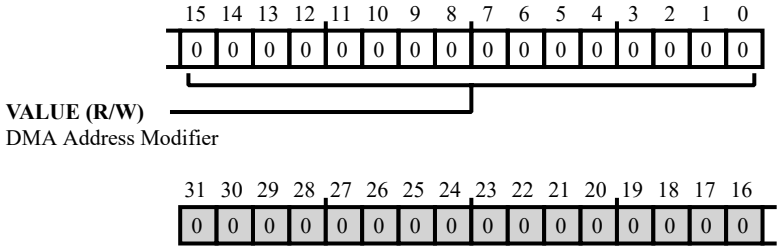

Figure 35-18: EMDMA_MOD0 Register Diagram

Table 35-22: EMDMA_MOD0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	DMA Address Modifier. The EMDMA_MOD0.VALUE bit field is the DMA address modifier.

External Modifier Register

The EMDMA_MOD1 register contains the external (channel 1 DMA) address modifier.

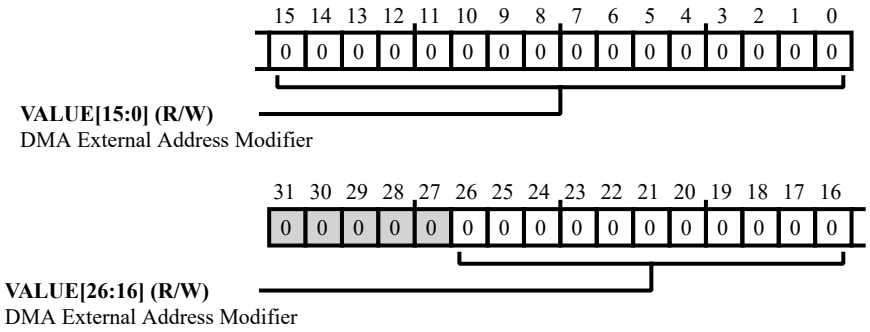

Figure 35-19: EMDMA_MOD1 Register Diagram

Table 35-23: EMDMA_MOD1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
26:0 (R/W)	VALUE	DMA External Address Modifier. The EMDMA_MOD1.VALUE bit field is the DMA external address modifier.

Delay Line Tap Count Register

The EMDMA_TCNT register is the tap count register for delay line DMA. This register holds the length of the tap list (the number of taps). The total number of words read from the delay line is equal to the EMDMA_TCNT (tap count) multiplied by the EMDMA_CNT1 (read block size).

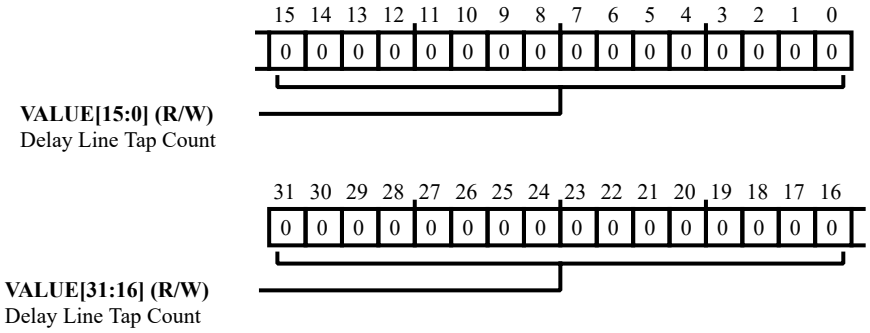

Figure 35-20: EMDMA_TCNT Register Diagram

Table 35-24: EMDMA_TCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Delay Line Tap Count. The EMDMA_TCNT.VALUE bit field is the tap count register for delay line DMA.

Tap List Pointer Register

The EMDMA_TPTR register holds the address of an array in memory which holds offsets to be used when accessing a delay line in system memory. The offset represents the first address of each read block.

Note: the lower 30-bits of this register are to be written with 30 MSBs of the word-aligned byte address of the array.

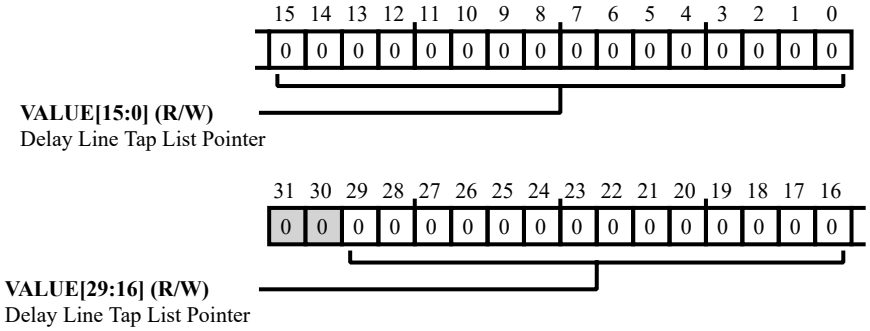

Figure 35-21: EMDMA_TPTR Register Diagram

Table 35-25: EMDMA_TPTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:0 (R/W)	VALUE	Delay Line Tap List Pointer. The EMDMA_TPTR.VALUE bit field contains the offsets to be used when accessing a delay line in system memory.

36 Cyclic Redundancy Check (CRC)

The CRC peripheral performs the cyclic redundancy check (CRC) of the block of data that is presented to the peripheral. The peripheral provides a means to verify periodically the integrity of the system memory, the contents of memory-mapped registers (MMRs), or communication message objects. It is based on a CRC32 engine that computes the signature of 32-bit data presented to the peripheral.

The dedicated hardware compares the calculated signature of the operation to a pre-loaded expected signature. If the two signatures fail to match, the peripheral generates an error.

The source channel of the memory-to-memory DMA channels can provide data. The CRC optionally forwards data to memory through the destination DMA channel. Alternatively, the peripheral supports data presented by any qualified controller of the CRC peripheral bus.

The CRC peripheral implements a reduced table-look-up algorithm to compute the signature of the data. The CRC uses a programmable 32-bit CRC polynomial to generate the look-up table (LUT) contents automatically.

More CRC peripheral modes allow for initializing large memory sections with a constant value, or for verifying that sections of memory are equal to a constant value.

NOTE: CRC is supported by MDMA0, MDMA1, MDMA4, and MDMA5 channels only.

CRC Features

The CRC peripheral supports a number of key features.

- Memory scan modes for memory verification
- Memory transfer modes for on-the-fly CRC calculations while transferring data from one memory to another
- A programmable 32-bit CRC polynomial with automatic LUT generation
- Data mirroring options

The CRC module also includes the following features.

- CRC checksum computation and comparison modes
- 32-bit programmable CRC polynomial with bit reverse option
- Automatic look-up table (LUT) generation

- Data mirroring options for endian and reflected polynomial cases
- Automatic clear and preset of results
- Fault and error interrupt reporting
- DMA and MMR based operation

Because the CRC module is closely tied to memory-to-memory DMA (MDMA) channel pairs, the use cases include the following features.

- Memory scan mode with CRC compute or compare
- Memory transfer mode with CRC compute or compare
- Memory fill operation with 32-bit data patterns
- Memory verify operation
- MMR write access to FIFO of destination DMA
- MMR read access to FIFO of source DMA
- Profiting from advanced DMA features, like descriptor mode and bandwidth control or monitor

CRC Functional Description

The CRC peripheral supports a number of modes of operation that allow for the initialization and verification of regions of memory. The peripheral supports efficient memory-fill and verification operations on regions of memory with or against a constant value. These modes of operation do not require the CRC engine to calculate a signature. Other modes of operation allow for the calculation of CRC signature and verification for a memory region. The modes allow for on-the-fly CRC calculation when performing memory-to-memory DMA transfers from one memory region to another.

To minimize the need for core accesses, the peripheral interfaces with one or more (depending on processor features) memory-to memory DMA (MDMA) channels. This connectivity permits flexible configuration, in which data can be written-to or read-from the peripheral using DMA transactions, core transactions, or a combination of both.

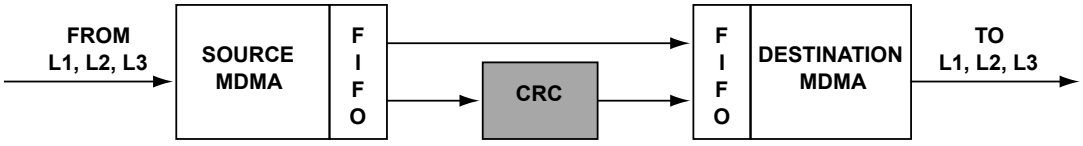

Figure 36-1: Memory Flow

ADSP-2184x CRC Register List

The Cyclic Redundancy Check (CRC) unit includes the data comparison, polynomial operation, and look up table generation features needed for CRC operation. The CRC provides CRC protection as specified by many functional safety requirements. This unit facilitates the system software's ability to periodically check the correctness

of the code/data available in memory. A set of registers govern CRC operations. For more information on CRC functionality, see the CRC register descriptions.

Table 36-1: ADSP-2184x CRC Register List

Name	Description
CRC_COMP	Data Compare Register
CRC_CTL	Control Register
CRC_DCNT	Data Word Count Register
CRC_DCNTCAP	Data Count Capture Register
CRC_DCNTRLD	Data Word Count Reload Register
CRC_DFIFO	Data FIFO Register
CRC_FILLVAL	Fill Value Register
CRC_INEN	Interrupt Enable Register
CRC_INEN_CLR	Interrupt Enable Clear Register
CRC_INEN_SET	Interrupt Enable Set Register
CRC_POLY	Polynomial Register
CRC_RESULT_CUR	CRC Current Result Register
CRC_RESULT_FIN	CRC Final Result Register
CRC_STAT	Status Register

ADSP-2184x CRC Interrupt List

Table 36-2: ADSP-2184x CRC Interrupt List

Interrupt ID	Name	Description	Sensitivity	DMA Channel
34	CRC0_ERR	CRC0 Error	Level	
35	CRC1_ERR	CRC1 Error	Level	
40	CRC0_DCNTEXP	CRC0 Datacount Expiration	Level	
41	CRC1_DCNTEXP	CRC1 Datacount Expiration	Level	
42	CRC2_ERR	CRC2 Error	Level	
43	CRC3_ERR	CRC3 Error	Level	
48	CRC2_DCNTEXP	CRC2 Datacount Expiration	Level	
49	CRC3_DCNTEXP	CRC3 Datacount Expiration	Level	

CRC Definitions

To make the best use of the CRC, it is useful to understand the following terms.

CRC

Acronym for Cyclic Redundancy Check. An error detection code that can detect changes within a block of data.

CRC Polynomial

The 32-bit polynomial used by the CRC engine to generate the look-up table required for the CRC implementation

LUT

Acronym for the Look-up Table. The look-up table is automatically generated from the supplied 32-bit CRC polynomial.

DMA

Acronym for Direct Memory Access. Used to describe a data transfer that takes place through a DMA channel allowing data distribution around a system without intervention from the core.

MDMA

Acronym for Memory-To-Memory DMA transfer that often requires the use of two DMA channels to transfer data from one memory region to another memory region. One DMA channel is configured as a source channel and the second as a destination channel.

CRC Block Diagram

The ***CRC Block Diagram*** shows the functional block diagram of the CRC. The following sections describe the blocks.

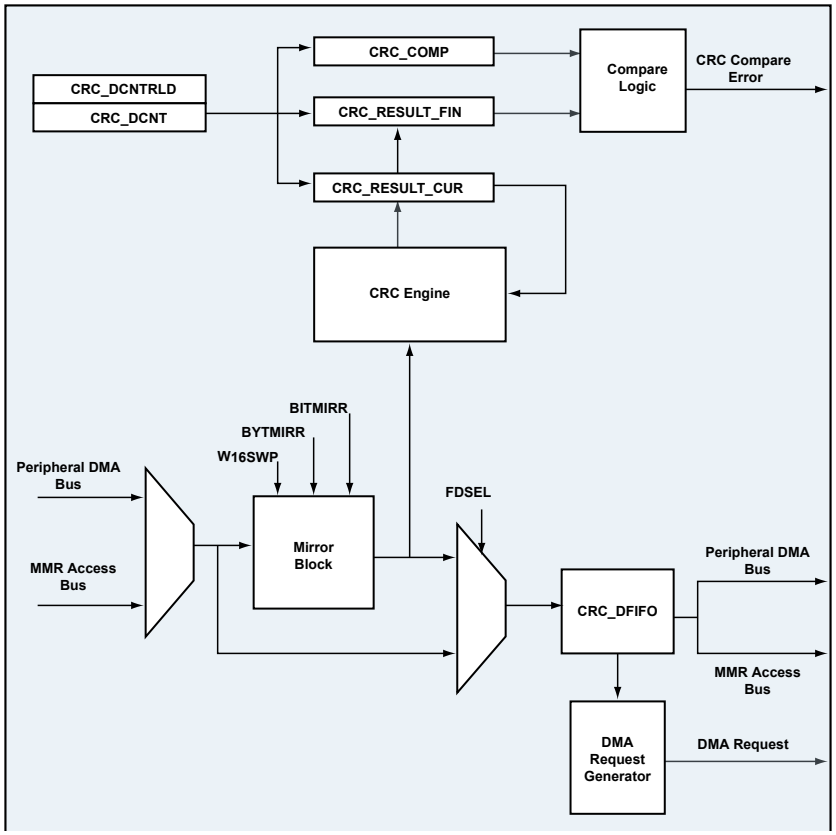

Figure 36-2: CRC Block Diagram

Peripheral DMA Bus

The CRC peripheral provides both an incoming and outgoing datapath to the peripheral DMA bus. The MDMA source channel is interfaced to the incoming datapath providing data to the CRC peripheral. For memory transfer and data fill modes, the CRC uses the MDMA destination channel to either output the data from the CRC FIFO or use the data for the fill operation.

MMR Access Bus

The core uses the MMR access bus to access all the memory-mapped registers of the peripheral for configuration, status, and debug purposes. The core can also use the MMR access bus to feed data to the CRC peripheral or read data from the FIFO of the CRC peripheral. The CRC operation is an alternative to the DMA channel operation to read data from the FIFO.

Data received by MMR writes can transfer to destination DMA. Similarly, data received by source DMA can be output through the MMR interface. Optionally, intermediate results can be made available to the MMR interface.

Mirror Block

The mirror block individually controls bit-reversing of the polynomial, the computation results, and the expected result. Bit mirroring, byte mirroring, word swapping, and any combination of these operations can control endian and the reflection of processed data.

Data FIFO

The CRC data FIFO is a 32-bit-wide 4-entry FIFO. The FIFO is accessible to both the peripheral DMA bus and the MMR access bus. The FIFO status is accessible from the CRC_STAT register.

DMA Request Generator

The DMA request generator is responsible for granting incoming DMA requests from the source DMA channel and issuing outgoing DMA requests to the destination DMA channel.

CRC Engine

The CRC engine is a 32-bit CRC engine that implements the reduced table look-up scheme. The CRC engine provides support for a user-programmable 32-bit polynomial that the CRC uses to load the look-up table parameters required for the CRC calculation. The CRC engine is a single cycle implementation operating on 32 bits of data per cycle.

Compare Logic

The compare logic takes the final CRC signature and compares it to the expected CRC signature, generating a CRC compare error when the signatures do not match. A compare error can flag a system fault.

CRC Architectural Concepts

A 32-bit polynomial is required before calculation of the CRC signature can occur. The CRC uses the polynomial to generate the contents of an internal look-up table that the reduced table look-up implementation requires. The look-up table is automatically generated when the polynomial is written. It must be initialized prior to any operation that requires the use of the CRC engine.

The mirror block logic can manipulate the data presented to the CRC engine before the CRC uses the data in the calculation of the CRC signature. The data mirror operation is configurable to allow for bit reversing, byte reversing, and 16-bit word swapping operations on the incoming data. For memory transfer compute-and-compare operations, programs can configure the peripheral to output the data in the same form in which it was received. Or, the operation can output the mirrored data in the same manner that it is presented to the CRC engine.

While the CRC peripheral is in operation, the status of the FIFO is continually updated and reflected in the CRC_STAT register. The FIFO status is required for core-based accesses to the CRC peripheral. The status indicates when:

- The CRC peripheral can receive data

- Data is available for reading from the FIFO
- The result of the CRC_RESULT_CUR register has been updated

The status of the CRC_RESULT_CUR register indicates that the current CRC calculation has completed and the result is available.

Look-up Table

The look-up table consists of a set of sixteen 32-bit registers that hardware populates automatically when a write access takes place to the CRC_POLY register. 16 clock cycles are required to generate all 16 look-up table entries. The status of the process for generating the look-up table is reflected in CRC_STAT.LUTDONE allowing for software to poll on the completion of the event or for generation of an interrupt.

NOTE: Hardware must populate the look-up table before any operation using the CRC peripheral can take place, even if the operation does not use the CRC engine. The peripheral does not issue any data requests until the table generation process is complete. In addition, the CRC_STAT.IBR field, that indicates the input buffer status as required for core-based transfers, is only valid upon completion of the process for generating the look-up table.

Data Mirroring

The data mirror block can be configured to manipulate the incoming data before the data passes to the CRC engine and, optionally, to the FIFO. This configuration allows the peripheral to handle various forms of endianness and to function with reflected polynomials.

There are three configuration bits that control the data mirroring process: CRC_CTL.BITMIRR, CRC_CTL.BYTMIRR, and CRC_CTL.W16SWP. The ***Data Mirroring Options*** table details how these options affect the incoming data and the output generated by the mirror block.

Table 36-3: Data Mirroring Options

W16SWP	BYTMIRR	BITMIRR	Output Data
0	0	0	Dout[31:0] = Din[31:0]
0	0	1	Dout[31:0] = Din[24:31],Din[16:23],Din[8:15],Din[0:7]
0	1	0	Dout[31:0] = Din[7:0],Din[15:8],Din[23:16],Din[31:24]
0	1	1	Dout[31:0] = Din[0:7],Din[8:15],Din[16:23],Din[24:31]
1	0	0	Dout[31:0] = Din[15:0], D[31:16]
1	0	1	Dout[31:0] = Din[8:15],Din[0:7], Din[24:31],Din[16:23]
1	1	0	Dout[31:0] = Din[23:16],Din[31:24], Din[7:0],Din[15:8]
1	1	1	Dout[31:0] = Din[16:23],Din[24:31], Din[0:7],Din[8:15]

When the CRC is configured to operate in the memory transfer compute-and-compare mode, the bit-reversed output data can be written to the FIFO. This feature is controlled through the CRC_CTL.FDSEL field.

In addition to providing bit swapping and mirror options to the incoming data, the CRC peripheral also supports bit mirroring on the following registers.

- CRC_RESULT_CUR and CRC_RESULT_FIN, controlled through the CRC_CTL.RSLTMIRR field. When mirroring is enabled, the values to be written to these registers are fully bit-reversed before the write operation occurs.
- CRC_POLY, controlled through the CRC_CTL.POLYMIRR field. When mirroring is enabled, the 32-bit polynomial is fully bit-reversed before the write operation to the register occurs.
- CRC_COMP, controlled through the CRC_CTL.CMPMIRR field. When mirroring is enabled, the contents to be loaded to this register are fully bit-reversed before the write operation occurs.

FIFO Status and Data Requests

The CRC peripheral provides indication of the input and output buffer status through CRC_STAT.IBR and CRC_STAT.OBR respectively. For core-based operations, software must monitor these status fields prior to writing to or reading from the CRC FIFO. No write to the CRC FIFO can occur while CRC_STAT.IBR indicates that the buffer is not ready to accept data. Similarly, the CRC FIFO cannot be read until CRC_STAT.OBR indicates that data is available.

The memory scan modes of operation only require the monitoring of the input buffer status. The memory transfer, compute-and-compare mode uses both input and output buffer status. If the current result of the CRC computation is required, then software must verify that the current operation has completed and that the intermediate result is ready. The CRC_STAT.IRR indicates the status.

NOTE: The memory transfer fill mode of operation requires the use of a DMA channel. The CRC does not support core reads from the CRC FIFO for this mode of operation.

Memory transfer, compute-and-compare mode uses burst transactions to make the most efficient use of the available resources. In this mode, when the FIFO is initially empty and the peripheral is enabled, the CRC_STAT.IBR bit indicates that the CRC is ready to accept data. The peripheral generates data requests to the source DMA channel (if the CRC uses DMA). While the number of words remaining in the CRC_DCNT register is greater than the FIFO depth, the peripheral issues data requests or accepts incoming data in bursts. The peripheral continues until the CRC FIFO becomes full.

Once full, the CRC_STAT.IBR and CRC_STAT.OBR bits are updated, and then the CRC issues outgoing data requests. Only when the FIFO is empty can the peripheral accept further incoming data, and the CRC_STAT.IBR and CRC_STAT.OBR bits are updated once again.

Once CRC_DCNT is decremented such that the number of words waiting for processing is less than the number required to fill the FIFO, the burst mode of operation is disabled. Incoming data is accepted when the FIFO is not full. Outgoing data is available when the FIFO is not empty. Therefore, there are no restrictions requiring the word count to be a multiple of the FIFO depth.

All other CRC modes of operation indicate that incoming data can be accepted when the FIFO is not full. Outgoing data is available when the FIFO is not empty.

The CRC_CTL.OBRSTALL and CRC_CTL.IRRSTALL bit configurations also influence how the CRC generates data requests and status bits. The following list describes the bits.

- The CRC_CTL.OBRSTALL bit can be configured such that the CRC peripheral stalls as soon as there is output data available in the FIFO. Use this mode of operation only in memory transfer, compute-and-compare mode. This mode results in the processing of one 32-bit word at a time. The peripheral does not request or accept incoming data until the current value being processed is read from the peripheral.
- The CRC_CTL.IRRSTALL bit can be configured so that the CRC peripheral stalls all further incoming data requests until the CRC_RESULT_CUR register is read after being updated. Use this mode of operation for CRC signature generation. It is not applicable to memory transfer data-fill mode or memory scan data-verify mode of operation.

CRC Operating Modes

The following sections describe the various operating modes of the CRC interface.

Data Transfer Modes

The CRC peripheral supports two main categories of operation involving data transfers:

- Memory scan mode
- Memory transfer mode

Memory scan modes are read-only operations that allow the contents of memory to be read into the peripheral and verified for correctness. There are two forms of memory scan mode:

- CRC compute-and-compare performs a CRC calculation on data presented to the peripheral and compares the CRC result with a pre-determined and pre-loaded result. An error is generated when the results differ.
- Data verify compares each 32-bit data word presented to the CRC peripheral to a pre-loaded 32-bit value and generates an error when the data differs.

Both modes of operation require at the most, a single DMA channel to read the data from memory into the peripheral. No data is forwarded to the data output or destination DMA. The CRC can also use core-driven transfers for either of these modes of operation.

The memory transfer modes involve memory write or memory read-and-write operations allowing for memory to be initialized or transferred from one region of memory to another. There are two forms of memory transfer mode:

- CRC compute-and-compare performs a full data transfer from one memory region to another memory region. The CRC generates a signature on the data presented and compares it with a pre-determined and pre-loaded result. An error is generated when the results differ.
- Data fill initializes a region of memory with a pre-loaded 32-bit constant value.

The CRC compute-and-compare mode of operation requires both incoming and outgoing data channels. The operation occurs either using DMA channels, using core-driven write or read operations to and from the FIFO

or using a combination of both. The data fill mode of operation requires only a memory write DMA destination channel—this mode does not support core driven operations.

Memory Scan Compute-and-Compare Mode

In this mode of operation, the CRC engine of the peripheral is enabled. The mode is configured through the CRC_CTL.OPMODE field and the CRC engine performs a 32-bit CRC operation on the incoming data stream.

The length of the data stream is configured through the CRC_DCNT register. The accumulated result of the CRC operation is contained in the CRC_RESULT_CUR register. As the CRC engine processes each 32-bit word, the CRC_DCNT register is decremented and CRC_RESULT_CUR is updated.

Once CRC_DCNT decrements to zero, the contents of the CRC_RESULT_CUR register are copied to CRC_RESULT_FIN and CRC_STAT.DCNTEXP is updated accordingly. The CRC uses the CRC_COMP register to store the expected result of the operation. After the CRC calculation, CRC_COMP is compared with CRC_RESULT_FIN and CRC_STAT.CMPERR is updated to reflect the status of the compare operation. CRC_STAT.CMPERR must be cleared before the next CRC operation is performed.

The CRC peripheral also contains the CRC_DCNTRLD register. The CRC uses this register to reload CRC_DCNT upon completion of the CRC operation in preparation for the next transfer.

The initial seed of the CRC computation can be configured through CRC_CTL.AUTOCLRZ and CRC_CTL.AUTOCLRF. This configuration provides a way to reset CRC_RESULT_CUR to 0x00000000, 0xFFFFFFFF or to leave the current register contents untouched for the next operation.

The peripheral can be configured to allow for the compare error and data expiration events to generate an interrupt.

Memory Scan Data Verify

In this mode of operation, the CRC engine of the peripheral is not required. The mode is enabled through the CRC_CTL.OPMODE field. Each 32-bit word of the data stream is compared with a constant value that is stored in the CRC_COMP register. The CRC_DCNT register contains the number of words for comparison. The CRC_DCNT register is decremented upon receiving a new 32-bit word from the data stream. If the compare operation fails, the CRC_STAT.CMPERR bit is updated and the contents of CRC_DCNT are captured in the CRC_DCNTCAP register. This information can be used to identify the location in the data stream where the error occurred. Clear the CRC_STAT.CMPERR field to re-enable capturing of further errors.

Once CRC_DCNT decrements to zero, CRC_STAT.DCNTEXP is updated accordingly to signal the end of the operation. The peripheral can be configured to allow for the compare error and data expiration events to generate an interrupt.

Memory Transfer Compute-and-Compare Mode

In this mode of operation, the CRC engine of the peripheral is enabled. The mode is configured through the CRC_CTL.OPMODE field and the CRC engine performs a 32-bit CRC operation on the incoming data stream.

The length of the data stream is configured through the CRC_DCNT register. The accumulated result of the CRC operation is contained in the CRC_RESULT_CUR register. As the CRC engine processes each 32-bit word, the CRC_DCNT register is decremented and CRC_RESULT_CUR is updated.

Once CRC_DCNT decrements to zero, the contents of the CRC_RESULT_CUR register are copied to CRC_RESULT_FIN and CRC_STAT.DCNTEXP is updated accordingly. The CRC uses the CRC_COMP register to store the expected result of the operation. Upon completion of the CRC calculation, CRC_COMP is compared with CRC_RESULT_FIN and CRC_STAT.CMPERR is updated to reflect the status of the compare operation. Clear CRC_STAT.CMPERR before the next CRC operation is performed.

The CRC peripheral also contains CRC_DCNTRLD register. The CRC uses this register to reload CRC_DCNT upon completion of the CRC operation in preparation for the next transfer.

The initial seed of the CRC computation can be configured through CRC_CTL.AUTOCLRZ and CRC_CTL.AUTOCLRF. This configuration provides a means to reset CRC_RESULT_CUR to 0x00000000, 0xFFFFFFFF or to leave the current register contents untouched for the next operation.

The peripheral can be configured to allow for the compare error and data expiration events to generate an interrupt.

Memory Transfer Data Fill Mode

In this mode of operation, the CRC engine of the peripheral is not required. The mode is enabled through the CRC_CTL.OPMODE field. The CRC_FILLVAL register is written with a 32-bit value. The CRC uses this value to initialize a block memory through the memory-to-memory DMA destination channel. When the CRC peripheral and the DMA destination channel are enabled, the contents of the CRC_FILLVAL register is written to the DMA channel to initialize the memory region. The CRC_DCNT register contains the number of words for the write operation.

Once CRC_DCNT decrements to zero, CRC_STAT.DCNTEXP is updated accordingly to signal the end of the operation. The peripheral can be configured to allow for the data expiration event to generate an interrupt.

CRC Event Control

The CRC peripheral can enable certain CRC status operations to generate an interrupt event to the system event controller. There, a CRC error can be qualified as a system fault.

Interrupt Signals

The CRC peripheral can generate two interrupt requests that are enabled as events to SEC1 for fault operations. One is a CRC status interrupt and the other is a CRC error interrupt.

The CRC_STAT.CMPERR status bit can be configured as an interrupt and is signaled through the CRC error interrupt signal. The CRC_STAT.CMPERR status field is set whenever the CRC peripheral performs a compare operation that fails. This status can be the result of a failed memory scan data-verify operation that compares the contents of a memory range with a constant 32-bit value. Or, it can be the result of a CRC signature calculated for a memory region that does not match the expected pre-programmed result for a memory-compare operation.

The CRC_STAT.DCNTEXP status bit is set when the CRC_DCNT register has decremented to zero. The status indicates that the CRC peripheral has now processed all the data requested for the current CRC operation. The CRC can also use this signal to generate an interrupt. The interrupt is signaled on the CRC status interrupt signal.

Both these status bits can be configured to generate and interrupt through the CRC_INEN register. The CRC_INEN register also has bit set, CRC_INEN_SET, and bit clear CRC_INEN_CLR equivalent registers that the CRC uses for the enabling and disabling of these interrupt sources.

The CRC_STAT register has two write one to clear (W1C) fields for clearing the two interrupt sources.

NOTE: Disabling the CRC peripheral through the CRC_CTL.BLKEN bit does not result in the clearing of interrupt sources. Clear the interrupt sources using a W1C operation to the CRC_STAT register.

CRC Programming Model

It is important to note the following restrictions when using the CRC peripheral with the DMA channels:

1. When enabling the CRC peripheral and the DMA channels, enable the CRC peripheral prior to enabling the DMA channels.
2. When disabling the CRC peripheral and the DMA channels, disable the DMA channels prior to disabling the CRC peripheral.

CRC Mode Configuration

Describes a number of tasks showing the various operation modes of the CRC peripheral.

- Look-up Table Generation
- Core Driven Memory Scan Compute-and-Compare Mode
- DMA Driven Memory Scan Compute-and-Compare Mode
- Core Driven Memory Scan Data Verify Mode
- DMA Driven Memory Scan Data Verify Mode
- Core Driven Memory Transfer Compute-and-Compare Mode
- DMA Driven Memory Transfer Compute-and-Compare Mode
- DMA Driven Memory Transfer Data Fill Mode

Look-up Table Generation

Describes the steps required to initialize the CRC peripheral LUT.

1. Write the 32-bit CRC polynomial of choice to the CRC_POLY register.

   ADDITIONAL INFORMATION: This operation results in the CRC peripheral starting the LUT initialization process. The CRC_STAT.LUTDONE bit is updated to reflect the operation is in progress.

2. Poll the CRC_STAT.LUTDONE bit until the status bit indicates that the operation is completed.

The CRC peripheral has completed initialization of all the LUT registers and is now ready for data operations. The CRC_STAT.LUTDONE bit remains in the current state until the CRC_POLY register is written again, or the peripheral or processor are reset.

Core Driven Memory Scan Compute-and-Compare Mode

Performs CRC signature calculation and verification for a region of memory using core transactions. The CRC peripheral is configured such that it operates in burst mode due to the stalling options configured through disabling the CRC_CTL register.

The task assumes the following:

- The polynomial has been loaded and the look-up table is fully initialized
- All CRC interrupts have been serviced (none pending)
- The CRC block is disabled per CRC_CTL.BLKEN

1. Initialize the CRC_DCNT register.

   ADDITIONAL INFORMATION: The value loaded must represent the number of 32-bit words in the memory region for which the software calculates and verifies the signature.

2. Initialize the CRC_DCNTRLD register.

   ADDITIONAL INFORMATION: This value is used to reload the CRC_DCNT register upon completion of current CRC operation. If no further operation is needed, then this register can be initialized to zero.

3. Initialize the CRC_RESULT_CUR register.

   ADDITIONAL INFORMATION: This register can be initialized to provide an initial seed for the CRC operation that is about to take place.

4. Initialize the CRC_COMP register.

   ADDITIONAL INFORMATION: This register contains the pre-calculated final CRC signature result for the memory region that the software uses in the final compare operation.

5. Initialize the CRC_INEN register.

   ADDITIONAL INFORMATION: The CRC uses this register to enable the generation of the CRC interrupts for notification of compare errors and block completion. Configure these interrupts. If enabled, ensure that the corresponding interrupt handlers are also configured.

6. Initialize CRC_CTL register with the CRC_CTL.OPMODE bit set to memory scan compute-and-compare mode and the CRC_CTL.BLKEN bit configured to enable the CRC peripheral.
   - Disable the CRC_CTL.OBRSTALL and CRC_CTL.IRRSTALL bit options for this task example.
   - Configure all mirroring and bit reversal options.

- Configure CRC auto-clear options.

The CRC peripheral is now enabled and ready for the core or DMA channel to write data.

7. Write memory region data to the CRC peripheral.
   a. While CRC_STAT.IBR bit indicates that the input buffer is ready, write the CRC_DFIFO register with 32-bit data.

      ADDITIONAL INFORMATION: Repeat this step until all data has been written.
8. Poll the CRC_STAT.DCNTEXP bit if the interrupt was disabled.

   ADDITIONAL INFORMATION: Perform this step only if counter expired interrupt is disabled. Polling ensures that all the data has been processed.
9. Poll the CRC_STAT.CMPERR bit if the interrupt was disabled to check for a compare error.

   ADDITIONAL INFORMATION: Perform this step only if the compare error interrupt is not enabled.
10. Write to the CRC_STAT register to clear both the CRC_STAT.DCNTEXP and CRC_STAT.CMPERR bits.

    ADDITIONAL INFORMATION: If interrupts were enabled, then clear of these status bits within the interrupt handlers for the respective interrupts.

    The CRC compute-and-compare operation is now complete. The CRC peripheral is ready to be configured for the next CRC operation.

The integrity check of the memory through the expected CRC signature has completed. The final result is indicated through the CRC_STAT.CMPERR bit and the corresponding interrupt when enabled.

Clear any W1C CRC status bits before performing more CRC operations.

DMA Driven Memory Scan Compute-and-Compare Mode

Performs CRC signature calculation and verification for a region of memory using DMA transactions. The CRC peripheral is configured such that it operates in the burst mode of operation due to the stalling options configured through disabling CRC_CTL.

The task assumes the following:

- The polynomial has been loaded and the look-up table is fully initialized
- All CRC interrupts have been serviced (none pending)
- The CRC block is disabled per the CRC_CTL.BLKEN bit.

1. Initialize the CRC_DCNT register.

   ADDITIONAL INFORMATION: The value loaded must represent the number of 32-bit words in the memory region for which the software calculates and verifies the signature.

2. Initialize the CRC_DCNTRLD register.

   ADDITIONAL INFORMATION: This value is used to reload the CRC_DCNT register upon completion of current operation. If no further operation is needed, then this register can be initialized to zero.

3. Initialize the CRC_RESULT_CUR register.

   ADDITIONAL INFORMATION: This register can be initialized to provide an initial seed for the CRC operation that is about to take place.

4. Initialize the CRC_COMP register.

   ADDITIONAL INFORMATION: This register contains the pre-calculated final CRC signature result for the memory region that the software uses in the final operation.

5. Initialize the CRC_INEN register.

   ADDITIONAL INFORMATION: The CRC module uses this register to enable the generation of the CRC interrupts for notification of compare errors and block completion. Configure these interrupts, as needed. If enabled, ensure that the corresponding interrupt handlers are also configured.

6. Initialize the CRC_CTL register with the CRC_CTL.OPMODE bit set to memory scan compute compare mode and the CRC_CTL.BLKEN bit configured to enable the CRC peripheral.

   - Disable the CRC_CTL.OBRSTALL and CRC_CTL.IRRSTALL bit options for this task example.
   - Configure all mirroring and bit reversal options.
   - Configure all CRC auto clear options.

   The CRC peripheral is now enabled and ready for the core or DMA channel to write data.

7. Configure and enable the memory-to-memory source DMA channel for memory read STOP mode.

   ADDITIONAL INFORMATION: This step starts the data transfer from the memory region and writes the data to the CRC peripheral.

8. Poll the CRC_STAT.DCNTEXP bit if the interrupt was disabled.

   ADDITIONAL INFORMATION: Perform this step only if the counter expired interrupt is disabled. Polling ensures all the data has been processed.

9. Poll the CRC_STAT.CMPERR bit if the interrupt was disabled to check for a compare error.

   ADDITIONAL INFORMATION: Perform this step only if the compare error interrupt is not enabled.

10. Write the CRC_STAT register to clear both the CRC_STAT.DCNTEXP and CRC_STAT.CMPERR bits.

    ADDITIONAL INFORMATION: If interrupts were enabled, then clear these status bits within the interrupt handlers for the respective interrupts.

    The CRC compute-and-compare operation is now complete. The CRC peripheral is ready to be configured for the next CRC operation.

The integrity check of the memory through the expected CRC signature has completed and the final result indicated is through CRC_STAT.CMPERR and the corresponding interrupt, when enabled.

Clear any W1C CRC status bits before performing a further CRC operation. Clear any W1C status bits of the memory-to-memory source DMA channel before the next CRC operation.

Core Driven Memory Scan Data Verify Mode

Reads a region of memory using core transactions and performs a compare operation on each 32-bit word against a single pre-loaded 32-bit constant. The compare error interrupt is enabled to capture and log the location of any compare errors.

The task assumes the following:

- The polynomial has been loaded and the look-up table is fully initialized
- All CRC interrupts have been serviced (none pending)
- The CRC block is disabled per CRC_CTL.BLKEN

The interrupt service routine for the compare error interrupt reads and stores the contents of CRC_DCNTCAP register to a buffer before clearing the compare error interrupt.

1. Initialize the CRC_DCNT register.

   ADDITIONAL INFORMATION: The value loaded must represent the number of 32-bit words in the memory region for which the software calculates and verifies the signature.

2. Initialize the CRC_DCNTRLD register.

   ADDITIONAL INFORMATION: This value is used to reload the CRC_DCNT register upon completion of current CRC operation. If no further operation is needed, then this register can be initialized to zero.

3. Initialize the CRC_COMP register.

   ADDITIONAL INFORMATION: This register contains the 32-bit constant that the memory region is expected to be filled with. Each 32 bit of data presented to the peripheral is compared with this value.

4. Initialize the CRC_INEN register.

   ADDITIONAL INFORMATION: The CRC module uses this register to enable the generation of the CRC interrupts for notification of compare errors and block completion. Configure these interrupts. If enabled, ensure that the corresponding interrupt handlers are also configured.

5. Initialize the CRC_CTL register with the CRC_CTL.OPMODE bit set to memory scan data verify mode and the CRC_CTL.BLKEN bit configured to enable the CRC peripheral.

   The CRC peripheral is now enabled and ready for the core or DMA channel to write data.

6. Write memory region data to the CRC peripheral.

a. Poll the CRC_STAT.IBR bit until input buffer is ready.

b. Write the CRC_DFIFO register with 32-bit data.

ADDITIONAL INFORMATION: Repeat these two steps until the entire memory region has been written to the CRC peripheral.

7. Poll the CRC_INEN_SET.DCNTEXP bit if the interrupt was disabled.

   ADDITIONAL INFORMATION: Perform this step only if counter expired interrupt is disabled. Polling ensures all the data has been processed.

8. Check if the buffer used to capture the CRC_DCNTCAP register upon a compare error has any new entries.

   ADDITIONAL INFORMATION: The values captures in the buffer provide a means to locate where in the memory region the failures occurred.

9. Write to the CRC_STAT to clear both the CRC_INEN_SET.DCNTEXP and CRC_INEN.CMPERR bits.

   ADDITIONAL INFORMATION: If interrupts were enabled, the clear these status bits within the interrupt handlers for the respective interrupts.

   The CRC memory scan-verify operation is now complete. The CRC peripheral is ready to be configured for the next CRC operation.

The result of the integrity check of the memory with the 32-bit constant is indicated through the CRC_INEN.CMPERR bit and the corresponding interrupt, when enabled. Each comparison error is traceable due to the logging of CRC_DCNTCAP from within the compare error interrupt handler.

Clear any W1C CRC status bits before performing a further CRC operation.

DMA Driven Memory Scan Data Verify Mode

The memory scan data verify mode reads a region of memory using DMA transactions and performs a compare operation on each 32-bit word against a single pre-loaded 32-bit constant. The compare error interrupt is enabled to capture and log the location of any compare errors.

The task assumes the following:

- The polynomial has been loaded and the look-up table is fully initialized
- All CRC interrupts have been serviced (none pending)
- The CRC block is disabled per the CRC_CTL.BLKEN bit

The interrupt service routine for the compare error interrupt reads and stores the contents of the CRC_DCNTCAP register to a buffer before clearing the compare error interrupt.

1. Initialize the CRC_DCNT register.

ADDITIONAL INFORMATION: The value loaded must represent the number of 32-bit words in the memory region for which the software calculates and verifies the signature.

2. Initialize the CRC_DCNTRLD register.

   ADDITIONAL INFORMATION: The CRC module uses this register to reload the CRC_DCNT register upon completion of current CRC operation. If no further operation is needed, then this register can be initialized to zero.

3. Initialize the CRC_COMP register.

   ADDITIONAL INFORMATION: This register contains the 32-bit constant that the memory region is expected to be filled with. Each 32 bit of data presented to the peripheral is compared with this value.

4. Initialize the CRC_INEN register.

   ADDITIONAL INFORMATION: The CRC module uses this register to enable the generation of the CRC interrupts for notification of compare errors and block completion. Configure these interrupts, as needed. If enabled, ensure that the corresponding interrupt handlers are also configured.

5. Initialize the CRC_CTL register with the CRC_CTL.OPMODE bit set to memory scan data verify mode and CRC_CTL.BLKEN configured to enable the CRC peripheral.

   The CRC peripheral is now enabled and ready for the core or DMA channel to write the data.

6. Configure and enable the memory-to-memory source DMA channel for memory read STOP mode.

   ADDITIONAL INFORMATION: This step starts the data transfer from the memory region and writes the data to the CRC peripheral.

7. Poll the CRC_STAT.DCNTEXP bit if the interrupt was disabled.

   ADDITIONAL INFORMATION: Perform this step only if counter expired interrupt is disabled. Polling ensures all the data has been processed.

8. Check if the buffer used to capture the CRC_DCNTCAP register upon a compare error has any new entries.

   ADDITIONAL INFORMATION: The values captures in the buffer provide a means to locate where in the memory region the failures occurred.

9. Write the CRC_STAT register to clear both the CRC_STAT.DCNTEXP and CRC_STAT.CMPERR bits.

   ADDITIONAL INFORMATION: If interrupts were enabled, then clear these status bits within the interrupt handlers for the respective interrupts.

   The CRC memory scan-verify operation is now complete. The CRC peripheral is ready to be configured for the next CRC operation.

The result of the integrity check of the memory with the 32-bit constant is indicated through the CRC_STAT.CMPERR bit and the corresponding interrupt when enabled. Each comparison error is traceable due to the logging of the CRC_DCNTCAP register from within the compare error interrupt handler.

Clear any W1C CRC status bits and DMA status bits before performing a further CRC operation.

Core Driven Memory Transfer Compute-and-Compare Mode

The memory transfer compute-and-compare mode performs CRC signature calculation and verification for a region of memory using core transactions while copying the contents to another memory region. The CRC peripheral is configured such that it operates in the burst mode of operation due to the stalling options configured through disabling the CRC_CTL register.

The task assumes the following:

- The polynomial has been loaded and the look-up table is fully initialized
- All CRC interrupts have been serviced (none pending)
- The CRC block is disabled per the CRC_CTL.BLKEN bit

1. Initialize the CRC_DCNT register.

   ADDITIONAL INFORMATION: The value loaded must represent the number of 32-bit words in the memory region for which the software calculates and verifies the signature.

2. Initialize the CRC_DCNTRLD register.

   ADDITIONAL INFORMATION: This value is used to reload the CRC_DCNT register upon completion of the current CRC operation. If no further operation is needed, then this register can be initialized to zero.

3. Initialize the CRC_RESULT_CUR register.

   ADDITIONAL INFORMATION: This register can be initialized to provide an initial seed for the CRC operation that is about to take place.

4. Initialize the CRC_COMP register.

   ADDITIONAL INFORMATION: This register contains the pre-calculated final CRC signature result for the memory region that the software uses in the final compare operation.

5. Initialize the CRC_INEN register.

   ADDITIONAL INFORMATION: The CRC module uses this register to enable the generation of the CRC interrupts for notification of compare errors and block completion. Configure these interrupts, as needed. If enabled, ensure that the corresponding interrupt handlers are also configured.

6. Initialize the CRC_CTL register with the CRC_CTL.OPMODE bit set to memory scan compute-and-compare mode and the CRC_CTL.BLKEN bit configured to enable the CRC peripheral.

   a. Disable the CRC_CTL.OBRSTALL bit and the CRC_CTL.IRRSTALL bit options for this task example.

   b. Configure all mirroring and bit reversal options.

c. Configure CRC auto clear options

The CRC peripheral is now enabled and ready for the core or DMA channel to write data.

7. Write memory region data to the CRC peripheral and read it back to the new destination.
   a. While the CRC_STAT.IBR bit indicates that the input buffer is ready, write the CRC_DFIFO register with 32-bit data.
   b. While the CRC_STAT.OBR bit indicates that the output buffer is ready, read the CRC_DFIFO register and store data to new destination.

      ADDITIONAL INFORMATION: Repeat these two steps until all required data has been processed through the CRC peripheral and copied to the new destination.
8. Poll the CRC_STAT.DCNTEXP bit if the interrupt was disabled.

   ADDITIONAL INFORMATION: Perform this step only if the counter expired interrupt is disabled. Polling ensures all the data has been processed.
9. Poll the CRC_STAT.CMPERR bit if the interrupt was disabled to check for a compare error.

   ADDITIONAL INFORMATION: Perform this step only if the compare error interrupt is not enabled.
10. Write the CRC_STAT register to clear both CRC_STAT.DCNTEXP and CRC_STAT.CMPERR bits.

    ADDITIONAL INFORMATION: If interrupts were enabled, then clear these status bits within the interrupt handlers for the respective interrupts.

    The CRC compute-and-compare operation is now complete. The CRC peripheral is ready to be configured for the next CRC operation. The memory region has also been copied to its new destination.

The memory region has been copied to a new location and an integrity check of the memory through the expected CRC signature has also completed. The final result is indicated through the CRC_STAT.CMPERR bit and the corresponding interrupt when enabled.

Clear any W1C CRC status bits before performing a further CRC operation.

DMA Driven Memory Transfer Compute-and-Compare Mode

The memory transfer compute-and-compare mode performs CRC signature calculation and verification for a region of memory using DMA transactions. The memory region is also copied to another memory region using memory-to-memory DMA transfers. The CRC peripheral is configured such that it operates in burst mode due to the stalling options configured through disabling CRC_CTL.

The task assumes the following:

- The polynomial has been loaded and the look-up table is fully initialized
- All CRC interrupts have been serviced (none pending)

- The CRC block is disabled per the CRC_CTL.BLKEN register.

1. Initialize the CRC_DCNT register.

   ADDITIONAL INFORMATION: The value loaded must represent the number of 32-bit words in the memory region for which the software calculates and verifies the signature.

2. Initialize the CRC_DCNTRLD register.

   ADDITIONAL INFORMATION: This value is used to reload the CRC_DCNT register upon completion of current CRC operation. If no further operation is needed, then this register can be initialized to zero.

3. Initialize the CRC_RESULT_CUR register.

   ADDITIONAL INFORMATION: This register can be initialized to provide an initial seed for the CRC operation that is about to take place.

4. Initialize the CRC_COMP register.

   ADDITIONAL INFORMATION: This register contains the pre-calculated final CRC signature result for the memory region that the software uses in the final compare operation.

5. Initialize the CRC_INEN register.

   ADDITIONAL INFORMATION: The CRC module uses this register to enable the generation of the CRC interrupts for notification of compare errors and block completion. Configure these interrupts, as needed. If enabled, ensure that the corresponding interrupt handlers are also configured.

6. Initialize the CRC_CTL register with the CRC_CTL.OPMODE bit set to memory scan compute compare mode and CRC_CTL.BLKEN configured to enable the CRC peripheral.

   a. Disable the CRC_CTL.OBRSTALL and the CRC_CTL.IRRSTALL bit options for this task example.

   b. Configure all mirroring and bit reversal options

   c. Configure CRC auto clear options

   The CRC peripheral is now enabled and ready for the core or DMA channel to write data.

7. Configure and enable the memory-to-memory source DMA channel for memory read STOP mode and destination DMA channel for memory write STOP mode.

   ADDITIONAL INFORMATION: This step starts the data transfer from one memory region to another through the memory-to-memory DMA channels and the CRC peripheral.

8. Poll the CRC_STAT.DCNTEXP bit if the interrupt was disabled.

   ADDITIONAL INFORMATION: Perform this step only if counter expired interrupt is disabled. Polling ensures all the data has been processed.

9. Poll the CRC_STAT.CMPERR bit if the interrupt was disabled to check for a compare error.

ADDITIONAL INFORMATION: Perform this step only if the compare error interrupt is not enabled.

10. Write the CRC_STAT register to clear both the CRC_STAT.DCNTEXP and the CRC_STAT.CMPERR bits.

    ADDITIONAL INFORMATION: If interrupts were enabled, then clear these status bits within the interrupt handlers for the respective interrupts.

    The CRC compute-and-compare operation is now complete. The CRC peripheral is ready to be configured for the next CRC operation. The memory region has also been copied to its new destination.

The integrity check of the memory through the expected CRC signature has completed and the final result is indicated through the CRC_STAT.CMPERR bit and the corresponding interrupt when enabled. The memory region has also been copied to its final destination.

Clear any W1C CRC status bits before performing a further CRC operation. Also, clear any W1C status bits of the memory-to-memory source and destination DMA channels before the next CRC operation.

DMA Driven Memory Transfer Data Fill Mode

This mode initializes a region of memory to a constant 32-bit value using DMA transactions.

The task assumes the following:

- The polynomial has been loaded and the look-up table is fully initialized
- All CRC interrupts have been serviced (none pending)
- The CRC block is disabled per the CRC_CTL.BLKEN bit

1. Initialize the CRC_DCNT register.

   ADDITIONAL INFORMATION: The value loaded must represent the number of 32-bit words in the memory region for which the software calculates and verifies the signature.

2. Initialize the CRC_DCNTRLD register.

   ADDITIONAL INFORMATION: This value is used to reload the CRC_DCNT register upon completion of current CRC operation. If no further operation is needed, then this register can be initialized to zero.

3. Initialize the CRC_FILLVAL register.

   ADDITIONAL INFORMATION: This register contains the 32-bit constant that the CRC module uses to fill the memory region.

4. Initialize the CRC_INEN register.

   ADDITIONAL INFORMATION: The CRC module uses this register to enable the generation of the CRC interrupts for notification of block completion. Configure these interrupts as required. If enabled, ensure that the corresponding interrupt handlers are also configured.

5. Initialize the CRC_CTL register with the CRC_CTL.OPMODE bit set to memory transfer fill mode and the CRC_CTL.BLKEN bit configured to enable the CRC peripheral.

   The CRC peripheral is now enabled and is ready for the DMA channel to write data.

6. Configure and enable the memory-to-memory destination DMA channel for memory write STOP mode.

   ADDITIONAL INFORMATION: This step starts the data transfer taking the constant 32-bit value from the CRC peripheral and writing the data to the DMA channel.

7. Poll the CRC_STAT.DCNTEXP bit if the interrupt was disabled.

   ADDITIONAL INFORMATION: Perform this step only if counter expired interrupt is disabled. Polling ensures that all the data has been processed.

8. Write the CRC_STAT register to clear the CRC_STAT.DCNTEXP bit.

   ADDITIONAL INFORMATION: If interrupts were enabled, then clear this status bit within the interrupt handlers for the respective interrupts.

   The CRC memory transfer fill operation is complete, and the CRC peripheral is ready to be configured for the next CRC operation.

The memory region is filled with the constant data and the CRC peripheral is ready to be configured for a new operation.

Clear any W1C CRC status bits and DMA status bits before performing a further CRC operation.

ADSP-2184x CRC Register Descriptions

Cyclic Redundancy Check Unit (CRC) contains the following registers.

Table 36-4: ADSP-2184x CRC Register List

Name	Description
CRC_COMP	Data Compare Register
CRC_CTL	Control Register
CRC_DCNT	Data Word Count Register
CRC_DCNTCAP	Data Count Capture Register
CRC_DCNTRLD	Data Word Count Reload Register
CRC_DFIFO	Data FIFO Register
CRC_FILLVAL	Fill Value Register
CRC_INEN	Interrupt Enable Register
CRC_INEN_CLR	Interrupt Enable Clear Register
CRC_INEN_SET	Interrupt Enable Set Register

Table 36-4: ADSP-2184x CRC Register List (Continued)

Name	Description
CRC_POLY	Polynomial Register
CRC_RESULT_CUR	CRC Current Result Register
CRC_RESULT_FIN	CRC Final Result Register
CRC_STAT	Status Register

Data Compare Register

The CRC_COMP register contains the value corresponding to the expected CRC result or signature for the current data stream. At the end of the operation, the content of this register is used to compare against the result produced by the CRC operation. In data verify mode, each incoming data value is compared with the content of this register.

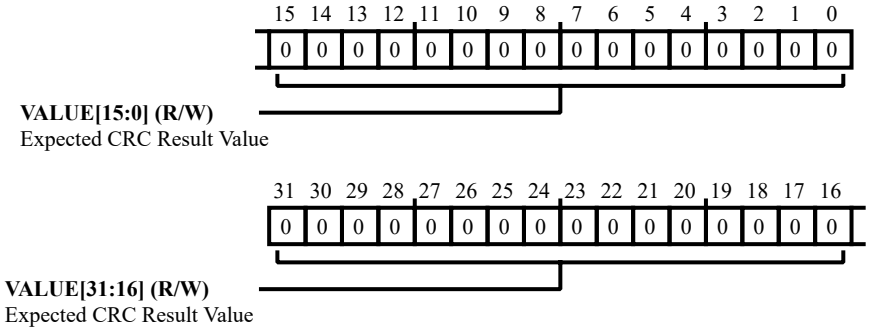

Figure 36-3: CRC_COMP Register Diagram

Table 36-5: CRC_COMP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Expected CRC Result Value. The CRC_COMP.VALUE bit field contains the value corresponding to the expected CRC result or signature for the current data stream.

Control Register

The CRC_CTL register configures the operation modes and settings for the CRC.

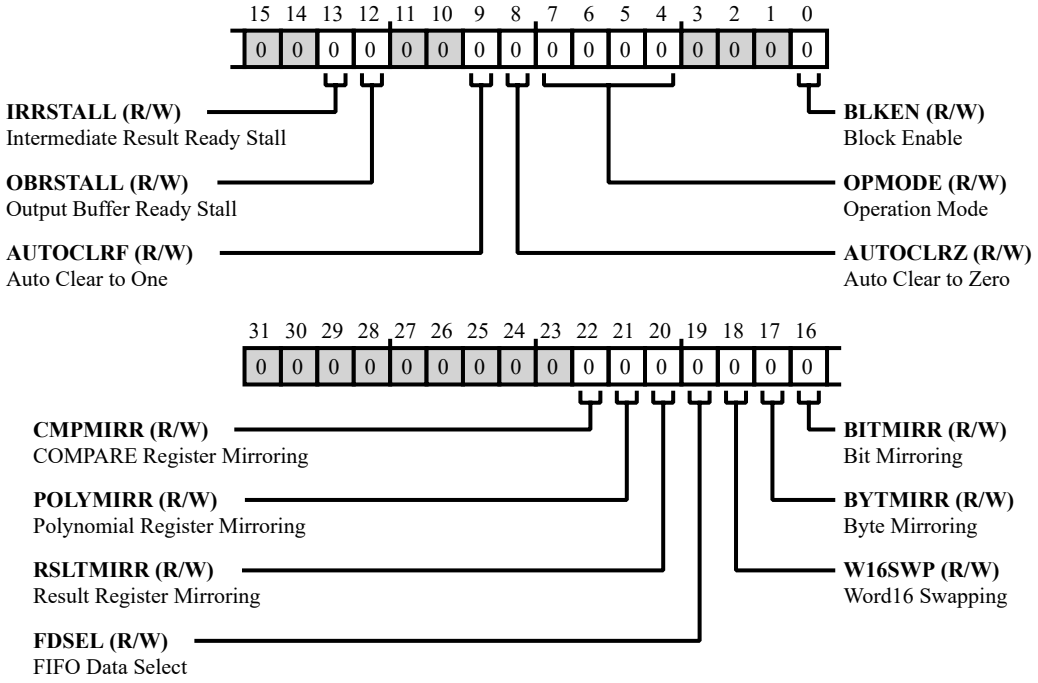

Figure 36-4: CRC_CTL Register Diagram

Table 36-6: CRC_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
22 (R/W)	CMPMIRR	COMPARE Register Mirroring. The CRC_CTL.CMPMIRR bit enables data mirroring for the CRC_COMP compare register. When enabled, the 32-bit value in this register is fully bit mirrored (reversed). The bit-reversed value is used for comparison with the CRC_RESULT_FIN register.	
		0	Disable compare mirroring
		1	Enable compare mirroring
21 (R/W)	POLYMIRR	Polynomial Register Mirroring. The CRC_CTL.POLYMIRR bit enables data mirroring for the CRC_POLY polynomial register. When enabled, the 32-bit value in this register is fully bit mirrored (reversed). The bit-reversed value is used for CRC computations.	
		0	Disable polynomial mirroring
		1	Enable polynomial mirroring

Table 36-6: CRC_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
20 (R/W)	RSLTMIRR	Result Register Mirroring. The CRC_CTL.RSLTMIRR bit enables data mirroring for the CRC_RESULT_CUR and CRC_RESULT_FIN result registers. When enabled, the 32-bit values in these registers are fully bit mirrored (reversed).	
		0	Disable result mirroring
		1	Enable result mirroring
19 (R/W)	FDSEL	FIFO Data Select. The CRC_CTL.FDSEL bit selects whether the CRC writes modified or unmodified data to the FIFO in memory transfer mode. If enabled, the data written is affected by the state of the data mirroring selections (CRC_CTL.BITMIRR, CRC_CTL.BYTMIRR, and CRC_CTL.W16SWP) before being written to the FIFO.	
		0	Write unmodified data to FIFO
		1	Write modified data to FIFO
18 (R/W)	W16SWP	Word16 Swapping. The CRC_CTL.W16SWP bit enables the CRC's data mirror block to swap the upper and lower 16-bit words within the 32-bit input data, before further processing.	
		0	Disable word16 swapping
		1	Enable word16 swapping
17 (R/W)	BYTMIRR	Byte Mirroring. The CRC_CTL.BYTMIRR bit enables the CRC's data mirror block to mirror the bytes within the 32-bit input data, before further processing.	
		0	Disable byte mirroring
		1	Enable byte mirroring
16 (R/W)	BITMIRR	Bit Mirroring. The CRC_CTL.BITMIRR bit enables the CRC's data mirror block to mirror the bits within each byte of the 32-bit input data, before further processing.	
		0	Disable bit mirroring
		1	Enable bit mirroring
13 (R/W)	IRRSTALL	Intermediate Result Ready Stall. The CRC_CTL.IRRSTALL bit enables stalling the state machine for input data when there is a valid intermediate result to be read in the CRC_RESULT_CUR register. This feature should be used only in CRC computation modes (for example, CRC_CTL.OPMODE =1 or =3).	
		0	Do not stall
		1	Stall on IRR

Table 36-6: CRC_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	OBRSTALL	Output Buffer Ready Stall. The CRC_CTL.OBRSTALL bit enables stalling the state machine for input data when there is valid data in the output buffer. This feature should be used only in memory-to-memory transfer modes (for example, CRC_CTL.OPMODE =1).	
		0	Do not stall
		1	Stall on OBR
9 (R/W)	AUTOCLRF	Auto Clear to One. The CRC_CTL.AUTOCLRF bit enables auto clear to one when the CRC is in intermediate results ready stall mode (CRC_CTL.IRRSTALL=1) and the CRC data count expires (CRC_DCNT=0). Note that the CRC_CTL.AUTOCLRZ bit must be disabled, or the CRC_CTL.AUTOCLRF bit has no effect.	
		0	No auto clear
		1	Auto clear
8 (R/W)	AUTOCLRZ	Auto Clear to Zero. The CRC_CTL.AUTOCLRZ bit enables auto clear to zero when the CRC is in intermediate results ready stall mode (CRC_CTL.IRRSTALL=1) and the CRC data count expires (CRC_DCNT=0). Note that CRC_CTL.AUTOCLRF must be disabled, or the CRC_CTL.AUTOCLRZ has no effect.	
		0	No auto clear
		1	Auto clear
7:4 (R/W)	OPMODE	Operation Mode. The CRC_CTL.OPMODE bit field selects the memory transfer or scan mode.	
		0	Reserved
		1	CRC compute/compare memory transfer
		2	Data fill memory transfer
		3	CRC compute/compare memory scan
		4	Data verify memory scan
0 (R/W)	BLKEN	Block Enable. The CRC_CTL.BLKEN bit enables and disables the CRC operation.	
		0	Disable
		1	Enable

Data Word Count Register

The CRC_DCNT register holds the word count that is used for the CRC operation. On transfer of every 32-bit word, the CRC decrements by 1 the content of this register. When the count decrements to zero, this event triggers a CRC compare action, and the CRC_DCNT register is automatically loaded from the CRC_DCNTRLD register for the next CRC operation.

Note that the initial value programmed into the CRC_DCNT register may be different from what is programmed in the CRC_DCNTRLD register.

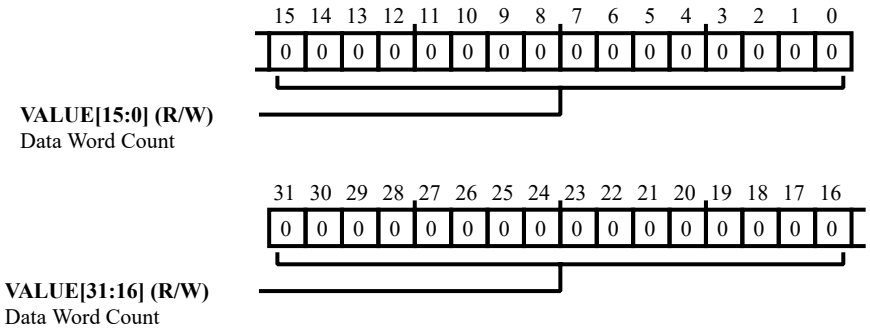

Figure 36-5: CRC_DCNT Register Diagram

Table 36-7: CRC_DCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Data Word Count. The CRC_DCNT.VALUE bit field holds the word count that is used for the CRC operation.

Data Count Capture Register

The CRC_DCNTCAP register captures the CRC_DCNT value when a compare operation fails in data verify mode. This capture can be used to track the position of an error in the data stream. The capture operation is enabled only if the CRC_STAT.CMPERR bit indicates no compare error. After an error occurs and the data count is captured, no further errors are logged until the CRC_STAT.CMPERR bit is cleared. To obtain the position of an error in the data stream, subtract the CRC_DCNTCAP register value from the initial CRC_DCNT.

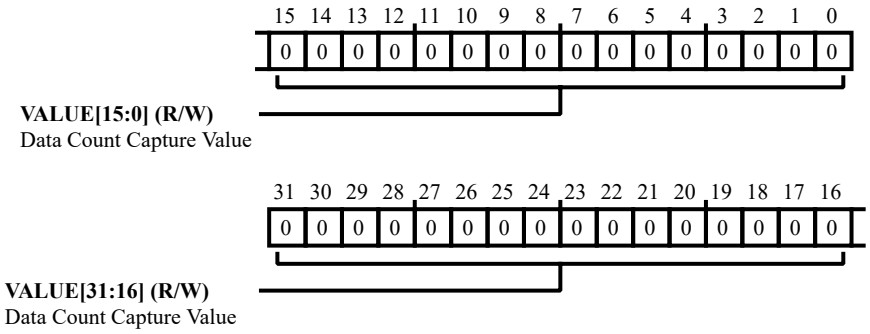

Figure 36-6: CRC_DCNTCAP Register Diagram

Table 36-8: CRC_DCNTCAP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Data Count Capture Value. The CRC_DCNTCAP.VALUE bit field contains the CRC_DCNT value when a compare operation fails in data verify mode.

Data Word Count Reload Register

The CRC_DCNTRLD register holds the value that the CRC automatically loads into CRC_DCNT when the CRC_DCNT decrements to 0. At startup, the value programmed in CRC_DCNT and the CRC_DCNTRLD register could be different. So, for the first iteration, the CRC operation happens for the count initially programmed in the CRC_DCNT register. While for subsequent CRC operations, the count is taken from the CRC_DCNTRLD register.

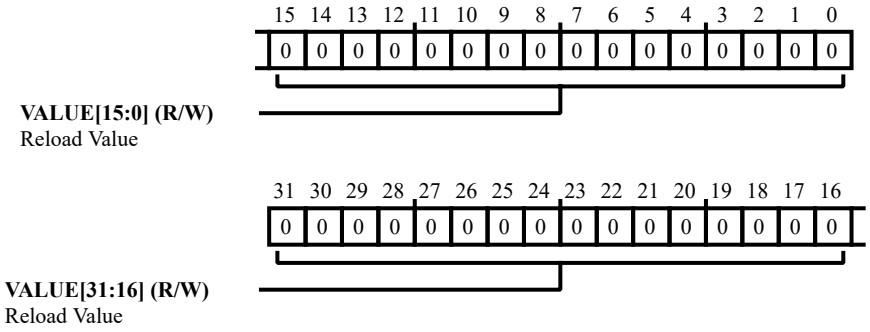

Figure 36-7: CRC_DCNTRLD Register Diagram

Table 36-9: CRC_DCNTRLD Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Reload Value. The CRC_DCNTRLD.VALUE bit field holds the value that automatically loads into CRC_DCNT when the CRC_DCNT decrements to 0.

Data FIFO Register

In memory transfer mode (non-data fill mode), the data from the DMA or processor core buses is written into the CRC_DFIFO on each input data grant (DMA grant or core write). Data is read from this FIFO on each output data grant (DMA grant or core read). FIFO status information is available in the CRC_STAT register. Whenever, the FIFO has valid data, output data requests are generated.

Note that in non-memory transfer mode and in data fill mode, the input data does not get written into this FIFO. So, this register should not be read in these modes.

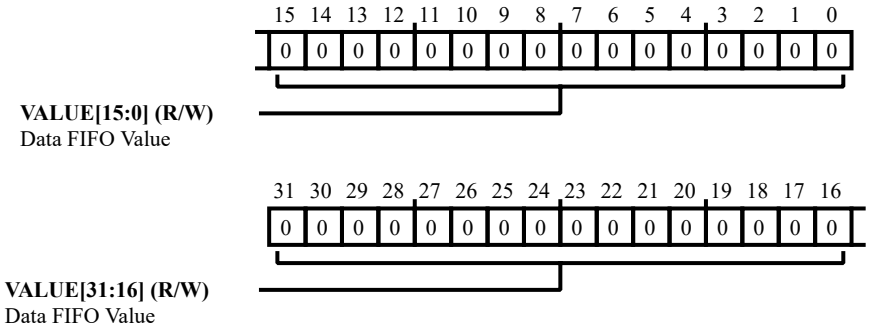

Figure 36-8: CRC_DFIFO Register Diagram

Table 36-10: CRC_DFIFO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Data FIFO Value. The CRC_DFIFO.VALUE bit field is the data from the DMA or processor core buses.

Fill Value Register

The CRC_FILLVAL register holds the value that the CRC uses for the memory fill operation. In data fill mode, the value programmed in this register is used for the memory fill operation.

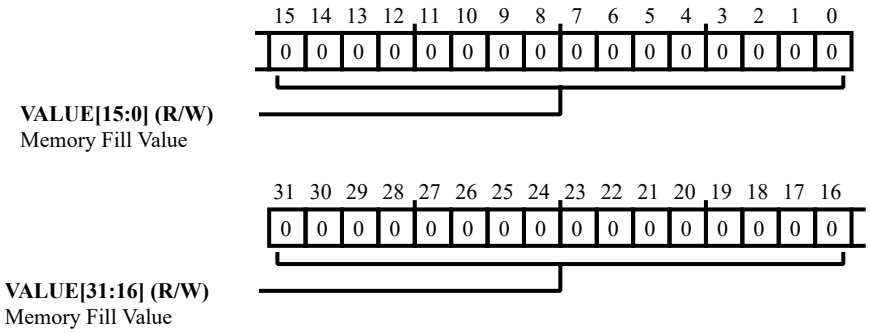

Figure 36-9: CRC_FILLVAL Register Diagram

Table 36-11: CRC_FILLVAL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Memory Fill Value. The CRC_FILLVAL.VALUE bit field holds the value that the CRC uses for the memory fill operation.

Interrupt Enable Register

The CRC_INEN register unmasks (enables) or masks (disables) interrupt requests generated in the CRC from going to the processor core.

Note that CRC interrupts are not disabled when the CRC is disabled (CRC_CTL.BLKEN =0).

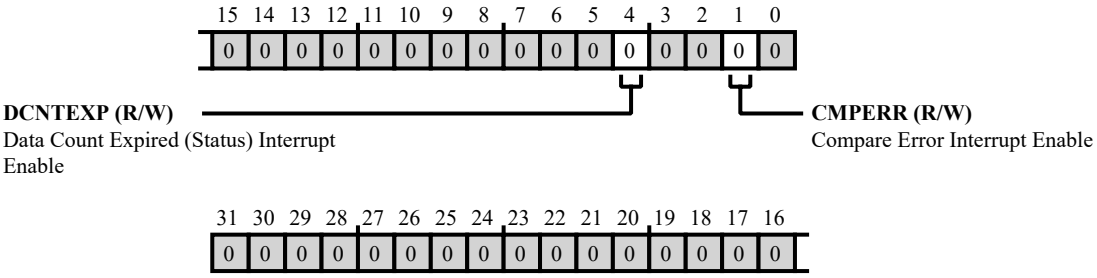

Figure 36-10: CRC_INEN Register Diagram

Table 36-12: CRC_INEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W)	DCNTEXP	Data Count Expired (Status) Interrupt Enable. The CRC_INEN.DCNTEXP enables (unmasks) the data count expired (CRC status) interrupt.	
		0	Disable (mask) interrupt
		1	Enable (unmask) interrupt
1 (R/W)	CMPERR	Compare Error Interrupt Enable. The CRC_INEN.CMPERR enables (unmasks) the data compare interrupt, which is generated when CRC data comparison fails.	
		0	Disable (mask) interrupt
		1	Enable (unmask) interrupt

Interrupt Enable Clear Register

The CRC_INEN_CLR register permits clearing individual bits in the CRC_INEN register without affecting other bits in the register.

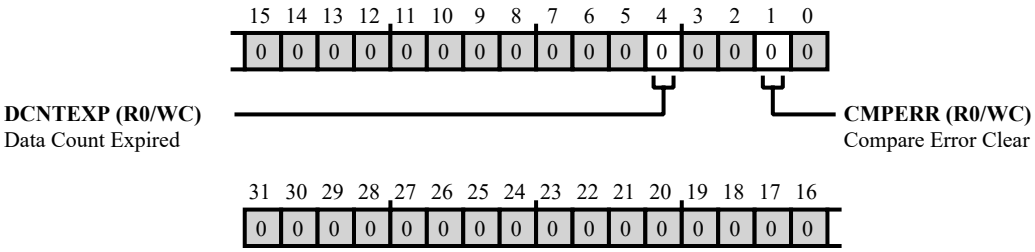

Figure 36-11: CRC_INEN_CLR Register Diagram

Table 36-13: CRC_INEN_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R0/WC)	DCNTEXP	Data Count Expired. The CRC_INEN_CLR.DCNTEXP bit clears the data count expired (status) interrupt.	
		0	No effect
		1	Clear bit
1 (R0/WC)	CMPERR	Compare Error Clear. The CRC_INEN_CLR.CMPERR bit clears the compare error interrupt.	
		0	No effect
		1	Clear bit

Interrupt Enable Set Register

The CRC_INEN_SET register permits setting individual bits in the CRC_INEN register without affecting other bits in the register.

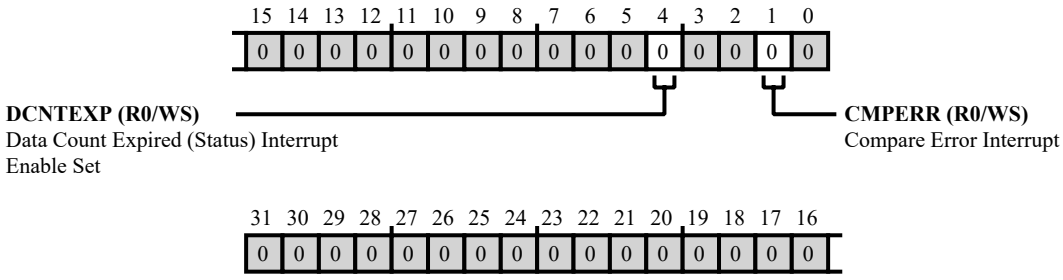

Figure 36-12: CRC_INEN_SET Register Diagram

Table 36-14: CRC_INEN_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R0/WS)	DCNTEXP	Data Count Expired (Status) Interrupt Enable Set. The CRC_INEN_SET.DCNTEXP bit sets the data count expired (status) interrupt.	
		0	No effect
		1	Set bit
1 (R0/WS)	CMPERR	Compare Error Interrupt. The CRC_INEN_SET.CMPERR bit sets the compare error interrupt.	
		0	No effect
		1	Set bit

Polynomial Register

The CRC_POLY register holds a 32-bit polynomial for CRC operations. Bit 31 corresponds to the coefficient of x31 of the CRC polynomial, bit 30 corresponds to the coefficient of x30, and so on through bit 0. A coefficient of x32 is assumed to be "1" for any polynomial that is selected. Based on the polynomial in the CRC_POLY register, the CRC generates a look-up table (LUT), which is used to compute the CRC of the incoming data stream.

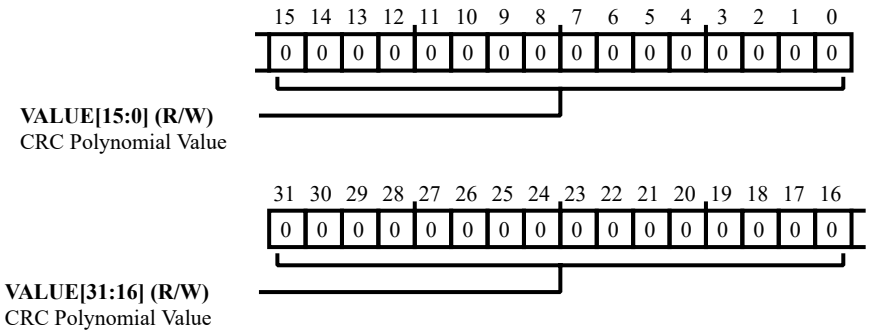

Figure 36-13: CRC_POLY Register Diagram

Table 36-15: CRC_POLY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	CRC Polynomial Value. The CRC_POLY.VALUE bit field holds the 32-bit polynomial for CRC operations.

CRC Current Result Register

The CRC_RESULT_CUR register holds the current or intermediate CRC result. It is updated when new data is written into the CRC. Each time the CRC_DCNT expires, the CRC loads the value from this register into the CRC_RESULT_FIN register. The CRC_RESULT_CUR register may be set to auto clear to zero or auto clear to ones when CRC_DCNT expires by configuring the CRC_CTL.AUTOCLRZ and CRC_CTL.AUTOCLRF bits. Before starting a CRC operation, the CRC_RESULT_CUR register should be programmed to the desired value.

Note that this register can be read by the processor core at any time.

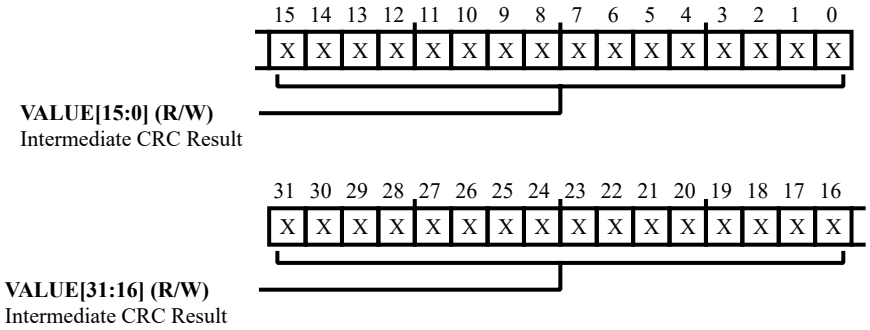

Figure 36-14: CRC_RESULT_CUR Register Diagram

Table 36-16: CRC_RESULT_CUR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Intermediate CRC Result. The CRC_RESULT_CUR.VALUE bit field holds the current or intermediate CRC result.

CRC Final Result Register

The CRC_RESULT_FIN register holds the final CRC computed for a data stream. A data stream is a DMA of CRC_DCNT number of words into the CRC. When CRC_DCNT decrements to zero for each data stream, the CRC loads the CRC_RESULT_FIN register with the value from the CRC_RESULT_CUR register.

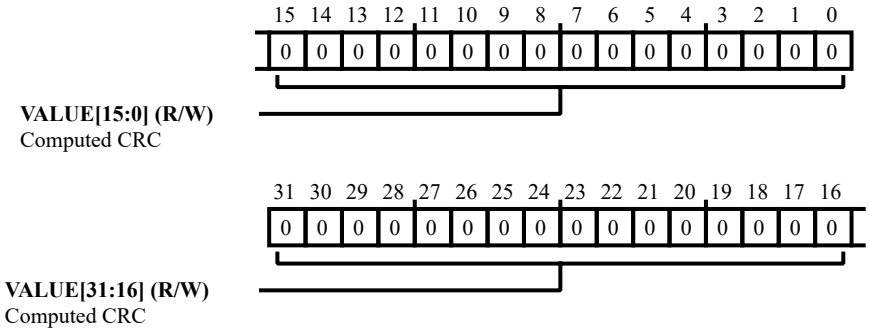

Figure 36-15: CRC_RESULT_FIN Register Diagram

Table 36-17: CRC_RESULT_FIN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Computed CRC. The CRC_RESULT_FIN.VALUE bit field holds the final CRC computed for a data stream.

Status Register

The CRC_STAT register indicates the status for CRC operations and interrupt generation.

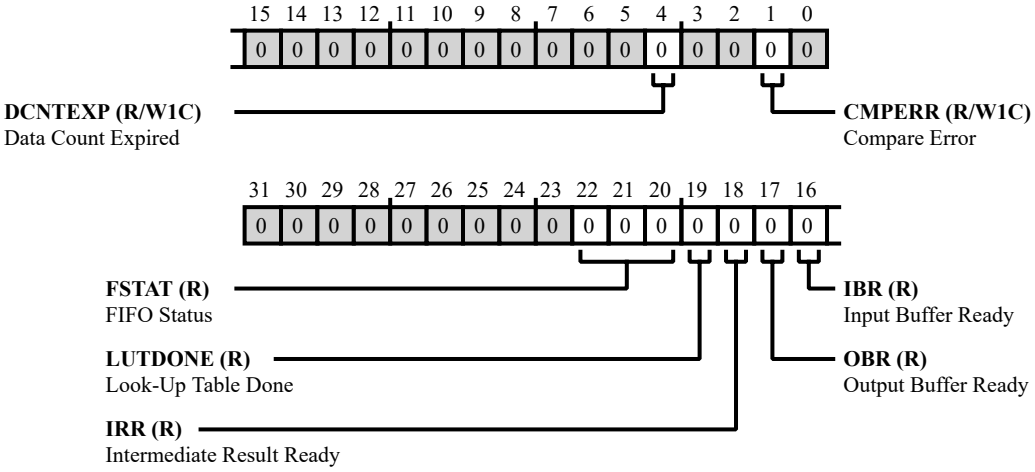

Figure 36-16: CRC_STAT Register Diagram

Table 36-18: CRC_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
22:20 (R/NW)	FSTAT	FIFO Status. The CRC_STAT.FSTAT indicates the current FIFO status. This field is read-only.	
		0	FIFO empty
		1	FIFO has 1 data
		2	FIFO has 2 data
		3	FIFO has 3 data
		4	FIFO has 4 data (full)
19 (R/NW)	LUTDONE	Look-Up Table Done. The CRC_STAT.LUTDONE bit indicates that the CRC has generated the look-up table for the current polynomial. This read-only bit is cleared at reset and cleared when the CRC_POLY is written.	
		0	No status
		1	LUT generation done

Table 36-18: CRC_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
18 (R/NW)	IRR	Intermediate Result Ready. The CRC_STAT.IRR bit indicates that the CRC has updated the CRC_RESULT_CUR register with intermediate CRC results for the new data written to the CRC. The processor core should read from the CRC_RESULT_CUR register only after detecting CRC_STAT.IRR =1. This read-only bit is cleared by CRC hardware and is valid when the CRC_CTL.IRRSTALL bit is enabled.	
		0	No status
		1	Intermediate results ready
17 (R/NW)	OBR	Output Buffer Ready. The CRC_STAT.OBR bit indicates that the CRC has data ready for the processor core to read. The processor core should read from the CRC only after detecting CRC_STAT.OBR =1. This read-only bit is cleared by CRC hardware.	
		0	No status
		1	Output buffer ready
16 (R/NW)	IBR	Input Buffer Ready. The CRC_STAT.IBR bit indicates that the CRC is ready to accept a processor core write. The processor core should write to the input register only after detecting that CRC_STAT.IBR =1. This read-only bit is cleared by CRC hardware.	
		0	No status
		1	Input buffer ready
4 (R/W1C)	DCNTEXP	Data Count Expired. The CRC_STAT.DCNTEXP bit indicates that the CRC_DCNT has expired. This W1C bit is not automatically cleared when the CRC is disabled (CRC_CTL.BLKEN =0). When the CRC sets this bit on CRC_DCNT expiry, the CRC generates the CRC_INEN.DCNTEXP interrupt.	
		0	No status
		1	Data counter expired
1 (R/W1C)	CMPERR	Compare Error. The CRC_STAT.CMPERR bit indicates that a CRC mismatch or data mismatch has been detected. This W1C bit is not automatically cleared when the CRC is disabled (CRC_CTL.BLKEN =0). When the CRC sets this bit on detecting a mismatch, the CRC generates the CRC_INEN.CMPERR interrupt. While this bit is set, the CRC_DCNTCAP register is disabled from capturing the data count values.	
		0	No status
		1	Compare error

37 System Security

The requirements to protect content, keys, intellectual property, and other sensitive information have become increasingly prevalent. The processor contains several modules and system elements that contribute to creating a secure operating environment for trusted code to execute.

The modules and system elements for security are:

- Boot Kernel
- Secure Core
- System Protection Unit (SPU)
- Security Packet Engine (PKTE)
- Public Key Accelerator (PKA)
- Public Key Interrupt Controller (PKIC)
- System Memory Protection Unit (SMPU)
- DEBUG through the Test Access Port Controller (TAPC)
- One-Time Programmable (OTP) memory
- Cryptographic Accelerators (optionally) and Hardware Security Module (HSM)

NOTE: This product includes security features for protecting embedded non-volatile memory contents and preventing execution of non-authorized code. Enabling security on this device (either by the ordering party or the subsequent receiving parties), limits the ability of Analog Devices to conduct failure analysis on returned devices. Contact Analog Devices, Inc. for details on the failure analysis limitations for this device.

Security Features

The security infrastructure in the system provides the following features:

- Secure operating environment for secure code execution
- Protecting sensitive IP from theft by malicious users or competitors

- Protecting sensitive data (for example cipher keys)
- Allowing debugging while still maintaining security

Security Functional Description

In order to provide a secure operating environment in a system, it requires the involvement of multiple elements.

Boot Kernel

The boot kernel is the root of trust for a secure system. Since the boot kernel is developed by Analog Devices, Inc., is stored in ROM, and can't be changed, it can be trusted. The boot kernel validates the authenticity of the application binary image that needs to be booted in. It also handles decrypting the binary image if it's encrypted.

Verifying the authenticity of the application binary asserts that

1. The image is not tampered with or altered
2. The image came from a trusted developer

If the image is encrypted, it ensures confidentiality since the boot image is stored on an external storage device and can be more easily read or stolen than in the part.

Once the boot kernel can verify and optionally decrypt the boot image, it can be loaded into the processor for execution. At this point, the *chain of trust* is continued with the verified application.

Secure Booting

Secure booting is when the boot kernel uses cryptographic algorithms to perform checks on the application binary and to decrypt it. When security is enabled, signature verification and optional decryption on the application binary are both performed by secure boot. See Security Mode Configuration.

Secure Core

In a system with multiple requester and completer resources, not everything is considered secure. There are secure and non-secure peripherals and secure and non-secure segments of memory.

For a system to be considered secure, a secure core that can access and execute instructions (verified application) from secure memory must be configured. Typically, in a single core processor, either the core security is hardwired, or the core can switch between secure and non-secure modes.

System Protection Unit (SPU)

The SPU in the system serves two functions. First, it acts as a gatekeeper, guarding against non-secure accesses to secure resources (peripherals). Second, it is used to define which resources in the system are secure or non-secure requesters and which resources in the system are secure or non-secure completers.

NOTE: Though the SPU can be configured by secure or non-secure requester, the first steps that the verified secure application must perform are:

1. Configure the SPU as a secure completer itself so only other secure requesters can configure it
2. Define and configure the secure requesters and completers using the SPU

This way, once the SPU is secure and other secure requesters and completers are configured, non-secure requesters cannot tamper with the security privileges of secure requesters and completers nor can non-secure resources be changed to a secure resource.

System Memory Protection Unit (SMPU)

Similar to the SPU protecting the MMR address range for peripherals, the SMPU can guard memory ranges or pages. Memory pages can be configured as secure or non-secure. Again, like in the case of the SPU, the SMPU can guard against non-secure transaction attempts to secure memory.

NOTE: A verified application should reside in memory configured as secure. By default the SMPU has all memory configured as secure. When the program needs to update the memory protections using the SMPU, the application and its data should remain in secure memory.

Debug

The typical way of accessing a system is through the debug port via a JTAG or serial wire interface. When these access points are not secure, sensitive IP such as cipher keys can be exposed and code can be changed to disable other security settings. To guard against this type of attack or security hole and still provide debugging capabilities for a developer, a debug unit with security features is used.

When the developer first receives the part, they can define a JTAG/DEBUG key that is programmed into OTP memory. Once security is enabled, the debug unit compares the key sent from the host debugger with the key inside the system. If a match occurs, debug access to secure resources are allowed.

One-Time-Programmable (OTP) Memory

Customer programmable OTP memory is used to safely and securely store sensitive information such as cipher keys.

In a public key algorithm (for example, ECDSA which is used in secure boot), the public key is used to verify the digital signature that accompanies the application binary. The private key is used by the developer on the host development machine to create the digital signature. The public and private key pair is unique, plus the public key needs to be stored in non-volatile, one-time-programmable memory. When the public key can be changed then users can generate their own public/private key pairs and successfully boot in malicious code. This can either re-purpose the part or change security configurations to allow easier access to sensitive information stored elsewhere in the OTP memory.

Cryptographic Accelerators

Cryptographic algorithms are mathematical tools to help provide security. Hardware engines provide some advantages but are not necessarily required. For computationally expensive operations like those used in Elliptic Curve

Cryptography, like ECDSA used in secure boot, the operations can be accelerated while the core performs other tasks. Also, it's less likely that the hardware engine can be hacked to change the results.

Hardware Security Module (HSM)

While cryptographic accelerators primarily optimize performance, the Hardware Security Module (HSM) can also serve as the dedicated root of trust for the SoC. The HSM is an autonomous subsystem that includes its own processor, isolated memory, and cryptographic engines. Its primary function is to manage the lifecycle of high-value assets—such as encryption keys and certificates—within a secure boundary that is inaccessible to the main application cores. By performing sensitive operations (like key generation and signing) internally, the HSM ensures that secret keys are never exposed to the host operating system, significantly reducing the attack surface against software-based vulnerabilities.

Security Mode Configuration

Security as a feature does not necessarily be employed by the user. There are no steps to disable security, if security protection is not required. The part does not have security enabled.

To use the security features using cryptographic accelerators, perform the following steps:

- Generate the public/private key pair on the host development machine.[1]
- Program OTP memory with the public key.[2]
- Program OTP memory with the decryption key if the application binary needs to be encrypted.[2]
- Program OTP memory with the debug/JTAG key.[2]
- Develop the application and sign it, creating the digital signature with the private key.[1]
- If confidentiality is required, encrypt the application binary before signing it.
- Set the LOCK bit in OTP memory to enable security. After this, subsequent boots are secure boots.[2, 3]

[1] Software tools are provided with developments tools to generate keys, sign boot streams, and also perform encryption. Refer to the development tools manuals for details on how to use.

[2]Refer to the OTP Chapter for programming the OTP and other related information.

[3]Refer to the Booting Chapter for more information on Secure Booting and other related information.

HSM Assisted Secure Boot Flow

In this implementation, the SoC retains the role of the primary boot master upon coming out of reset. The secure boot sequence is a staged process where the SoC first provisions the security subsystem before delegating sensitive tasks.

1. HSM Initialization and Staging—The SoC loads the HSM application firmware from external storage into the intermediate memory. Once the image is staged, the SoC releases the HSM from reset. The HSM then boots from the intermediate memory, initializing its isolated environment and authenticating the HSM firmware integrity.
2. Runtime Security Services (SIC Protocol)—Once operational, the HSM transitions to a service-provider role, communicating with the SoC via the Secure Inter-Processor Communication (SIC) protocol. For subsequent boot stages, specifically the incoming Secure Image, the SoC offloads all cryptographic validation to the HSM. Tasks such as ECDSA signature verification and AES decryption, previously handled by direct crypto accelerator access, are now executed within the secure boundary of the HSM, ensuring that the verification keys and decrypted code remain isolated from the main application core.

All the relevant asset specific to HSM boot are programmed in HSM OTP space.

Status and Error Signals

In a fully functional secure system, non-secure resources should not even attempt to access a secure resource. When this happens, either the code has been altered or replaced with malicious code or the system contains a coding error.

Errors or error events are dependent on the configuration of the SPU and SMPU, the protection units which guard against security violations. In the case of the SMPU, the error can simply be captured, captured and interrupt generated, or the access prevented without capturing any error. It is the developer's responsibility to:

1. Determine when there was an error because of a blocked access.
2. Determine how to handle a blocked access. For example fix the bug (offline) or try to use a different resource (run time).

38 System Protection Unit (SPU)

In a system with multiple system MMR requesters, peripheral configurations can be changed unintentionally, leading to bad data or even system malfunctions. The peripherals are shared resources in the system. The SPU restricts access to certain MMRs, similar to the functionality of a semaphore.

The SPU also protects peripherals based on security settings. It is part of the overall security infrastructure of the processor.

SPU Features

The SPU has the following features:

- Write-protect system MMR from certain system requesters and core requesters.
- Simultaneously lock multiple peripheral configuration registers through a global lock mechanism.
- Write-protect and block access to its own write-protection registers from other system requesters.
- Defined security privileges to peripherals and system resources.
- Security protection to guard secure peripheral MMRs against non-secure accesses.

SPU Functional Description

The following sections provide information on the function of the SPU.

ADSP-2184x SPU Register List

The System Protection Unit (SPU) provides a set of registers that can protect system resources from errant writes. The protection categories are global lock (protects configuration registers) and write protect register lock (protects the write protect register). For more information on SPU functionality, see the SPU register descriptions.

Table 38-1: ADSP-2184x SPU Register List

Name	Description
SPU_CTL	Control Register
SPU_SECURECHK	Secure Check Register

Table 38-1: ADSP-2184x SPU Register List (Continued)

Name	Description
SPU_SECURECTL	Secure Control Register
SPU_SECUREC[n]	Secure Core Registers
SPU_SECUREP[n]	Secure Peripheral Register
SPU_STAT	Status Register
SPU_WP[n]	Write Protect Register n

ADSP-2184x SPU Interrupt List

Table 38-2: ADSP-2184x SPU Interrupt List

Interrupt ID	Name	Description	Sensitivity	DMA Channel
306	SPU0_INT	SPU0 Interrupt	Level	

Peripheral Register Write Protection

The SPU has a write-protection register (SPU_WP[n]) associated with each peripheral. Each of these write-protection registers has the exact same bits that correspond to a particular SMMR requester (for example, Core 0, MDMA). When the bits are set, the SPU locks the corresponding SMMR requesters from accessing the register address space of the associated peripheral. The bits in the register can be cleared to allow access to the registers of the peripheral again. When the SPU initializes the write-protection register, any writes that are in-progress complete before the SPU blocks subsequent writes.

In the ***SPU Write Protect Registers*** figure, each write-protect register in the SPU is associated with a particular peripheral.

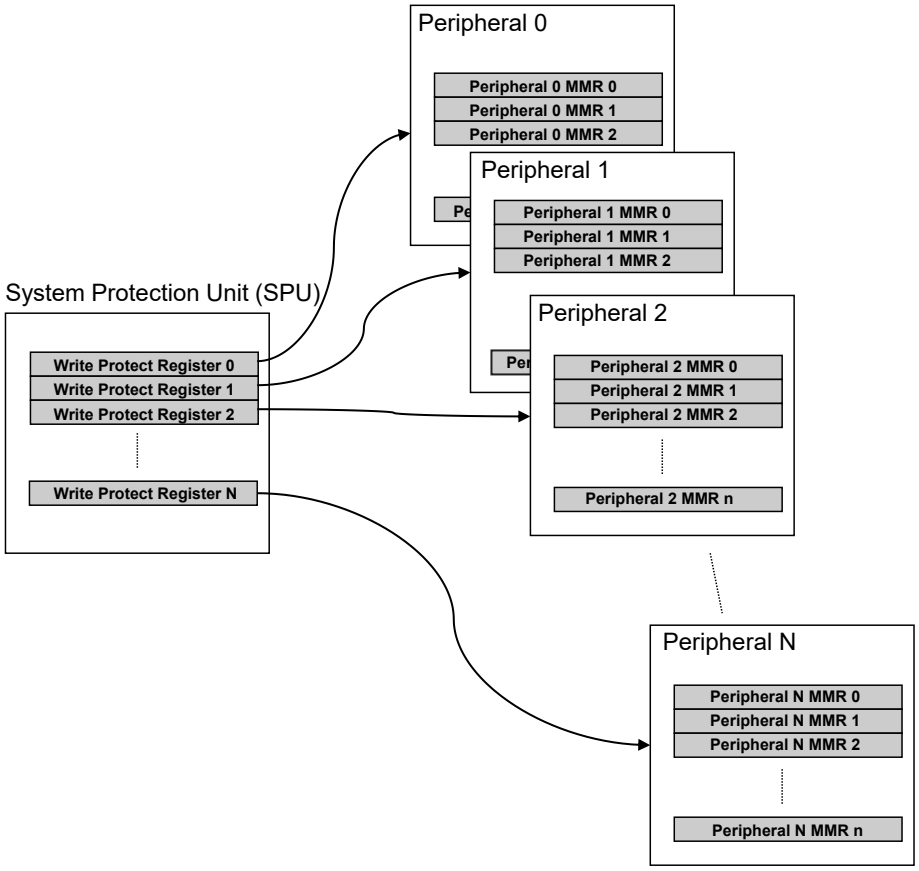

Figure 38-1: SPU Write Protect Registers

In the figure, a write-protect register in the SPU module blocks write-attempts to the MMR space of the associated peripheral. The bits in the write-protect register specify from which requesters to block write-access.

NOTE: A SPU write protection register (`SPU_WP[n]`) exists for the SPU alone. If all defined bits are set in this register for the SPU, any configurations in the SPU are locked and cannot be changed. Only a system reset can restore access to the SPU.

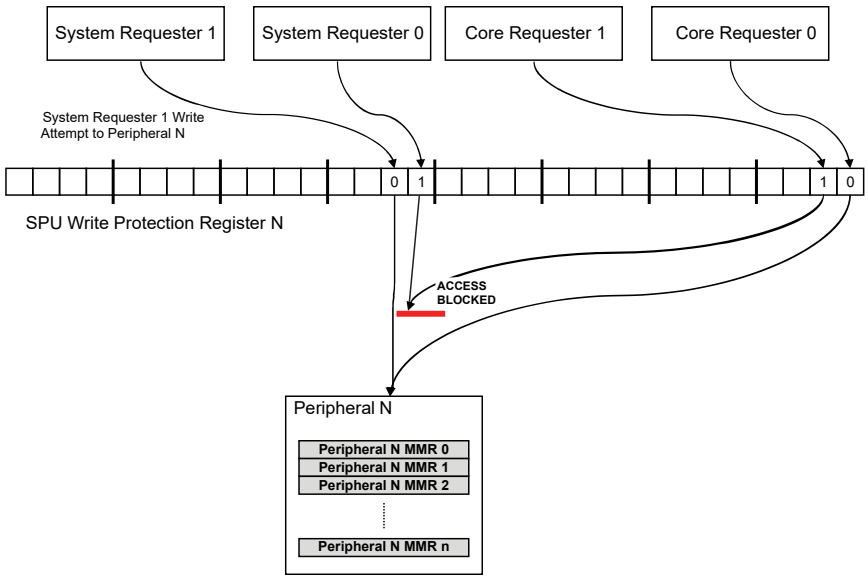

Figure 38-2: SPU Write-Protect Register Blocking Access from System Requester 0 and Core Requester 1

Global Locking

The SPU also has global locking capability. When enabled by setting `SPU_CTL.GLCK` bit field to a value other than 0xAD, a system-wide global lock signal is active. Some peripherals have a lock enable bit in their control register. When this bit is set, the peripheral recognizes the global lock signal and blocks further write-accesses to its own control register. Access to the configuration register of the peripheral is enabled when the global lock is turned off in the SPU.

The ***Global Locking*** figure is a conceptual diagram. The diagram shows how the SPU module (or any peripheral) blocks any write attempts to its control register when:

- The global lock signal from the SPU is active, and
- The global lock enable bit is set in the control register of the peripheral

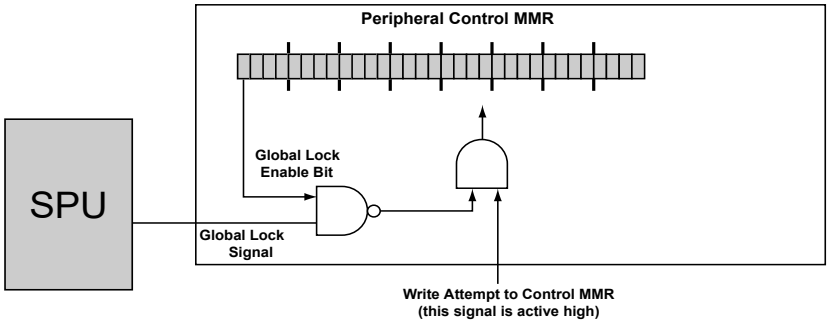

Figure 38-3: Global Locking

The SPU can write-protect its own registers. When the `SPU_CTL.WPLCK` bit is set and global locking is enabled, the SPU blocks accesses to the SPU write-protection registers. To enable write access to the write-protection registers in the SPU, disable the global locking.

SPU Block Diagram

The ***SPU System-Level Block Diagram*** shows a system-level block diagram of where the SPU is located in the system. It resides between the SMMR interface and the system crossbar. Depending on the configuration of the SPU write-protect registers, it can block access to some peripherals from certain SMMR requesters.

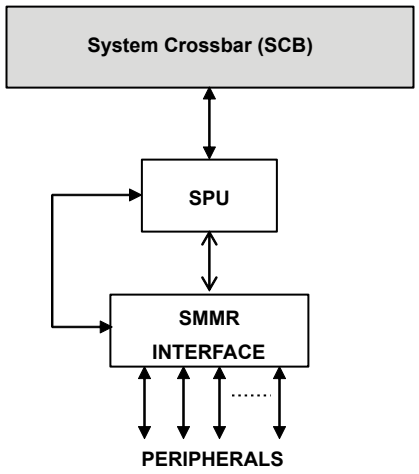

Figure 38-4: SPU System-Level Block Diagram

SPU Architectural Concepts

As shown in the block diagram, the SPU sits between the system crossbar (SCB) and the SMMR interface to the peripherals. The SPU gates any MMR access to any peripheral from any requester that comes through the SCB. Depending on the configuration of the write-protection registers in the SPU, the SPU does or does not allow the MMR write to go through.

The SPU also checks whether the transaction is a secure or non-secure transaction and blocks it according to the configured security setting for the target destination. A secure requester can generate secure read or secure write transactions which can access secure or non-secure completers. A non-secure requester can generate non-secure read or non-secure write transactions and can only access non-secure completers.

SPU Event Control

The system protection unit provides write-protection against MMRs peripherals and its own write-protect registers. If a write attempt is made to any locked MMR peripheral the SPU has write-protected, it blocks the write. The SPU generates a bus error to the requester that attempted the write. That requester does or does not generate an event, based on the returned error.

The SPU can be configured to generate an interrupt for the write-protection violation by setting the `SPU_CTL.PINTEN` bit. The SPU can also be configured to generate an interrupt for a security violation by setting the `SPU_SECURECTL.SINTEN` bit. If either one or both bits is triggered, the `SPU_STAT.VIRQ` bit is set.

The SPU can also lock its own registers from write attempts. If a write-attempt is made to a locked register in the SPU, the SPU blocks it and records it as an error in the SPU_STAT.LWERR bit. Again, the SPU generates a bus error to the requester that attempted the write.

The requester does or does not generate an event, based on the returned error.

The SPU does not generate an event for a blocked write access to an SPU register. If the SPU_CTL.PINTEN bit is set, the SPU triggers an interrupt for this blocked access attempt.

The global lock is enabled by setting the SPU_CTL.GLCK bit to something other than 0xAD. If the lock bit is set in that same configuration register, a peripheral can block write access to its configuration register. When the SPU blocks a write attempt, the peripheral logs and reports the failed attempt. The SPU is unaware and therefore does not provide any indication of a failed write attempt to the configuration register of the peripheral.

SPU Programming Model

The system protection unit (SPU) consists of write-protect and access-protect registers. Each one corresponds to a different peripheral instance. Bits in the write-protect registers correspond to system requesters that can modify the MMR contents of the peripherals. By writing to these write-protect registers, the corresponding memory-mapped registers of the peripheral are write-protected against requesters whose bits in the write-protect register are set.

The SPU globally locks the control register of the peripheral. Peripherals that support this feature have a lock enable bit in their control register. The peripheral blocks any additional write attempts to its control register from any requester when:

- The global lock signal is active from the SPU, and
- The lock enable bit of the peripheral is set

If the lock enable bit of a peripheral is not set and the global lock signal is active, access to that control register of the peripheral is still allowed. To grant access again, disable the global lock signal from the SPU by writing the value 0xAD into the SPU_CTL.GLCK bit field.

Another protection mechanism that the SPU offers is write-protection against the write-protection registers. If the write protect register lock bit (SPU_CTL.WPLCK) is set and the global lock signal is active, writes to the write-protect registers of the SPU are blocked. To re-enable access to the write-protect registers in the SPU, deactivate the global lock signal by writing 0xAD into the SPU_CTL.GLCK bit field.

For security, the SPU provides a set of SPU_SECUREC[n] registers (one for each processor core from Analog Devices) to configure their security settings. The SPU also provides a set of SPU_SECUREP[n] registers (one for each peripheral instance) to configure their security settings.

Enabling and Disabling the SPU

The SPU is always operating. There are no bits to enable or disable the SPU. The SPU configuration can be updated at any time. Any ongoing transactions finish before a new configuration is in effect. By default, the SPU does not write-protect any of the MMRs.

Write-Protecting the SPU

The SPU is treated like any other peripheral in the system. As such, the SPU also has an associated write-protection register. If this write-protection register is configured to block all writes from all requesters, any SPU configuration remains the same until the next system reset.

Checking the Security State

In some cases while running a peripheral, an application system requester does not know whether they are a secure requester generating secure transactions or not. The SPU provides a means for checking the security state of the requester through the SPU_SECURECHK register. When read by a secure requester, the register reads 0xFFFFFFFF and when read by a non-secure requester, the value is 0x00000000.

SPU Mode Configuration

The SPU can provide address range-wide protection by write-protecting the peripherals MMR address range from system MMR requesters. It can also provide register wide protection using global locking. Peripherals that support this feature can enable it in their respective configuration register. When the SPU enables the global lock signal, all subsequent writes to the configuration register of the peripheral are blocked until the global lock signal is deasserted. Similarly, the write-protection registers of the SPU can be write-protected using the global lock signal as well. The SPU uses all these modes of operation together.

Locking Write-Protect Registers

Use the following steps to lock (write-protect) a register.

1. Set the SPU_CTL.WPLCK bit and configure the SPU_CTL.GLCK field to something other than 0xAD.

The SPU write-protect registers are blocked from further write accesses.

Protecting a Peripheral

Use the following procedure to protect a peripheral.

1. Determine which peripheral needs protection and locate the corresponding write-protect register (SPU_WP[n]) in the SPU. See the Write-Protect and Secure Peripheral Registers section.
2. Determine the SMMR requesters from which the peripheral needs protection. Then, set the corresponding bit or bits in the write-protect register (SPU_WP[n]) for the peripheral. See the Write-Protect and Secure Peripheral Registers section.

After setting the write-protect register for the particular peripheral, the identified SMMR requesters are blocked from writing to any MMR in the address space of the peripheral. This block remains in place until the bits in the write-protect register are cleared.

Configuring Security Privileges of a Peripheral

Use the following procedure to configure the security privileges of a peripheral.

1. Determine the peripheral and its corresponding secure peripheral register (SPU_SECUREP[n]) in the SPU. See the Write-Protect and Secure Peripheral Registers section.
2. If the peripheral is to be a secure completer that only accepts secure transactions, set bit 0 (SPU_SECUREP[n].SSEC).
3. If the peripheral is to be a secure requester that generates secure transactions (keeping in mind not all peripherals can be requesters), set bit 1 (SPU_SECUREP[n].MSEC).

This procedure sets the security privileges of a peripheral.

NOTE: Only a secure requester can set security privileges, keeping the chain of trust intact. If a non-secure requester configures the security privileges, it can undermine security protection.

ADSP-2184x SPU Register Descriptions

System Protection Unit (SPU) contains the following registers.

Table 38-3: ADSP-2184x SPU Register List

Name	Description
SPU_CTL	Control Register
SPU_SECURECHK	Secure Check Register
SPU_SECURECTL	Secure Control Register
SPU_SECUREC[n]	Secure Core Registers
SPU_SECUREP[n]	Secure Peripheral Register
SPU_STAT	Status Register
SPU_WP[n]	Write Protect Register n

Control Register

The SPU control register (SPU_CTL) provides a global lock for configuration registers as well as control for locking the write protect (SPU_WP[n]) registers. It also controls the generation of an interrupt to report blocked accesses.

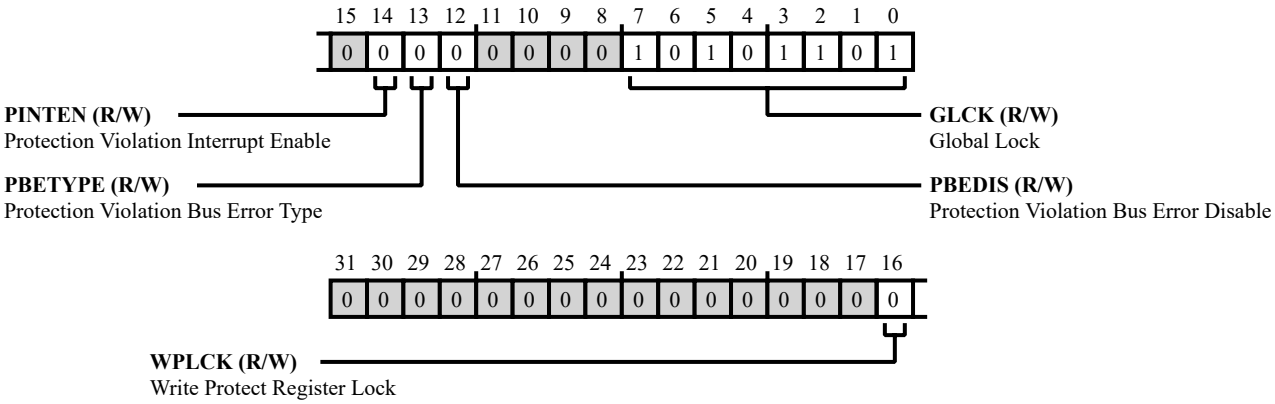

Figure 38-5: SPU_CTL Register Diagram

Table 38-4: SPU_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W)	WPLCK	Write Protect Register Lock. When the SPU_CTL.WPLCK bit is set in combination with the SPU_CTL.GLCK bit, writes to the SPU's write protect registers are blocked and return an error.	
		0	Disable
		1	Enable
14 (R/W)	PINTEN	Protection Violation Interrupt Enable. When the SPU_CTL.PINTEN bit is set (=1), a block of any transaction according to the configured settings produces an interrupt.	
		0	Disable
		1	Enable
13 (R/W)	PBETYPE	Protection Violation Bus Error Type.	
		0	Reserved
		1	Reserved
12 (R/W)	PBEDIS	Protection Violation Bus Error Disable.	
		0	Reserved
		1	Reserved

Table 38-4: SPU_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	GLCK	Global Lock. The `SPU_CTL.GLCK` controls the global lock signal. The global lock signal provides register-based write protection. Writing 0xAD to this field disables the lock, and writing any other value enables the lock.

Secure Check Register

The SPU_SECURECHK register reads by secure requesters return 0xFFFFFFFF. Reads by non-secure requesters return 0x00000000.

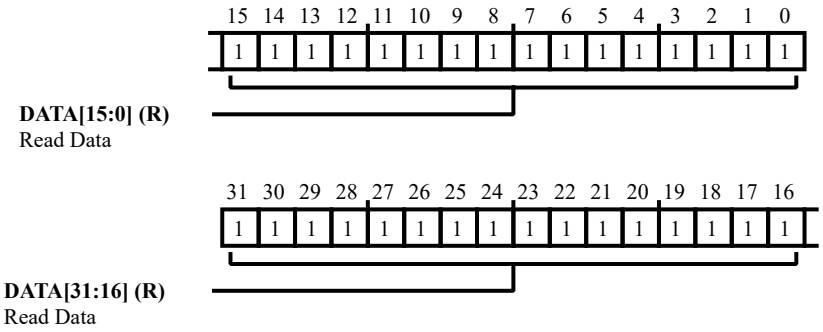

Figure 38-6: SPU_SECURECHK Register Diagram

Table 38-5: SPU_SECURECHK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	DATA	Read Data. The SPU_SECURECHK.DATA bit field performs reads. Reads by secure requesters return 0xFFFFFFFF. Reads by non-secure requesters return 0x00000000.

Secure Control Register

The SPU Secure Control Register (SPU_SECURECTL) allows the user to lock write access to all the SPU_SECUREC[n] and SPU_SECUREP[n] registers as well as configure the interrupt generation in an event of a security error. It also allows bulk clear of the SSEC bits and/or MSEC bits in the SPU_SECUREP[n] registers.

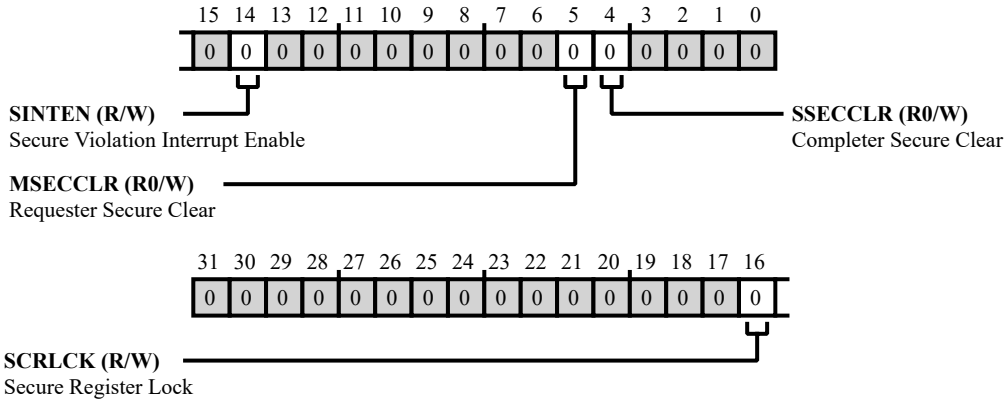

Figure 38-7: SPU_SECURECTL Register Diagram

Table 38-6: SPU_SECURECTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W)	SCRLCK	Secure Register Lock. When the SPU_SECURECTL.SCRLCK bit is set in combination with the SPU_CTL.GLCK bit, writes to the Security Configuration registers (SPU_SECUREC[n] and SPU_SECUREP[n]) are blocked and return an error which is captured in the SPU_STAT.LWERR bit.	
		0	Disable
		1	Enable
14 (R/W)	SINTEN	Secure Violation Interrupt Enable. The SPU_SECURECTL.SINTEN bit generates an interrupt if a security violation was captured. Interrupt status is provided in the SPU_STAT.VIRQ bit.	
		0	Disable
		1	Enable
5 (R0/W)	MSECCLR	Requester Secure Clear. When the SPU_SECURECTL.MSECCLR bit is set, the SPU_SECUREP[n].MSEC bits in all SPU_SECUREP[n] registers are cleared. The SPU_SECURECTL.MSECCLR bit always reads back as a 0.	
		0	No Action
		1	Clear All Requester Secure Control Bits

Table 38-6: SPU_SECURECTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R0/W)	SSECCLR	Completer Secure Clear. When the SPU_SECURECTL.SSECCLR bit is set, the SPU_SECUREP[n].SSEC bits in all SPU_SECUREP[n] registers are cleared. The SPU_SECURECTL.SSECCLR bit always reads back as a 0.	
		0	No Action
		1	Clear All Completer Secure Control Bits

Secure Core Registers

A SPU register exists for every DSP core in the system. The SEC field enables or disables security for features in the core.

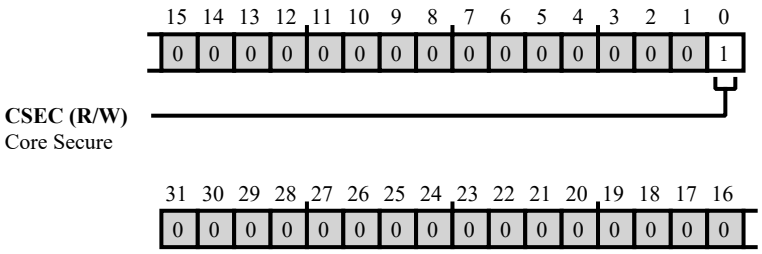

Figure 38-8: SPU_SECUREC[n] Register Diagram

Table 38-7: SPU_SECUREC[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	CSEC	Core Secure. The `SPU_SECUREC[n].CSEC` bit controls whether non-secure accesses are allowed to L1 memory of the processor core. When =1, the core (as a completer) is set as secure meaning only secure transactions are allowed to L1.	
		0	Disable
		1	Enable

Secure Peripheral Register

In the system, each SPU_SECUREP[n] register is assigned to a specific MMR address range associated with one peripheral. Each SPU_SECUREP[n] has a Completer Secure (SSEC) bit and a Requester Secure (MSEC) bit. When the SSEC bit is set, the SPU will only allow secure requesters generating secure transactions to access the peripheral's MMR address space. When the MSEC bit is set, the associated peripheral will be secure and will generate secure transactions.

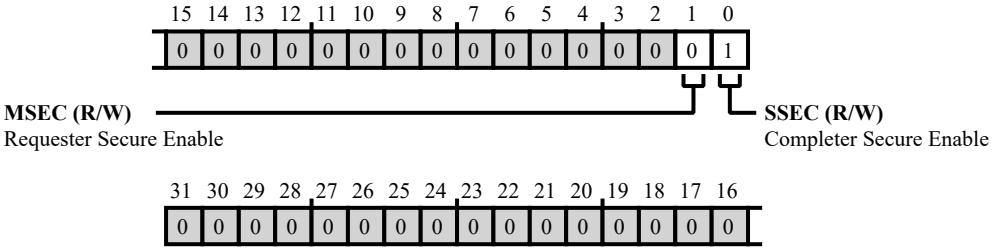

Figure 38-9: SPU_SECUREP[n] Register Diagram

Table 38-8: SPU_SECUREP[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	MSEC	Requester Secure Enable. The SPU_SECUREP[n].MSEC bit controls whether the peripheral generates secure transactions as a requester. When clear (=0), the peripheral generates non-secure transactions as a requester (if applicable). When set (=1), the peripheral generates secure transactions as a requester.	
		0	Disable
		1	Enable
0 (R/W)	SSEC	Completer Secure Enable. The SPU_SECUREP[n].SSEC bit controls whether the peripheral is protected from non-secure transactions. When clear (=0), the security status of the transaction is ignored. When set (=1), only secure transactions are allowed to access the address space of the peripheral and non-secure transactions are blocked.	
		0	Disable
		1	Enable

Status Register

The SPU_STAT register indicates if there have been any errors, active interrupts and global lock status.

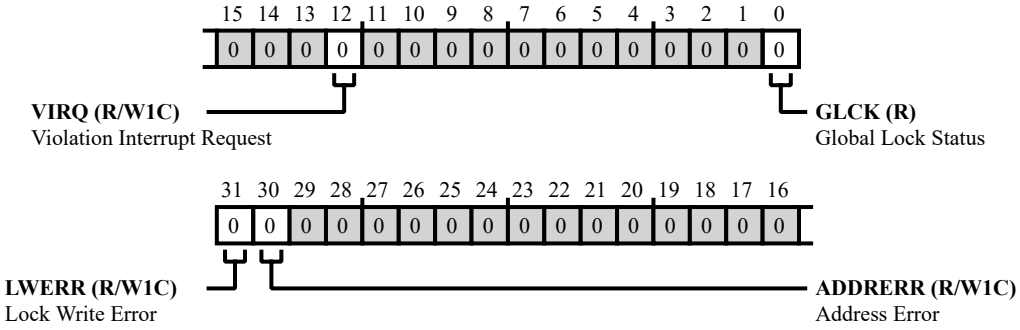

Figure 38-10: SPU_STAT Register Diagram

Table 38-9: SPU_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W1C)	LWERR	Lock Write Error. The SPU_STAT.LWERR indicates whether there has been an attempted write to a register in the SPU with its lock bit (SPU_CTL.WPLCK or SCRLCK) set while SPU_CTL.GLCK was asserted. This bit is W1C.	
		0	Inactive
		1	Active
30 (R/W1C)	ADDRERR	Address Error. The SPU_STAT.ADDRERR indicates whether there has been an attempted write to a read-only register or an access an invalid address in the SPU MMR address range. This bit is W1C.	
		0	Inactive
		1	Active
12 (R/W1C)	VIRQ	Violation Interrupt Request. The SPU_STAT.VIRQ bit indicates that a security and/or protection violation has been detected and interrupt asserted. This is a W1C bit.	
		0	Inactive
		1	Active
0 (R/NW)	GLCK	Global Lock Status. The SPU_STAT.GLCK indicates whether the global lock is enabled or disabled.	
		0	Disabled (global_lock=0)
		1	Enabled (global_lock=1)

Write Protect Register n

In the system, each SPU_WP[n] register is assigned to a specific MMR address range associated with one peripheral. When the appropriate bits are set, writes to the peripheral from a specific requester are blocked and an error is returned to the requester. For more information, see the processor specific additional information for the SPU_WP[n] register.

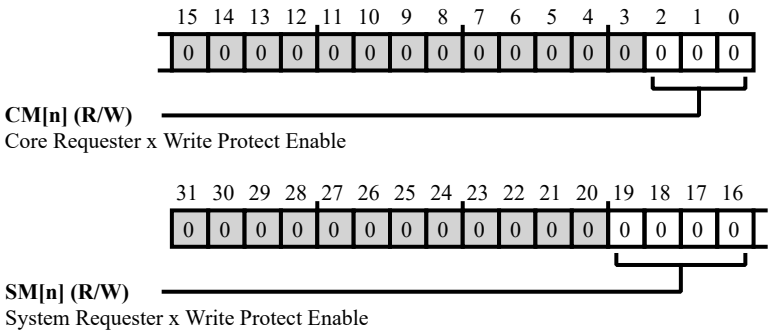

Figure 38-11: SPU_WP[n] Register Diagram

Table 38-10: SPU_WP[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19:16 (R/W)	SM[n]	System Requester x Write Protect Enable. The SPU_WP[n].SM[n] bits correspond to different system requesters in the system. When a particular bit is set in this field, the corresponding system requester cannot write to the corresponding peripheral's MMR address space. The write attempt is blocked by the SPU.
2:0 (R/W)	CM[n]	Core Requester x Write Protect Enable. The SPU_WP[n].CM[n] bits correspond to different cores in the system. When a particular bit is set in this field, the corresponding core cannot write to the corresponding peripheral's MMR address space. The write attempt is blocked by the SPU.

Write-Protect, Secure Peripheral, and Secure Core Registers

The SPU consists of a collection of write-protect registers each of which are associated with a specific peripheral or target. The SPU also has a collection of secure peripheral registers which are also associated with specific peripherals. The table gives the write-protect register and secure peripheral number for each of the peripherals that are provided with write protection and security through the SPU. The SPU for the processor is configured with 136 write-protect registers and also 136 secure peripheral registers. The number corresponding to a peripheral correlates to both the Write-Protect register and the Secure Peripheral register.

For each processor, there are different numbers of controllers that are able to access the SMMR space

The SPU_WP[n] register shows which bits enable the protection against which controller.

For each peripheral, there is a corresponding write-protect register, SPU_WP[n], and secure peripheral register, SPU_SECUREP[n]. The table shows the write-protect register and secure peripheral number for each peripheral.

Processor-Specific Information

Global Locking

The global lock signal from the SPU along with the peripheral lock bit can be used to provide lock functionality for the control MMR of the peripheral. The Global Lock (`SPU_CTL.GLCK`) field determines whether global lock is enabled or not. Global Lock is disabled if the `SPU_CTL.GLCK` field is 0xAD (default value), otherwise it is enabled. The following is a list of peripherals that have the global lock bit in their control MMR.

- General-Purpose IO (GPIO)
- System Event Controller (SEC0)
- Trigger Routing Unit (TRU0
- Clock Generation Unit (CGU0)
- Clock Generation Unit1 (CGU1)
- Clock Distribution Unit (CDU0)
- Dynamic Power Management (DPM)
- Reset Control Unit (RCU0)
- System Protection Unit (SPU0)
- L2 Memory Controller (L2CTL0)

39 Security Packet Engine (PKTE)

The PKTE is a security packet engine designed to off-load the host processor to improve the speed of applications requiring cryptographic processing. The packet engine contains a set of modules for encryption and decryption, hashing, and pseudo-random number generation.

PKTE Features

The PKTE has the following features.

- Hardware assisted processing for the cryptographic ciphers, hashes, and pseudo-random number generation
- Header and trailer processing for Internet security protocols
- DMA capability to move data in and out of the engine efficiently and to allow the engine to run autonomously while moving data
- Interrupt controller to signal module status and errors
- Clock manager for enabling or disabling different features to save power

NOTE: Not all algorithms, decrypt, and hash functions and extra features are available on all product models. For complete information on included features, see the product-specific data sheet.

NOTE: This packet engine provides support for various network security protocols by processing headers and trailers as well as accelerating cryptographic functions. Not all processors have direct support for Ethernet. As such, the packet engine can still be used if Ethernet is indirectly used.

PKTE Functional Description

The packet engine contains a set of modules for encryption and decryption, hashing, and pseudo-random number generation. The following sections describe these functional blocks.

ADSP-2184x PKTE Register List

The Security Packet Engine (PKTE) provides security-related features. A set of registers governs PKTE operations. For more information on PKTE functionality, see the PKTE register descriptions.

Table 39-1: ADSP-2184x PKTE Register List

Name	Description
PKTE_ARC4STATE_ADDR	Packet Engine ARC4 State Record Address
PKTE_ARC4STATE_BUF	Starting Entry of 256-byte ARC4 State Buffer
PKTE_BUF_PTR	Packet Engine Buffer Pointer Register
PKTE_BUF_THRESH	Packet Engine Buffer Threshold Register
PKTE_CDRBASE_ADDR	Packet Engine Command Descriptor Ring Base Address
PKTE_CDSC_CNT	Packet Engine Command Descriptor Count Register
PKTE_CDSC_INCR	Packet Engine Command Descriptor Count Increment Register
PKTE_CFG	Packet Engine Configuration Register
PKTE_CLK_CTL	PE Clock Control Register
PKTE_CONT	PKTE Continue Register
PKTE_CTL_STAT	Packet Engine Control Register
PKTE_DATAIO_BUF	Starting Entry of 256-byte Data Input/Output Buffer
PKTE_DEST_ADDR	Packet Engine Destination Address
PKTE_DMA_CFG	Packet Engine DMA Configuration Register
PKTE_ENDIAN_CFG	Packet Engine Endian Configuration Register
PKTE_HLT_CTL	Packet Engine Halt Control Register
PKTE_HLT_STAT	Packet Engine Halt Status Register
PKTE_IMSK_DIS	Interrupt Mask Disable Register
PKTE_IMSK_EN	Interrupt Mask Enable Register
PKTE_IMSK_STAT	Interrupt Masked Status Register
PKTE_INBUF_CNT	Packet Engine Input Buffer Count Register
PKTE_INBUF_INCR	Packet Engine Input Buffer Count Increment Register
PKTE_INT_CFG	Interrupt Configuration Register
PKTE_INT_CLR	Interrupt Clear Register
PKTE_INT_EN	Interrupt Enable Register
PKTE_IUMSK_STAT	Interrupt Unmasked Status Register
PKTE_LEN	Packet Engine Length Register
PKTE_OUTBUF_CNT	Packet Engine Output Buffer Count Register
PKTE_OUTBUF_DECR	Packet Engine Output Buffer Count Decrement Register
PKTE_PE_ALT_KEY_STATUS	PE Alternative Key stat register
PKTE_PE_CACHE_CTRL_0	Packet Engine Cache Control 0

Table 39-1: ADSP-2184x PKTE Register List (Continued)

Name	Description
PKTE_PE_CACHE_CTRL_1	Packet Engine Cache Control 1
PKTE_RDRBASE_ADDR	Packet Engine Result Descriptor Ring Base Address
PKTE_RDSC_CNT	Packet Engine Result Descriptor Count Registers
PKTE_RDSC_DECR	Packet Engine Result Descriptor Count Decrement Registers
PKTE_RING_CFG	Packet Engine Ring Configuration
PKTE_RING_PTR	Packet Engine Ring Pointer Status
PKTE_RING_STAT	Packet Engine Ring Status
PKTE_RING_THRESH	Packet Engine Ring Threshold Registers
PKTE_SA_ADDR	Packet Engine SA Address
PKTE_SA_ARC4IJPTR	ARC4 i and j Pointer Register
PKTE_SA_CMD0	SA Command 0
PKTE_SA_CMD1	SA Command 1
PKTE_SA_IDIGEST[n]	SA Inner Hash Digest Registers
PKTE_SA_KEY[n]	SA Key Registers
PKTE_SA_NONCE	SA Initialization Vector Register
PKTE_SA_ODIGEST[n]	SA Outer Hash Digest Registers
PKTE_SA_RDY	SA Ready Indicator
PKTE_SA_SEQNUM[n]	SA Sequence Number Register
PKTE_SA_SEQNUM_MSK[n]	SA Sequence Number Mask Registers
PKTE_SA_SPI	SA SPI Register
PKTE_SRC_ADDR	Packet Engine Source Address
PKTE_STAT	Packet Engine Status Register
PKTE_STATE_ADDR	Packet Engine State Record Address
PKTE_STATE_BYTE_CNT[n]	State Hash Byte Count Registers
PKTE_STATE_IDIGEST[n]	State Inner Digest Registers
PKTE_STATE_IV[n]	State Initialization Vector Registers
PKTE_USERID	Packet Engine User ID

ADSP-2184x PKTE Interrupt List

Interrupt ID	Name	Description	Sensitivity	DMA Channel
226	PKTE0_IRQ	PKTE0 Interrupt	Level	

PKTE Definitions

Command Descriptor

An 8-word structure that is either written directly into the packet command MMR set or is placed in a Command Descriptor Ring (CDR) in the processor memory. The packet engine sequentially processes the structure. The command descriptor contains the information that varies for every packet. This information includes pointers to the SA record, the state information, the source packet, and the destination packet.

Command Descriptor Ring (CDR)

A circular contiguous portion of memory which is used to manage one or more command descriptions for the packet engine.

Result Descriptor

When the packet engine completes the processing of a packet, it writes a result descriptor with the state information. The result descriptor can be read directly from the result register set or from the Result Descriptor Ring (RDR) in the processor memory.

Result Descriptor Ring (RDR)

A circular contiguous portion of memory which holds the mirror or copy of the CDR but contains the result descriptors. The RDR and CDR can be overlaid on top of each other.

Security Association (SA) Record

A structure that contains the remainder of the information the packet engine requires to process a packet. Most of the information fields in the SA record such as the key and encryption mode are static for the lifetime of the association. The fields do not require frequent manipulation by the processor core. The SA record non-static fields are the sequence number and sequence number mask. The SA record can have a corresponding state record for saving results from the current operations that are useful for future operations. The state record can hold the IV, the hash byte count, and the intermediate hash digest.

Cipher

A method or algorithm to encrypt or decrypt information

Hash

A cryptographic hash is a function that takes an arbitrary block of data and returns a fixed-size bit string. Four main properties define the function:

- It is easy to compute a hash value for any given input
- It is infeasible to generate the original input from a given hash
- It is infeasible to modify the input without changing the resulting hash
- It is infeasible to find two different inputs that result in the same hash

Autonomous Ring Mode (ARM)

Mode of operation in which most of the parameters as well as the data are set up in memory and moved to the engine for configuration and processing through DMA.

Target Command Mode (TCM)

Mode of operation where some parameters are set up in memory and moved into the packet engine through DMA while the other parameters are directly written to the registers. DMA moves the input and output data in and out of the engine.

Direct Host Mode (DHM)

Mode of operation that does not use DMA. All parameters are directly written to and read from the MMRs. The input and output are written to and read from the FIFO buffers.

Cipher Module

The cipher module does the symmetric encrypt or decrypt operations for:

- Data Encryption Standard (DES)
- Triple-DES
- ARC4
- Advanced Encryption Standard (AES) algorithms

The cipher module supports standard modes for DES and AES that include Electronic Code Book (ECB) and Cipher Block Chaining (CBC). The key size for DES is 56 bits, for Triple-DES is 168 bits. The AES module also provides support for AES counter-modes for IPsec and SRTP. All AES modes can use key sizes of 128 bits and 192/256 bits. Key scheduling is automatic and done in parallel with the encrypt or decrypt operation.

Hash Module

The hash module is tightly coupled with the encrypt or decrypt module and provides hardware accelerated one-way hash functions. Operations that combine both hash and encrypt or decrypt functions are provided to reduce processing time for data that needs both applied. For hash-then-decrypt operations, the packet engine performs parallel execution of both functions from the input buffer. For encrypt-then-hash operations, the processing is pipelined from the input buffer to provide minimum latency. An offset can be specified between the start of hashing and the start of encryption to support protocols such as IPsec or SRTP. The HMAC keyed hashing mechanism is supported for MD5, SHA-1, SHA-2-224 and SHA-2-256. The SSL-MAC is supported for MD5 and SHA-1.

Pseudo-Random Number Generator

Cipher algorithms that operate in CBC mode or counter-mode, require an IV. This IV must not be secret; however the IV must be unpredictable and unique for each execution of the encryption process. Pseudo-random number generators are deterministic algorithms that output statistically independent and unbiased numbers. True random number generators are non-deterministic and use the randomness that occurs in a physical process. The packet engine incorporates an ANSI X9.31 compliant Pseudo Random Number Generator (PRNG) that it can use to generate unique IVs using strong encryption. The ANSI X9.31 PRNG is defined as part of the ANSI X9 standards that are used to secure financial transactions. The function can also be used for pseudo-random number generation as part of an implementation of the digital signature standard described in NIST FIPS PUB 186-2.

The PRNG function, as defined by ANSI X9.31, is based on the AES cipher. This section describes the function to promote understanding of the different inputs and outputs of the PRNG function itself.

NOTE: The PRNG in the packet engine is only based on the AES cipher with 128-bit keys. Other ciphers and key lengths are not supported for the PRNG based on ANSI X9.31.

Let $e \times K(Y)$ represent the AES encryption of Y under the key K.

The PRNG function uses three inputs:

- K, a 128-bit key
- V, a 128-bit seed value
- DT, a 128-bit date/ time vector which is updated on each iteration

The intermediate value I is the result of an AES encryption of the data and time vector under key K.

$I = e \times K(DT)$

That value I is then XOR-ed with the seed V and AES encrypted under key K. The result R is the output of the PRNG function.

$R = e \times K(I \text{ XOR } V)$

A new seed value V is generated from the AES encryption of the result R XOR'ed with the intermediate value I under the key K.

$V = e \times K(R \text{ XOR } I)$

The PRNG function is deeply integrated inside the datapath of the packet engine. The function is controlled indirectly through the PRNG mode bits in the PKTE_CTL_STAT.PRNGMD bit field of the command descriptor and the IV source selection bits in the PKTE_SA_CMD0.IVSRC bit field of the SA record.

The PKTE module supports four different modes.

1. Load IV from PRNG for the current operation: PKTE_CTL_STAT.PRNGMD = 0b00 and PKTE_SA_CMD0.IVSRC = 0b11.
2. PRNG init mode initializes the PRNG with a key, seed, and date/time value: PKTE_CTL_STAT.PRNGMD = 0b01.

   Before the PRNG function can be used, it must be initialized with a key, seed, and date/time value. At initialization, the key, seed, and date/time values are programmed. Other PRNG operations do not change the key, however the seed, and date/time values are updated (not re-programmed). The date/time is updated every 128 system clock cycles.

   The date/time is a 128-bit value with randomly distributed number of ones and zeros. It must not be all zeros.

   The ***SA Record for PRNG Init Operation*** table shows how the key, seed and date/time values are loaded into the PKTE registers for initialization.

Table 39-3: SA Record for PRNG Init Operation

Parameter	SA Field	Description
K	SA_KEY0	PRNG key [127:96]
	SA_KEY1	PRNG key [95:64]
	SA_KEY2	PRNG key [63:32]
	SA_KEY3	PRNG key [31:0]
V	SA_IDIGEST0	PRNG seed [127:96]
	SA_IDIGEST1	PRNG seed [95:64]
	SA_IDIGEST2	PRNG seed [63:32]
	SA_IDIGEST3	PRNG seed [31:0]
DT	SA_ODIGEST0	PRNG date/time [127:96]
	SA_ODIGEST1	PRNG date/time [95:64]
	SA_ODIGEST2	PRNG date/time [63:32]
	SA_ODIGEST3	PRNG date/time [31:0]

3. PRNG generate mode generates pseudo-random data on initialized key, seed, and date/time value: PKTE_CTL_STAT.PRNGMD = 0b10.

   The PRNG function can be used to generated pseudo-random data for other purposes than IVs. For this mode, the PRNG must have been initialized once with the PRNG init mode.

The PRNG generate mode uses the initialized key and unique changing date/time value as inputs. The pseudo-random data is output to the output buffer of the packet engine.

The LEN field in the command descriptor indicates the amount of pseudo random data that is generated in multiples of 16 bytes. The maximum is 255 × 16 = 4080 bytes.

In autonomous ring mode, the output data is copied to the host memory at the destination address in the command descriptor. In direct host mode, the host must read the data directly from the output buffer. No SA record is used for this function.

Directly after the PRNG generate mode, a new pseudo-random number is generated and available for the next operation that uses the option PKTE_SA_CMD0.IVSRC = PRNG.

4. PRNG test mode generates pseudo-random data on initialized key, seed, and input (test) data: PKTE_CTL_STAT.PRNGMD = 0b11.

   The PRNG test mode can be used to test the correctness of the PRNG function. This mode is similar to the PRNG generate mode, except that the data is read from the input buffer of the packet engine, instead of the date/time value.

   For this mode, the PRNG must have been initialized once with the PRNG Init mode.

   The LEN field in the command descriptor indicates the amount of pseudo-random data to be generated in multiples of 16 bytes. The maximum is limited to the LEN field in bytes.

   In autonomous ring mode, the output data is copied to the host memory at the destination address in the command descriptor. In the direct host mode, the host must read the data directly from the output buffer. No SA record is used for this function.

   Directly after the PRNG test mode, a new pseudo-random number is generated and available for the next operation that uses the option PKTE_SA_CMD0.IVSRC = PRNG.

Packet Engine Processing Details

This section describes data processing through the packet engine. It describes padding and supported algorithms for each protocol.

A valid Security Association (SA) must be created before packet processing can start. A formatted SA record must reside in memory and be accessible to the packet engine. The host processor application is responsible for these tasks.

Crypto Padding

Padding is the process of adding data to fill-out a fixed-size plain text data structure. Three factors determine when to use a pad field:

1. If a block cipher encryption algorithm is used, a pad field is used to expand the plain text to a multiple of the block size.
2. Padding can be used to ensure that the cipher text terminates on an n-byte boundary.

3. Padding can conceal the actual length of the payload.

To facilitate peak encrypt or decrypt performance, the packet engine supports the following most commonly used padding functions in hardware:

1. Pad generation and insertion of pad bytes to the end of plain text prior to encryption, for outbound operations.
2. Pad verification to check for correct padding after decrypting a packet for inbound operations.
3. Pad consumption to strip the pad bytes from the plain text data after decrypting a packet, for inbound operations.

Pad Generation and Insertion

The pad type and quantity of bytes the packet engine inserts depends on the plain text length and the value of the following fields:

- `PKTE_SA_CMD0.PADTYPE` and `PKTE_SA_CMD0.EXTPAD` defines the type of padding
- `PKTE_CTL_STAT.PADVAL` defines a value that is inserted in the pad
- `PKTE_SA_CMD0.CIPHER` enforces a certain pad alignment
- `PKTE_SA_CMD1.CIPHERMD` enforces a certain pad alignment
- `PKTE_SA_CMD0.SCPAD` allows stream ciphers to be padded
- `PKTE_CTL_STAT.PADCTLSTAT` controls the pad alignment

The `PKTE_CTL_STAT.PADCTLSTAT` bit field of the result descriptor returns the total number of inserted pad bytes.

Pad Types

The pad type bit field (`PKTE_SA_CMD0.PADTYPE`) and the extended pad bit (`PKTE_SA_CMD0.EXTPAD`) select the pad type for the extended protocol group. The packet engine can generate different pad types in hardware as described in the ***Pad Examples*** table.

The `PKTE_CTL_STAT.PADVAL` bit field, together with the number of pad bytes, defines the value that is inserted in the pad. The format of the pad and the use of this field is best explained in an example (see the ***Pad Examples*** table).

For the IPsec pad type, this field holds the value that is inserted into the next header field (in the ESP trailer) of the innermost operation's header. For the Constant pad type or the Constant SSL pad type, this field holds the inserted fixed constant pad value. For all other pad types, this field is not used and must be zero.

Table 39-4: Pad Types

Pad Type	Value	Description
IPSec	0b000	Append 0 to 255 pad bytes, followed by a pad length byte and a next header byte. The first pad byte appended to the plain text is numbered 1, with subsequent pad bytes making up a monotonically increasing sequence: 1, 2, 3 and up. Append the pad length field that indicates the number of pad bytes (0–255), where a value of zero indicates no pad bytes present. Append the next header byte as specified in the `PKTE_CTL_STAT.PADVAL` field of the command descriptor. A minimum of 2 bytes are appended; zero pad bytes plus the pad length byte plus the next header byte, in which case the `PKTE_CTL_STAT.PADCTLSTAT` field in the result descriptor returns 0x02. A maximum of 257 bytes can be appended, in which case the `PKTE_CTL_STAT.PADCTLSTAT` field in the descriptor returns 0x01.
PKCS#7	0b001	Appends 1–128 pad bytes with a pad byte value equal to the pad length (1–128).
Constant	0b010	Appends 0–255 pad bytes of a user-specified character to the plain text data. This character is specified in the `PKTE_CTL_STAT.PADVAL` field of the command descriptor.
Zero	0b011	Appends 0–255 pad bytes of 0x00 to the plain text data.
Constant SSL	0b110	Appends 0–255 pad bytes of a user-specified character to the plain text data, followed by a 'pad length' byte (0–255). This character is specified in the `PKTE_CTL_STAT.PADVAL` field of the command descriptor. A total of 256 bytes can be appended, in which case the pad field returns 0x00.

For example, the ***Pad Examples*** table shows the appended pad for any of the pad types for an outbound (encrypt) operation. The table shows a plain text input of 2 bytes using the 8-byte block cipher crypto-algorithm DES-ECB and a `PKTE_CTL_STAT.PADVAL` field value of 0xAA.

Table 39-5: Pad Examples

Pad Type	Pad field (extended to Plain Text)	`PKTE_CTL_STAT`
IPSec	0x01, 0x02, 0x03, 0x04, 0x04, 0xAA	0x06
PKCS#7	0x06, 0x06, 0x06, 0x06, 0x06, 0x06	0x06
Constant	0xAA, 0xAA, 0xAA, 0xAA, 0xAA, 0xAA	0x06
Zero	0x00, 0x00, 0x00, 0x00, 0x00, 0x00	0x06
Constant SSL	0xAA, 0xAA, 0xAA, 0xAA, 0xAA, 0x05	0x06

Pad Length

The ***Pad Alignment*** table lists the alignment (boundaries) to which the packet engine will pad, based on:

- The selected crypto algorithm
- Crypto mode
- The value of the pad stream cipher bit
- The value of pad control

The minimum number of inserted pad bytes depends on the cipher algorithm, selected using the PKTE_SA_CMD0.CIPHER bit field, and the cipher mode, selected using the PKTE_SA_CMD1.CIPHERMD bit field.

For block ciphers, the plain text data is always (as a minimum) padded to the next block boundary. More pad bytes beyond the algorithm or protocol alignment requirements can be inserted using the pad control (PKTE_CTL_STAT.PADCTLSTAT) in the command descriptor. This feature can be used for *traffic flow security* to conceal the number of plain text bytes in an encrypted packet.

Encrypt operations that use block ciphers have minimum pad requirements based on their block size. The packet engine enforces a minimum pad alignment for block ciphers according to the ***Pad Alignment*** table. For ESP outbound operations, the minimum pad alignment is forced to 4 bytes.

For stream ciphers and null crypto the data is never padded when the stream cipher pad bit (PKTE_SA_CMD0.SCPAD) =0. When PKTE_SA_CMD0.SCPAD =1 the plain text data is padded to the length as defined by the PKTE_CTL_STAT.PADCTLSTAT bits in the command descriptor.

NOTE: The SSL protocol does not allow padding to exceed the ciphers block length. This length is 8 bytes for DES/Triple-DES and 16 bytes for AES. For SSL, the packet engine does not enforce this pad alignment value. The host processor must ensure that the PKTE_CTL_STAT.PADCTLSTAT bit field is configured correctly.

Table 39-6: Pad Alignment

Pad Control **PADCTLSTAT = PKTE_CTL_STAT[31:24]**			**0x00**	**0x01*1**	**0x02**	**0x04**	**0x08**	**0x10**	**0x20**	**0x40**	**0x80*2**
Crypto Algorithm	**Crypto Mode**	**Pad Stream Ciphers**	**%8**	**%1**	**%4**	**%8**	**%16**	**%32**	**%64**	**%128**	**%256**
DES	ECB, CBC	N/A	8	8	8	8	16	32	64	128	256
AES	ECB, CBC	N/A	16	16	16	16	16	32	64	128	256
	CTR, ICM with ESP	N/A	8	4	4	8	16	32	64	128	256
	CTR, ICM no ESP	no	0	0	0	0	0	0	0	0	0
		yes	8	0	4	8	16	32	64	128	256
NULL	with ESP	N/A	8	4	4	8	16	32	64	128	256
	no ESP	no	8	0	0	0	0	0	0	0	0
		yes	8	0	4	8	16	32	64	128	256
ARC4	with ESP	N/A	8	4	4	8	16	32	64	128	256
	no ESP	no	0	0	0	0	0	0	0	0	0
		yes	8	0	4	8	16	32	64	128	256

*1 When PKTE_CTL_STAT.PADCTLSTAT is configured for no padding (0x01), it does not mean that no padding bytes are inserted. When PKCS#7 padding is selected, a pad length field with a value =1 is inserted. When SSL or TLS padding is selected, a pad length field with a value =0 is inserted. When IPsec padding is selected, a pad length field is forced to (PKTE_CTL_STAT.PADCTLSTAT=0x20). When zero pad and constant pad are selected, no pad bytes are inserted.

*2 Pad type PKCS#7 supports a maximum length of 128 pad bytes, so the packet engine overrules a 256-byte alignment (PKTE_CTL_STAT.PADCTLSTAT=0x80) to a 128-byte boundary (PKTE_CTL_STAT.PADCTLSTAT=0x40).

The packet engine does not constrain the pad type that is used for an operation; any pad type can be used for each operation. The user must be aware that some protocol specifications only allow specific pad types. The SRTP specification does not have padding defined as padding performed by RTP. The host must pad the RTP packet.

The host software can implement padding that is not supported in hardware. In this case, the host must select the *zero pad* type and set the PKTE_CTL_STAT.PADCTLSTAT bit field in the packet descriptor to zero (no padding). The hardware padding engine does not add any bytes. When using a block cipher, the host must insert pad bytes. Then, the data to be encrypted (plain text and pad bytes) are a multiple of the block ciphers boundary. For stream ciphers, any number of pad bytes can be added.

Pad Verification and Consumption

The packet engine can validate a pad type against the expected values. The value of the following bits controls the pad verify function:

- PKTE_SA_CMD0.PADTYPE and PKTE_SA_CMD0.EXTPAD define the type of padding
- PKTE_SA_CMD0.CIPHER enforces a certain pad alignment
- PKTE_SA_CMD1.CIPHERMD enforces a certain pad alignment
- PKTE_SA_CMD0.SCPAD allows stream ciphers to be padded

When packet processing is complete, the status byte in the first word of the result descriptor reports the pad verification status. Refer to the Table 39-28 Extended Error Codes - Status Encoding table.

The PKTE_CTL_STAT.PADCTLSTAT bits in the first word of the result descriptor return the total number of detected pad bytes and returns zero for a pad verify error.

When the IPsec pad type is selected, the PKTE_CTL_STAT.PADVAL bit field of the result descriptor returns the next header field. For IPsec ESP outbound operations, this field returns the decimal value 50. For IPsec inbound operations and basic inbound operations that use the IPsec pad mode, the packet engine returns the next header field it detects on the header of the innermost operation. This value is typical for the payload protocol, such as TCP or UDP. However, in bundling scenarios or in IPv6 with destination option headers, another header value could be seen. For all other inbound operations, the returned pad value is zero.

Pad verification is performed for inbound (decrypt) operations that use IPsec, TLS/DTLS or PKCS#7 pad type:

- In combination with a block cipher algorithm: DES-ECB, DES-CBC, AES-ECB, AES-CBC,
- In combination with a stream cipher and stream cipher padding PKTE_SA_CMD0.SCPAD enabled: AES-CTR, AES-ICM and ARC4
- In combination with null-crypto (no encryption).

Pad Types

The PKTE_SA_CMD0.PADTYPE bit field and the extended pad PKTE_SA_CMD0.EXTPAD bit selects the pad type for the extended protocol group pad type. The packet engine can verify the different pad types in hardware as described in the ***Pad Types*** table.

The constant and zero pad types are not verified since they do not include a pad length field. The SSL pad type is not verified since it does not have a defined pattern.

Table 39-7: Pad Types

Pad Type	SA_CMD0[18, 7:6]	Description
IPSec	0b000	Verify that the pad field includes 0–255 pad bytes, followed by a correct pad length and a next header byte. Verify that pad bytes appended to the plain text are an incremental count, starting at one. Verify that the pad length field is the number of pad bytes (0–255), where a value of zero indicates no pad bytes present. Verify that a next header byte is present as the last byte of the packet, the value is not verified. This is after removal of the ICV. The total number of detected pad bytes is returned in the PKTE_CTL_STAT.PADCTLSTAT field in the result descriptor. **NOTE:** A minimum of 2 bytes must be present, zero pad bytes plus the pad length byte plus the next header byte. In this case the PKTE_CTL_STAT.PADCTLSTAT field in the descriptor returns 0x02. A maximum of 257 bytes can be present, in which case the PKTE_CTL_STAT.PADCTLSTAT field in the result descriptor returns 0x01. The value of the next header byte is returned in the PKTE_CTL_STAT.PADVAL field in the result descriptor.
PKCS#7	0b001	Verify that the pad field includes 1–128 pad bytes, with a pad byte value equal to the pad length (1–128).

When a block cipher is used and the payload is not padded to the nearest block size boundary, as required by the protocol, a *block size error* is generated for all pad types.

Pad Consumption

The packet engine can optionally consume the decrypted pad bytes for an inbound operation that uses the IPsec, SSL, TLS/DTLS, or PKCS#7 pad types. The pad types constant and zero are not consumed since they do not include a pad length field.

Pad consumption (or stripping) is selected on a flow-by-flow basis in the SA-record with the PKTE_SA_CMD1.CPYPAD bit. When this bit is set, the length returned in the LEN field of the result descriptor is the total length of the plain text including the pad. When the PKTE_SA_CMD1.CPYPAD is disabled, the detected pad length, as returned in the PKTE_CTL_STAT.PADCTLSTAT bits, is subtracted from the total length and then returned in the LEN field of the result descriptor.

The pad is always written to the result packet buffer in memory. When the PKTE_SA_CMD1.CPYPAD bit is disabled, only the result length is corrected.

Crypto and Hash Algorithms

The packet engine supports a wide range of crypto and hash algorithms to accelerate basic operations and protocol operations. These algorithms are:

- Basic Encrypt and Basic Decrypt Operations
- Basic Hash Operations
- Basic Encrypt-Hash and Basic Hash-Decrypt Operations
- IPSec ESP Operations
- SRTP Operations

The following tables provide allowed algorithm combinations. Those algorithms not listed in the tables are invalid and can give unexpected results.

NOTE: Not all crypto and hash algorithms are available on all product models. For information on algorithm availability, see the product-specific data sheet.

IV Processing

An initialization vector (IV) is necessary to start a cipher stream or a block cipher in any of the streaming modes of operation. The IV must be unique for each packet. The IV ensures that all cipher texts are unique even if produced by the same encryption key. This functionality prevents every packet from needing a unique encryption key.

Depending on the packet engine operation, the IV can be loaded from different sources. The IV format depends on the algorithm and the source of the IV. The ***Format of the IV*** table provides an overview of all IV formats.

Table 39-15: Format of the IV

Algorithm	IV Source (`PKTE_SA_CMD0.IVSRC`)	Format	IV Offset (`PKTE_SA_CMD1.HSHCOFFST`)
DES/Triple-DES (CBC)	Previous Result of IV	Internal IV register [63:0]	0x00
	Input Buffer	Input buffer [63:0]	0x02
	Saved IV	State Record Saved IV [63:0]	0x00
	Automatic	PRNG output [63:0]	0x00
AES (CBC)	Previous Result of IV	Internal IV register [127:0]	0x00
	Input Buffer	Input Buffer [127:0]	0x04
	Saved IV	State Record Saved IV [127:0]	0x00
	Automatic	PRNG output [127:0]	0x00
AES (ICM) for Basic and SRTP	Input Buffer	Input Buffer [127:0]	0x04
	Saved IV	State Record Saved IV [127:0]	0x00
AES (CTR) for Basic and IP-sec	Input Buffer	SA_NONCE || Input Buffer[63:0] || 0x00000001	0x02
	Saved IV	State Record Saved IV [127:0]	0x00
	Automatic	SA_NONCE || PRNG output [95:32] || 0x00000001	0x00

Notes:

1. The `PKTE_SA_CMD1.HSHCOFFST` bit field provides the IV offset. The offset is only applicable for basic hash or encrypt operations. For protocol operations, the offset is automatically enforced.

2. AES-CTR: The Nonce value as described in RFC 3686, is mapped to the PKTE_SA_NONCE register. This Nonce value remains constant for the lifetime of the security association.
3. The host processor controls the IV update using the save-IV bit (PKTE_SA_CMD0.SVIV). When part of a packet is processed using a stream cipher and the encrypt or decrypt data is not an integer multiple of the block size, the saved IV is invalid. It must not be used to resume processing the packet.
4. The packet engine supports automatic IV generation for outbound operations. A new IV is generated for every packet with the internal PRNG. This automatic IV generation can be used for all DES, Triple-DES, and AES modes that use an IV, except for AES-ICM mode.
5. For outbound operations, automatic IV generation is the most efficient. No additional I/O is required, and the host processor does not need to provide the IV. When the saved IV option supplies the IV, the IV must be changed for each packet sent. This activity happens when the packet engine writes back the IV to the state record after processing.
6. Outbound IPsec operations put the IV explicitly at the front of the packet. For an inbound IPsec operation, loading from the input buffer is most efficient and always used.
7. CBC processing must not use a predictable IV. Do not use the saved IV and previous result IV options for CBC processing. Refer to RFC 3602 for more details.

ARC4 Processing

The ARC4 algorithm supports two modes of operation: stateless and stateful. For SSL, TLS and DTLS operations that use the ARC4 algorithm, the mode must be set to stateful.

Stateless Mode. Each packet is processed with a newly initialized ARC4 key taken from the key field of the SA record. In this mode, the state information from the SA is never to be read.

CAUTION: When an ARC4 operation in stateless mode is interrupted by an *Interface Error* and the ARC4 state building process is aborted, the next packet fails. The ARC4 is not reset between two packets. For the next packet the ARC4 proceeds from the internal state that it was aborted. A soft reset *does not* reset the ARC4 internal state, a hardware reset is required.

Stateful Mode. When the PKTE_CTL_STAT.INITARC4 bit =1, the ARC4 algorithm initializes using the key specified in the SA record. When the PKTE_CTL_STAT.INITARC4 bit =0, the ARC4 context is read from the ARC4 state field of the SA record and the*i* and *j* pointer field of the SA record. The encrypt and decrypt processing continues from this algorithm state.

The packet engine supports ARC4 key sizes of 40 bits to 128 bits. Longer keys can be used, but they cannot be made inside the packet engine.

The host processor applies ARC4 key scheduling function to the s-box and puts the 256-byte result into the ARC4 state record. It writes the *i* and *j* pointers in the SA (initial $i = 1$, $j = 0$). The host programs the packet engine and specifies stateful operation to continue the ARC4 algorithm.

Hash State Loading

The hash state can be loaded from various sources, depending on the selected protocol and hash algorithm. The ***Different Sources for Loading the Hash State*** table provides a list of all the options.

Table 39-16: Different Sources for Loading the Hash State

Hash Algorithm **PKTE_SA_CMD0.HASHSRC =**	From SA 0b00	RESERVED 0b01	From State 0b10	No Load 0b11
SHA-1	yes	-	yes	Yes
SHA-224	Yes	-	Yes	Yes
SHA-256	Yes	-	Yes	Yes
Null hash	x	x	x	x

Sequence Number Processing

The packet engine supports sequence number generation and verification for IPsec and extended SSL, TLS, and DTLS protocol operations.

A Sequence Number (SN) is an unsigned number that a sender must implement, and a receiver can use to support anti-replay service (replay attacks) for a specific SA. This processing includes detection of the same packet that arrives more than once and detection of packets that arrive in an incorrect sequence and is outside an accepted level of order relative to the last received packet.

The packet engine supports the following options.

- Sequence number loaded from SA for outbound operations and is retrieved from the input packet for inbound operations.

The sequence number and sequence number mask fields are part of the SA record.

Sequence Number Processing in Extended SSL/TLS

SSL and TLS use an implicit sequence number of 64 bits that is not send in the packet but part of the hash.

For inbound operations, no sequence number verification is performed; instead, an incorrect sequence number results in an authentication error (`PKTE_CTL_STAT.AUTHERR`).

For outbound operations, with `PKTE_SA_CMD0.HDRPROC` enabled and `PKTE_SA_CMD1.ENSQNCHK` enabled, the packet engine generates a sequence number error when the 64-bit sequence number counter overflows (counter is 2^{64}-1 and increments to 0). The host processor must not send the packet.

For both outbound and inbound operations, with `PKTE_SA_CMD0.HDRPROC` enabled and `PKTE_SA_CMD1.ENSQNCHK` enabled, the packet engine reads the sequence number from the `PKTE_SA_SEQNUM[n]` registers in the SA. When the operation is finished, the packet engine stores the incremented sequence number in the same SA fields. The sequence number mask `PKTE_SA_SEQNUM_MSK[n]` registers in the SA are not used.

For both outbound and inbound operations, with PKTE_SA_CMD0.HDRPROC disabled, the packet engine does not increment the sequence number. It expects the host to provide the sequence number through the input buffer as part of the header.

Sequence Number Processing in DTLS

DTLS uses an explicit sequence number of 64 bits that is sent in the packet. The DTLS sequence number is composed of the epoch (16 bits) and packet sequence number (48 bits) that together form the 64-bit number, like the TLS sequence number. The epoch is incremented after each *Change Cipher Spec* message. The packet sequence number is incremented per packet starting from zero after each change cipher spec message.

For outbound operations, with PKTE_SA_CMD0.HDRPROC enabled, the packet engine reads the sequence number from the PKTE_SA_SEQNUM[n] fields in the SA, then inserts the sequence number in the packet. Then the packet engine stores the incremented sequence number in the PKTE_SA_SEQNUM[n] fields in the SA. The sequence number mask PKTE_SA_SEQNUM_MSK[n] fields in the SA are not used.

For outbound operations, with PKTE_SA_CMD0.HDRPROC enabled and PKTE_SA_CMD1.ENSQNCHK enabled, the packet engine generates a sequence number error when the 48-bit sequence number counter overflows (counter is $2^{48} - 1$ and increments to 0). The host must not send the packet.

For outbound operations, with PKTE_SA_CMD0.HDRPROC disabled or PKTE_SA_CMD1.ENSQNCHK disabled, the packet engine does not increment and verify a sequence number counter overflow, and therefore never generates a sequence number error. With PKTE_SA_CMD0.HDRPROC disabled the Packet Engine does not update the sequence number and sequence number mask fields in the SA and expects the host to provide the sequence number through the input buffer as part of the header.

For inbound operations, with PKTE_SA_CMD0.HDRPROC enabled and PKTE_SA_CMD1.ENSQNCHK enabled, the packet engine verifies the PKTE_SA_SEQNUM[n] fields against the sequence number in the packet using the PKTE_SA_SEQNUM_MSK[n] from the SA. Three situations can occur:

1. If the received sequence number falls outside and above the 64-bit sequence number mask, the mask is shifted. The packet engine updates the SA with the received sequence number and the shifted sequence number mask.
2. If the received sequence number falls inside the 64-bit sequence number mask and is not a duplicate sequence number (the same as received before), the corresponding bit in the mask is set. The packet engine updates the SA with the received sequence number and the updated sequence number mask.
3. If the received sequence number falls outside the 64-bit sequence number mask or matches and earlier received number a sequence number error is generated. The packet engine does not update the sequence number and sequence number mask fields in the SA. The host must discard the packet.

For inbound operations, with PKTE_SA_CMD0.HDRPROC disabled or PKTE_SA_CMD1.ENSQNCHK disabled, the packet engine does not verify the sequence number against the sequence number in the packet and therefore never generates a sequence number error.

With PKTE_SA_CMD0.HDRPROC disabled the packet engine does not update the sequence number and sequence number mask fields in the SA and expects the host to provide the sequence number through the input buffer as part of the header.

The following tables provide details of sequence number processing.

Table 39-17: Sequence Number Generation and Verification Control (Outbound)

Header Processing SA_CMD0[19]	Anti-Replay Service SA_CMD1[29]	Description
Outbound		
1	1	Sequence number generation (increment)
1	1	Sequence number overflow check (2^{32}–1) to zero for IPsec, (2^{48}–1) to zero for DTLS and (2^{64}–1) to zero for Extended SSL/TLS.
1	0/1	Sequence number update in SA
0/1	0/1	Extended sequence number update in SA

Table 39-18: Sequence Number Generation and Verification Control (Inbound)

Header Processing SA_CMD0[19]	Anti-Replay Service SA_CMD1[29]	Description
Inbound		
1	1	Sequence number verification (check against sequence number and sequence number mask in SA). Applicable only for IPsec and DTLS.
1	0/1	Sequence number update in SA, except on authentication error
1	1	Sequence number mask update in SA. Applicable only for IPsec and DTLS.
0/1	0/1	Extended sequence number update in SA

PKTE Block Diagram

The ***PKTE Block Diagram*** shows the functional blocks within the PKTE.

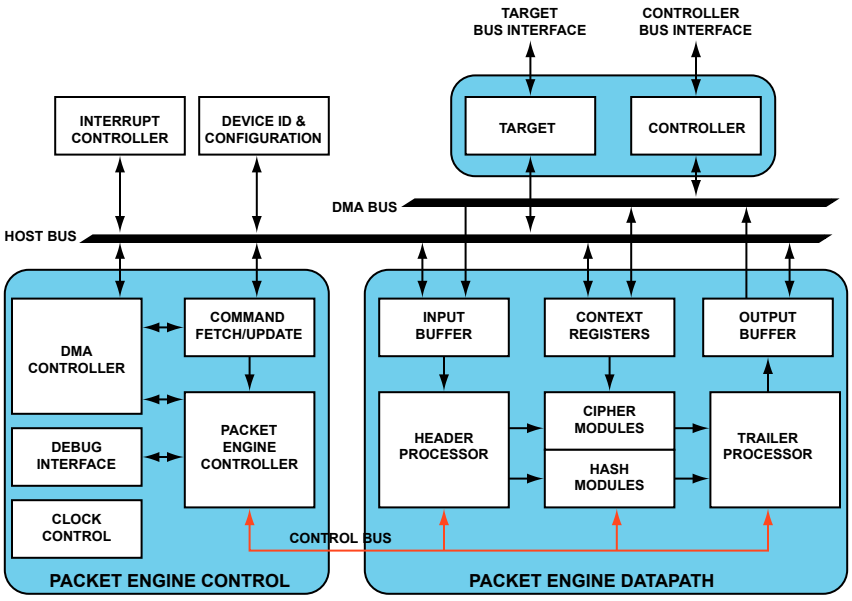

Figure 39-1: PKTE Block Diagram

PKTE Architectural Concepts

The following descriptions provide details on the functional blocks within the security packet engine.

Packet Engine

The packet engine contains symmetric cipher and hash engines. It is optimized to off-load intensive cryptographic operations from the host processor. It can perform parallel and pipelined encryption and hashing operations, reducing the latency, and processing time for packets that need both operations applied. The processor core provides the command information and packet data for the packet engine. The packet engine can run autonomously, using its local DMA controller to perform DMA transfers across the main bus to access the memory of the processor core. The DMA process incorporates flow-control to guarantee proper data flow. Two elements provide the command information that defines the processing for each packet:

- Command descriptor
- SA record

When the packet engine finishes the operation, it updates the SA record, when needed, and provides a result descriptor.

The packet engine has four different modes of operation. The modes give the processor core various levels of control over the command information and packet data transfers to and from the packet engine.

- Autonomous Ring Mode (ARM)
- Target Command Mode (with and without result descriptor ring) (TCM)
- Direct Host Mode (DHM)

Input/Output FIFO Buffers

The data for the packet engine is buffered at both input and output. These buffers decouple the DMA I/O process from the cipher and hash modules inside the packet engine. This functionality enables large DMA burst sizes and allows the crypto engines to process data during I/O latency periods. Data moves automatically from the input buffer through the encryption and hash engines to the output buffer. When the output buffer is full, the process stops until the data is read and space is available in the output buffer. Each buffer is a 256-byte dual-port RAM.

Parallel Operations

The hash functionality and encrypt or decrypt functionality are tightly coupled. Operations that combine both hash and encrypt or decrypt functions are available to reduce processing time for data that must apply both. For hash-then-decrypt operations, the packet engine performs parallel execution of both functions from the input buffer. For encrypt-then-hash operations, the processing is pipelined from the input buffer to provide minimum latency. An offset can be specified between the start of the hashing and the start of the encryption to support protocols such as IPSec and SRTP.

DMA Controller

The packet engine uses a high-performance DMA controller for autonomous data transfers for:

- Command descriptor reads
- SA record and state record reads
- Packet data read
- Result packet writes
- SA record and state record writes
- Result descriptor writes

Interrupt Controller

The packet engine includes an interrupt controller that, under programmable configuration control, can generate an interrupt on completion of certain operations. Individual interrupts can be masked and cleared. The interrupt registers show both the raw and masked interrupt status of the internal interrupts. The processor core can use interrupts, together with their associated threshold settings, to optimize the overall packet processing in the system. One interrupt can inform the processor core that the input side of the packet engine is almost empty to avoid a stall-on-empty condition. One interrupt can inform the host that the output side is almost full to avoid a stall-on-full condition. The controller uses several interrupts to inform the processor core about errors inside the packet engine. All available interrupts are combined into a single output port as either a level- or edge-active programmable interrupt output.

Clock Controller

The packet engine includes a clock controller that generates clock enable signals. A clock manager external to the packet engine uses the clock enable signals to switch the clocks to modules in the packet engine, reducing power consumption. The power saving can be significant, depending on the crypto-operation and the idle time of the packet engine. The clock controller generates the clock enable signals dynamically depending on the current crypto-operation. A clock control register provides the processor core the possibility to override this dynamic process.

PKTE Operating Modes

The packet engine can be configured in one of three command modes. For all modes the packet engine can generate an interrupt at completion of packet processing:

- Autonomous Ring Mode (ARM). The core prepares descriptors in the CDR and then initiates a descriptor fetch by triggering the packet engine. When a packet operation is complete, the packet engine writes the result descriptor out into a ring in host memory using the system requester bus interface.
- Target Command Mode (TCM). The core directly writes the command descriptors to the packet command register set to initiate a packet operation. This process eliminates an extra DMA transfer to fetch a descriptor, but requires the core to synchronously initiate packet processing. This mode can be configured both without RDR or with RDR. In the latter case, the packet engine writes the result descriptor out into the RDR in host memory using the system requester bus interface.

- Direct Host Mode (DHM). The core has full control over the packet engine and uses the system completer bus interface. The core provides all the command descriptors, SA record and state record, and packet input data. When the packet engine completes processing, the core must read the packet output data, the SA record, the state record, and the result descriptors.

Autonomous Ring Mode (ARM)

The *Autonomous Ring Mode* allows the packet engine and the host processor to operate asynchronously. A queue of multiple packets in the host processor memory can be processed continuously to provide the highest possible throughput. The packet engine autonomously fetches the command descriptor, the SA record, and optionally the state record and the input data from host processor memory. After the packet engine finishes processing, it autonomously writes the output data, updates the SA and state record, and writes the result descriptor in the host processor memory. It accesses the host processor memory through DMA read transfers across the system bus requester.

This mode uses both command descriptor ring (CDR) and result descriptor ring (RDR).

Physically the CDR, RDR, SA record, source packet, and result packet can all be in different memories depending on the system memory architecture. The host processor writes command descriptors to the CDR in host processor memory. Then, it writes to the `PKTE_CDSC_INCR` register with the number of command descriptors that it prepared in the CDR. This write to the `PKTE_CDSC_INCR` register is the trigger for the packet engine to fetch the command descriptors sequentially from the CDR. When a command descriptor is fetched and written to the internal packet command register set, the descriptor is validated. If the ownership bits are set for the packet engine and the command is valid, processing starts. If not, that command is discarded, and a result descriptor is written to the RDR with the error code *invalid command descriptor*. In this mode, the host processor can set a threshold on the CDR and enable an associated interrupt. The packet engine generates an interrupt when the number of command descriptors in the CDR is equal or below the threshold value.

The SA record and state record that contains the crypto context information are stored in a memory area. The packet engine autonomously accesses the memory area through DMA transfers across the system bus requester. Also, the source packet and result packet are stored in a memory area that the packet engine autonomously accesses through the same bus requester interface.

After decoding the command descriptor, the packet engine fetches the SA record and then, optionally, the state record.

Then, the source packet is fetched and stored in the input buffer. Packets less than the size of the input buffers are fetched entirely at once. Larger packets are fetched in parts that completely fill the input buffer. The packet engine initiates a new fetch each time the number of empty spaces in the input buffer reaches its threshold value. When the first packet data is available in the input buffer, the crypto engines start processing the data. After processing, the crypto engines write the result packet to the output buffer.

The packet engine writes the result packet from the output buffer to host processor memory when the number of bytes in the output buffer reaches its threshold value. Packets less than the threshold value are written entirely at once. Larger packets are written in parts that completely empty the output buffer

The source packet data fetching, data processing, and result packet data writing are parallel processes that continue until the last result packet is written to host processor memory. Then, the packet engine optionally writes the SA record and the state record to update the crypto context information. As a final step, the packet engine writes the result descriptor to the RDR. The host processor must either poll the RDR or wait for an interrupt from the packet engine to determine when packet processing is complete.

Target Command Mode (TCM)

This mode provides a synchronous interface between the processor core and the packet engine. The Command Descriptor Ring (CDR) is disabled and the processor core initiates packet processing by writing the command descriptor directly to the internal command descriptor MMRs of the packet engine. The Result Descriptor Ring (RDR) is optional.

- For `PKTE_CFG.MODE` =01, the RDR is disabled and the processor core reads the result descriptor directly from the internal result descriptor register set for the packet engine.
- For `PKTE_CFG.MODE` =10, the RDR is enabled and stored in a memory area that the packet engine can access through its requester bus interface as in autonomous ring mode.

In target command mode, the packet engine autonomously fetches the SA record, state record, source packet data as in autonomous ring mode. Also, as in ARM, after processing, the packet engine updates state fields of the SA record and state record in the host processor memory.

Direct Host Mode (DHM)

This mode provides a synchronous interface between the processor core and the packet engine. The packet engine is under full control of the processor core. The host processor writes the command descriptors, SA record, and state record directly to the packet engine registers. Then, the processor core writes the source packet data into the input buffer. When processing is complete, the processor core reads back the result packet data from the output buffer. Finally, it reads the result descriptor, the updated SA record, and state record directly from the packet engine registers.

PKTE Event Control

The following section provides information about interrupts in the PKTE module.

PKTE Interrupt Signals

The Packet Engine has an internal Interrupt Controller with 9 interrupt sources. There are 7 registers associated with the interrupt controller:

1. Interrupt Unmasked Status - `PKTE_IUMSK_STAT`
2. Interrupt Mask Status - `PKTE_IMSK_STAT`
3. Interrupt Clear Register - `PKTE_INT_CLR`
4. Interrupt Enable Register - `PKTE_INT_EN`

5. Interrupt Mask Disable - PKTE_IMSK_DIS
6. Interrupt Mask Enable - PKTE_IMSK_EN
7. Interrupt Configuration - PKTE_INT_CFG

The ***Packet Engine Interrupt Controller Block Diagram*** shows the blocks of the interrupt controller.

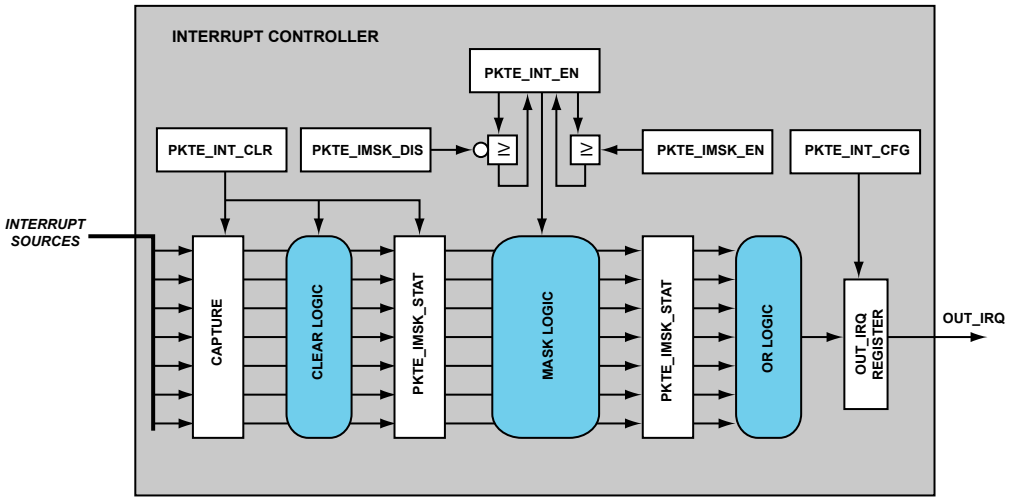

Figure 39-2: Packet Engine Interrupt Controller Block Diagram

All of the interrupt sources are pulse or level events in their native form.

These interrupts are captured and stored at their unmasked and masked status in their respective PKTE_IUMSK_STAT and PKTE_IMSK_STAT registers. This allows the host processor to read the status of any interrupt source either before or after the mask is applied.

The PKTE_INT_EN register provides a mask to select what interrupt source are enabled to the output interrupt request. Writing a one to the PKTE_INT_CLR register resets both the masked and unmasked interrupt.

The PKTE_IMSK_EN and PKTE_IMSK_DIS registers can be set to enable and disable individual interrupts respectively in the PKTE_INT_EN register. This avoids the need for read-modify-write operations from the host processor.

Ring Interrupts

Two interrupts are provided for efficient ring management: The CDR threshold interrupt (*cdrthrs*h) and the RDR threshold interrupt (*rdrthrsh*).

Command Descriptor Ring

The CDR threshold interrupt (cdrthrsh) is a level-based interrupt and connects to the threshold value in the PKTE_RING_THRESH.CDRTHRSH bit field. It enables the host processor to efficiently fill the CDR. The host processor writes command descriptors to the CDR with this interrupt masked until the CDR is full. Then the host processor enables the CDR threshold interrupt. When the interrupt is activated, the host processor clears the interrupt and it is guaranteed that it can put CDR threshold number of descriptors in the CDR.

Example Configuration:

```
PKTE_RING_CFG.RINGSZ=256,
PKTE_RING_THRESH.CDRTHRSH=224,
PKTE_INT_EN.CDRTHRSH=0 /*(IRQ disabled)*/
```

1. The host writes 8 Command Descriptors at once, then writes the PKTE_CDSC_INCR register to 8.
2. This is repeated until there are less than 8 empty entries in the CDR.
3. The fill level is now equal to the threshold (224)
4. The host enables the CDR threshold IRQ (PKTE_INT_EN.CDRTHRSH=1)
5. The packet engine processes packets and the fill level (PKTE_CDSC_CNT register) decreases.
6. Then the CDR threshold IRQ is activated as the fill level equals 224.
7. The host handles the interrupt, clears it, and continues with step #1.

Result Descriptor Ring

The RDR threshold interrupt (rdrthrsh) is a level-based interrupt and connects to the threshold value in the PKTE_RING_THRESH.RDRTHRSH bit field and the timeout value in the RD timeout (PKTE_RING_THRESH.RDTO) bit field. It enables the host processor to efficiently empty the RDR. The timeout reminds the host processor that when the threshold kicks in result descriptors stay long in the RDR and must be processed to reduce latency. The timeout counts when the ring is not empty, regardless of the fill level and restarts when the host processor writes the PKTE_RDSC_CNT register. Initially the host processor enables the RDR threshold interrupt. When the interrupt is activated the host processor reads result descriptors until the RDR is empty or contains less than the PKTE_RING_THRESH.RDRTHRSH number of descriptors.

Example Configuration:

```
PKTE_RING_CFG.RINGSZ=256,
PKTE_RING_THRESH.RDRTHRSH=32, timeout=1ms
PKTE_INT_EN.RDRTHRSH=1     /*(IRQ enabled)*/
```

1. The Packet Engine writes the Result Descriptor, timeout counter starts.
2. The Packet Engine writes 32 more Result Descriptors, fill level (PKTE_RDSC_CNT register) increases to 33.
3. The fill level exceeds threshold within 1ms, the RDR threshold IRQ is activated.
4. The host handles the interrupt, reads 8 Result Descriptors at once, then writes the PKTE_RDSC_DECR register with 8. The write to the PKTE_RDSC_DECR register restarts the timeout counter. The fill level is now under the threshold but there are still 25 descriptors left.
5. The Packet Engine writes 8 more Result Descriptors, fill level increases to 33.
6. The fill level exceeds threshold within 1 ms, the RDR threshold IRQ is activated.

7. The host handles the interrupt, reads 8 Result Descriptors at once, then writes the PKTE_RDSC_DECR register with 8. The write to the PKTE_RDSC_DECR register restarts the timeout counter. The fill level is now under the threshold but there are still 25 descriptors left.
8. After 1 ms, the timeout counter interrupt is activated.
9. The host handles the interrupt, reads 8 Result Descriptors at once, then writes the PKTE_RDSC_DECR register with 8. This is repeated until there are less than 8 full entries in the RDR. The fill level is now under the threshold and the RDR threshold IRQ interrupt is inactive. Each write to the PKTE_RDSC_DECR register restarts the timeout counter.

PKTE Programming Model

The host processor must always follow a pre-defined sequence of five phases required by the packet engine on a per packet basis when using direct host mode. The following sections describe the five phases.

Phase One. Write the Command Descriptor

1. Write the first command descriptor word with status and control information to the PKTE_CTL_STAT register.
2. Optionally, write the user ID to the PKTE_USERID register.
3. Write the last descriptor word to the PKTE_LEN register.
4. Write the value 0x1 to the PKTE_CDSC_CNT register. This operation triggers the packet engine to validate the command descriptor. When the command descriptor is invalid, an error is generated. (See the PKTE_CTL_STAT section in the Register Descriptions). When the command descriptor is valid, the packet engine waits for an PKTE_SA_RDY register write.

Phase Two. Write the State Registers, (ARC4 Buffer) and SA Registers

All required fields of the SA record and state record must be written. The fields required depend on the operation. The last field to be written is the PKTE_SA_RDY register. This register triggers the packet engine to start processing.

1. Write the required state record fields.
   - ARC4 state
   - IV
   - Digest count
   - State digest
2. Write the required SA record data.
3. To complete the SA record and state record, write the PKTE_SA_RDY register.

Phase Three. Write the Source Packet Data and Read Result Packet Data

The packet engine has input and output buffers. If a source packet is smaller than the size of the input buffer, then the packet can be written in one part. Otherwise, it must be written in multiple parts. The same applies to the output data. If the result packet size is smaller than the size of the output buffer, then the packet can be read in one part. Otherwise, it must be read in multiple parts.

NOTE: An outbound packet that is smaller than the size of the input buffer can increase in size due to padding and does not always fit in the output buffer. Conversely, an inbound packet that is larger than the size of the input buffer can decrease in size, and due to de-padding, can fit in the output buffer. If the input buffer becomes empty or the output buffer becomes full, the engine stalls.

Two following steps describe different situations:

- Source packet smaller than the size of the input buffer, start at step #1.
- Source packet larger than the size of the input buffer, start at step #3.

The host processor must follow these steps:

1. Write the source packet data. Write the full source packet to the input buffer. Go to step #4.
2. Write the input buffer count register (PKTE_INBUF_CNT) with the number of valid bytes that are written to the input buffer. This value must correspond to the value in the PKTE_LEN.TOTLEN field of the command descriptor rounded up to the next 4-byte multiple. Go to step #5 to check the packet engine status.
3. Write part of the source packet data. The PKTE_STAT.IBUFEMPTYCNT field indicates the amount of free space in the input buffer. Programs write the number of bytes determined by the setting in the PKTE_BUF_THRESH register. Write the (partial) source packet to the input buffer. The host processor must resume where it ended the previous write operation. Do not write more than the buffer size at once. Go to step 4.
4. Write the PKTE_INBUF_CNT register with the number of valid bytes written to the input buffer. Go to step 5 to check the packet engine status.
5. Check packet engine status. Wait for an interrupt or poll the PKTE_STAT register for any of the following conditions:
   - Condition 1–an error interrupt or any of the bits [7:5] in the PKTE_STAT register becomes active to indicate a packet processing error. Depending on the type of error, the host processor must take appropriate action. Usually, the result packet is not valid after a processing error has occurred. Go to phase 5 to read the result descriptor.
   - Condition 2–an operation done interrupt or the PKTE_STAT.OPDN bit becomes active (the packet engine completed processing). Go to step 8 to read the remaining output data.
   - Condition 3–an output buffer threshold interrupt or the PKTE_STAT.OBUFREQ bit becomes active. Go to step #6 to read a block of output data.

- Condition 4–an input buffer threshold interrupt or the PKTE_STAT.IBUFREQ bit becomes active. Go to step #3 to write a block of input data.

6. Read part of the output data. The PKTE_STAT.OBUFFULLCNT bit field indicates the number of bytes in the output buffer. This value is rounded up to full words. Programs read the number of bytes indicated in the PKTE_BUF_THRESH register. Read the (partial) output packet from the output buffer. The host processor must resume where it ended the previous read operation. Do not read more than the input buffer size at once. Go to step #7.
7. Write the PKTE_OUTBUF_CNT register with the number of valid bytes read from the output buffer. Go to step #5 to check the packet engine status.
8. Read the remaining output data. The PKTE_STAT.OBUFFULLCNT bit field indicates the number of bytes in the output buffer. This value is rounded up to words. Read the (partial) packet output data from the output buffer. The host processor must resume where it ended the previous read operation. Go to step #9.
9. Write the PKTE_OUTBUF_CNT register with the number of valid bytes read from the output buffer. Go to phase four.

Phase Four. Read the Result Descriptor

1. Read the first result descriptor word from the PKTE_CTL_STAT.
2. Optionally read the user ID from the PKTE_USERID register.
3. Read the last result descriptor word from the PKTE_LEN register.
4. Write the value 0x1 to the PKTE_RDSC_DECR register. This operation allows the packet engine to accept new command descriptors. Go to phase five.

Phase Five. Read the SA Record and State Record

Depending on the operation, the SA record or state record is updated. Check the bit fields [23:16] in the PKTE_CTL_STAT register for the following conditions:

- Condition 1 - At least one error bit in the bit fields [23:16] of the PKTE_CTL_STAT register is set. Do not update the local host processor maintained version of the SA record and state record but take any required action.
- Condition 2 - None of the error bits in the bit fields [23:16] of the PKTE_CTL_STAT register is set, the packet is processed normally (without errors). Update the host processor maintained version of the SA record and state record with the result read from the packet engine registers:
  - ARC4 state
  - Sequence number
  - Sequence number mask
  - Result IV

- Result digest count
- Result digest

PKTE Mode Configuration

Before using the packet engine, it must be configured. The mode of the packet engine must be defined and the PRNG (if used) must be initialized.

Configure the packet engine in one of three command modes:

- Autonomous Ring Mode: `PKTE_CFG.MODE` =b'11
- Target Command Mode: `PKTE_CFG.MODE` =b'10
- Direct Host Mode: `PKTE_CFG.MODE` =b'00

PKTE Programming Concepts

The following sections provide conceptual information for programming the PKTE.

Packet Engine Descriptor

IMPORTANT: Depending on the mode, ARM, TCM, or DHM, the descriptor is either:

- in the memory of the host processor in the command descriptor ring, or
- written directly to the descriptor registers in the packet engine

References to descriptor registers are for either the register that is mirrored in the descriptor structure in memory or for the actual register itself.

Command descriptors are host-supplied commands that control the real-time operation of the packet engine. The packet engine returns result descriptors at the end of an operation that provide the status information to the host. The ***Command Descriptor Structure*** and the ***Result Descriptor Structure*** tables show these descriptors.

Table 39-20: Command Descriptor Structure

Word Offset	31:24	23:20	19:16	15:8	7:0	Address Offset

When the packet engine is configured for autonomous ring mode, command descriptors and result descriptors reside in a ring in host memory. Command descriptors are automatically fetched from the Command Descriptor Ring (CDR) through DMA into the command descriptor registers. When an operation is complete, the result descriptors are automatically read from the packet engine and through DMA to the Result Descriptor Ring (RDR).

When the packet engine is configured for direct host mode, the host processor manually writes the command descriptor directly to the internal command descriptor MMR set. When an operation is complete, the host processor manually reads the result descriptor directly from the result descriptor MMR set.

The target command mode is a combination of the direct host mode and the autonomous ring mode. The host processor writes the command descriptor directly to the internal command descriptor register set. When an operation is complete there are two options.

1. The host processor can read the result descriptor directly from the result descriptor registers.
2. The result descriptors reside in a ring in host memory and the result descriptors are automatically DMA'd from the packet engine to the RDR.

When the host processor writes a command descriptor to the command descriptor registers, the packet engine is triggered when the host processor updates the `PKTE_CDSC_CNT` register. This functionality guarantees that all fields in the command descriptor are valid before the command is executed.

Descriptor Processing

This section describes the functional steps of the packet engine while processing the command descriptors.

Descriptor Ring Configuration

At initialization, the host processor specifies the size of the Command Descriptor Ring (CDR). The Result Descriptor Ring (RDR) has the same size.

NOTE: In some configurations, these two rings overlay each other with the results written on top of the command descriptors. This configuration is called overlaid ring mode.

When the packet engine is configured and enabled, it fetches the descriptors from the CDR using system bus requester reads.

Descriptor Ring Processing

To validate the descriptor exchange between the host processor and the packet engine, the ownership bits PKTE_CTL_STAT.PERDY and PKTE_CTL_STAT.HOSTRDY are used. One pair of ownership bits is in the first word of the descriptor (PKTE_CTL_STAT), and one pair is in the last word (PKTE_LEN). The 'consumer' of a descriptor must verify that both ownership pairs match to ensure that a race condition did not occur between one party writing and the other party reading the descriptor. A race condition can occur when a memory locking scheme is not used.

Each pair [PKTE_CTL_STAT.PERDY, PKTE_CTL_STAT.HOSTRDY] of ownership bits provide 3 states:

- b'00 = idle or null descriptor
- b'01 = host processor has written a descriptor in the CDR and passed ownership to the packet engine
- b'10 = packet engine processing complete: packet engine has written the descriptor in the RDR and passed ownership back to the host.
- b'11 = Reserved

At initialization, the host sets the entire CDR memory area to zero, when the CDR is used.

1. The host processor writes one or more command descriptors to the CDR. The host processor must set the PKTE_CTL_STAT.HOSTRDY bit to 1 and the PKTE_CTL_STAT.PERDY bit to 0 to indicate that ownership has passed to the packet engine. These bits are mirrored in the PKTE_LEN descriptor word.
2. The host processor must write the PKTE_CDSC_INCR register with the number of new valid command descriptors in the CDR.
3. The packet engine reads and validates one command descriptor.
4. The packet engine reads the SA record and state record, processes the packet, and updates the SA record and state record.

5. If the rings are not overlaid and the PKTE_CFG.ENCDRUPDT bit is 1, the packet engine writes the result descriptor to the CDR with the PKTE_CTL_STAT.HOSTRDY bit set to 0 and PKTE_CTL_STAT.PERDY bit set to 1. These bits are mirrored in the PKTE_LEN descriptor word.
6. The packet engine writes the result descriptor to the RDR. The packet engine sets the PKTE_CTL_STAT.PERDY bit to 1 and the PKTE_CTL_STAT.HOSTRDY bit to 0 to indicate that the ownership has passed to the host. These bits are mirrored in the PKTE_LEN descriptor word.
7. The packet engine decrements the value in the PKTE_CDSC_CNT register. If the value is not zero, the packet engine reads with the next command descriptor (step 3).
8. The packet engine increments the value in the PKTE_RDSC_CNT register.
9. The host processor reads one or more result descriptors from the RDR and processes the results.
10. The host processor must write the PKTE_RDSC_DECR register with the number of processed result descriptors in the RDR.

Descriptor Ownership

The ownership of the command descriptor and result descriptor is set by ownership bits in the first and last word of the respective descriptor, in the PKTE_CTL_STAT register and the PKTE_LEN register. For the command descriptor, it is the processor core that sets the ownership to the packet engine. For the result descriptor, it is the packet engine that sets the ownership to the host processor.

The packet engine reads the ownership bits before processing, irrespective of the mode of the packet engine. The ownership bits are used to validate and identify the descriptor. When two separate rings are used, the packet engine can be programmed to clear the ownership bits of the command descriptors in the CDR, so the host processor knows which descriptors have been processed.

NOTE: This update of the ownership bits can be disabled in the PKTE_CFG register when the host processor actively counts the number of descriptors in the CDR to prevent ring wrapping.

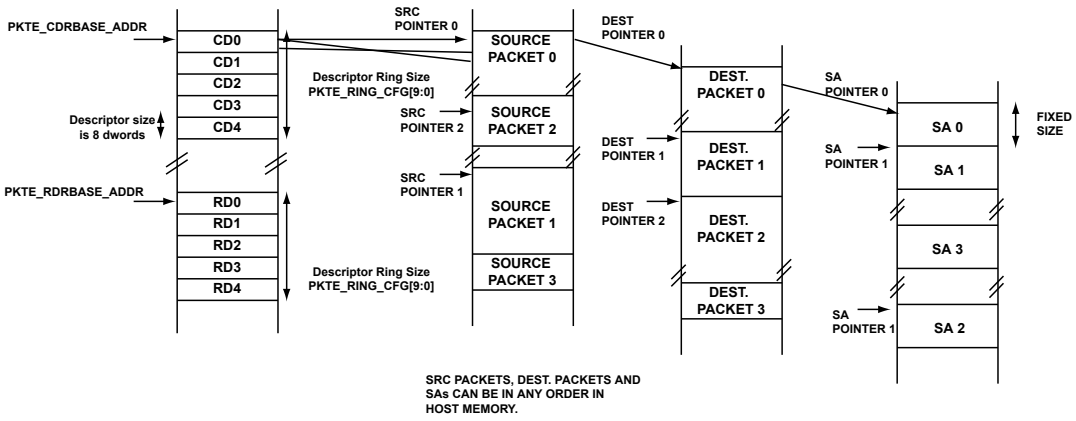

Figure 39-3: Descriptor Rings in Autonomous Ring Mode

SA Record and State Record Structure

The SA record is a packed structure that contains the remainder of the information needed by the packet engine to process a packet. Most of the information fields in the SA record, such as the key and encryption mode, are static for the lifetime of the association. The fields do not require frequent manipulation by the host processor. The SA record non-static fields are the sequence number and sequence number mask.

The SA record can have a corresponding state record that is used to save results from the current operations that can be used for future operations. The state record can hold the IV, the hash byte count, and the intermediate hash digest.

If an SA record is used for operations that use ARC4 processing in stateful mode, it has a corresponding ARC4 state record that holds the ARC4 State.

In this manual, the state record and the ARC4 state record are referred to as state record.

There is no practical limit to how many SA records and corresponding state records the packet engine can support.

In the autonomous ring mode and target command mode, once the packet engine has validated a command descriptor, it automatically fetches the SA record and optional state record. After processing, the packet engine updates the stateful fields in the SA record and state record in the host processor memory.

In direct host mode, after the descriptor is validated, the host must write the SA record directly into the internal registers of the packet engine. After processing, the host reads the stateful fields from the SA registers of the packet engine and saves them back to the SA record in the host processor memory.

SA Record Structure

The ***SA Record Structure*** table shows the structure for an SA Record. When using direct host mode, the corresponding elements are accessed directly with the registers. When using autonomous ring mode or target command mode, the SA Record is defined, configured, and accessed in host memory.

Table 39-22: SA Record Structure

Word Offset	Description (name)	Use
0	PKTE_SA_CMD0[31:0]	SA Control word 0 (all operations)
1	PKTE_SA_CMD1[31:0]	SA Control word 1 (all operations)
2	PKTE_SA_KEY0[31:0]	Key word (DES, Triple-DES, AES-128/192/256, ARC4,)
3	PKTE_SA_KEY1[63:32]	Key word (DES, Triple-DES, AES-128/192/256, ARC4,)

Table 39-22: SA Record Structure (Continued)

Word Offset	Description (name)	Use
4	PKTE_SA_KEY2[95:64]	Key word (Triple-DES, AES-128/192/256, ARC4,)
5	PKTE_SA_KEY3[127:96]	Key word (Triple-DES, AES-128/192/256, ARC4,)
6	PKTE_SA_KEY4[159:128]	Key word (Triple-DES, AES-192/256)
7	PKTE_SA_KEY5[191:160]	Key word (Triple-DES, AES-192/256)
8	PKTE_SA_KEY6[223:192]	Key word (AES-256)
9	PKTE_SA_KEY7[255:224]	Key word (AES-256)
10	PKTE_SA_IDIGEST0[31:0]	Inner Hash digest (Basic Hash and HMAC with MD5,SHA-1, SHA-224, SHA-256)
11	PKTE_SA_IDIGEST1[63:32]	Inner Hash digest (Basic Hash and HMAC with MD5,SHA-1, SHA-224, SHA-256)
12	PKTE_SA_IDIGEST2[95:64]	Inner Hash digest (Basic Hash and HMAC with MD5,SHA-1, SHA-224, SHA-256)
13	PKTE_SA_IDIGEST3[127:96]	Inner Hash digest (Basic Hash and HMAC with MD5,SHA-1, SHA-224, SHA-256)
14	PKTE_SA_IDIGEST4[159:128]	Inner Hash digest (Basic Hash and HMAC with SHA-1, SHA-224, SHA-256)
15	PKTE_SA_IDIGEST5[191:160]	Inner Hash digest (Basic Hash and HMAC with SHA-224, SHA-256)
16	PKTE_SA_IDIGEST6[223:192]	Inner Hash digest (Basic Hash and HMAC with SHA-224, SHA-256)

Table 39-22: SA Record Structure (Continued)

Word Offset	Description (name)	Use
17	PKTE_SA_IDIGEST7[255:224]	Inner Hash digest (Basic Hash and HMAC with SHA-256)

19	PKTE_SA_ODIGEST1[63:32]	Outer Hash digest (HMAC with MD5, SHA-1, SHA-224, SHA-256)
20	PKTE_SA_ODIGEST2[95:64]	Outer Hash digest (HMAC with MD5, SHA-1, SHA-224, SHA-256)
21	PKTE_SA_ODIGEST3[127:96]	Outer Hash digest (HMAC with MD5, SHA-1, SHA-224, SHA-256)
22	PKTE_SA_ODIGEST4[159:128]	Outer Hash digest (HMAC with SHA-1, SHA-224, SHA-256)
23	PKTE_SA_ODIGEST5[191:160]	Outer Hash digest (HMAC with SHA-224, SHA-256)
24	PKTE_SA_ODIGEST6[223:192]	Outer Hash digest (HMAC with SHA-224, SHA-256)
25	PKTE_SA_ODIGEST7[255:224]	Outer Hash digest (HMAC with SHA-256)
26	PKTE_SA_SPI[31:0]	SPI (IPsec), Type[23:16] / Version [15:0] (SSL, TLS, DTLS)
27	PKTE_SA_SEQNUM0[31:0]	Sequence Number (IPsec, SSL, TLS, DTLS with Header Processing)
28	PKTE_SA_SEQNUM1[63:32]	
29	PKTE_SA_SEQNUM_MSK0[31:0]	Sequence Number Mask (IPsec, DTLS inbound with Header Processing)
30	PKTE_SA_SEQNUM_MSK1[63:32]	
31	PKTE_SA_NONCE[31:0] / PKTE_SA_READY	Nonce value (AES-CTR, AES-ICM)/ARC4, i and

Table 39-22: SA Record Structure (Continued)

Word Offset	Description (name)	Use
		j pointers (ARC4,)/SA ready indicator (Direct Host Mode)

Some of these fields may be updated by the packet engine. These include:

- PKTE_SA_SEQNUM0
- PKTE_SA_SEQNUM1
- PKTE_SA_SEQNUM_MSK0
- PKTE_SA_SEQNUM_MSK1

All the other fields remain unchanged.

SA State Structure

The security association state structure contains information that may be updated after each packet, such as the IV and the intermediate hash result. The ***SA State Structure*** table shows the SA state structure and usage. In direct host mode, the elements are accessed directly using the PKTE registers. In target command mode and autonomous ring mode, this structure is defined and updated in host memory.

Table 39-23: SA State Structure

Word Offset	Description (name)	Use
0	PKTE_STATE_IV0[31:0]	Initialization Vector (DES, Triple DES, AES)
1	PKTE_STATE_IV1[63:32]	Initialization Vector (DES, Triple DES, AES)
2	PKTE_STATE_IV2[95:64]	Initialization Vector (AES)
3	PKTE_STATE_IV3[127:96]	Initialization Vector (AES)
4	PKTE_STATE_BYTE_CNT0[31:0]	Current hash byte count (MD5, SHA-1, SHA-224, SHA-256)
5	PKTE_STATE_BYTE_CNT1[63:32]	Current hash byte count (MD5, SHA-1, SHA-224, SHA-256)
6	PKTE_STATE_IDIGEST0[31:0]	Inner Hash digest (mirror of PKTE_SA_IDIGEST0)
7	PKTE_STATE_IDIGEST1[63:32]	Inner Hash digest (mirror of PKTE_SA_IDIGEST1)
8	PKTE_STATE_IDIGEST2[95:64]	Inner Hash digest (mirror of PKTE_SA_IDIGEST2)
9	PKTE_STATE_IDIGEST3[127:96]	Inner Hash digest (mirror of PKTE_SA_IDIGEST3)
10	PKTE_STATE_IDIGEST4[159:128]	Inner Hash digest (mirror of PKTE_SA_IDIGEST4)
11	PKTE_STATE_IDIGEST5[191:160]	Inner Hash digest (mirror of PKTE_SA_IDIGEST5)
12	PKTE_STATE_IDIGEST6[223:192]	Inner Hash digest (mirror of PKTE_SA_IDIGEST6)
13	PKTE_STATE_IDIGEST7[255:224]	Inner Hash digest (mirror of PKTE_SA_IDIGEST7)

ARC4 State Structure

The *ARC4 State Structure* table describes the state structure used with ARC4. When using the PKTE in direct host mode, these fields are accessed with the registers, starting at the value in the PKTE_ARC4STATE_BUF register. When using the PKTE in autonomous ring mode or target command mode, these fields are defined and accessed in a structure in host memory.

Table 39-24: ARC4 State Structure

Word Offset	Description (name)*1	Use
0	PKTE_ARC4_STATE0[3:0]*2	ARC4 (Basic, SSL and TLS)
1	PKTE_ARC4_STATE1[7:4]	
...	...	
62	PKTE_ARC4_STATE2[251:248]	
63	PKTE_ARC4_STATE3[255:252]	

*1 The indices in these fields indicate bytes.

*2 There are no corresponding named registers for these fields. PKTE_ARC4_STATE0 corresponds to PKTE_ARC4STATE_BUF and PKTE_ARC4_STATE1 corresponds to the 32-bit register following PKTE_ARC4STATE_BUF and so on.

Configuring Operations in the PKTE

The operation (cipher, hash function, and others) that the PKTE performs is configured primarily in the PKTE_SA_CMD0 register. The following sections include a series of tables to help configure the least significant 16 bits of the PKTE_SA_CMD0 register. These fields include:

- The operation code field (PKTE_SA_CMD0.OPCD)
- The direction field (PKTE_SA_CMD0.DIR)
- The operation group field (PKTE_SA_CMD0.OPGRP)
- The padding type (PKTE_SA_CMD0.PADTYPE)
- The cipher selection (PKTE_SA_CMD0.CIPHER)
- The hash selection (PKTE_SA_CMD0.HASH)

Basic Operations and Decoding

Table 39-25: Basic Operation Decoding

Error Code Description

The `PKTE_CTL_STAT` register is used to configure the packet engine for processing in Direct Host Mode (DHM) or Target Command Mode (TCM). The `PKTE_CTL_STAT` structure element in memory is used when the packet engine is configured for Autonomous Ring Mode (ARM). In both cases, when an operation is started, errors are reported in the status field (bits [23:16]) of this register or structure element. The ***Extended Error Codes - Status Encoding*** table provides a guide on how to decipher the meaning of the bits that are set when an error occurs.

Extended Error Codes

The following table provides information about the extended errors associated with the PKTE module.

Table 39-28: Extended Error Codes - Status Encoding

STATUS bits [23:16]	Hex Value	Priority	Description	Processing Result
0b0000_0000	0x00	NA	Successful completion. No errors occurred during processing of the packet.	Packet fully processed
0b----_---1	0x-1	NA	Authentication Error. For an inbound IPsec ESP operation, the Integrity Check Value (ICV) does not match the computed value. For an inbound SRTP operation, the authentication tag does not match the computed value. For a basic SSL/TLS, Extended SSL/TLS or DTLS operation the Message Authentication Code (MAC) does not match the computed value.	Packet fully processed

Table 39-28: Extended Error Codes - Status Encoding (Continued)

STATUS bits [23:16]	Hex Value	Priority	Description	Processing Result
0b----_--1-	0x-2	NA	Pad Verify Error. For inbound operations that use pad type Constant TLS, IPsec or PKCS#7, the decrypted pad does not match the expected values for the selected pad type.	Packet fully processed
0b----_-1--	0x-4	NA	Sequence Number Error. For an inbound IPsec or DTLS operation, there was a fault in the Anti-Replay Sequence Number. For an outbound IPsec packet, the sequence number overflows; count is 2^{32}– 1 and increments to 0. For an outbound DTLS operation, the sequence number overflows; count is 2^{48}– 1 and increments to 0. For an outbound SSL or TLS operation, the sequence number overflows; count is 2^{64}– 1 and increments to 0.	Packet fully processed
0b0000_1---	0x08	1	System Bus error. The requester bus interface generates an error due to ERROR response from system completer. The completer bus interface generates an error due to request for non-word (32-bit) access.	Packet is stopped. The host must reject the packet and apply a hardware reset to the system.
0b0001_1---	0x18	2	Invalid Command Descriptor Error. The ownership bits in the command descriptor are not set to the packet engine, after the PKTE_CDSC_CNT register is incremented.	Command descriptor is ignored, no packet is processed. The packet must be re-queued or discarded.
0b0010_1---	0x28	3	Invalid Crypto Operation Error. A reserved operation is selected.	The SA record is ignored, no packet is processed. The packet must be re-queued or discarded.
0b0011_1---	0x38	4	Invalid Crypto Algorithm Error. A reserved cipher is selected, refer to PKTE_SA_CMD0.CIPHER. A reserved hash is selected, refer to PKTE_SA_CMD0.HASH.	The SA record is ignored, no packet is processed. The packet must be re-queued or discarded.
0b0100_1---	0x48	5	SPI Error. On an inbound packet, the 32-bit SPI value in the packet does not match the value in the SA while header processing is enabled. Note: A failure caused by an SPI mismatch, in general should not occur because the host checks the SPI and does not send an incorrect SPI to the packet engine.	Packet is fully processed. The host must reject the packet.

Table 39-28: Extended Error Codes - Status Encoding (Continued)

STATUS bits [23:16]	Hex Value	Priority	Description	Processing Result
0b0101_1---	0x58	3	Zero Length Error. The packet length defined in the command descriptor PKTE_LEN.TOTLEN is zero, which is illegal.	Packet command is ignored, no packet processed. The host must reject the packet.
0b0110_1xxx	0x68	6	Invalid Packet Length Error. For Basic Encrypt-Hash and Hash-Decrypt operations: PKTE_LEN.TOTLEN < Hash/Encrypt Offset For IPsec ESP inbound operations: PKTE_LEN.TOTLEN < ICV length or PKTE_LEN.TOTLEN is non-4 byte aligned For SRTP inbound operations: PKTE_LEN.TOTLEN ≤ IV (opt.) + Bypass Offset + ROC For SSL inbound operations: PKTE_LEN.TOTLEN ≤ 1 or packet length > 65535 bytes (SSL packet-bypass length) For TLS and DTLS inbound operations: PKTE_LEN.TOTLEN ≤ 13 or payload length > 65535 bytes (data to be hashed) Note: For IPsec ESP the ICV is stripped before the length is checked.	Packet processing is stopped Result packet length is zero. The host must reject the packet and apply a software reset of the packet engine.
0b0111_1xxx	0x78	7	Block Size Error. The length of the inbound packet defined in the Command Descriptor PKTE_LEN.TOTLEN is not a multiple of the DES or AES block cipher length. For outbound packets the size is always automatically aligned (padded) to the correct block size. The hashed packet length is not a multiple of the hash block size for intermediate hash operation. For a final hash operation no error is generated. Note: For IPsec ESP operations the ICV is stripped before the block size is checked.	Packet is fully processed. The host must reject the packet.
0b1000_1xxx	0x88	8	Processing Error. The number of bytes in the input buffer is more than defined in the PKTE_LEN.TOTLEN field. The number of bytes written to the output buffer is less than processed in the datapath.	Packet processing stops. Result packet length is zero. The host must reject the packet and apply a software reset.
0b1010_1xxx 0b1111_1xxx	Reserved			

Number Format

When dealing with cryptographic functions, data and keys are large vectors. For instance, AES supports keys of sizes 128, 192, and 256 bits. When a key needs to be loaded or read, multiple 32-bit key registers are used, namely PKTE_SA_KEY[n] registers. The first key register PKTE_SA_KEY[n]0 holds bits 31:0, and PKTE_SA_KEY[n]1 holds the next thirty two bits 63:32, and so on.

Generally, for large vectors defined as Byte0, Byte1, Byte2, Byte3 and so on, the values are stored in the PKTE registers as PKTE_REG0 = Byte3Byte2Byte1Byte0, followed by PKTE_REG1 = Byte7Byte6Byte5Byte4 and so on.

PKTE Programming Examples

Use these examples to extend your understanding of PKTE features, operating modes, event control, and programming modes.

Calculating SHA in Direct Host Mode

This section describes how to configure the packet engine to calculate a hash digest using one of supported SHA algorithms in direct host mode. This configuration follows the procedure outlined in the *PKTE Programming Model* section.

1. Configure the packet engine for direct host mode by setting the PKTE_CFG.MODE bit =0
2. Set the ownership back to the packet engine to process a command descriptor by setting the PKTE_CTL_STAT.PERDY bit =0 and the PKTE_CTL_STAT.HOSTRDY bit =1.
3. Set the PKTE_CTL_STAT.HASHFINAL bit to indicate this command descriptor handles all the input data for the hash calculation. This configuration is needed for the packet engine because the last block requires special handling (see FIPS 180-4 for details).
4. Set size of the input data in bytes in the PKTE_LEN.TOTLEN bit field.
5. Also set the PKTE_LEN.PEDONE bit =0 and the PKTE_LEN.HSTRDY bit =1. These bits must be the same as the PKTE_CTL_STAT.PERDY and PKTE_CTL_STAT.HOSTRDY bits to guarantee ownership.
6. Set the PKTE_CDSC_CNT register =1 to trigger the packet engine to start validating the command descriptor. In this case, the PKTE_CTL_STAT, PKTE_LEN and PKTE_CDSC_CNT registers are the only command descriptor registers modified.
7. Configure the PKTE_SA_CMD0 and PKTE_SA_CMD1 registers to define the operation. For an SHA, set the PKTE_SA_CMD0.OPCD bit field =0b011 for hash operation and the PKTE_SA_CMD0.OPGRP bit field =0b00 for basic operation.
8. Select the specific SHA function using the PKTE_SA_CMD0.HASH bit field as follows.
   - For SHA-1, PKTE_SA_CMD0.HASH =0b0001
   - SHA-224, PKTE_SA_CMD0.HASH =0b0010
   - for SHA-256, PKTE_SA_CMD0.HASH =0b0011

9. Depending on the SHA selected, the appropriate digest length must be chosen for the PKTE_SA_CMD0.DIGESTLEN bit field as follows.
   - For SHA-1, PKTE_SA_CMD0.DIGESTLEN =0b0101 (5 words)
   - For SHA-224, PKTE_SA_CMD0.DIGESTLEN =0b0111 (7 words)
   - For SHA-256, PKTE_SA_CMD0.DIGESTLEN =0b1000 (8 words)
10. The SHA specifies initial constants. These constants can be pre-loaded or read from memory. In this example, by setting the PKTE_SA_CMD0.HASHSRC bit field =0b11, the packet engine provides the correct initial constants depending on the SHA chosen.
11. Next, set the PKTE_SA_CMD1.CPYDGST bit =1 and PKTE_SA_CMD1.CPYPAD bit =1 to move the result to the output buffer of the packet engine at the PKTE_DATAIO_BUF location.
12. At this point, write to the PKTE_SA_RDY register with any value to trigger the operation.
13. Start writing the input to the data buffer of the packet engine starting at the PKTE_DATAIO_BUF location.
14. Write the PKTE_INBUF_CNT register with the length of the input rounded up to the next multiple of 4. For example, if the input length is 30 bytes, set this register to 32.
15. Poll the PKTE_STAT register to see if any errors occurred or if the operation completed without errors.

Once the operation is done, the digest is available in the packet engine data I/O buffer.

NOTE: The input data or message is input into the packet engine data buffer in big endian format while the result or digest is little endian format.

Performing AES Decryption in Direct Host Mode

This section describes how to configure the packet engine to decrypt using AES-128 in direct host mode. This configuration follows the procedure outlined in the *PKTE Programming Model* section.

1. Configure the packet engine for direct host mode by setting the PKTE_CFG.MODE bit =0
2. Start configuring the command descriptor registers. Set the ownership back to the packet engine to process a command descriptor by setting the PKTE_CTL_STAT.PERDY bit =0 and the PKTE_CTL_STAT.HOSTRDY bit =1.
3. Next, configure the PKTE_LEN.TOTLEN bit field with the size of the packet or message to decrypt. If the entire input message (cipher text) fits into the 256-byte data I/O buffer of the packet engine, the process can be done in one shot.
4. Set the PKTE_LEN.PEDONE bit =0 and the PKTE_LEN.HSTRDY bit =1. These bits must have the same setting as the PKTE_CTL_STAT.PERDY and PKTE_CTL_STAT.HOSTRDY bits to guarantee ownership.

5. Set the PKTE_CDSC_CNT register =1 to trigger the packet engine to start validating the command descriptor. In this case, the PKTE_CTL_STAT, PKTE_LEN, and PKTE_CDSC_CNT registers are the only command descriptor registers modified.
6. Next, configure the PKTE_SA_CMD0 and PKTE_SA_CMD1 registers to define the operation.
   - For a AES decrypt inbound cipher operation, set the PKTE_SA_CMD0.OPCD bit field =0b000 and the PKTE_SA_CMD0.DIR bit field =0b1.
   - Set thePKTE_SA_CMD0.OPGRP bit field =0b00 for basic operation.
   - To choose the AES cipher, set the PKTE_SA_CMD0.CIPHER bit field =0b0011. Set the PKTE_SA_CMD0.HASH bit field to 0b1111 to choose the NULL function.
7. Next, set the PKTE_SA_CMD1.AESKEYLEN bit field to select the appropriate key length. In this case, setting it to 0b10 select 128 bits. Also, set PKTE_SA_CMD1.CIPHERMD bit field to select the mode. In this case, setting it to 0b01 select CBC mode.
8. Continue configuring the Security Association (SA) record by loading the key in the PKTE_SA_KEY[n] registers.
9. Next load the initialization vector in the SA state registers (PKTE_STATE_IV[n]).
10. Finally, write anything in to the PKTE_SA_RDY register to trigger the operation.
11. The input data can now be written into the data I/O buffer starting at PKTE_DATAIO_BUF.
12. After the data is written, write the length (or next multiple of 4) into PKTE_INBUF_CNT register.
13. Poll PKTE_STAT to see if any errors occurred or if the operation completed without errors.

Once the operation is done, the result can be found in the same data I/O buffer.

ADSP-2184x PKTE Register Descriptions

Security Packet Engine (PKTE) contains the following registers.

Table 39-29: ADSP-2184x PKTE Register List

Name	Description
PKTE_ARC4STATE_ADDR	Packet Engine ARC4 State Record Address
PKTE_ARC4STATE_BUF	Starting Entry of 256-byte ARC4 State Buffer
PKTE_BUF_PTR	Packet Engine Buffer Pointer Register
PKTE_BUF_THRESH	Packet Engine Buffer Threshold Register
PKTE_CDRBASE_ADDR	Packet Engine Command Descriptor Ring Base Address
PKTE_CDSC_CNT	Packet Engine Command Descriptor Count Register
PKTE_CDSC_INCR	Packet Engine Command Descriptor Count Increment Register

Table 39-29: ADSP-2184x PKTE Register List (Continued)

Name	Description
PKTE_CFG	Packet Engine Configuration Register
PKTE_CLK_CTL	PE Clock Control Register
PKTE_CONT	PKTE Continue Register
PKTE_CTL_STAT	Packet Engine Control Register
PKTE_DATAIO_BUF	Starting Entry of 256-byte Data Input/Output Buffer
PKTE_DEST_ADDR	Packet Engine Destination Address
PKTE_DMA_CFG	Packet Engine DMA Configuration Register
PKTE_ENDIAN_CFG	Packet Engine Endian Configuration Register
PKTE_HLT_CTL	Packet Engine Halt Control Register
PKTE_HLT_STAT	Packet Engine Halt Status Register
PKTE_IMSK_DIS	Interrupt Mask Disable Register
PKTE_IMSK_EN	Interrupt Mask Enable Register
PKTE_IMSK_STAT	Interrupt Masked Status Register
PKTE_INBUF_CNT	Packet Engine Input Buffer Count Register
PKTE_INBUF_INCR	Packet Engine Input Buffer Count Increment Register
PKTE_INT_CFG	Interrupt Configuration Register
PKTE_INT_CLR	Interrupt Clear Register
PKTE_INT_EN	Interrupt Enable Register
PKTE_IUMSK_STAT	Interrupt Unmasked Status Register
PKTE_LEN	Packet Engine Length Register
PKTE_OUTBUF_CNT	Packet Engine Output Buffer Count Register
PKTE_OUTBUF_DECR	Packet Engine Output Buffer Count Decrement Register
PKTE_PE_ALT_KEY_STATUS	PE Alternative Key stat register
PKTE_PE_CACHE_CTRL_0	Packet Engine Cache Control 0
PKTE_PE_CACHE_CTRL_1	Packet Engine Cache Control 1
PKTE_RDRBASE_ADDR	Packet Engine Result Descriptor Ring Base Address
PKTE_RDSC_CNT	Packet Engine Result Descriptor Count Registers
PKTE_RDSC_DECR	Packet Engine Result Descriptor Count Decrement Registers
PKTE_RING_CFG	Packet Engine Ring Configuration
PKTE_RING_PTR	Packet Engine Ring Pointer Status
PKTE_RING_STAT	Packet Engine Ring Status

Table 39-29: ADSP-2184x PKTE Register List (Continued)

Name	Description
PKTE_RING_THRESH	Packet Engine Ring Threshold Registers
PKTE_SA_ADDR	Packet Engine SA Address
PKTE_SA_ARC4IJPTR	ARC4 i and j Pointer Register
PKTE_SA_CMD0	SA Command 0
PKTE_SA_CMD1	SA Command 1
PKTE_SA_IDIGEST[n]	SA Inner Hash Digest Registers
PKTE_SA_KEY[n]	SA Key Registers
PKTE_SA_NONCE	SA Initialization Vector Register
PKTE_SA_ODIGEST[n]	SA Outer Hash Digest Registers
PKTE_SA_RDY	SA Ready Indicator
PKTE_SA_SEQNUM[n]	SA Sequence Number Register
PKTE_SA_SEQNUM_MSK[n]	SA Sequence Number Mask Registers
PKTE_SA_SPI	SA SPI Register
PKTE_SRC_ADDR	Packet Engine Source Address
PKTE_STAT	Packet Engine Status Register
PKTE_STATE_ADDR	Packet Engine State Record Address
PKTE_STATE_BYTE_CNT[n]	State Hash Byte Count Registers
PKTE_STATE_IDIGEST[n]	State Inner Digest Registers
PKTE_STATE_IV[n]	State Initialization Vector Registers
PKTE_USERID	Packet Engine User ID

Packet Engine ARC4 State Record Address

The PKTE_ARC4STATE_ADDR register holds the start address of the SA ARC4 state record.

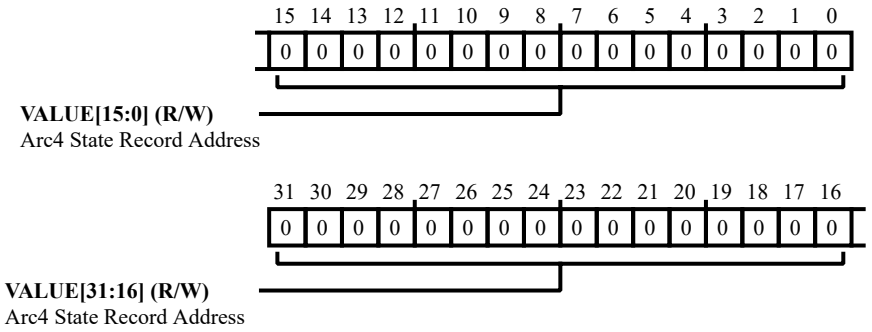

Figure 39-4: PKTE_ARC4STATE_ADDR Register Diagram

Table 39-30: PKTE_ARC4STATE_ADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Arc4 State Record Address.

Starting Entry of 256-byte ARC4 State Buffer

The PKTE_ARC4STATE_BUF register is used to store the pre-processed key that initializes the ARC4 module. In direct host mode, before processing starts, the Host must write the ARC4 state, starting from the base address and increment the address pointer for each write. When processing completes the Host must read the ARC4 state and copy it to the local Host maintained state record. After a reset, a read from any address in the address range of the ARC4 buffer returns an undefined value.

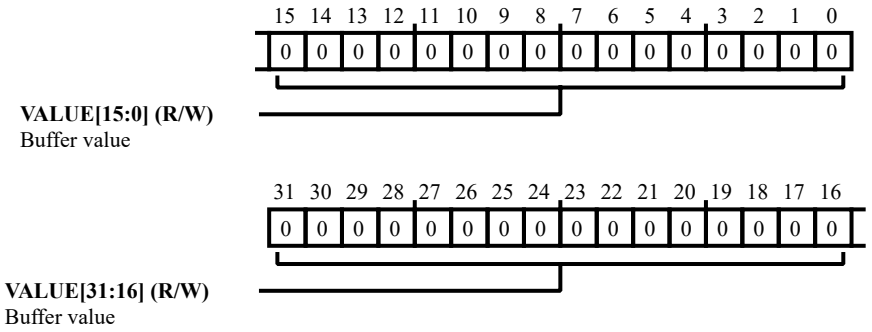

Figure 39-5: PKTE_ARC4STATE_BUF Register Diagram

Table 39-31: PKTE_ARC4STATE_BUF Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Buffer value. The PKTE_ARC4STATE_BUF.VALUE bit field stores the pre-processed key that initializes the ARC4 module.

Packet Engine Buffer Pointer Register

The PKTE_BUF_PTR register contains the offset of the next buffer address (entry) to be read or written by the packet engine. This register is used in direct host mode only.

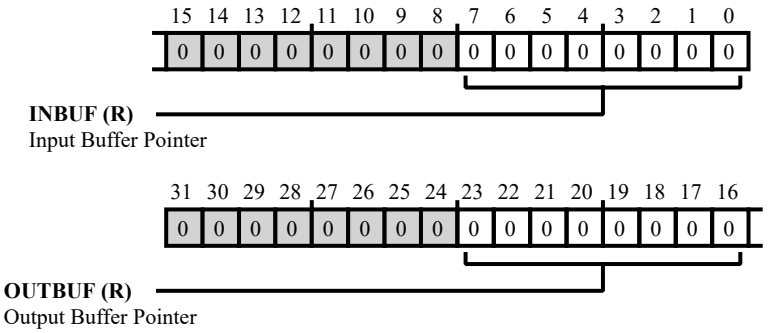

Figure 39-6: PKTE_BUF_PTR Register Diagram

Table 39-32: PKTE_BUF_PTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:16 (R/NW)	OUTBUF	Output Buffer Pointer. The PKTE_BUF_PTR.OUTBUF bit field indicates the offset of the next address (entry) in the output buffer that will be written next by the packet engine. This bit field is reset to zero after starting up and decremented by 4 at every output buffer write operation. Pointers wrap around; the maximum value this field can have equals the output buffer size minus 4.
7:0 (R/NW)	INBUF	Input Buffer Pointer. The PKTE_BUF_PTR.INBUF bit field indicates the offset of the next address (entry) in the input buffer that will be read next by the packet engine. The bit field is reset to zero after starting up and incremented by 4 at every input buffer read operation. Pointers wrap around; the maximum value this field can have equals the input buffer size minus 4.

Packet Engine Buffer Threshold Register

When in autonomous ring mode or target command mode, the PKTE_BUF_THRESH register defines the high- and low-level value at which the packet engine starts to transfer packet data in or out of the internal packet buffers. These parameters can be used to control the DMA burst size for packet data input and output from the packet engine. In direct host mode, this register contains both threshold values to reduce the amount of packet engine interrupts.

The input buffer threshold (ibufthrsh) interrupt indicates that the input buffer counter is less than or equal to the input buffer threshold value set in this register - this interrupt can be used to wake up a process that stalled on a full input buffer.

The output buffer threshold (obufthrsh) interrupt indicates that the output buffer counter exceeds the output buffer threshold setting. The output buffer interrupt remains active until the output buffer counter is decremented to zero again.

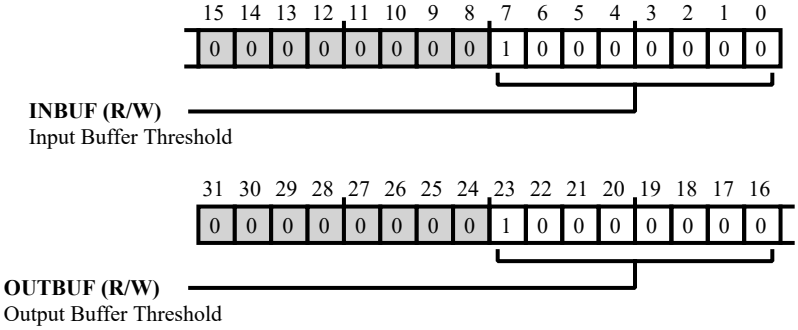

Figure 39-7: PKTE_BUF_THRESH Register Diagram

Table 39-33: PKTE_BUF_THRESH Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:16 (R/W)	OUTBUF	Output Buffer Threshold. The PKTE_BUF_THRESH.OUTBUF bit field specifies how many bytes must be available in the packet engine output buffer before an output transfer starts. Valid values range from 0 to 252, in multiples of 4. In autonomous ring mode, a value of 128 generally gives a good performance, but the optimal value depends on the system and application. In direct host mode, the output buffer threshold (obufthrsh) interrupt activates when the output buffer counter for the output buffer exceeds the value set in this field. A value of 128 generally gives a good performance, but the optimal value depends on the system and application.

Table 39-33: PKTE_BUF_THRESH Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	INBUF	Input Buffer Threshold. The `PKTE_BUF_THRESH.INBUF` bit field specifies how many bytes must be free in the packet engine input buffer before an input transfer starts. Valid values range from 0 to 252, in multiples of 4. In autonomous ring mode, a value of 128 generally gives a good performance, but the optimal value depends on the system and application. In direct host mode, the input buffer threshold (ibufthrsh) interrupt activates when the input buffer counter for the input buffer is below or equal the value set in this field. A value of 128 generally gives a good performance, but the optimal value depends on the system and application.

Packet Engine Command Descriptor Ring Base Address

The PKTE_CDRBASE_ADDR register holds the command descriptor ring base address in host memory. It is only applicable in autonomous ring mode. The PKTE_CDRBASE_ADDR register is ignored for all other modes when command descriptors are directly written into the descriptor registers.

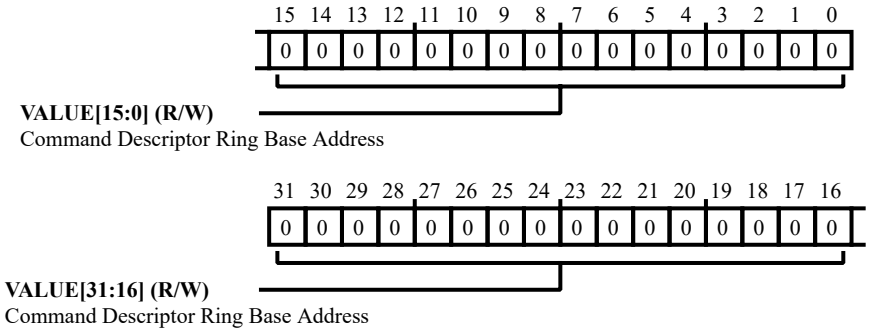

Figure 39-8: PKTE_CDRBASE_ADDR Register Diagram

Table 39-34: PKTE_CDRBASE_ADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Command Descriptor Ring Base Address. The PKTE_CDRBASE_ADDR.VALUE bit field specifies the base location of the command descriptor ring in the host memory space.

Packet Engine Command Descriptor Count Register

The PKTE_CDSC_CNT register holds the counter for the number of descriptors in the Command Descriptor Ring (CDR). It is decremented by the packet engine each time a valid descriptor is read from the CDR and processed.

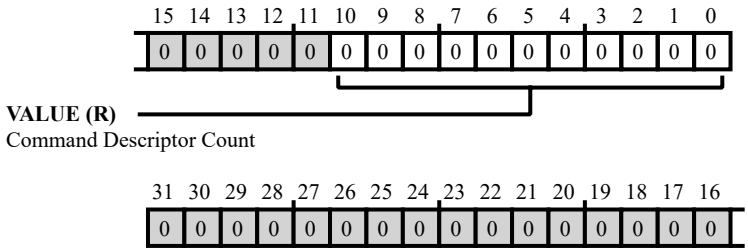

Figure 39-9: PKTE_CDSC_CNT Register Diagram

Table 39-35: PKTE_CDSC_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
10:0 (R/NW)	VALUE	Command Descriptor Count. The PKTE_CDSC_CNT.VALUE bit field provides the number of command descriptors in the command descriptor ring. The packet engine decrements the counter when a valid command descriptor is read from the CDR and processed.

Packet Engine Command Descriptor Count Increment Register

The PKTE_CDSC_INCR register is accessible by the host connected through the system completer bus. The host can increment the command descriptor counter by writing a value between 1 and 255 to the lowest byte of this register.

In autonomous ring mode, the host must prepare 1 to 255 valid command descriptors in the CDR and then write this register with a value between 1 and 255. The write triggers the packet engine to fetch the command descriptors from the CDR. In direct host mode or target command mode, the host must write one valid command descriptor to the internal descriptor registers and then write this register with the value 1, to indicate that one valid descriptor is available.

A CDR threshold interrupt is activated when the command descriptor counter is less than or equal to the threshold value set in the PKTE_RING_THRESH register. This interrupt can be used to wake up a process that stalled on a full CDR.

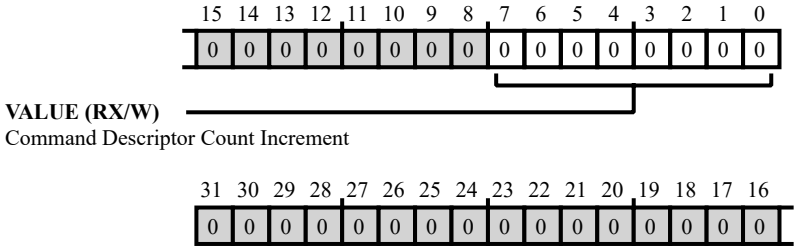

Figure 39-10: PKTE_CDSC_INCR Register Diagram

Table 39-36: PKTE_CDSC_INCR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (RX/W)	VALUE	Command Descriptor Count Increment. The value written to the PKTE_CDSC_INCR.VALUE bit field is added to the command descriptor counter. The counter is protected against overflow (see the PKTE_RING_STAT register description). Note that bits[10:8] should be written with zeros.

Packet Engine Configuration Register

The PKTE_CFG register is used to select static settings that control the packet-processing path. This register is typically the last one to be written during the initialization sequence. These settings are typically set at initialization and not changed again.

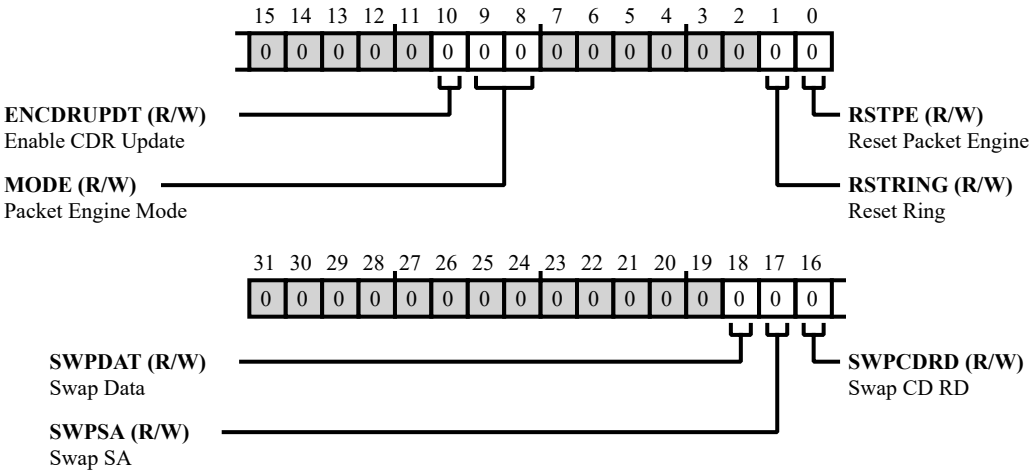

Figure 39-11: PKTE_CFG Register Diagram

Table 39-37: PKTE_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
18 (R/W)	SWPDAT	Swap Data. The PKTE_CFG.SWPDAT bit enables endian swap for packet data as configured in the PKTE_ENDIAN_CFG.MBSWAP bits for the packet data DMA read and write.	
		0	No Endian Swap
		1	Apply Endian Swap
17 (R/W)	SWPSA	Swap SA. The PKTE_CFG.SWPSA bit enables endian swap for a SA record as configured in the PKTE_ENDIAN_CFG.MBSWAP bits for the SA record and state record DMA read and write. If the PKTE_ENDIAN_CFG.MBSWAP bits specify "no endian swap", this bit is ignored.	
		0	No Endian Swap
		1	Apply Endian Swap

Table 39-37: PKTE_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W)	SWPCDRD	Swap CD RD. The PKTE_CFG.SWPCDRD bit enables endian swap for descriptors as configured in the PKTE_ENDIAN_CFG.MBSWAP bits for the command descriptor DMA read and result descriptor DMA write. If the PKTE_ENDIAN_CFG.MBSWAP bits specify "no endian swap", this bit is ignored.	
		0	No Endian Swap
		1	Apply Endian Swap
10 (R/W)	ENCDRUPDT	Enable CDR Update. The PKTE_CFG.ENCDRUPDT bit enables the packet engine to update, (clear the ownership bits) in the command descriptor in the CDR.	
		0	Do Not Clear Ownership Bits. The packet engine does not clear the ownership bits in the command descriptor when it completes an operation. The host application must clear the ownership bits in "old descriptors" before the packet engine is allowed to wrap around the CDR to re-encounter these "old descriptors". This setting has the advantage of eliminating a separate DMA write to the CDR.
		1	Clear Ownership Bits. The packet engine clears (set to zero) the ownership bits in the current command descriptor in the CDR. This prevents the packet engine from re-processing an "old descriptor" when it wraps around the CDR.
9:8 (R/W)	MODE	Packet Engine Mode. The PKTE_CFG.MODE bit field selects how the packet engine receives commands.	
		0	Direct Host Mode.
		1	Target Command Mode with Result Descriptor Ring Disabled.
		2	Target Command Mode with Result Descriptor Ring Enabled.
		3	Autonomous Ring Mode

Table 39-37: PKTE_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	RSTRING	Reset Ring. The PKTE_CFG.RSTRING bit resets the internal counters for the CDR and RDR, PKTE_CDSC_CNT and PKTE_RDSC_CNT registers) to zero. Resets the PKTE_RING_PTR register to the base address. After the reset the rings are empty. This bit must be written with a '1' to reset the descriptor ring manager and then re-written with a '0' to release the reset. Note that this bit can remain in the reset state if the CDR ring is disabled (PKTE_CFG.MODE is not 0b11). Note that this reset must be coordinated with the 'owner' of the descriptor ring to ensure that the pointers are in sync after the reset.	
		0	Release the Descriptor Ring Manager Reset
		1	Reset the Descriptor Ring Manager
0 (R/W)	RSTPE	Reset Packet Engine. The PKTE_CFG.RSTPE bit resets the packet engine and the state machine logic that drives header processing, DMA, and context management. The PKTE_CFG.RSTPE bit resets the PKTE_CTL_STAT and PKTE_LEN internal registers. This bit must be written with a 1 to reset the packet engine and then re-written with a 0 to release the reset. Note that this bit should not be used by a typical application. It is provided to use during development testing or to recover from critical errors. Note that the PKTE_CTL_STAT.PADVAL and PKTE_CTL_STAT.PADCTLSTAT bit fields are only reset when in autonomous ring mode, but the PKTE_CTL_STAT.PRNGMD bit is not reset. Halt mode is not affected by this reset as well. When exiting out of halt mode, a HW reset is required or a write to the PKTE_CONT register.	
		0	Release the Packet Engine Reset
		1	Reset the Packet Engine

PE Clock Control Register

The PKTE_CLK_CTL register controls the clock enable signals. This register can be used to enable the clock for read and write access to SA registers or to enable the required clock signals for certain crypto functions. The setting of this register overrides the packet engine dynamic clock enable.

In autonomous ring mode and target command modes, this register can be all zeros; the packet engine dynamically requests the external clock manager to activate the module clocks. This register can be used in combination with the debugging interface for internal register access.

In direct host mode, the clock enable bits for the packet engine (PKTE_CLK_CTL.ENPECLK) and for ARC4 (PKTE_CLK_CTL.ENARC4CLK) must be enabled to write and read the SA record and state record registers. All module clocks that are required for the current operation must be enabled during processing.

Note that all the clocks are enabled by default to reset all the registers within the packet engine. After a system reset the host can program this register to disable clocks for power reduction.

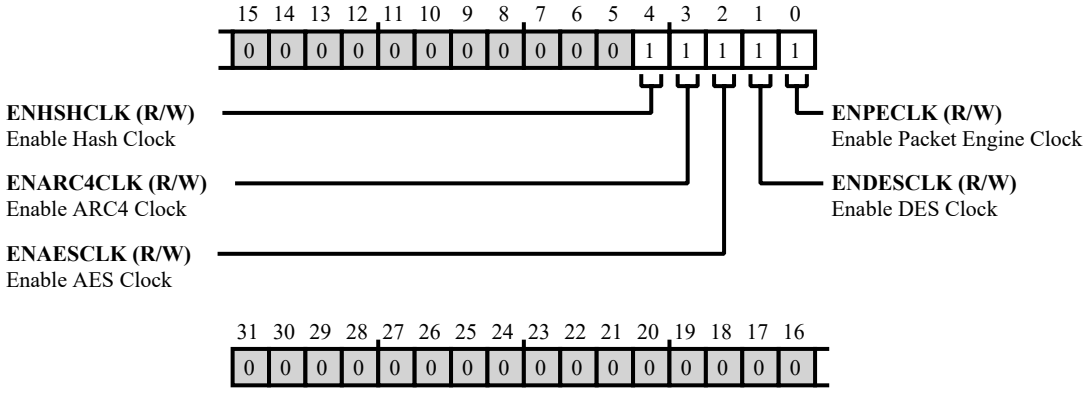

Figure 39-12: PKTE_CLK_CTL Register Diagram

Table 39-38: PKTE_CLK_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W)	ENHSHCLK	Enable Hash Clock. The PKTE_CLK_CTL.ENHSHCLK bit enables the clock to the hash functions.	
		0	Do not enable the hash clock
		1	Enable the hash clock
3 (R/W)	ENARC4CLK	Enable ARC4 Clock. The PKTE_CLK_CTL.ENARC4CLK bit enables the clock to the ARC4 function.	
		0	Do not enable the ARC4 clock
		1	Enable the ARC4 clock

Table 39-38: PKTE_CLK_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	ENAESCLK	Enable AES Clock. The `PKTE_CLK_CTL.ENAESCLK` bit enables the clock to the AES encrypt/decrypt function.	
		0	Do not enable the AES clock
		1	Enable the AES clock
1 (R/W)	ENDESCLK	Enable DES Clock. The `PKTE_CLK_CTL.ENDESCLK` bit enables the clock to the DES function.	
		0	Do not enable the DES clock
		1	Enable the DES clock
0 (R/W)	ENPECLK	Enable Packet Engine Clock. The `PKTE_CLK_CTL.ENPECLK` bit enables the clock in the PKTE data path.	
		0	Do not enable the PKTE data path clock
		1	Enable the PKTE data path clock

PKTE Continue Register

A write to the PKTE_CONT register (with any value) releases the packet engine from a halt state when in halt mode.

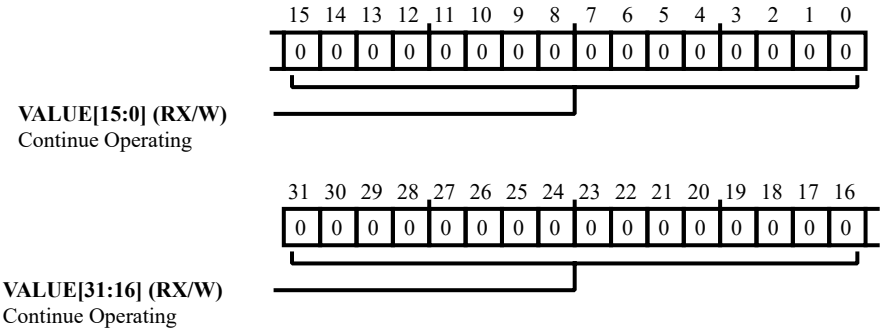

Figure 39-13: PKTE_CONT Register Diagram

Table 39-39: PKTE_CONT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (RX/W)	VALUE	Continue Operating. The PKTE_CONT.VALUE bit field releases the packet engine from a halt state when written with any value in halt mode.

Packet Engine Control Register

The PKTE_CTL_STAT register has a dual function. Together with the data in the SA, this register provides the basic command information for the packet engine to process a packet. When the packet engine successfully or unsuccessfully completes an operation, the packet engine control/status register provides the result status for the host.

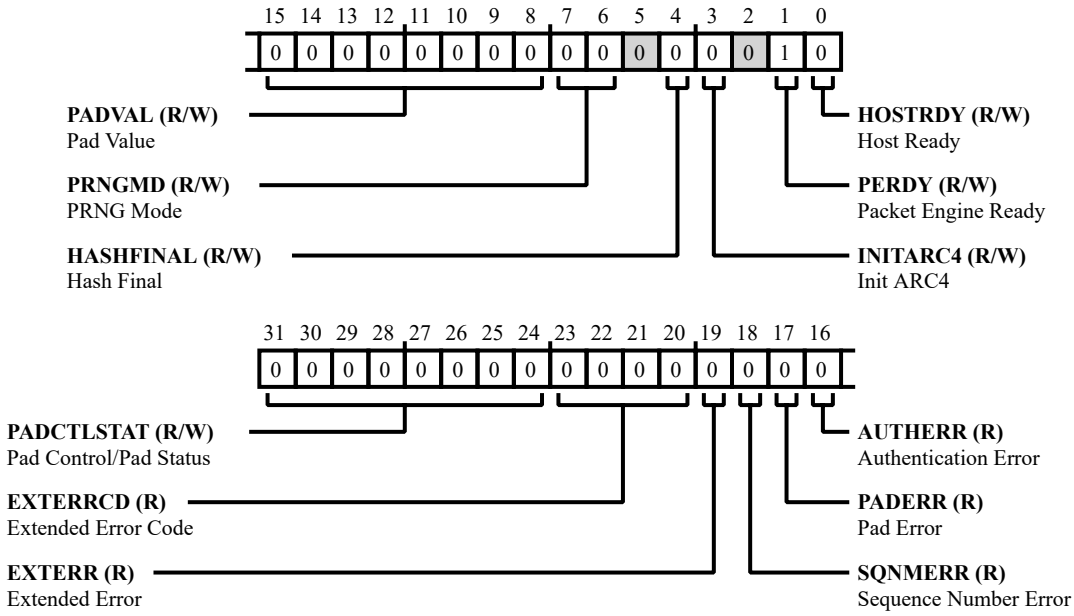

Figure 39-14: PKTE_CTL_STAT Register Diagram

Table 39-40: PKTE_CTL_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:24 (R/W)	PADCTLSTAT	Pad Control/Pad Status. The PKTE_CTL_STAT.PADCTLSTAT bit field is used to control the pad boundary for pad insertion (outbound) and after processing returns the number of inserted (outbound) or detected (inbound) pad bytes. For the command descriptor, the enumerations below provide the codes for the pad boundary for the outbound operations. This can be used for "traffic flow security" to conceal the number of payload bytes in an encrypted packet. For the result descriptor inbound operations that use pad types SSL, TLS, IPsec or PKCS#7, it returns the number of detected pad bytes. For all other inbound operations, it returns zero since the other pad modes do not allow implicit determination of pad count. If a "pad verify failure" occurs, it returns zero. For an outbound operation, it returns the number of inserted pad bytes for all pad types. The pad value includes added bytes such as the pad length and the next header field in an IPsec ESP pad type.	
		0	Align packet end to modulo 8-byte boundary

Table 39-40: PKTE_CTL_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		1	Align packet end to modulo 1-byte boundary
		2	Align packet end to modulo 4-byte boundary
		4	Align packet end to modulo 8-byte boundary
		8	Align packet end to modulo 16-byte boundary
		16	Align packet end to modulo 32-byte boundary
		32	Align packet end to modulo 64-byte boundary
		64	Align packet end to modulo 128-byte boundary
		128	Align packet end to modulo 256-byte boundary
23:20 (R/NW)	EXTERRCD	Extended Error Code. The PKTE_CTL_STAT.EXTERRCD bit field represents an encoded error condition.	
19 (R/NW)	EXTERR	Extended Error. The PKTE_CTL_STAT.EXTERR bit field provides an extended error code.	
		0	No Extended Error
		1	Extended Error
18 (R/NW)	SQNMERR	Sequence Number Error. The PKTE_CTL_STAT.SQNMERR bit indicates that for an inbound operation, there was a fault in the anti-replay sequence number. For an outbound operation, there was a sequence number overflow condition.	
		0	No Sequence Number Error
		1	Sequence Number Error
17 (R/NW)	PADERR	Pad Error. The PKTE_CTL_STAT.PADERR bit indicates that for an inbound operation the decrypted pad does not match the expected values.	
		0	No Pad Error
		1	Pad Error
16 (R/NW)	AUTHERR	Authentication Error. The PKTE_CTL_STAT.AUTHERR bit indicates that for an inbound operation the authentication value in the packet does not match the computed value.	
		0	No Authentication Error
		1	Authentication Error

Table 39-40: PKTE_CTL_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15:8 (R/W)	PADVAL	Pad Value. The PKTE_CTL_STAT.PADVAL bit field is used to pass the pad value between the host and the packet engine. Command Descriptor: (write-only) For outbound operations that use pad type IPsec, the host must populate this field with the value that is to be inserted into the next header field. For the IPsec ESP operation, this next header is part of the ESP trailer of the innermost operation's header and the value must be 50 decimal. For outbound encrypt operations that use the pad type constant or constant SSL, the host must specify the fixed constant value in this field. For all other outbound and inbound operations, this field is not used. Result Descriptor: (read only) For inbound operations that use pad type IPsec, the packet engine returns the next header field that it detects. For IPsec ESP inbound operations, this is the next header field in the innermost operation's header, which will typically be the value for the payload protocol, such as TCP or UDP. However, in bundling scenarios or in IPv6 with destination option headers, another header value could be seen. For all other outbound operations, the packet engine will not update this field. For all other inbound operations, the returned pad value is zero.	
7:6 (R/W)	PRNGMD	PRNG Mode. The PKTE_CTL_STAT.PRNGMD bits select the pseudo-random number generator mode.	
		0	Operation does not use the PRNG function. Operation does not use the PRNG function.
		1	PRNG Init. PRNG is initialized with a SEED, KEY and an LFSR value as defined in the SA.
		2	PRNG Generate. Pseudo-random data is generated with the LFSR as input value. Before this mode can be used, the PRNG must be initialized with a valid SEED, KEY and LFSR using PRNG Init (PKTE_CTL_STAT.PRNGMD=b'01).
		3	PRNG Test. It can be used to test the PRNG function with custom input data. Before this mode can be used, the PRNG must be initialized once with a valid SEED using PRNG Init (PKTE_CTL_STAT.PRNGMD=b'01).

Table 39-40: PKTE_CTL_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/W)	HASHFINAL	Hash Final. When the PKTE_CTL_STAT.HASHFINAL bit is zero, the data to be hashed must be a multiple of the hash block size, 64 bytes for SHA-1, MD5, SHA-224, SHA-256. This bit is only applicable for Basic Hash, Basic Encrypt-Hash and Basic Hash-Decrypt operations that use the SHA-1, MD5, SHA-224, SHA-256 hash algorithm. The PKTE_CTL_STAT.HASHFINAL bit is overruled for HMAC operations that always completes the hash and always returns the last written value on a read by the host.	
		0	Perform Intermediate Hash Operation. The packet engine performs an intermediate hash operation by generating an intermediate hash digest on the data presented on the input. No hash pad is applied.
		1	Perform Final Hash Operation. The packet engine appends the required final hash pad and generates the final hash digest on the data presented on the input. This completes the hash operation.
3 (R/W)	INITARC4	Init ARC4. The PKTE_CTL_STAT.INITARC4 bit initializes the ARC4 crypto algorithm with a new key. This bit always returns the last written value on a read by the host. This bit is only applicable for operations that use the ARC4 algorithm and must be zero for all other operations.	
		0	Load ARC4 State and ARC4 i/j pointer from the SA The ARC4 State and ARC4 i/j pointer are loaded from the SA to continue the encrypt/decrypt processing from the previous algorithm state.
		1	Read ARC4 key from the SA-record and initialize ARC4 S-boxes using this key The ARC4 key is read from the SA-record, the ARC4 S-boxes are initialized using this key, prior to the encryption/decryption of data. This bit overrules Stateful mode as defined in bits [9:8] of PKTE_SA_CMD1.
1 (R/W)	PERDY	Packet Engine Ready. The PKTE_CTL_STAT.PERDY bit indicates that the packet engine has completed processing the command descriptor and returns the result descriptor with ownership set to the host. This bit can be reset to 0 by the host and the packet engine, but only the packet engine can set this bit. When the packet engine is idle (not processing), this bit always returns '1' on a read by the host.	

Table 39-40: PKTE_CTL_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W)	HOSTRDY	Host Ready. The `PKTE_CTL_STAT.HOSTRDY` bit indicates that the host has populated the command descriptor. This bit can be reset to 0 by the host and the packet engine, but only the host can set this bit. When the packet engine is idle (not processing), this bit always returns '0' on a read by the host.

Starting Entry of 256-byte Data Input/Output Buffer

When in direct host mode, the source packet data is written here to be transferred to the packet engine. The host can monitor the available space in the input buffer through the PKTE_STAT register. This is also the location in the packet engine from where output data is read when in direct host mode. The host can monitor the available bytes in the output buffer through the PKTE_STAT register.

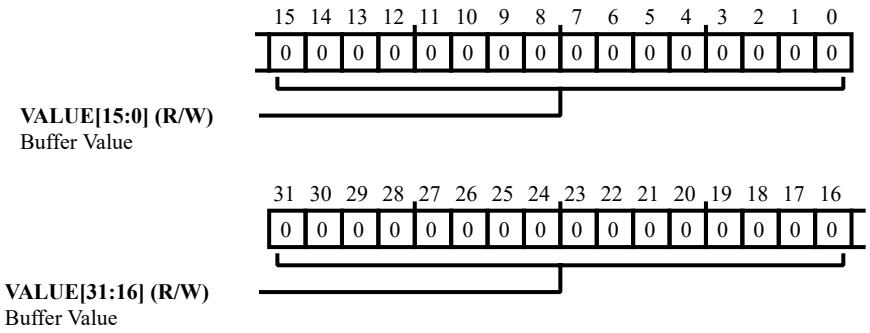

Figure 39-15: PKTE_DATAIO_BUF Register Diagram

Table 39-41: PKTE_DATAIO_BUF Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Buffer Value.

Packet Engine Destination Address

The PKTE_DEST_ADDR register holds the starting (byte) address to write the result packet from the requested operation.

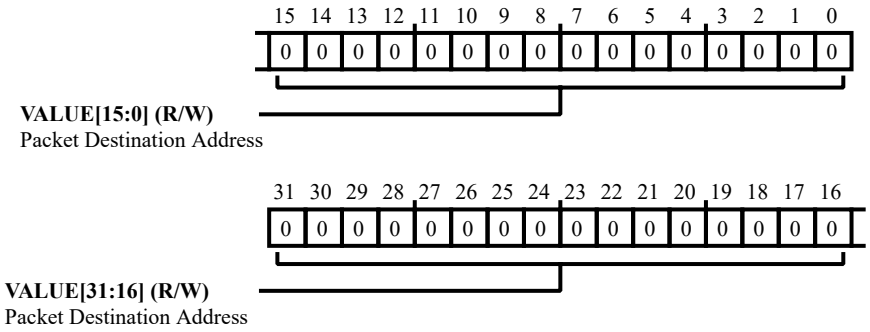

Figure 39-16: PKTE_DEST_ADDR Register Diagram

Table 39-42: PKTE_DEST_ADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Packet Destination Address.

Packet Engine DMA Configuration Register

The PKTE_DMA_CFG register configures the maximum burst transfer size, enables incremental transfers, and insertions IDLE cycles between two bus transfers.

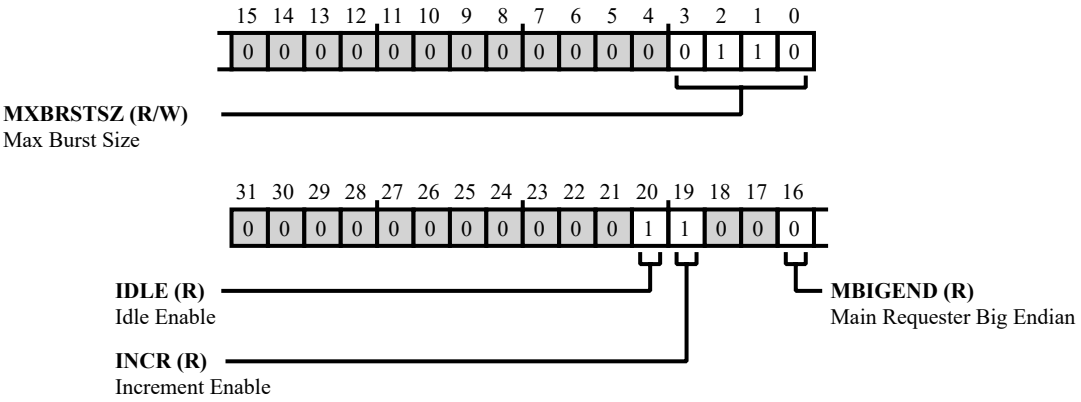

Figure 39-17: PKTE_DMA_CFG Register Diagram

Table 39-43: PKTE_DMA_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
20 (R/NW)	IDLE	Idle Enable. The PKTE_DMA_CFG.IDLE bit allows the peripheral bus requester to insert one additional IDLE transfer between two successive peripheral bus requester burst operations. This provides the arbiter one additional cycle to hand over the grant to another peripheral bus requester.	
		0	The peripheral bus requester inserts no IDLE cycle between two successive burst operations
		1	The peripheral bus requester inserts one additional IDLE transfer between two successive burst operations

Table 39-43: PKTE_DMA_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
19 (R/NW)	INCR	Increment Enable. The PKTE_DMA_CFG.INCR bit lets the peripheral bus requester generate INC4, INC8 and INC16 type of burst transfers. By default, the peripheral bus requester generates the largest possible incremental burst of unspecified length (INCR) with a maximum length (in bytes) as configured by the PKTE_DMA_CFG.MXBRSTSZ bit field. In case there are less than 4 bytes of data available or the 1kB boundary will be crossed using a burst operation, then a single transfer of size byte is generated. When the PKTE_DMA_CFG.INCR bit is set, the peripheral bus requester generates one or more incremental burst of specified length (INC4, INC8, INC16). In case there is less data available then the smallest possible burst (INC4) or the 1kB boundary will be crossed using a burst operation, then an unspecified length burst or a single transfer of size byte is generated.	
		0	The bus requester will generate only INCR burst types
		1	The bus requester will generate INC4, INC8 and INC16 burst types
16 (R/NW)	MBIGEND	Main Requester Big Endian. The PKTE_DMA_CFG.MBIGEND bit determines whether the engine is used in a little or big endian system.	
		0	Little endian
		1	Big endian
3:0 (R/W)	MXBRSTSZ	Max Burst Size. The PKTE_DMA_CFG.MXBRSTSZ bit field configures the maximum size of an unspecified length burst (INC) at the bus in bytes. When there is less data available than the PKTE_DMA_CFG.MXBRSTSZ bit field setting or the 1kB boundary will be crossed using a burst operation, then the length of the burst can be less than PKTE_DMA_CFG.MXBRSTSZ. Any requested transfers larger than this size are broken up in to multiple burst transfers of this size or less.	

Packet Engine Endian Configuration Register

The packet engine incorporates a powerful interface specific endian handler. This endian handler allows byte lane swapping in each direction for data passing through the host interface.

The PKTE_ENDIAN_CFG register configures the byte order function for the peripheral bus requester and peripheral bus completer interface. The bits for the peripheral bus requester are combined in four sets of two bits; each group configures a byte swap function for a particular DMA transfer. The same applies for the peripheral bus completer interface.

The PKTE_ENDIAN_CFG register also defines the endian swapping that occurs for host-initiated target transfers and for packet engine requester DMA read and write transfers. Individual endian swap enable bits in the configuration (PKTE_CFG) register can enable the endian swap for various transaction types: command descriptors and result descriptors, SA records and state records, packet data.

In direct host mode, only target operations are supported. Only the target endian configuration of this register is applicable.

Note: This register is typically programmed once during the initialization phase, although software is allowed to dynamically change the setting in this register just before initiating a data transfer. The developer will have to analyze the benefit of the cycles needed to write the endian register dynamically versus handling endian swapping for some data structures in the host system (most modern processors support a byte swap in zero cycles). Certainly the endian swap should be set correctly for the packet data, since this represents the majority of the data transferred.

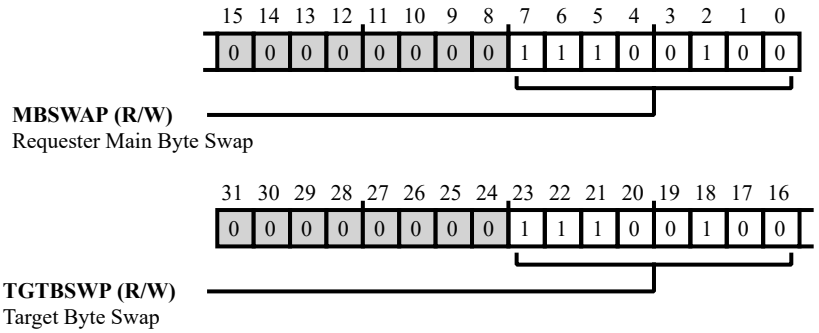

Figure 39-18: PKTE_ENDIAN_CFG Register Diagram

Table 39-44: PKTE_ENDIAN_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:16 (R/W)	TGTBSWP	Target Byte Swap. The PKTE_ENDIAN_CFG.TGTBSWP bit field configures the byte swap for peripheral bus target transfers. Note that only target word transfers are supported. Each double-bit field in this register specifies the source of the indicated byte lane. The field values are interpreted as follows: 00 = byte 0, 01 = byte 1, 10 = byte 2, 11 = byte 3. Note: Setting the value 0xE4 defines no swap (little endian) and setting value 0x1B defines a full byte swap within a 32-bit word (big endian).
7:0 (R/W)	MBSWAP	Requester Main Byte Swap. The PKTE_ENDIAN_CFG.MBSWAP bit field configures the byte swap for peripheral bus requester multi-byte transfers, including command descriptors, result descriptors, SA records, state records and packet data. Separate controls in the PKTE_CFG register can enable this swap individually for each of the 4 types of data. Each double-bit field in this register specifies the source of the indicated peripheral bus byte lane. The field values are interpreted as follows: 00=byte 0, 01=byte 1, 10=byte 2, 11=byte 3. Note: Setting the value 0xE4 defines no swap (little endian) and setting value 0x1B defines a full byte swap within a 32-bit word (big endian).

Packet Engine Halt Control Register

Th PKTE_HLT_CTL register controls the packet engine halt mode. This register can be used for debugging purposes while processing in autonomous ring mode or target command mode. During the halt mode, the host can read all internal registers for examination without side-effects. When halted, the host should not write to any registers. To continue packet engine operation, the host must write to the PKTE_CONT (PKTE continue) register.

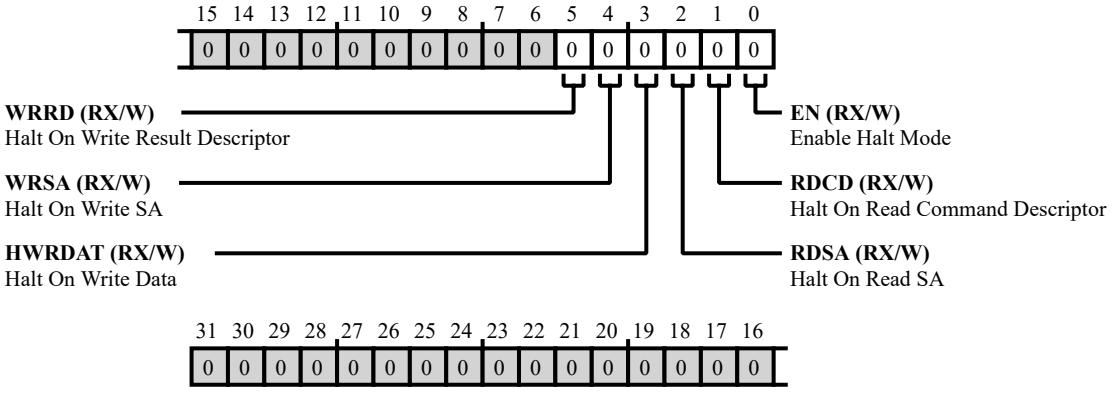

Figure 39-19: PKTE_HLT_CTL Register Diagram

Table 39-45: PKTE_HLT_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (RX/W)	WRRD	Halt On Write Result Descriptor. The PKTE_HLT_CTL.WRRD bit halts the packet engine in the HALT_WRITE_STATUS state after it completes a result descriptor write operation to the result descriptor ring. The host can use this bit to examine the result descriptor that is currently in the host memory.	
		0	Do not halt the Packet Engine operation
		1	Halt the Packet Engine operation
4 (RX/W)	WRSA	Halt On Write SA. The PKTE_HLT_CTL.WRSA bit halts the packet engine in the HALT_WRITE_SA state after it completes an SA write operation to the host memory. The host can use this bit to examine the security context that is currently in the host memory.	
		0	Do not halt the Packet Engine operation
		1	Halt the Packet Engine operation

Table 39-45: PKTE_HLT_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (RX/W)	HWRDAT	Halt On Write Data. The PKTE_HLT_CTL.HWRDAT bit halts the packet engine in the HALT_DATA state after it completes writing the result packet data to the host memory. The host can use this bit to examine the result packet that is currently in the host memory.	
		0	Do not halt the Packet Engine operation
		1	Halt the Packet Engine operation
2 (RX/W)	RDSA	Halt On Read SA. The PKTE_HLT_CTL.RDSA bit halts the packet engine in the HALT_READ_SA state after it completes an SA read operation from the host memory. The host can use this bit to examine the security context that is currently in the SA registers.	
		0	Do not halt the Packet Engine operation
		1	Halt the Packet Engine operation
1 (RX/W)	RDCD	Halt On Read Command Descriptor. The PKTE_HLT_CTL.RDCD bit halts the packet engine in the HALT_READ_DESCR state after it completes a command descriptor read operation from the command descriptor ring. It will halt whether the descriptor is valid or invalid. The host can use this bit to examine the command descriptor that is currently in the internal command descriptor registers.	
		0	Do not halt the Packet Engine operation
		1	Halt the Packet Engine operation
0 (RX/W)	EN	Enable Halt Mode. The PKTE_HLT_CTL.EN bit enables halt mode where the packet engine can halt processing at any processing state as indicated by bits [5:1]. When halted, the packet engine continues operation on a write to the PKTE_CONT register.	
		0	Do not enable halt mode
		1	Enable halt mode

Packet Engine Halt Status Register

The PKTE_HLT_STAT register reflects the status of the packet engine in halt mode. This register can be used for debugging purposes while processing in autonomous ring mode or target command mode. When the packet engine is halted, the host can read all internal registers for examination without side effects. The host should not write to any registers.

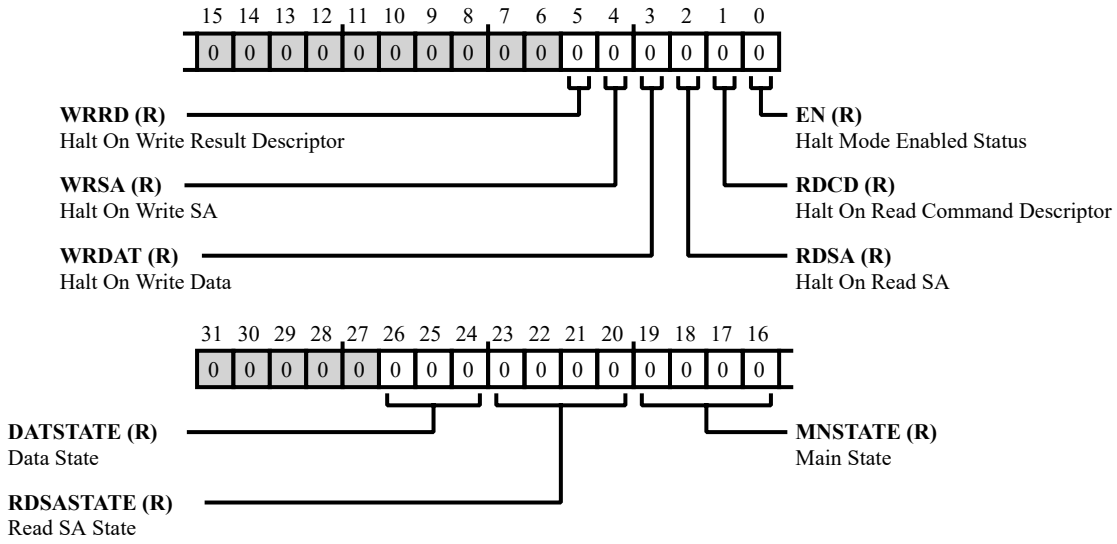

Figure 39-20: PKTE_HLT_STAT Register Diagram

Table 39-46: PKTE_HLT_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
26:24 (R/NW)	DATSTATE	Data State. The PKTE_HLT_STAT.DATSTATE bit field indicates the state of the packet engine read data FSM.	
		0	DATA_IDLE, no operation
		1	DATA_READ
		2	DATA_WRITE
		3	DATA_WAIT
		5	DATA_PAD_READ
		6	DATA_BYP_READ
		7	RESERVED
23:20 (R/NW)	RDSASTATE	Read SA State. The PKTE_HLT_STAT.RDSASTATE bit field indicates the state of the packet engine read SA FSM.	

Table 39-46: PKTE_HLT_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		0	SA_IDLE, no operation
		1	SA_READ_CMD
		2	SA_READ_STATE_IV
		3-5	RESERVED
		6	SA_READ_ARC4_STATE
		7	SA_READ_WAIT
		8	RESERVED
		9	SA_WRITE_PROT_HDR
		10	RESERVED
		11	SA_WRITE_IV
		12	SA_WRITE_DIGEST
		13	SA_WRITE_ARC4_IJ_PNTR
		14	SA_WRITE_ARC4_STATE
		15	SA_WRITE_WAIT
19:16 (R/NW)	MNSTATE	Main State. The `PKTE_HLT_STAT.MNSTATE` bit field indicates the state of the packet engine main FSM.	
		0	MAIN_IDLE, no operation
		1	MAIN_READ_CD, reading command descriptor
		2	MAIN_READ_SA, reading SA
		3	MAIN_DATA, processing data
		4	MAIN_WRITE_SA, writing SA
		5	MAIN_WRITE_STATUS, writing status
		6	MAIN_WRITE_CD, updating command descriptor
		7	MAIN_WRITE_RD, updating result descriptor
		8	MAIN_INIT_WAIT, wait single clock
		9	MAIN_HALT_READ_CD, halt after read command descriptor
		10	MAIN_HALT_READ_SA, halt after read SA
		11	MAIN_HALT_DATA, halt after processing data
		12	MAIN_HALT_WRITE_SA, halt after write SA

Table 39-46: PKTE_HLT_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		13	MAIN_WAIT_FOR_CLOCK, wait for clocks to be active
		15	MAIN_HALT_WRITE_RD, halt after write result descriptor
5 (R/NW)	WRRD	Halt On Write Result Descriptor. The PKTE_HLT_STAT.WRRD bit reflects the value in the PKTE_HLT_CTL.WRRD bit.	
4 (R/NW)	WRSA	Halt On Write SA. The PKTE_HLT_STAT.WRSA bit reflects the value in the PKTE_HLT_CTL.WRSA bit.	
3 (R/NW)	WRDAT	Halt On Write Data. The PKTE_HLT_STAT.WRDAT bit reflects the value in the PKTE_HLT_CTL.HWRDAT bit.	
2 (R/NW)	RDSA	Halt On Read SA. The PKTE_HLT_STAT.RDSA bit reflects the value in the PKTE_HLT_CTL.RDSA bit.	
1 (R/NW)	RDCD	Halt On Read Command Descriptor. The PKTE_HLT_STAT.RDCD bit reflects the value in the PKTE_HLT_CTL.RDCD bit.	
0 (R/NW)	EN	Halt Mode Enabled Status.	
		0	Halt mode not enabled
		1	Halt mode enabled

Interrupt Mask Disable Register

The host can use the PKTE_IMSK_DIS register to clear individual bits in the PKTE_INT_EN register for the host interrupt. This register is a bitmap for each of the possible interrupt sources: A 1 clears the interrupt enable bit, a 0 does not affect the interrupt enable bit in the PKTE_INT_EN register. Clearing the enable bits through this register avoids the time-consuming read-modify-write operation on the host.

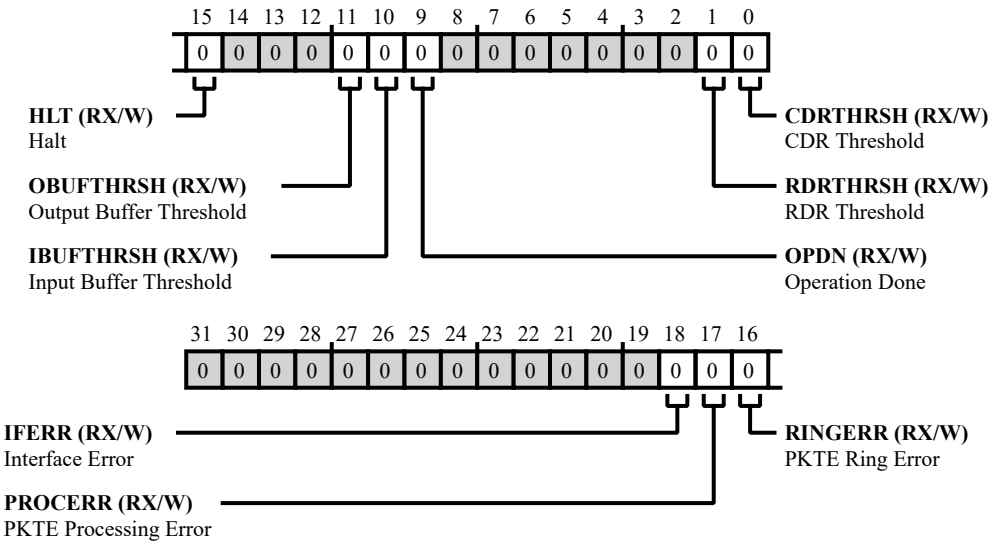

Figure 39-21: PKTE_IMSK_DIS Register Diagram

Table 39-47: PKTE_IMSK_DIS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
18 (RX/W)	IFERR	Interface Error. Write the PKTE_IMSK_DIS.IFERR bit to clear when the host requests a non 32-bit access to the packet engine or when the packet engine receives an error writing data back out to the host memory system.
17 (RX/W)	PROCERR	PKTE Processing Error. Write the PKTE_IMSK_DIS.PROCERR bit to clear an extended error that occurred before, during or after processing the current packet in the packet engine.
16 (RX/W)	RINGERR	PKTE Ring Error. Write the PKTE_IMSK_DIS.RINGERR bit to clear a CDR overflow or an RDR underflow.
15 (RX/W)	HLT	Halt. Write the PKTE_IMSK_DIS.HLT bit to clear when the packet engine is in the halt state.

Table 39-47: PKTE_IMSK_DIS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
11 (RX/W)	OBUFTHRSH	Output Buffer Threshold. Write the `PKTE_IMSK_DIS.OBUFTHRSH` bit to clear the output buffer counter exceeds the output buffer threshold value defined in `PKTE_BUF_THRESH.OUTBUF` bit.
10 (RX/W)	IBUFTHRSH	Input Buffer Threshold. Write the `PKTE_IMSK_DIS.IBUFTHRSH` bit to clear when the input buffer counter is less than or equal to the input buffer threshold value defined in `PKTE_BUF_THRESH.INBUF` bit.
9 (RX/W)	OPDN	Operation Done.
1 (RX/W)	RDRTHRSH	RDR Threshold. Write the `PKTE_IMSK_DIS.RDRTHRSH` bit to clear when the number of result descriptors for the host in the RDR exceeds the RD threshold value in the `PKTE_RING_THRESH.RDRTHRSH` bit, or the RD counter for the RDR in the `PKTE_RDSC_CNT` register is non-zero for more than $2^{(N+10)}$ internal system clock cycles.
0 (RX/W)	CDRTHRSH	CDR Threshold. Write the `PKTE_IMSK_DIS.CDRTHRSH` bit to clear when the number of command descriptors for the packet engine in the CDR is less than or equal to the CD threshold value in the `PKTE_RING_THRESH.CDRTHRSH` bit.

Interrupt Mask Enable Register

The host can use the PKTE_IMSK_EN register to set individual bits in the PKTE_INT_EN register for the host interrupt. This register is a bitmap for each of the possible interrupt sources: A 1 sets the interrupt enable bit, a 0 does not affect the interrupt enable bit in the PKTE_INT_EN register. Setting the enable bits through this register avoids the time-consuming read-modify-write operation on the host.

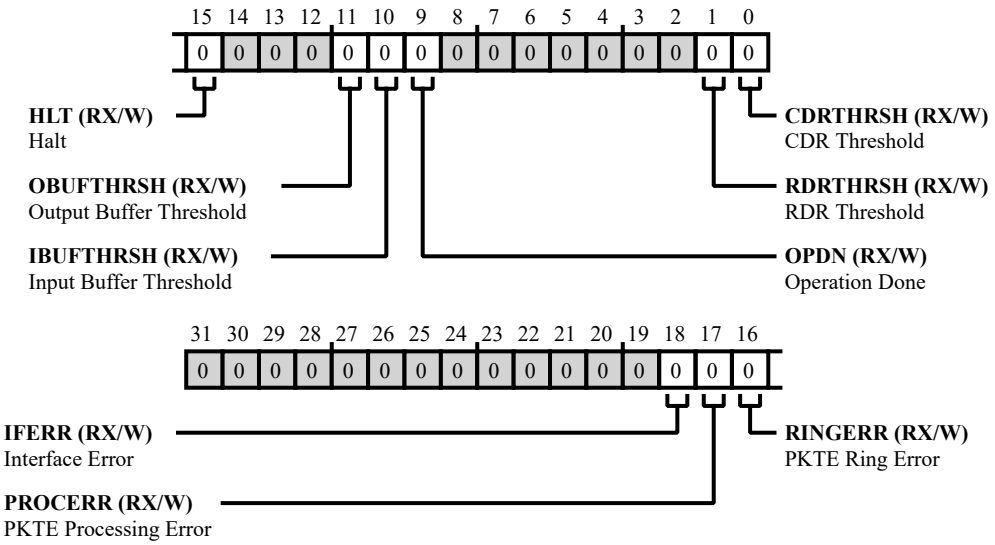

Figure 39-22: PKTE_IMSK_EN Register Diagram

Table 39-48: PKTE_IMSK_EN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
18 (RX/W)	IFERR	Interface Error. Set the PKTE_IMSK_EN.IFERR bit to indicate a host request for a non 32-bit access to the packet engine or when the packet engine receives an error writing data back out to the host memory system.
17 (RX/W)	PROCERR	PKTE Processing Error. Set the PKTE_IMSK_EN.PROCERR bit to indicate an extended error occurred before, during or after processing the current packet in the packet engine.
16 (RX/W)	RINGERR	PKTE Ring Error.
15 (RX/W)	HLT	Halt. Set the PKTE_IMSK_EN.HLT bit to indicate when the packet engine is in the halt state.

Table 39-48: PKTE_IMSK_EN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
11 (RX/W)	OBUFTHRSH	Output Buffer Threshold. Set the PKTE_IMSK_EN.OBUFTHRSH bit to indicate that the output buffer counter exceeds the output buffer threshold value defined in the PKTE_BUF_THRESH.OUTBUF bit.
10 (RX/W)	IBUFTHRSH	Input Buffer Threshold. Set the PKTE_IMSK_EN.IBUFTHRSH bit to indicate the input buffer counter is less than or equal to the input buffer threshold value defined in PKTE_BUF_THRESH.INBUF bit.
9 (RX/W)	OPDN	Operation Done.
1 (RX/W)	RDRTHRSH	RDR Threshold. Set the PKTE_IMSK_EN.RDRTHRSH bit to indicate when the number of result descriptors for the host in the RDR exceeds the RD threshold value in the PKTE_RING_THRESH.RDRTHRSH bit, or the RD counter for the RDR in PKTE_RDSC_CNT register is non-zero for more than $2^{(N+10)}$ internal system clock cycles.
0 (RX/W)	CDRTHRSH	CDR Threshold. Set the PKTE_IMSK_EN.CDRTHRSH bit to indicate when the number of command descriptors for the packet engine in the CDR is less than or equal to the CD threshold value in the PKTE_RING_THRESH.CDRTHRSH bit.

Interrupt Masked Status Register

The PKTE_IMSK_STAT register provides interrupt status visibility to the host, after the interrupt mask is applied. This lets the host view the selected sources of interrupts that are directed to the interrupt output signal, that is connected to the system interrupt controller. As with the unmasked status register, all interrupt bits are latched and must be cleared using the PKTE_INT_CLR register in order to capture a subsequent event. A 1 indicates that the associated interrupt is present.

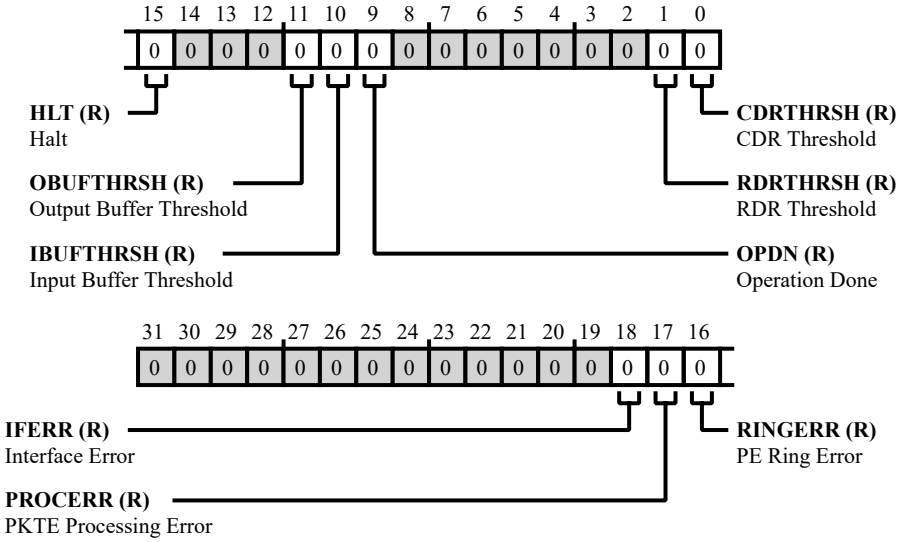

Figure 39-23: PKTE_IMSK_STAT Register Diagram

Table 39-49: PKTE_IMSK_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
18 (R/NW)	IFERR	Interface Error. The PKTE_IMSK_STAT.IFERR bit is set when the host requests a non 32-bit access to the packet engine or when the packet engine receives an error writing data back out to the host memory system.
17 (R/NW)	PROCERR	PKTE Processing Error. The PKTE_IMSK_STAT.PROCERR bit is when an extended error occurred before, during or after processing the current packet in the packet engine.
16 (R/NW)	RINGERR	PE Ring Error. The PKTE_IMSK_STAT.RINGERR bit is set on a CDR overflow or an RDR underflow.
15 (R/NW)	HLT	Halt. The PKTE_IMSK_STAT.HLT bit is set when the packet engine is in the HALT state.

Table 39-49: PKTE_IMSK_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
11 (R/NW)	OBUFTHRSH	Output Buffer Threshold. The PKTE_IMSK_STAT.OBUFTHRSH bit is set when the output buffer counter exceeds the output buffer threshold value defined in PKTE_BUF_THRESH.OUTBUF bit.
10 (R/NW)	IBUFTHRSH	Input Buffer Threshold. The PKTE_IMSK_STAT.IBUFTHRSH bit is set when the input buffer counter is less than or equal to the input buffer threshold value defined in PKTE_BUF_THRESH.INBUF bit.
9 (R/NW)	OPDN	Operation Done.
1 (R/NW)	RDRTHRSH	RDR Threshold. The PKTE_IMSK_STAT.RDRTHRSH bit is set when the number of result descriptors for the host in the RDR exceeds the RD threshold value in the PKTE_RING_THRESH.RDRTHRSH bit, or the RD counter for the RDR in PKTE_RDSC_CNT register is non-zero for more than $2^{(N+10)}$ internal system clock cycles.
0 (R/NW)	CDRTHRSH	CDR Threshold. The PKTE_IMSK_STAT.CDRTHRSH bit is set when the number of command descriptors for the packet engine in the CDR is less than or equal to the CD threshold value in the PKTE_RING_THRESH.CDRTHRSH bit.

Packet Engine Input Buffer Count Register

The PKTE_INBUF_CNT register provides the number of bytes available in the input buffer. The PKTE_INBUF_CNT register is used in direct host mode only.

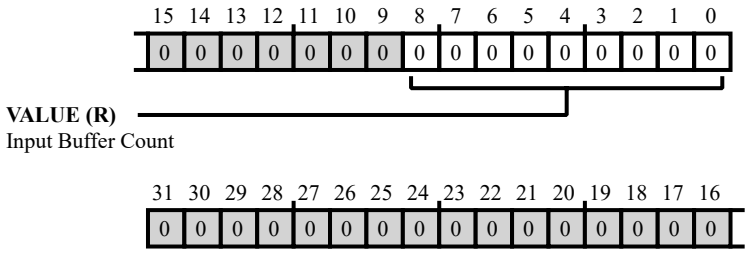

Figure 39-24: PKTE_INBUF_CNT Register Diagram

Table 39-50: PKTE_INBUF_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
8:0 (R/NW)	VALUE	Input Buffer Count. The PKTE_INBUF_CNT.VALUE bit field provides the number of bytes in the input buffer. The packet engine decrements the counter by 4 when a 32-bit word is read from the input buffer.

Packet Engine Input Buffer Count Increment Register

A host connected through the system completer bus can increment the input buffer counter by writing a value between 4 and 256, in multiples of 4, to the lowest bits of this register. The PKTE_INBUF_INCR register is used in direct host mode only.

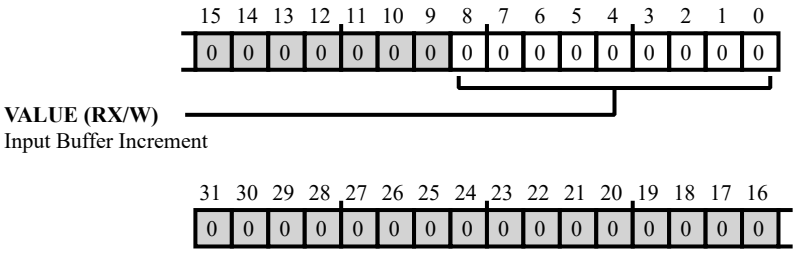

Figure 39-25: PKTE_INBUF_INCR Register Diagram

Table 39-51: PKTE_INBUF_INCR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
8:0 (RX/W)	VALUE	Input Buffer Increment. The value written is added to the input buffer counter. Valid values range from 4 to 256, in multiples of 4.

Interrupt Configuration Register

The PKTE_INT_CFG register configures the interrupt type that is sent to the interrupt line connected to the system interrupt controller. (Note that this only effects the final output of the interrupt subsystem).

Configuring the interrupt output type for pulse causes the interrupt signal to pulse low for two clock cycles when activated. When set for level, the interrupt signal is set low until cleared by the host (it follows the bit in the masked status register). For the host, this is typically set to level.

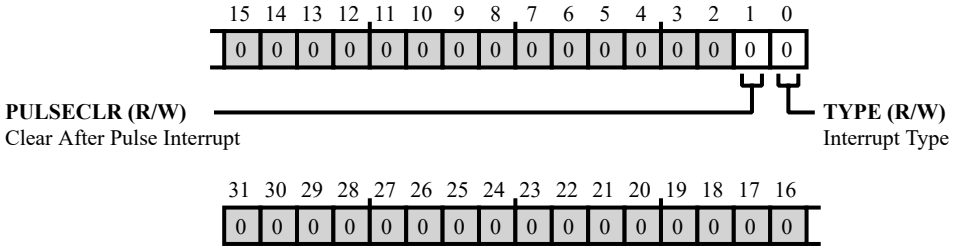

Figure 39-26: PKTE_INT_CFG Register Diagram

Table 39-52: PKTE_INT_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	PULSECLR	Clear After Pulse Interrupt. The PKTE_INT_CFG.PULSECLR bit clears the latched interrupt source after the pulse interrupt.	
		0	Manually clear pulse interrupt source. Do not automatically clear the interrupt sources after pulsing the interrupt output. Clear the source by writing to the PKTE_INT_CLR register.
		1	Automatically clear pulse interrupt source. After pulsing the interrupt output, automatically clear the sources.
0 (R/W)	TYPE	Interrupt Type. The PKTE_INT_CFG.TYPE bit selects the type, pulse or level, for the interrupt output to the system.	
		0	Level. The interrupt output is a level signal that is set low when an enabled interrupt is active until the interrupt is cleared.
		1	Pulse. The interrupt output is a two clock cycle low-active pulse, activated when an enabled interrupt is active.

Interrupt Clear Register

The PKTE_INT_CLR register allows the host processor to clear pending interrupts. A 1 written to a given bit in this register clears the corresponding interrupt. A 0 leaves the interrupt latch unchanged for that position.

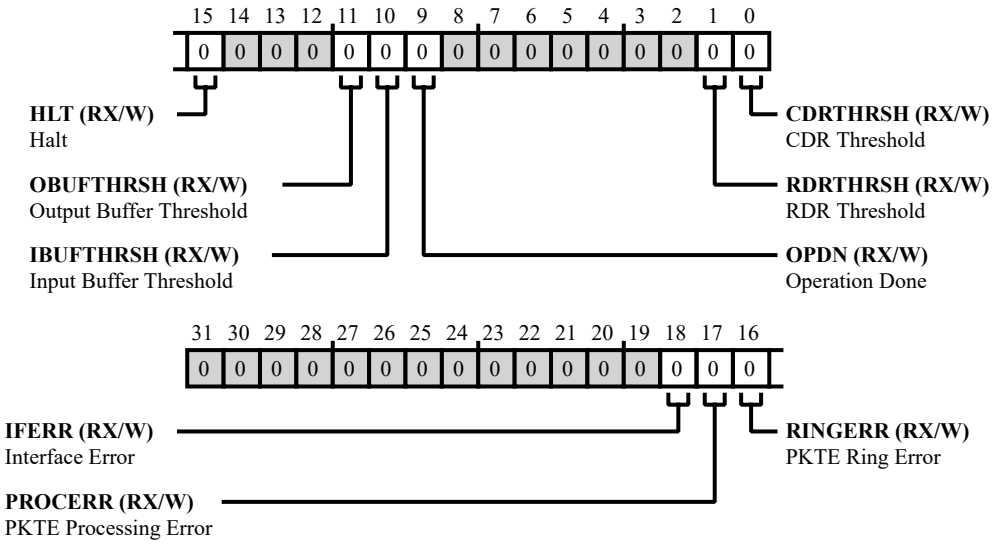

Figure 39-27: PKTE_INT_CLR Register Diagram

Table 39-53: PKTE_INT_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
18 (RX/W)	IFERR	Interface Error. The PKTE_INT_CLR.IFERR bit is set when the host requests a non 32-bit access to the packet engine or when the packet engine receives an error writing data back out to the host memory system.
17 (RX/W)	PROCERR	PKTE Processing Error. The PKTE_INT_CLR.PROCERR bit is set when an extended error occurred before, during or after processing the current packet in the packet engine.
16 (RX/W)	RINGERR	PKTE Ring Error. The PKTE_INT_CLR.RINGERR bit is set on a CDR overflow or an RDR underflow.
15 (RX/W)	HLT	Halt. The PKTE_INT_CLR.HLT bit is set when the packet engine is in the HALT state.
11 (RX/W)	OBUFTHRSH	Output Buffer Threshold. The PKTE_INT_CLR.OBUFTHRSH bit is set when the output buffer counter exceeds the output buffer threshold value defined in PKTE_BUF_THRESH.OUTBUF bit.

Table 39-53: PKTE_INT_CLR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
10 (RX/W)	IBUFTHRSH	Input Buffer Threshold. The PKTE_INT_CLR.IBUFTHRSH bit is set when the input buffer counter is less than or equal to the input buffer threshold value defined in PKTE_BUF_THRESH.INBUF bit.
9 (RX/W)	OPDN	Operation Done.
1 (RX/W)	RDRTHRSH	RDR Threshold. The PKTE_INT_CLR.RDRTHRSH bit is set when the number of result descriptors for the host in the RDR exceeds the RD threshold value in the PKTE_RING_THRESH.RDRTHRSH bit, or the RD counter for the RDR in PKTE_RDSC_CNT register is non-zero for more than $2^{(N+10)}$ internal system clock cycles.
0 (RX/W)	CDRTHRSH	CDR Threshold. The PKTE_INT_CLR.CDRTHRSH bit is set when the number of command descriptors for the packet engine in the CDR is less than or equal to the CD threshold value in the PKTE_RING_THRESH.CDRTHRSH bit.

Interrupt Enable Register

The PKTE_INT_EN register configures the interrupt mask for the host interrupt. This register is a bitmap for each of the possible interrupt sources. A 1 enables the interrupt source and a 0 disables the source. If an interrupt source is disabled, a cleared bit also clears the matching interrupt in the PKTE_IMSK_STAT register.

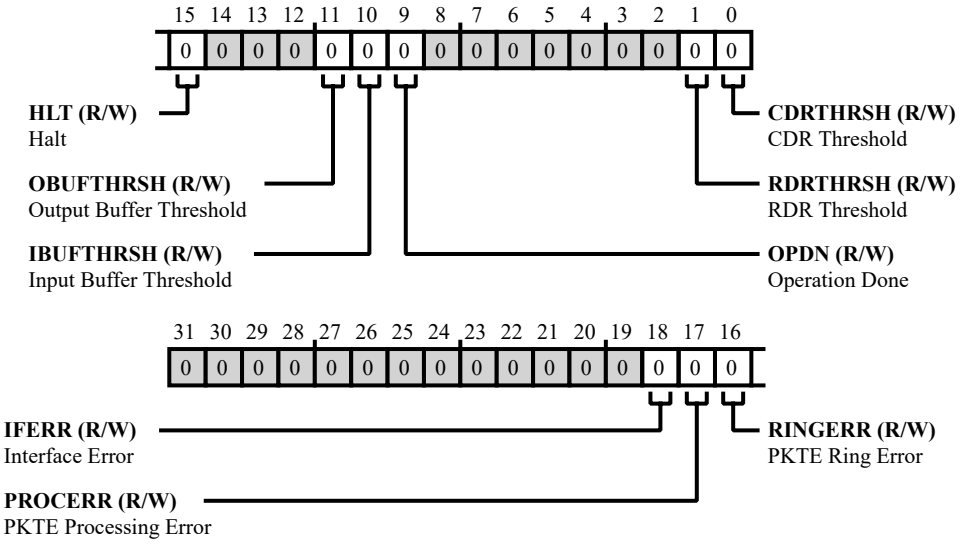

Figure 39-28: PKTE_INT_EN Register Diagram

Table 39-54: PKTE_INT_EN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
18 (R/W)	IFERR	Interface Error. Set the PKTE_INT_EN.IFERR bit for host requests for a non 32-bit access to the packet engine interrupt or when the packet engine receives an error writing data back out to the host memory system.
17 (R/W)	PROCERR	PKTE Processing Error. Set the PKTE_INT_EN.PROCERR bit to enable the extended error occurred before, during or after processing the current packet in the packet engine interrupt.
16 (R/W)	RINGERR	PKTE Ring Error. Set the PKTE_INT_EN.RINGERR bit to enable the CDR overflow or RDR underflow interrupt.
15 (R/W)	HLT	Halt. Set the PKTE_INT_EN.HLT bit for when the packet engine is in the HALT state.
11 (R/W)	OBUFTHRSH	Output Buffer Threshold. Set the PKTE_INT_EN.OBUFTHRSH bit for to trigger an interrupt when the output buffer counter exceeds the output buffer threshold value defined in the PKTE_BUF_THRESH.OUTBUF bit.

Table 39-54: PKTE_INT_EN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
10 (R/W)	IBUFTHRSH	Input Buffer Threshold. Set the PKTE_INT_EN.IBUFTHRSH bit for to trigger an interrupt when the input buffer counter is less than or equal to the input buffer threshold value defined in the PKTE_BUF_THRESH.INBUF bit.
9 (R/W)	OPDN	Operation Done.
1 (R/W)	RDRTHRSH	RDR Threshold. Set the PKTE_INT_EN.RDRTHRSH bit for to trigger an interrupt when the number of result descriptors for the host in the RDR exceeds the RD threshold value in the PKTE_RING_THRESH.RDRTHRSH bit, or the RD counter for the RDR in PKTE_RDSC_CNT register is non-zero for more than $2^{(N+10)}$ internal system clock cycles.
0 (R/W)	CDRTHRSH	CDR Threshold. Set the PKTE_INT_EN.CDRTHRSH bit for to trigger an interrupt when the number of command descriptors for the packet engine in the CDR is less than or equal to the CD threshold value in the PKTE_RING_THRESH.CDRTHRSH bit.

Interrupt Unmasked Status Register

The PKTE_IUMSK_STAT register provides interrupt status visibility to the host, prior to the interrupt mask being applied. Using this register, the host can view all potential sources of incoming interrupts. All of these sources, whether masked in or out, are latched in this register and must be cleared using the PKTE_INT_CLR register in order to capture a subsequent event. A 1 indicates that the associated interrupt is present.

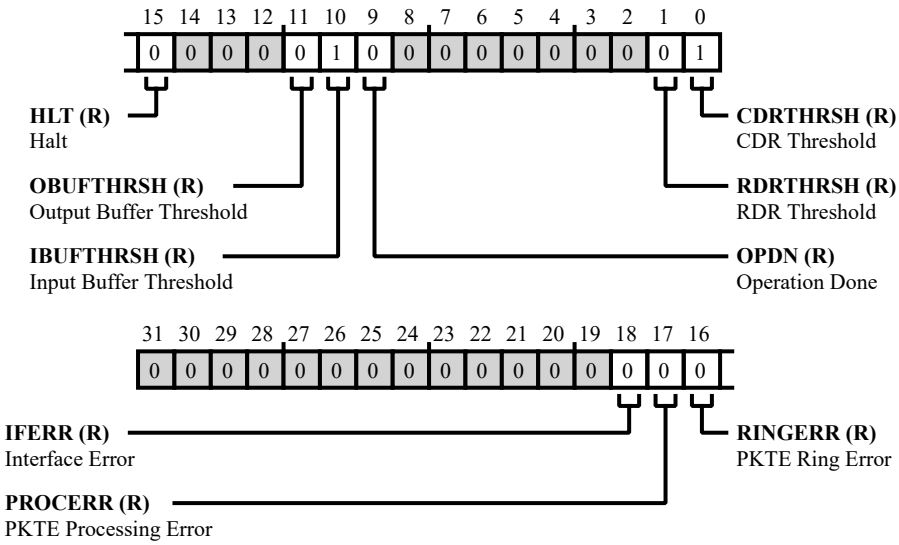

Figure 39-29: PKTE_IUMSK_STAT Register Diagram

Table 39-55: PKTE_IUMSK_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
18 (R/NW)	IFERR	Interface Error. The PKTE_IUMSK_STAT.IFERR bit is set when the host requests a non 32-bit access to the packet engine or when the packet engine receives an error writing data back out to the host memory system.
17 (R/NW)	PROCERR	PKTE Processing Error. The PKTE_IUMSK_STAT.PROCERR bit is set when an extended error occurred before, during or after processing the current packet in the packet engine.
16 (R/NW)	RINGERR	PKTE Ring Error. The PKTE_IUMSK_STAT.RINGERR bit is set on a CDR overflow or an RDR underflow.
15 (R/NW)	HLT	Halt. The PKTE_IUMSK_STAT.HLT bit is set when the packet engine is in the HALT state.

Table 39-55: PKTE_IUMSK_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
11 (R/NW)	OBUFTHRSH	Output Buffer Threshold. The PKTE_IUMSK_STAT.OBUFTHRSH interrupt is triggered when the output buffer counter exceeds the output buffer threshold value defined in PKTE_BUF_THRESH.OUTBUF bit.
10 (R/NW)	IBUFTHRSH	Input Buffer Threshold. The PKTE_IUMSK_STAT.IBUFTHRSH interrupt is triggered when the input buffer counter is less than or equal to the input buffer threshold value defined in PKTE_BUF_THRESH.INBUF bit.
9 (R/NW)	OPDN	Operation Done.
1 (R/NW)	RDRTHRSH	RDR Threshold. The PKTE_IUMSK_STAT.RDRTHRSH bit is set when the number of result descriptors for the host in the RDR exceeds the RD threshold value in the PKTE_RING_THRESH.RDRTHRSH, or the RD counter for the RDR in PKTE_RDSC_CNT register is non-zero for more than $2^{(N+10)}$ internal system clock cycles.
0 (R/NW)	CDRTHRSH	CDR Threshold. The PKTE_IUMSK_STAT.CDRTHRSH bit is set when the number of command descriptors for the packet engine in the CDR is less than or equal to the CD threshold value in the PKTE_RING_THRESH.CDRTHRSH bit.

Packet Engine Length Register

The PKTE_LEN register gives the length of the packet, the bypass data and a second set of ownership bits.

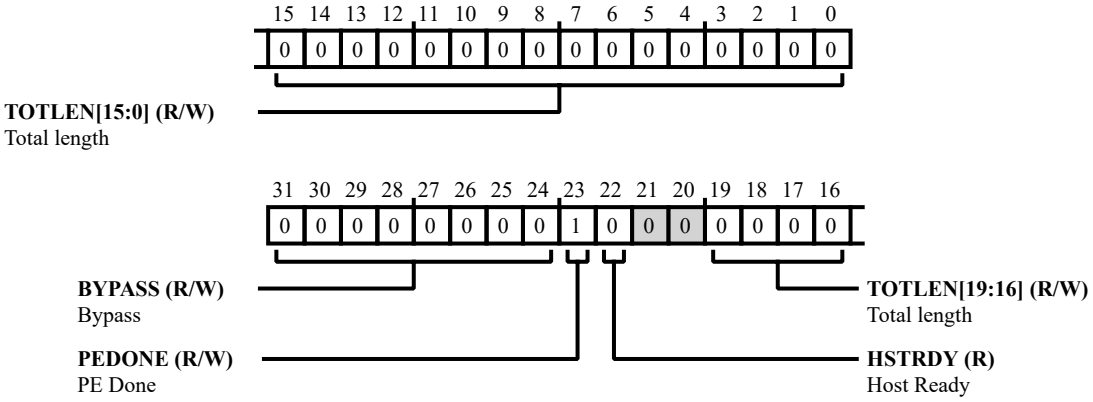

Figure 39-30: PKTE_LEN Register Diagram

Table 39-56: PKTE_LEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	BYPASS	Bypass. The PKTE_LEN.BYPASS bit field indicates the length of data in words that must bypass the packet engine and are directly copied from the source buffer to the destination buffer. The packet engine does not process this data. Valid bypass offsets range from 0 (0x00) to 255 (0xFF) words. For SRTP operations, this field specifies the offset in words between the hash and encrypt/decrypt data.
23 (R/W)	PEDONE	PE Done. The PKTE_LEN.PEDONE bit is a mirrored bit from the PKTE_CTL_STAT.PERDY bit. The bit is repeated here to guarantee ownership consistency between the first and last word. When the packet engine fetches a descriptor, these bits must match or the descriptor is discarded and fetched again.
22 (R/NW)	HSTRDY	Host Ready. The PKTE_LEN.HSTRDY bit is a mirrored bit of the PKTE_CTL_STAT.HOSTRDY bit. The bit is repeated here to guarantee ownership consistency between the first and last word. It should also be set along with the PKTE_CTL_STAT.HOSTRDY bit when the command descriptor is finished being populated. When the packet engine fetches a descriptor, these bits must match or the descriptor is discarded and fetched again.

Table 39-56: PKTE_LEN Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
19:0 (R/W)	TOTLEN	Total length. Command Descriptor: The PKTE_LEN.TOTLEN bit field indicates the total length (in bytes) of all data to be passed to the packet engine's input buffer for an operation. Exceptions are the PRNG init and PRNG generate operations. The PRNG init operation does not require any input data; this field must be zero. For the PRNG generate operation, this field indicates the number of pseudo-random bytes to be generated. Valid lengths range from 16 (0x00010) to 255*16 = 4080 (0x00FF0) bytes in multiples of 16 bytes. Valid lengths for the basic operation range from 1 (0x00001) to 1,048,575 (0xFFFFF) bytes. This is the length of the data to be encrypted or hashed and includes the bypass data and padding bytes. Valid lengths for IPsec ESP range from 1 (0x00001) to 65535 (0x0FFFF) bytes. This is the length of the IP payload. Valid lengths for SSL v3.0, TLS v1.x and DTLS range from 1 (0x00001) to 16383 (0x03FFF). This is the length of the payload. Valid lengths for SRTP range from 1 (0x00001) to 65535 (0x0FFFF). This is the length of the payload. Note: A length of zero bytes is illegal and will result in an error status code in the result descriptor. Result Descriptor: Upon completion of an operation, the PKTE_LEN.TOTLEN field indicates the result length of the result packet. Valid lengths range from 1 (0x001) to 1,048,575 (0xFFFFF) bytes. This includes the bypass data and padding bytes. Note: When an extended error (PKTE_CTL_STAT[18]=1) is reported in the result descriptor and no packet data is processed, this field returns zero.

Packet Engine Output Buffer Count Register

The PKTE_OUTBUF_CNT register provides the number of data bytes there are in the output buffer. The PKTE_OUTBUF_CNT register is used in direct host mode only.

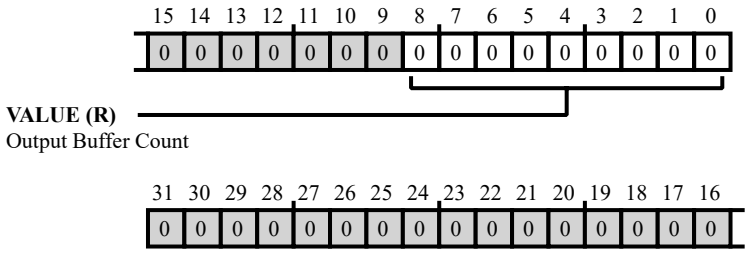

Figure 39-31: PKTE_OUTBUF_CNT Register Diagram

Table 39-57: PKTE_OUTBUF_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
8:0 (R/NW)	VALUE	Output Buffer Count. The PKTE_OUTBUF_CNT.VALUE bit field provides the number of bytes in the output buffer. The packet engine increments the counter by 4 when a 32-bit word is written to the output buffer.

Packet Engine Output Buffer Count Decrement Register

A host connected via the system completer bus can decrement the output buffer counter by writing a value between 4 and 256, in multiples of 4, to the lowest bits of this register. The PKTE_OUTBUF_DECR register is used in direct host mode only.

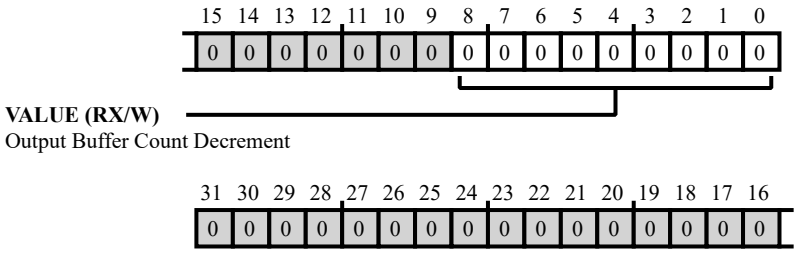

Figure 39-32: PKTE_OUTBUF_DECR Register Diagram

Table 39-58: PKTE_OUTBUF_DECR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
8:0 (RX/W)	VALUE	Output Buffer Count Decrement. The PKTE_OUTBUF_DECR.VALUE bit field is the value written is subtracted to the output buffer counter. Valid values range from 4 to 256, in multiples of 4.

PE Alternative Key stat register

The Key registers can be written in support of several cipher modes and key sizes.

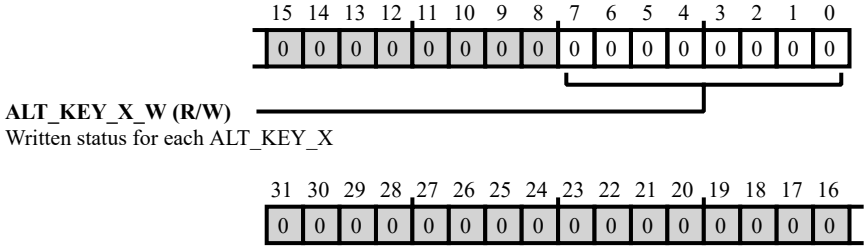

Figure 39-33: PKTE_PE_ALT_KEY_STATUS Register Diagram

Table 39-59: PKTE_PE_ALT_KEY_STATUS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	ALT_KEY_X_W	Written status for each ALT_KEY_X.

Packet Engine Cache Control 0

Packet Engine Cache Control 0

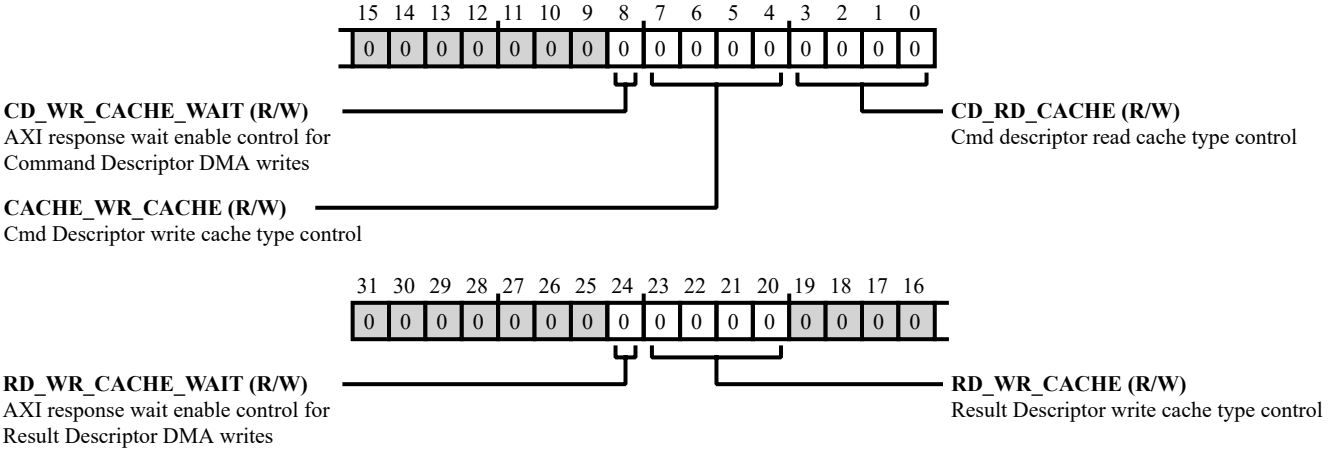

Figure 39-34: PKTE_PE_CACHE_CTRL_0 Register Diagram

Table 39-60: PKTE_PE_CACHE_CTRL_0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
24 (R/W)	RD_WR_CACHE_WAIT	AXI response wait enable control for Result Descriptor DMA writes.
23:20 (R/W)	RD_WR_CACHE	Result Descriptor write cache type control.
8 (R/W)	CD_WR_CACHE_WAIT	AXI response wait enable control for Command Descriptor DMA writes.
7:4 (R/W)	CACHE_WR_CACHE	Cmd Descriptor write cache type control.
3:0 (R/W)	CD_RD_CACHE	Cmd descriptor read cache type control.

Packet Engine Cache Control 1

Packet Engine Cache Control 1

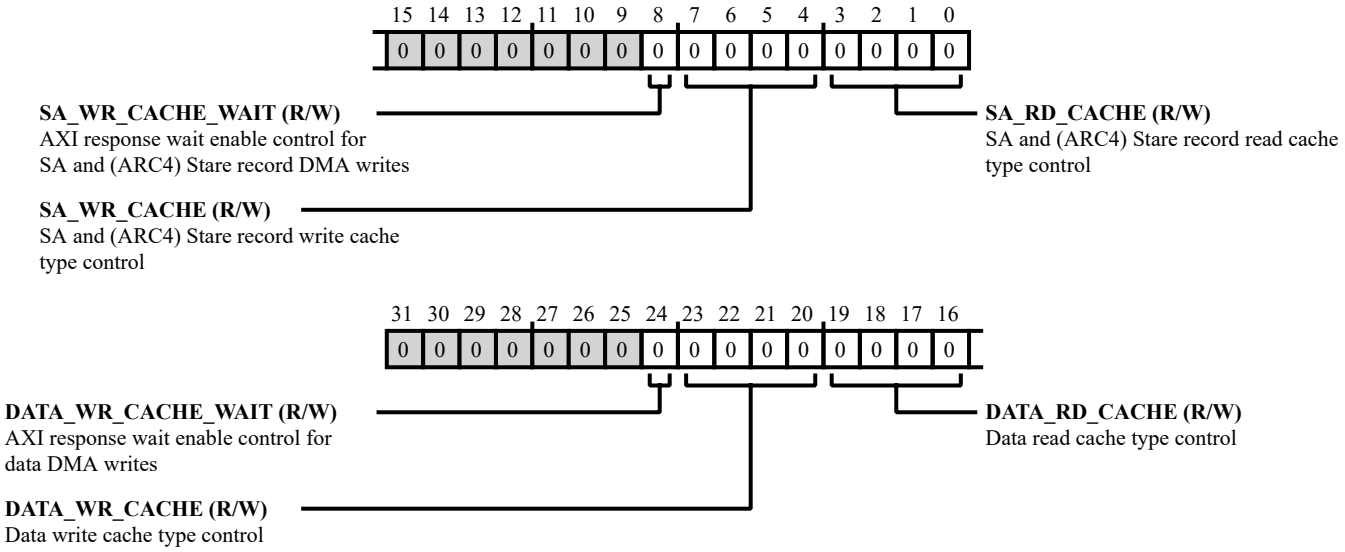

Figure 39-35: PKTE_PE_CACHE_CTRL_1 Register Diagram

Table 39-61: PKTE_PE_CACHE_CTRL_1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
24 (R/W)	DATA_WR_CACHE_WAIT	AXI response wait enable control for data DMA writes.
23:20 (R/W)	DATA_WR_CACHE	Data write cache type control.
19:16 (R/W)	DATA_RD_CACHE	Data read cache type control.
8 (R/W)	SA_WR_CACHE_WAIT	AXI response wait enable control for SA and (ARC4) Stare record DMA writes.
7:4 (R/W)	SA_WR_CACHE	SA and (ARC4) Stare record write cache type control.
3:0 (R/W)	SA_RD_CACHE	SA and (ARC4) Stare record read cache type control.

Packet Engine Result Descriptor Ring Base Address

The PKTE_RDRBASE_ADDR register holds the result descriptor ring base address in host memory. It is only applicable in autonomous ring mode and target command mode with RDR enabled. Note that in target command mode, the CDR is not used, but the RDR must be configured when enabled so that the packet engine knows where to write the result descriptors.

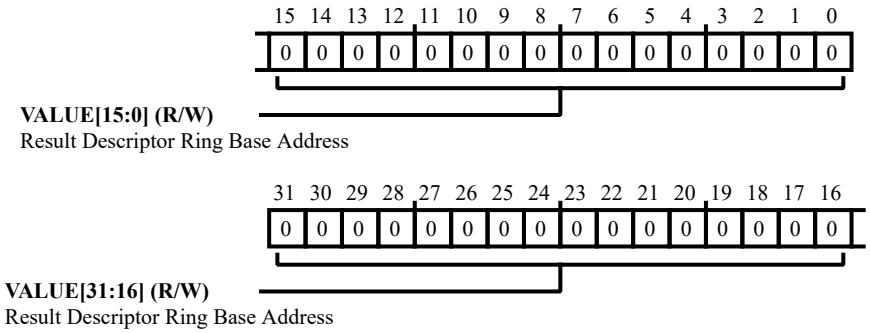

Figure 39-36: PKTE_RDRBASE_ADDR Register Diagram

Table 39-62: PKTE_RDRBASE_ADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Result Descriptor Ring Base Address. The PKTE_RDRBASE_ADDR.VALUE bit field specifies the base location of the result descriptor ring in the host memory space.

Packet Engine Result Descriptor Count Registers

The PKTE_RDSC_CNT register holds the counter for the number of descriptors in the Result Descriptor Ring (RDR). It is incremented by the packet engine each time a valid result descriptor is written to the RDR.

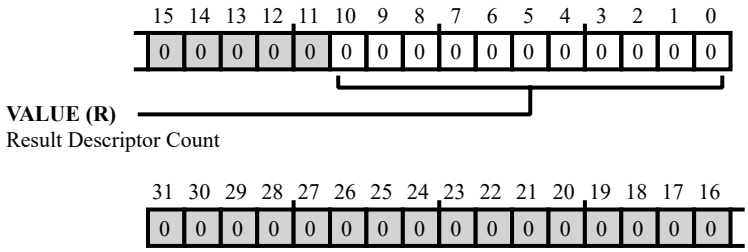

Figure 39-37: PKTE_RDSC_CNT Register Diagram

Table 39-63: PKTE_RDSC_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
10:0 (R/NW)	VALUE	Result Descriptor Count. The PKTE_RDSC_CNT.VALUE bit field provides the number of result descriptors in the result descriptor ring. The packet engine increments the counter when a valid result descriptor is written to the RDR.

Packet Engine Result Descriptor Count Decrement Registers

The PKTE_RDSC_DECR register is accessible by the host connected through the system completer bus can decrement the result descriptor counter by writing a value between 1 and 255 to the lowest byte of this register.

With an RDR enabled, this is the number of result descriptors that have been read by the host. With an RDR disabled, this indicates that the host has read one valid result descriptor.

In autonomous ring mode or target command mode with the RDR enabled, the host must process 1 to 255 result descriptors from the RDR and then write this register with the number of result descriptors that have been processed by the host.

In direct host mode or target command mode with the RDR disabled, the host must read one result descriptor from the internal descriptor registers and then write this register with the value 1, to indicate that one valid descriptor is read. An RDR threshold interrupt is activated when the result descriptor counter exceeds the threshold value set in the PKTE_RING_THRESH register. This interrupt can be used to wake up a process that stalled on an empty RDR.

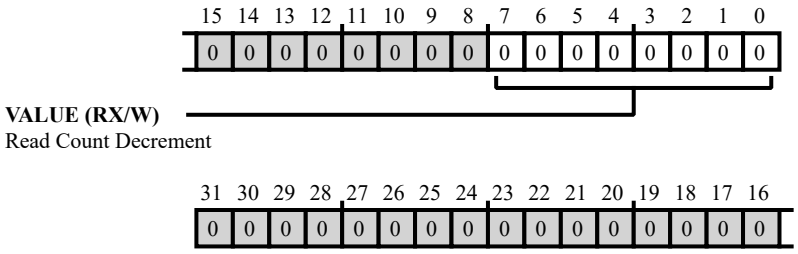

Figure 39-38: PKTE_RDSC_DECR Register Diagram

Table 39-64: PKTE_RDSC_DECR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (RX/W)	VALUE	Read Count Decrement. The value written to the PKTE_RDSC_DECR.VALUE bit field is subtracted from the result descriptor counter. The counter is protected against underflow (See the PKTE_RING_STAT register). Note that bits [10:8] should be written with zeros.

Packet Engine Ring Configuration

The PKTE_RING_CFG register configures the size (in number of descriptor ring entries minus 1) for both the command descriptor ring and result descriptor ring in host memory. This register is only applicable for autonomous ring mode and target command mode with RDR enabled.

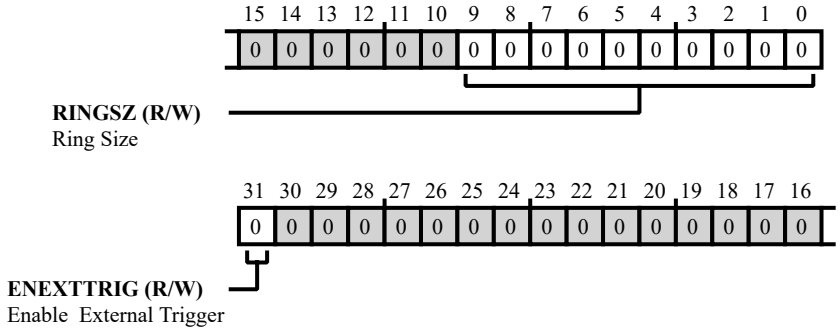

Figure 39-39: PKTE_RING_CFG Register Diagram

Table 39-65: PKTE_RING_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	ENEXTTRIG	Enable External Trigger. The PKTE_RING_CFG.ENEXTTRIG signal enables the increment of the PKTE_CDSC_CNT register through the external input pin ext_cd_cnt_incr and enables the decrement of the PKTE_RDSC_CNT fields through the external input pin ext_rd_cnt_decr.
9:0 (R/W)	RINGSZ	Ring Size. The PKTE_RING_CFG.RINGSZ bit field specifies the size of the command ring in number of descriptors, minus 1. Valid sizes range from 1 (for 2 descriptors) to 1023 (for 1024 descriptors). The accompanying result ring will have the same size.

Packet Engine Ring Pointer Status

The PKTE_RING_PTR register holds the pointers to the current entry of the Command Descriptor Ring (CDR) and Result Descriptor Ring (RDR).

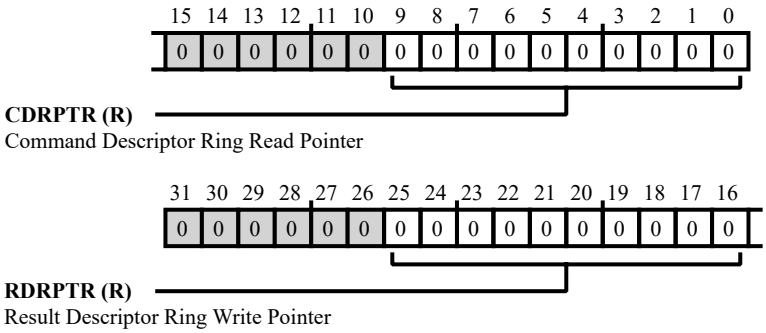

Figure 39-40: PKTE_RING_PTR Register Diagram

Table 39-66: PKTE_RING_PTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
25:16 (R/NW)	RDRPTR	Result Descriptor Ring Write Pointer. The PKTE_RING_PTR.RDRPTR bit field indicates the entry number in the RDR that will be written next by the packet engine. The PKTE_RING_PTR.RDRPTR bit field is reset to zero after starting up and updated after every result descriptor write DMA operation. Pointers wrap around; the maximum value this field can have equals the contents of the ring size (PKTE_RING_CFG.RINGSZ) bit field.
9:0 (R/NW)	CDRPTR	Command Descriptor Ring Read Pointer. The PKTE_RING_PTR.CDRPTR bit field indicates the entry number in the CDR that will be read next by the packet engine. The PKTE_RING_PTR.CDRPTR bit field is reset to zero after starting up and updated after every command descriptor read DMA operation. Pointers wrap around; the maximum value this field can have equals the contents of the ring size (PKTE_RING_CFG.RINGSZ) field.

Packet Engine Ring Status

The PKTE_RING_STAT register gives indication of either a Command Descriptor Ring (CDR) overflow or a Result Descriptor Ring (RDR) underflow. A ring error (ringerr) interrupt in the interrupt controller is activated on a command descriptor ring overflow or a result descriptor ring underflow. This type of error can occur when the host and the packet engine get out-of-sync. The host can read this register to retrieve information on which ring is corrupted. The corrupted ring must be reset and reinitialized. See the PKTE_CFG.RSTRING bit.

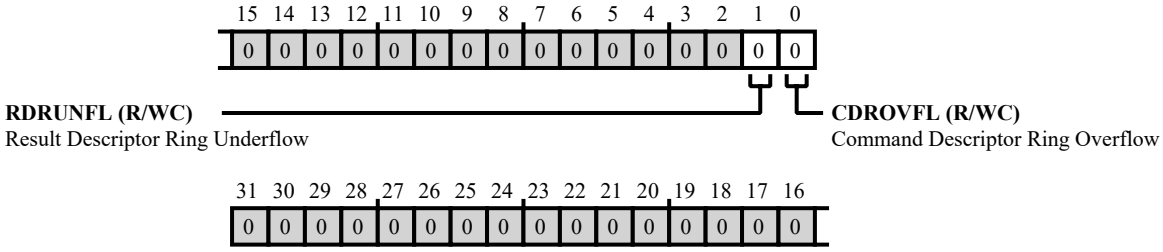

Figure 39-41: PKTE_RING_STAT Register Diagram

Table 39-67: PKTE_RING_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
1 (R/WC)	RDRUNFL	Result Descriptor Ring Underflow. The PKTE_RING_STAT.RDRUNFL bit is set when the command descriptor count (PKTE_RDSC_CNT) register is decremented below zero. This bit is reset with a write of any value.
0 (R/WC)	CDROVFL	Command Descriptor Ring Overflow. The PKTE_RING_STAT.CDROVFL bit is set when the command descriptor count (PKTE_CDSC_CNT) register is incremented above the ring size (PKTE_RING_CFG.RINGSZ) bits. This bit is reset with a write of any value.

Packet Engine Ring Threshold Registers

To reduce the amount of packet engine result interrupts, the PKTE_RING_THRESH register contains threshold and time-out values.

The CDR threshold (cdrthrsh) interrupt indicates that the command descriptor counter is less than or equal to the CDR threshold (cdrthrsh) value set in this register. This interrupt can be used to wake up a process that stalled on a full CDR.

The RDR threshold (rdrthrsh) interrupt indicates that the result descriptor counter exceeds the result descriptor threshold set here, or that the result descriptor counter is non-zero for a time longer than the result descriptor time-out setting. The RDR result interrupt remains active until the result descriptor counter is decremented below the RDR threshold (rdrthrsh) value. In case the interrupt is the result of a time-out and the result descriptor counter is below the threshold value, the result descriptor counter must be decremented once before the interrupt can be cleared in the interrupt controller.

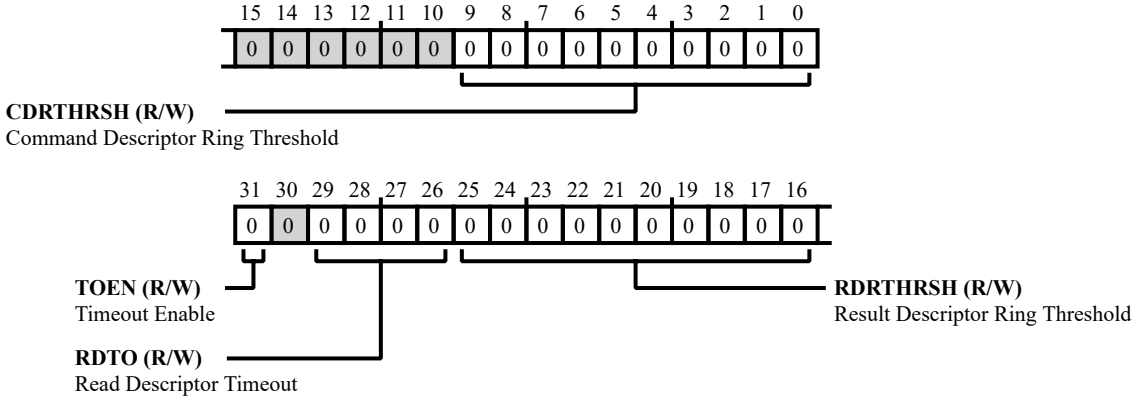

Figure 39-42: PKTE_RING_THRESH Register Diagram

Table 39-68: PKTE_RING_THRESH Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/W)	TOEN	Timeout Enable. A 1 in the PKTE_RING_THRESH.TOEN bit indicates the result descriptor timeout counter is enabled. This bit can be used to de-activate the timeout counter to save power.

Table 39-68: PKTE_RING_THRESH Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
29:26 (R/W)	RDTO	Read Descriptor Timeout. The timeout enable (PKTE_RING_THRESH.TOEN) bit in this register must be set to activate this PKTE_RING_THRESH.RDTO result descriptor timeout counter. The rdrthrsh interrupt activates when the RD counter for the RDR is non-zero for more than $2^{(N+10)}$ internal system clock cycles, where 'N' is the value set in this field. Valid settings range from 0 to 15. The minimum time-out value for N=0 is 1024 clock cycles and the maximum time-out value for N=15 is 33554432 clock cycles. At 100 MHz, this is 5.12 us for N=0 and ~335.55 ms for N=15. Note: The time-out delay may not be exact - expect a variation on the order of 1024 system clock cycles (just more than one microsecond at 100 MHz system clock frequency).
25:16 (R/W)	RDRTHRSH	Result Descriptor Ring Threshold. The rdrthrsh interrupt activates when the RD counter for the RDR exceeds the value set in the PKTE_RING_THRESH.RDRTHRSH field. Valid settings range from 0 to 1023.
9:0 (R/W)	CDRTHRSH	Command Descriptor Ring Threshold. The cdrthrsh interrupt activates when CD counter for the CDR is below or equal the value set in the PKTE_RING_THRESH.CDRTHRSH field. Valid settings range from 0 to 1023.

Packet Engine SA Address

The PKTE_SA_ADDR register holds the start address of the SA record.

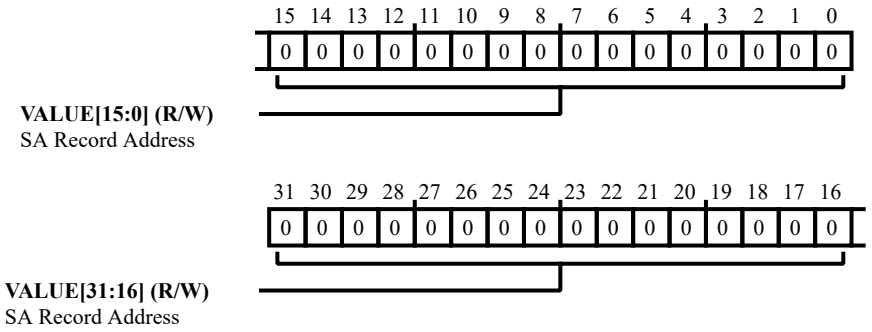

Figure 39-43: PKTE_SA_ADDR Register Diagram

Table 39-69: PKTE_SA_ADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	SA Record Address. The PKTE_SA_ADDR.VALUE bit field holds the start address of the SA record.

ARC4 i and j Pointer Register

When starting a new ARC4 operation the PKTE_SA_ARC4IJPTR register contains the initialization value, which is zeros. After processing the ARC4 algorithm it contains the latest status of the ARC4_IJ_PNTR.

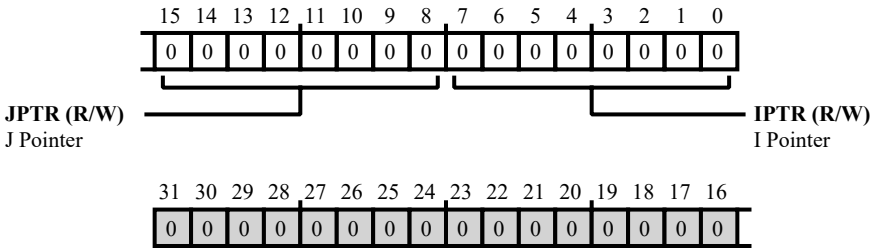

Figure 39-44: PKTE_SA_ARC4IJPTR Register Diagram

Table 39-70: PKTE_SA_ARC4IJPTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:8 (R/W)	JPTR	J Pointer. The PKTE_SA_ARC4IJPTR.JPTR bit field contains the j pointer into s-box array for swapping bytes with i pointer.
7:0 (R/W)	IPTR	I Pointer. The PKTE_SA_ARC4IJPTR.IPTR bit field contains the i pointer into s-box array for swapping bytes with j pointer.

SA Command 0

The two SA command registers, PKTE_SA_CMD0 and PKTE_SA_CMD1, are used to control the cryptographic operation of the packet engine. The PKTE_SA_CMD0 register contains the major control bits to define an operation while the PKTE_SA_CMD1 register contains the minor control bits. In direct host mode, this is a write-only register.

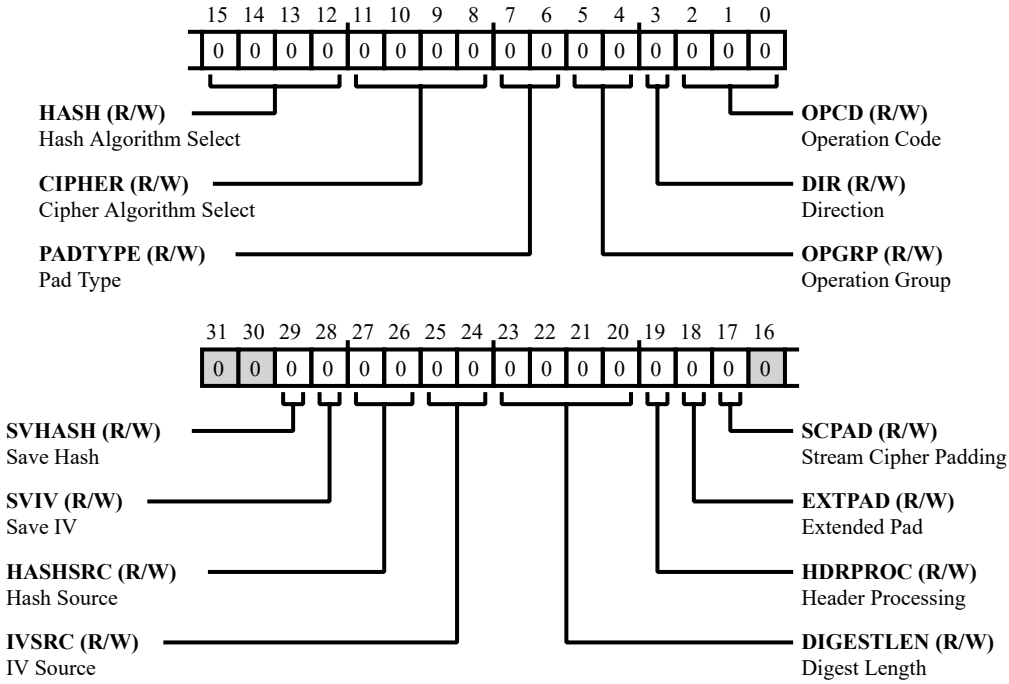

Figure 39-45: PKTE_SA_CMD0 Register Diagram

Table 39-71: PKTE_SA_CMD0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R/W)	SVHASH	Save Hash. The PKTE_SA_CMD0.SVHASH bit indicates that the Hash State is saved to the STATE_BYTE_CNT_X and STATE_IDIGEST_X fields in the SA record in memory after completion of a crypto operation.	
		0	Hash state is not saved
		1	Hash state is saved

Table 39-71: PKTE_SA_CMD0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
28 (R/W)	SVIV	Save IV. The `PKTE_SA_CMD0.SVIV` bit field indicates that for DES or the AES the Initialization Vector (IV) is saved to the STATE_IV_X fields in the state record , or the ARC4 state is saved to the ARC4 state record, after completion of the crypto operation.	
		0	ARC4 State is not saved.
		1	ARC4 State is not saved.
27:26 (R/W)	HASHSRC	Hash Source. The `PKTE_SA_CMD0.HASHSRC` bit field selects the source of the hash digest used by the algorithm.	
		0	From SA. Digest only hash byte count is forced to 0x40.
		1	Reserved
		2	From State. Read saved inner hash digest and saved hash byte count.
		3	No Load. Use the hash algorithm defined constants for the initial hash. Hash byte count is 0x00.
25:24 (R/W)	IVSRC	IV Source. The `PKTE_SA_CMD0.IVSRC` bit field selects the source of the initialization vector used by the crypto algorithm.	
		0	No load. Use previous result IV, not applicable for inbound data. This option should never be used for operations with DES-CBC or AES-CBC, (see RFC3602) or any AES counter modes
		1	From input buffer. The IV is provided as part of the input data stream.
		2	From State. Read STATE_IV_X, from the SA structure. Refer to inner hash digest register structure. Useful for resume operations.
		3	From internal PRNG. Not applicable for inbound operations.
23:20 (R/W)	DIGESTLEN	Digest Length. The `PKTE_SA_CMD0.DIGESTLEN` bit field defines the length of the hash digest in words as put in the output buffer.	
		0	3 Words (96-bit output)
		1	1 Word
		2	2 Words

Table 39-71: PKTE_SA_CMD0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		3	3 Words (IPsec)
		4	4 Words (MD5 and AES-based hash)
		5	5 Words (SHA-1)
		6	6 Words
		7	7 Words (SHA-224)
		8	8 Words (SHA-256)
		9	Reserved
		10	10 bytes (SRTP and TLS)
		11-15	Reserved
19 (R/W)	HDRPROC	Header Processing. The PKTE_SA_CMD0.HDRPROC bit enables header processing for protocol operations. There is no header-processing support for basic SSL, basic TLS and SRTP protocol operations as defined in the protocol group (see the Crypto and Hash Algorithms section). This bit must be zero for these operations; however, the protocol header must be supplied to the packet engine since it is part of the hash calculation. Refer to the protocol specifications for more information about header-processing support for a protocol.	
		0	No header processing
		1	Header processing; insert the protocol header for outbound operations, verify the protocol header for inbound operations.
18 (R/W)	EXTPAD	Extended Pad. The PKTE_SA_CMD0.EXTPAD bit extends the number of padding types. Used in combination with PKTE_SA_CMD0.PADTYPE.	
17 (R/W)	SCPAD	Stream Cipher Padding. The PKTE_SA_CMD0.SCPAD bit enables padding for stream ciphers algorithms.	
15:12 (R/W)	HASH	Hash Algorithm Select. The PKTE_SA_CMD0.HASH bit field selects the hash algorithm.	
		0	MD5
		1	SHA-1
		2	SHA-224
		3	SHA-256
		4-14	Reserved
		15	Null

Table 39-71: PKTE_SA_CMD0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11:8 (R/W)	CIPHER	Cipher Algorithm Select. The PKTE_SA_CMD0.CIPHER bit field selects the cipher algorithm to be used for encryption and decryption. Note: Each type of protocol operation supports different sets of crypto algorithms. Refer to the Crypto and Hash Algorithms general processing section for details of the supported algorithms.	
		0	DES
		1	Triple-DES
		2	ARC4
		3	AES
		4-14	Reserved
		15	Null
7:6 (R/W)	PADTYPE	Pad Type. The PKTE_SA_CMD0.PADTYPE bit field indicates the type of crypto that must be generated for outbound packets or checked for inbound packets.	
		0	Select IPSec operation (if Bit 18=0); Reserved (if Bit 18=1)
		1	PKCS#7 (if Bit 18=0); Select TLS/DTLS Pad, required for TLS/DTLS operation (if Bit 18=1)
		2	Constant pad (if Bit 18=0); Select Constant SSL Pad, required for SSL operation (if Bit 18=1)
		3	Zero pad (if Bit 18=0), Reserved (if Bit 18=1)
5:4 (R/W)	OPGRP	Operation Group. The PKTE_SA_CMD0.OPGRP bit field defines the operation groups. Refer to the Basic Operations and Decoding section for more information.	
		0	Basic operation group
		1	Protocol operation group
		2	Extended protocol operations group
		3	Reserved
3 (R/W)	DIR	Direction. The PKTE_SA_CMD0.DIR bit field selects the direction of operation.	
		0	Outbound operations
		1	Inbound operations

Table 39-71: PKTE_SA_CMD0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
2:0 (R/W)	OPCD	Operation Code. The `PKTE_SA_CMD0.OPCD` bit field selects the operation within the operation group.

SA Command 1

The PKTE_SA_CMD1 register contains the minor control bits that define an operation. In direct host mode, this is a write-only register.

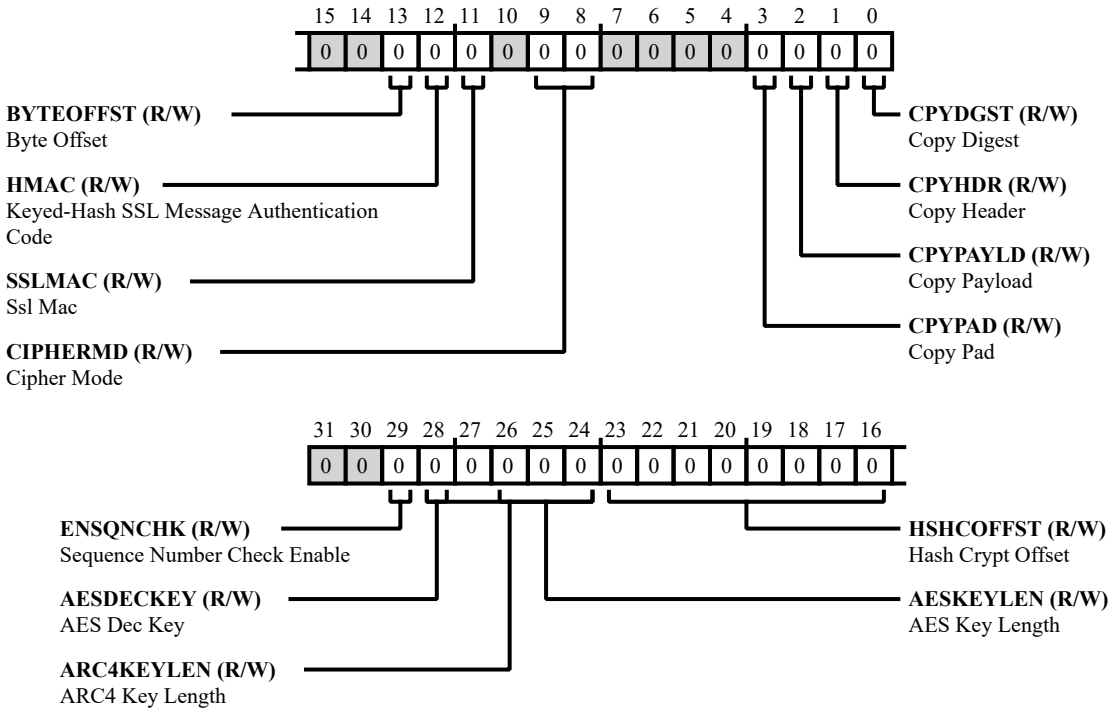

Figure 39-46: PKTE_SA_CMD1 Register Diagram

Table 39-72: PKTE_SA_CMD1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R/W)	ENSQNCHK	Sequence Number Check Enable. The PKTE_SA_CMD1.ENSQNCHK bit defines that the key in the SA key field is an AES encrypt key or an AES decrypt key.	
		0	Disable sequence number check
		1	Enable sequence number check
28 (R/W)	AESDECKEY	AES Dec Key. If the PKTE_SA_CMD1.AESDECKEY bit is set, the key in loaded in the PKTE_SA_KEY[n] registers are expected to be the key from the last round from key expansion. If not set, the key loaded in the PKTE_SA_KEY[n] registers are expected to be the same key used during the encryption process.	
		0	AES key is an encrypt key.
		1	AES key is a decrypt key.

Table 39-72: PKTE_SA_CMD1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
26:24 (R/W)	AESKEYLEN	AES Key Length. The PKTE_SA_CMD1.AESKEYLEN bit field select the size of the key used for the AES algorithm in increments of 64 bits.	
		0-1	Reserved
		2	128 Bits
		3	192 Bits
		4	256 Bits
		5-7	Reserved
28:24 (R/W)	ARC4KEYLEN	ARC4 Key Length.	
23:16 (R/W)	HSHCOFFST	Hash Crypt Offset. For Basic Encrypt-Hash and Basic Hash-Decrypt operations, the PKTE_SA_CMD1.HSHCOFFST bit field specifies the offset between the hash data and the encrypt/decrypt data. The data to be hashed is assumed to come first, with an offset to the beginning of encrypt/decrypt data. When PKTE_SA_CMD1.BYTEOFFST, bit 13, is zero, then the offset is defined in 32-bit words. When an initialization vector is loaded through the input buffer, valid values range from "IV size" to 255. In all other cases, valid values range from 0 to 255. When PKTE_SA_CMD1.BYTEOFFST, bit 13, is one, then the offset is defined in 8-bit bytes. When an initialization vector is loaded through the input buffer, valid values range from "IV size" to 255. In all other cases, valid values range from 4 to 255. (The IV size is two words for DES, Triple-DES and AES-CTR and four words for AES-CBC and AES-ICM operations). Other operations do not use these bits (a default value is applied by the packet engine).	
13 (R/W)	BYTEOFFST	Byte Offset. The PKTE_SA_CMD1.BYTEOFFST bit defines how the PKTE_SA_CMD1.HSHCOFFST, bits of this register are used.	
		0	HASH_CRYPT_OFFSET is defined in 32-bit words
		1	HASH_CRYPT_OFFSET is defined in 8-bit bytes
12 (R/W)	HMAC	Keyed-Hash SSL Message Authentication Code. For basic operations that include hashing, the PKTE_SA_CMD1.HMAC bit enables the HMAC processing, which calls for an extra outer hash operation.	
		0	Standard Hash
		1	HMAC Processing

Table 39-72: PKTE_SA_CMD1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11 (R/W)	SSLMAC	Ssl Mac.	
		0	Standard Hash
		1	SSL-MAC processing
9:8 (R/W)	CIPHERMD	Cipher Mode. The `PKTE_SA_CMD1.CIPHERMD` bit field selects the crypto mode to be used for the cipher algorithm.	
		0	Electronic Code Book (ECB) used for DES and AES
		1	Cipher Block Chaining (CBC) used for DES and AES
		2	AES Counter Mode (CTR) for IPsec using a 32-bit counter
		3	AES Integer Counter Mode (ICM) for SRTP using a 16-bit counter. Note: This is implemented as a 32-bit counter, the Host must check for an overflow from the value 0xFF to zero and then refresh the IV.
3 (R/W)	CPYPAD	Copy Pad. The `PKTE_SA_CMD1.CPYPAD` bit indicates that the padding data for an inbound operation is copied to the output buffer and saved in memory.	
		0	Do not copy the padding to output
		1	Copy padding to output
2 (R/W)	CPYPAYLD	Copy Payload. The `PKTE_SA_CMD1.CPYPAYLD` bit indicates that the payload data is copied to the output buffer and saved in memory.	
		0	Do not copy the payload to output
		1	Copy payload to output
1 (R/W)	CPYHDR	Copy Header. The `PKTE_SA_CMD1.CPYHDR` bit indicates that the protocol header is copied to the output buffer and saved in memory. For Basic Encrypt-Hash and Basic Hash-Decrypt operations, the header is defined as the Hash/Crypt Offset data (authenticated only).	
		0	Do not copy the header to output
		1	Copy header to output

Table 39-72: PKTE_SA_CMD1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/W)	CPYDGST	Copy Digest. The PKTE_SA_CMD1.CPYDGST bit copies the hash result is to the output buffer and saves in memory. The length of the hash result is defined by the PKTE_SA_CMD0.DIGESTLEN field.	
		0	Do not copy hash result to output
		1	Copy hash result to output, when the command descriptor PKTE_CTL_STAT.HASHFINAL bit is set.

SA Inner Hash Digest Registers

The PKTE_SA_IDIGEST[n] registers are a set of eight 32-bit read/write registers.

For MD5, SHA-1, SHA-224 and SHA-256, these read/write registers are used to enter a start hash state, and to read the interim or final hash digest.

For IPsec, TLS and DTLS operations that make use of MD5, SHA-1, SHA-224 or SHA-256 with basic hash or HMAC authentication with the PKTE_SA_CMD0.HASHSRC bits = 00 (from SA), these registers hold the pre-computed inner hash digest. This is the hash of the hash-key padded with 0x36 hex. The starting hash byte count is automatically set to 64 decimal / 0x40 hex (to indicate that 64 bytes have already been processed through the hash).

For SSL operations that make use of SSL-MAC-MD5 with the PKTE_SA_CMD0.HASHSRC bits = 00 (from SA), these registers hold the inner hash pre-compute; this is the hash of the MAC_WRITE_SECRET padded with 0x36 hex. The starting hash byte count is automatically set to 64 decimal / 0x40 hex (to indicate that 64 bytes have already been processed through the hash).

For SSL operations that make use of SSL-MAC-SHA-1 with the PKTE_SA_CMD0.HASHSRC bits = 00 (from SA), these registers hold the MAC_WRITE_SECRET. Note that it is not possible to calculate a hash pre-compute for SHA-1 in combination with SSL-MAC (specification flaw). The packet engine appends the hash-key pad (0x36 hex) and sets the starting hash byte count automatically to 60 decimal / 0x3C hex (to indicate that 60 bytes have already been prepared for the hash).

The reset value for these registers is zero.

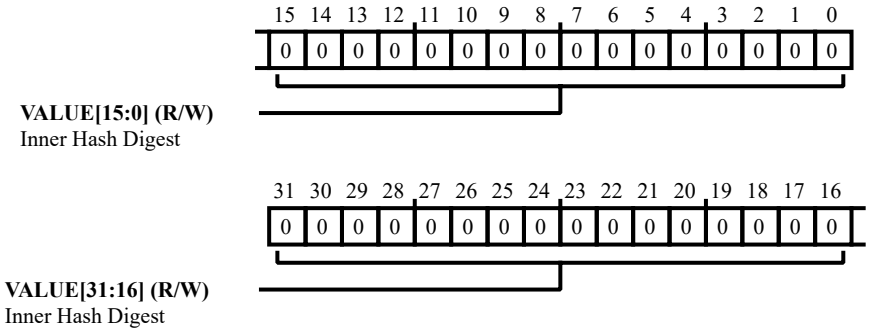

Figure 39-47: PKTE_SA_IDIGEST[n] Register Diagram

Table 39-73: PKTE_SA_IDIGEST[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Inner Hash Digest.

SA Key Registers

These are the PKTE_SA_KEY[n] registers for DES, Triple-DES, ARC4 and AES: A set of eight 32-bit write only registers. The reset value of these registers is zero.

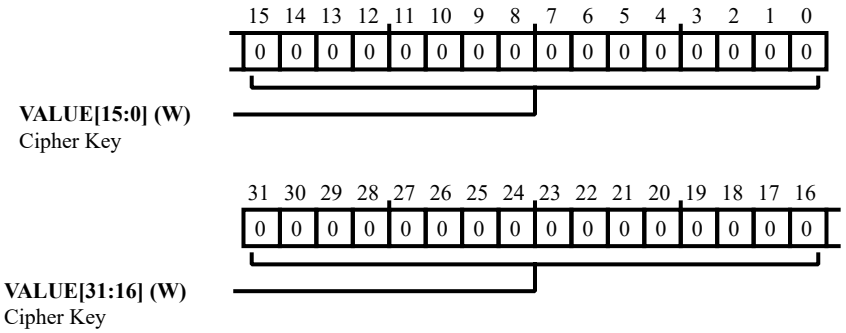

Figure 39-48: PKTE_SA_KEY[n] Register Diagram

Table 39-74: PKTE_SA_KEY[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (RX/W)	VALUE	Cipher Key.

SA Initialization Vector Register

The PKTE_SA_NONCE register is used for operations that make use of the IV value loaded from the SA record. This register is used both to enter a starting IV state, as well as for reading the interim or final IV. For IPsec outbound operations, it is recommended that the automatic IV insertion mode be used, this register is not needed. For IPsec inbound operations, the IV is extracted from the header of the packet.

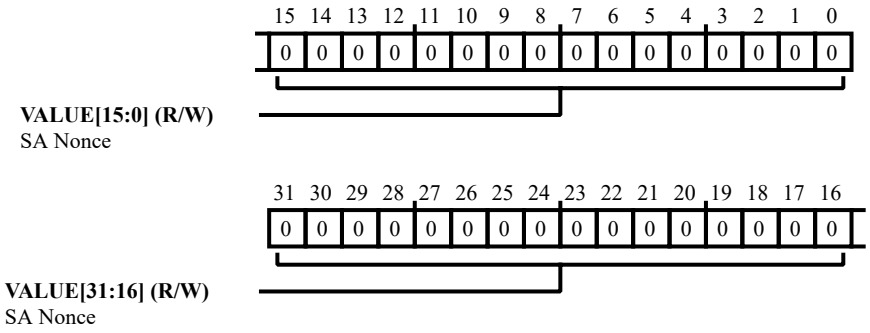

Figure 39-49: PKTE_SA_NONCE Register Diagram

Table 39-75: PKTE_SA_NONCE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	SA Nonce.

SA Outer Hash Digest Registers

The PKTE_SA_ODIGEST[n] registers are a set of five eight 32-bit write-only registers.

For write operations, these registers contain the pre-computed outer hash digest for IPsec operations with basic HMAC operations with the PKTE_SA_CMD0.HASHSRC bits = 00 (from SA).

For MD5, SHA-1, SHA-224 and SHA-256, these read/write registers hold a start hash state, or the interim outer hash digest. They are only used for HMAC processing.

For IPsec, SSL, TLS, DTLS and SRTP operations that make use of MD5, SHA-1, SHA-224 or SHA-256 with HMAC authentication with the PKTE_SA_CMD0.HASHSRC bits = 00 (from SA), these registers hold the pre-computed outer hash digest. This is the hash of the hash-key padded with 0x5C hex. The starting hash byte count is automatically set to 64 decimal / 0x40 hex (to indicate that 64 bytes have already been processed through the hash).

For SSL operations that make use of SSL-MAC-MD5 with the PKTE_SA_CMD0.HASHSRC bits = 00 (from SA), these registers hold the outer hash pre-compute; this is the hash of the MAC_WRITE_SECRET padded with 0x5C hex. The starting hash byte count is automatically set to 64 decimal / 0x40 hex (to indicate that 64 bytes have already been processed through the hash).

For SSL operations that make use of SSL-MAC-SHA-1 with the PKTE_SA_CMD0.HASHSRC bits = 00 (from SA), these registers hold the MAC_WRITE_SECRET. Note that it is not possible to calculate a hash pre-compute for SHA-1 in combination with SSL-MAC (specification flaw). The packet engine appends the required hash-key pad (0x5C hex) and sets the starting hash byte count automatically to 60 decimal / 0x3C hex (to indicate that 60 bytes have already been prepared for the hash).

The reset value for these registers is zero.

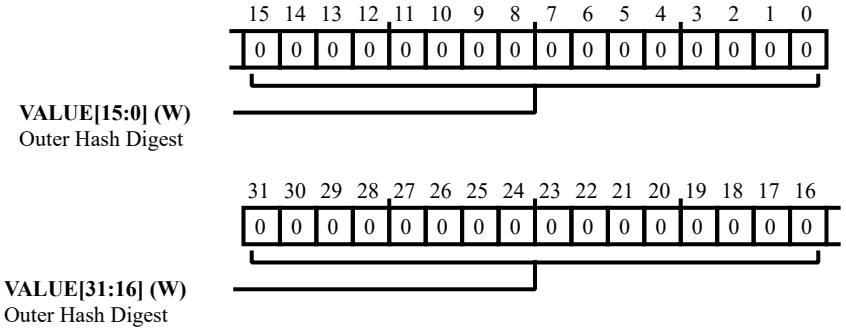

Figure 39-50: PKTE_SA_ODIGEST[n] Register Diagram

Table 39-76: PKTE_SA_ODIGEST[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (RX/W)	VALUE	Outer Hash Digest.

SA Ready Indicator

In direct host mode, a write to the PKTE_SA_RDY register triggers the packet engine to start processing using the command descriptor, SA record and state record in the packet engine registers. This register MUST be written for all direct host mode packet operations. It is intended that this register is written in sequence; as the entire SA record is written.

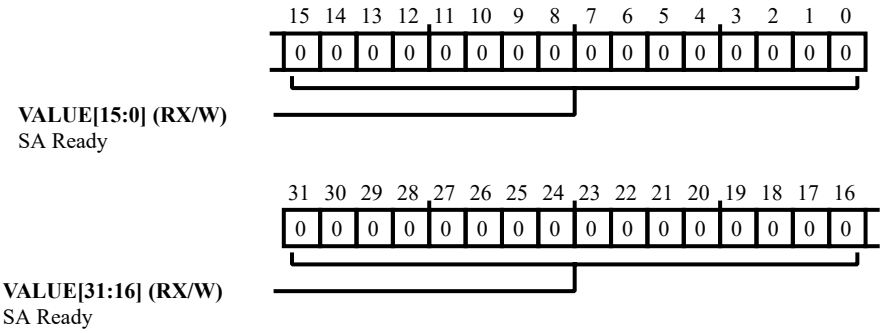

Figure 39-51: PKTE_SA_RDY Register Diagram

Table 39-77: PKTE_SA_RDY Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (RX/W)	VALUE	SA Ready.

SA Sequence Number Register

The PKTE_SA_SEQNUM[n] registers are a set of two read/write registers and are used for IPsec ESP, SSL, TLS, DTLS operations to specify the anti-replay sequence number value that is to be placed in the ESP header (outbound), or to be checked against for inbound packets. The packet engine manages this counter value for both inbound and outbound operations.

Outbound: The host writes the counter value stored in the SA record to this register to start an IPsec, SSL, TLS, DTLS operation. The packet engine automatically increments the count if header processing is selected. Upon successful completion, the host reads back this value and writes it to the SA record.

Inbound: The host writes the counter value stored in the SA record to this register to start an IPsec or DTLS operation. The packet engine automatically performs the specified inbound processing (per RFC 4303) as it processes the packet. As a result, the expected count value may or may not be updated during processing. Upon successful completion, the host should read back this value and write it to the SA record.

Note: The description is only for the direct host mode. The sequence number for autonomous ring mode and target command mode are updated by the packet engine.

The reset value of this register is zero.

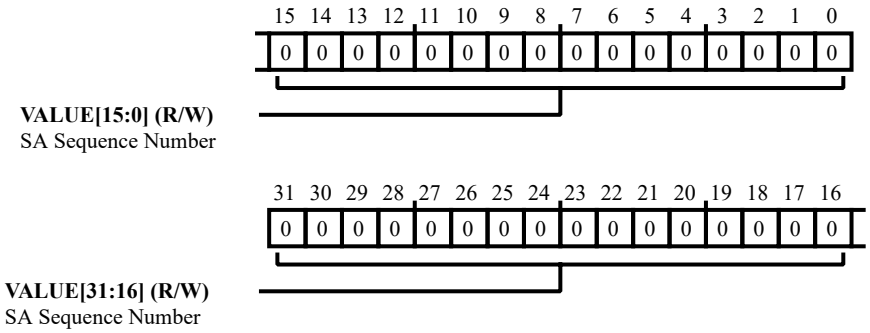

Figure 39-52: PKTE_SA_SEQNUM[n] Register Diagram

Table 39-78: PKTE_SA_SEQNUM[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	SA Sequence Number.

SA Sequence Number Mask Registers

The PKTE_SA_SEQNUM_MSK[n] registers are a set of two read/write registers and are used for IPsec ESP and DTLS operations to specify the anti-replay sequence number mask value for inbound operations. The packet engine manages this counter value automatically.

Inbound: The host writes the counter value stored in the SA record into this register upon starting an IPsec, DTLS operation. The packet engine automatically performs the specified inbound processing (per RFC 4303) as it processes the packet. As a result, the new mask value may or may not be updated during processing. Upon successful completion, the host should read back this value and write it to the SA record.

Outbound: not used.

Note that the above description only applies to the direct host mode, for autonomous ring mode and target command mode the packet engine extracts the sequence number mask from the SA record.

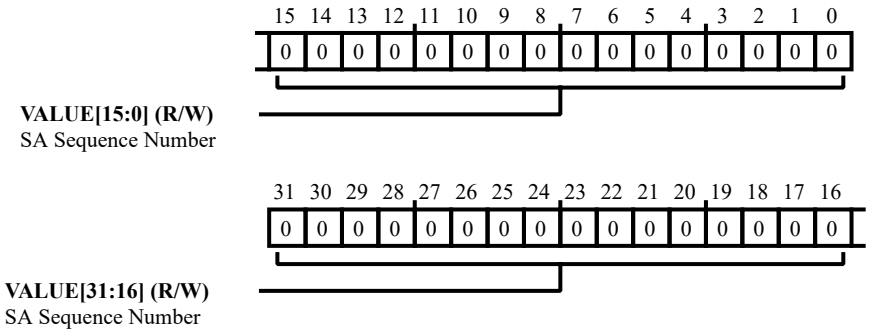

Figure 39-53: PKTE_SA_SEQNUM_MSK[n] Register Diagram

Table 39-79: PKTE_SA_SEQNUM_MSK[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	SA Sequence Number.

SA SPI Register

For IPsec operations, the PKTE_SA_SPI register is written with the SPI (Security Parameters Index) associated with the inbound or outbound flow.

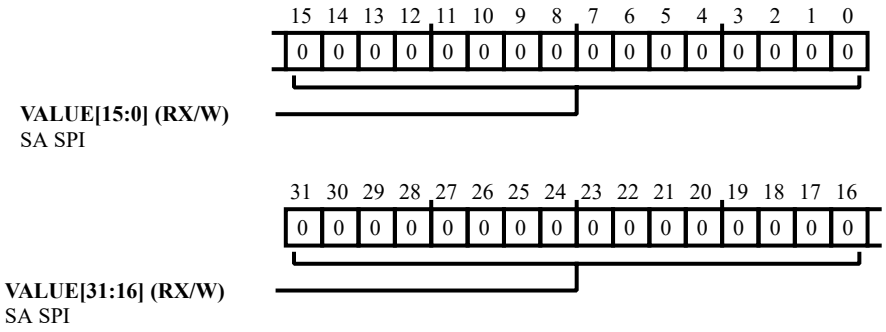

Figure 39-54: PKTE_SA_SPI Register Diagram

Table 39-80: PKTE_SA_SPI Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (RX/W)	VALUE	SA SPI. The PKTE_SA_SPI.VALUE bit field is used for IPsec ESP operations to specify the Security. Parameters Index (SPI) value that is to be placed in the ESP header. There is no need to read back this value at the end of an operation, since the Packet Engine does not change it. For SSL, TLS and DTLS this register stores the 8-bit TYPE field in bits [23:16], and the 16-bit Version field in bits [15:0] that are part of the protocol header.

Packet Engine Source Address

The PKTE_SRC_ADDR register holds the starting (byte) address for the packet to be processed.

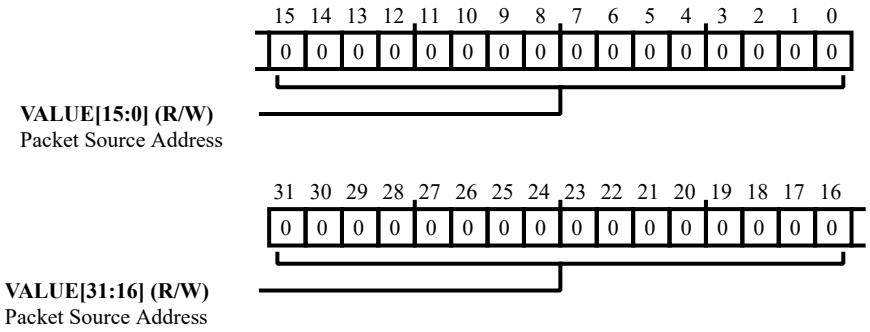

Figure 39-55: PKTE_SRC_ADDR Register Diagram

Table 39-81: PKTE_SRC_ADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Packet Source Address. The PKTE_SRC_ADDR.VALUE bit field holds the starting (byte) address for the packet to be processed.

Packet Engine Status Register

The PKTE_STAT register is used to provide the status of the packet engine. This register is useful in the direct host mode to determine when data must be written to or read from the packet engine, or for debugging the software when errors occur. This register can be ignored in autonomous ring mode and target command mode where the DMA engine controls the packet data I/O. This is a read-only register. A write to any of the bits has no effect.

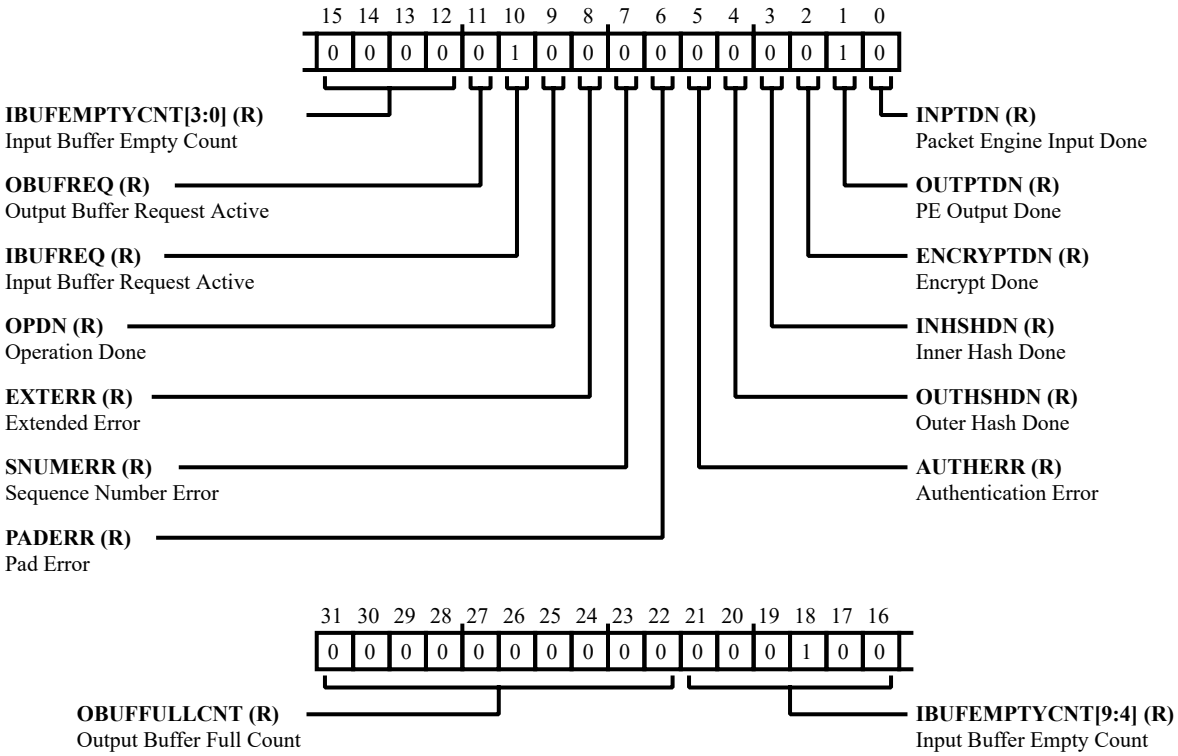

Figure 39-56: PKTE_STAT Register Diagram

Table 39-82: PKTE_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:22 (R/NW)	OBUFFULLCNT	Output Buffer Full Count. The PKTE_STAT.OBUFFULLCNT bit field indicates the number of 32-bit words that are available in the packet engine output buffer. It works in conjunction with bit 11 from this register. When bit 11 is asserted, to indicate a request for output, the word count matches the specified output buffer threshold setting in the PKTE_BUF_THRESH register. For the last output for a given packet, any value from 1 dword to the full output buffer threshold can be seen. Transfers must be a multiple of full dwords. The application must read the PKTE_LEN field in the result descriptor to determine the exact byte-length of the result.

Table 39-82: PKTE_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
21:12 (R/NW)	IBUFEMPTYCNT	Input Buffer Empty Count. The PKTE_STAT.IBUFEMPTYCNT bit field indicates the number of 32-bit empty spaces that are available in the packet engine input buffer. It works in conjunction with the PKTE_STAT.IBUFREQ bit (10) from this register. The value in the register is deducted from the specified packet length, so will never exceed the number of dwords that remain in the packet. For packets smaller than the buffer size, this register typically indicates that buffer space is available for the entire packet (rounded up to the nearest dword). For very large packets, these bits usually have a value around the maximum buffer size, indicating that the full input buffer is available.	
11 (R/NW)	OBUFREQ	Output Buffer Request Active. The PKTE_STAT.OBUFREQ bit indicates that the packet engine requests output data to be read from the output buffer.	
		0	No request for output data
		1	Request for output data
10 (R/NW)	IBUFREQ	Input Buffer Request Active. The PKTE_STAT.IBUFREQ bit indicates that the packet engine requests input data to be written to the input buffer.	
		0	No request for input data
		1	Request for input data
9 (R/NW)	OPDN	Operation Done. The PKTE_STAT.OPDN bit indicates that the packet engine has finished processing a packet when in direct host mode. This bit is zero in autonomous ring mode and target command mode.	
		0	Packet engine is idle
		1	Packet engine has finished processing a packet
8 (R/NW)	EXTERR	Extended Error. The PKTE_STAT.EXTERR bit indicates that an extended error occurred for this packet. For more information, refer to table Extended Error Codes - Status Encoding.	
		0	No extended error
		1	Extended error

Table 39-82: PKTE_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7 (R/NW)	SNUMERR	Sequence Number Error. For an inbound operation, the PKTE_STAT.SNUMERR bit indicates that there was a fault in the anti-replay sequence number. For an outbound operation, there was a sequence number overflow condition. For more information, refer to table Extended Error Codes - Status Encoding.	
		0	No sequence number error
		1	Input done, all bytes written to input buffer
6 (R/NW)	PADERR	Pad Error. The PKTE_STAT.PADERR bit indicates that an inbound crypto pad fault is detected. For more information about pad verification, refer to the Pad Verification and Consumption section.	
		0	No pad error
		1	Pad error
5 (R/NW)	AUTHERR	Authentication Error. The PKTE_STAT.AUTHERR bit indicates that an inbound ICV (for IPsec) or TAG (for SRTP) or MAC (for SSL/TLS/DTLS) fault is detected; the value carried within the packet did not match the value just computed.	
		0	No authentication error
		1	Authentication error
4 (R/NW)	OUTHSHDN	Outer Hash Done. The PKTE_STAT.OUTHSHDN bit indicates that the outer hash processing for this packet is finished.	
		0	Outer hash busy
		1	Outer hash done
3 (R/NW)	INHSHDN	Inner Hash Done. The PKTE_STAT.INHSHDN bit indicates that the inner hash processing for this packet is finished.	
		0	Inner hash busy
		1	Inner hash done
2 (R/NW)	ENCRYPTDN	Encrypt Done. The PKTE_STAT.ENCRYPTDN bit indicates that the encryption or decryption for this packet is finished.	
		0	Encryption or decryption busy
		1	Encryption or decryption done

Table 39-82: PKTE_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/NW)	OUTPTDN	PE Output Done. The PKTE_STAT.OUTPTDN bit indicates that the output data for the current packet is read from the packet engine output buffer.	
		0	Output not done, more output bytes available
		1	Output done, all bytes read from the output buffer
0 (R/NW)	INPTDN	Packet Engine Input Done. The PKTE_STAT.INPTDN bit indicates that the number of bytes specified in the command descriptor PKTE_LEN field is written into the packet engine input buffer.	
		0	Input not done, more input bytes expected
		1	Input done, all bytes written to input buffer

Packet Engine State Record Address

The PKTE_STATE_ADDR register holds the start address of the SA state record.

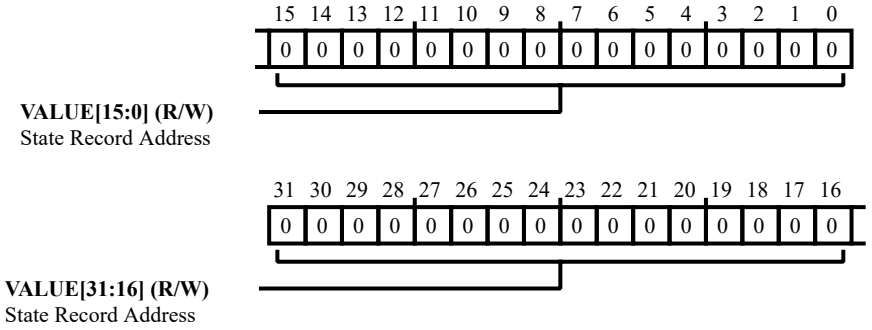

Figure 39-57: PKTE_STATE_ADDR Register Diagram

Table 39-83: PKTE_STATE_ADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	State Record Address. The PKTE_STATE_ADDR.VALUE bit field holds the start address of the SA state record.

State Hash Byte Count Registers

The PKTE_STATE_BYTE_CNT[n] registers are used to enter a starting hash byte count, as well as to read the interim or final byte count.

For some hash operations, these registers are ignored and the byte count is internally set to 64 (0x40 hex) to indicate that the first 64 bytes (512 bits) hash block has been processed using a pre-computed hash state. These operations are:

All IPsec, SSL, TLS, DTLS and SRTP operations that use authentication; the "pre-computed" inner and outer hash digests are loaded from SA words 10 - 19.

Basic operations with PKTE_SA_CMD0.HASHSRC bits = 00 (from SA) specified. For Basic Hash with no HMAC, a pre-computed digest is loaded from SA words 10 - 14. For Basic Hash with HMAC, the inner and outer digests are loaded from SA words 10 - 19.

Note: Protocol operations can not be suspended in mid-packet and resumed later, therefore protocol operations do not use these registers.

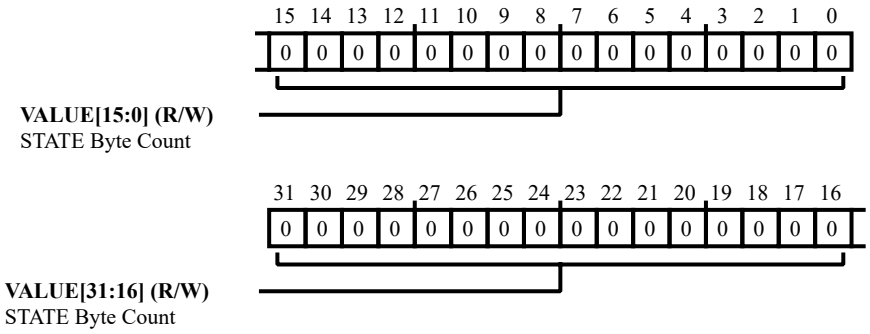

Figure 39-58: PKTE_STATE_BYTE_CNT[n] Register Diagram

Table 39-84: PKTE_STATE_BYTE_CNT[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	STATE Byte Count.

State Inner Digest Registers

The PKTE_STATE_IDIGEST[n] registers consist of eight 32-bit registers. These read/write registers are used to read the interim or final hash digest. The PKTE_STATE_IDIGEST[n] registers are only used with basic operations involving basic hash, and are typically used for operations that must be suspended and resumed in the middle of a hash. The interim hash state can be read from these registers along with the hash byte-count from the previous register. Both can be restored when resuming the hash. The appropriate save hash state (PKTE_SA_CMD0.SVHASH=1) and load hash from state (PKTE_SA_CMD0.HASHSRC=0b10) settings must be used. These registers are a mirror of the SA record inner hash digest register.

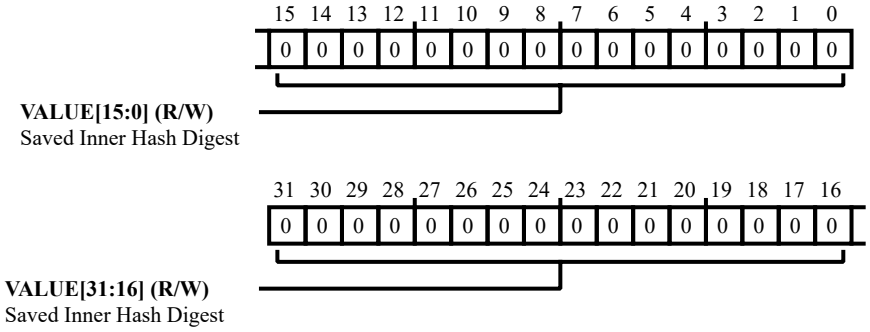

Figure 39-59: PKTE_STATE_IDIGEST[n] Register Diagram

Table 39-85: PKTE_STATE_IDIGEST[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Saved Inner Hash Digest.

State Initialization Vector Registers

The PKTE_STATE_IV[n] consists of four 32-bit registers. These registers are used to enter a starting IV state and to read the interim or final IV. PKTE_STATE_IV0 and PKTE_STATE_IV1 are used with DES/3DES cipher while PKTE_STATE_IV0 to PKTE_STATE_IV3 are used with AES cipher. The reset value of these registers is zero.

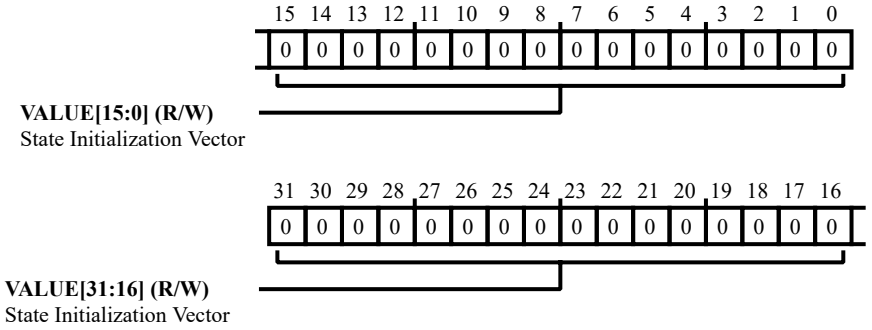

Figure 39-60: PKTE_STATE_IV[n] Register Diagram

Table 39-86: PKTE_STATE_IV[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	State Initialization Vector. The PKTE_STATE_IV[n].VALUE bit field is used to enter a starting IV state and to read the interim or final IV.

Packet Engine User ID

The PKTE_USERID register is a read/write register that gives identification to a command descriptor and the resultant result descriptor. The host is free to use this field for its own purpose. The host can write a unique identifier to the register in direct host mode or includes it as part of the command descriptor in autonomous ring mode. The PKTE_USERID register value passes though the packet engine without alteration to the result descriptor to be read back by the host.

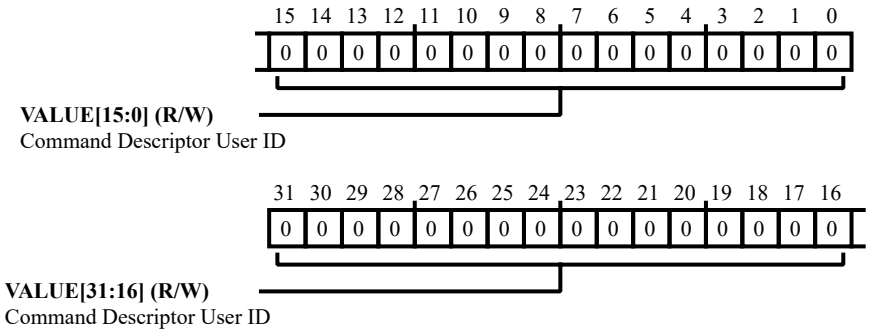

Figure 39-61: PKTE_USERID Register Diagram

Table 39-87: PKTE_USERID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Command Descriptor User ID. The PKTE_USERID.VALUE bit field gives identification to a command descriptor and the resultant result descriptor.

40 Public Key Accelerator (PKA)

The PKA helps offload computationally-intensive operations commonly found in public key cryptography algorithms.

PKA Features

The PKA engine provides the following basic operations:

- Large vector addition, subtraction, and combined addition/subtraction
- Large vector shift right or left
- Large vector multiplication, division (with and without quotient)
- Large vector compare and copy

The PKA engine provides the following complex operations:

- Large vector unsigned value modular exponentiation
- Large vector unsigned value modular exponentiation using the 'Chinese Remainders Theorem' (CRT) method with pre-calculated Q inverse vector
- Modular inversion: Given A and M, calculate B such that ((A × B) MOD M) = 1
- ECC point addition/doubling on elliptic curve $y^2 = x^3 + ax + b \pmod p$ with prime number *p* and input values *a* and *b* to the operation. Adding two identical points automatically performs point doubling.
- ECC point multiplication on elliptic curve $y^2 = x^3 + ax + b \pmod p$ with prime number *p* and input values *a* and *b* to the operation. A version of the 'Montgomery ladder' algorithm is used to provide side channel attack resistance.

The PKA also contains hardware logic to automatically zero out the PKA RAM buffer to clear out any information that is considered sensitive or secure.

PKA Functional Description

The following sections provide details on the function of the PKA module.

ADSP-2184x PKA Register List

The Public Key Accelerator module (PKA) provides security-related features. A set of registers governs PKA operations. For more information on PKA functionality, see the PKA register descriptions.

Table 40-1: ADSP-2184x PKA Register List

Name	Description
PKA_ALEN	PKA Vector_A Length
PKA_APTR	PKA Vector_A Address
PKA_BLEN	PKA Vector_B Length
PKA_BPTR	PKA Vector_B Address
PKA_COMPARE	PKA Compare Result
PKA_CPTR	PKA Vector_C Address
PKA_DIVMSW	PKA Most-Significant-Word of Divide Remainder
PKA_DPTR	PKA Vector_D Address
PKA_FUNC	PKA Function
PKA_RAM	Start of PKA RAM space
PKA_RESULTMSW	PKA Most-Significant-Word of Result Vector
PKA_SHIFT	PKA Bit Shift Value

PKA Definitions

The following definitions are helpful when using the PKA module.

Elliptic Curve Cryptography (ECC)

A form of public key cryptography based on elliptic curves over finite fields.

RSA

An acronym for Ron Rivest, Adi Shamir, and Leonard Adleman. It is another form of a public key cryptosystem.

Chinese Remainder Theorem (CRT)

A mathematical theorem used for simplifying time-consuming arithmetic used in public key algorithm computations.

Addition Chaining Table (ACT)

A method of speeding up exponentiation by repeatedly squaring the input, storing the result, and reusing the result as input. ACT2 uses a table with 2 address bits (4 entries) and ACT4 uses a table with 4 address bits (16 entries).

PKA Architectural Concepts

The following sections describe the PKA architecture.

Public Key Co-Processor (PKCP)

The Public Key Co-Processor (PKCP) handles the basic large vector processing such as addition, subtraction, multiplication, etc.

Sequencer

The sequencer is small processor that is part of the PKA which handles the more complicated vector processing for public key algorithms. Algorithms include modular exponentiation and the ECC addition and ECC multiply used in Elliptic Curve Cipher algorithms. It executes instructions stored from an internal pre-programmed ROM that handles these operations.

RAM

Input and output vectors are stored in a 4 kB RAM buffer that is part of the MMR space. The address of PKA_RAM is the beginning of the RAM space. This memory is also used as a scratchpad or workspace for the sequencer and PKCP. Programs must place the vectors appropriately following the constraints described in the ***Functional Description*** section of this chapter.

PKA Block Diagram

The ***PKA Block Diagram*** shows the top-level block diagram of the PKA engine. The PKA engine is comprised of five parts:

1. Registers for input, output, status, and control
2. Public Key Co-processor (PKCP) module which performs the basic suite of big number (vector) operations typically found in public key cryptography applications
3. Sequencer which controls modular exponentiation, elliptic curve cryptography, and modular inversion operations.
4. Program ROM associated with the PKA engine exclusively for the sequencer
5. PKA RAM holds the large input and output values as well as the workspace/scratchpad required from the sequencer and PKCP for operations.

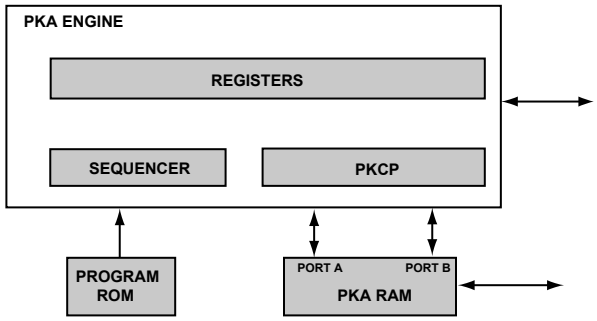

Figure 40-1: PKA Block Diagram

PKCP Vector Operations

The ***Summary of PKCP Vector Operations*** table lists the arguments and results for each PKCP vector operation.

Table 40-2: Summary of PKCP Vector Operations

Function	Mathematical Operation	Vector A	Vector B	Vector C	Vector D
Multiply	A x B → C	Multiplicand	Multiplier	Product	N/A
Add	A + B → C	Addend	Addend	Sum	N/A
Subtract	A - B → C	Minuend	Subtracthend	Difference	N/A
AddSub	A + C - B → D	Addend	Subtracthend	Addend	Result
Right Shift	A >> Shift → C	Input	N/A	Result	N/A
Left Shift	A << Shift → C	Input	N/A	Result	N/A
Divide	A mod B → C, A div B → D	Dividend	Divisor	Remainder	Quotient
Modulo	A mod B → C	Dividend	Divisor	Remainder	N/A
Compare	A = B, A < B, A > B	Input 1	Input 2	N/A	N/A
Copy	A → C	Input	N/A	Result	N/A

To obtain correct result, the input vectors must meet the requirements presented in the ***Operational Restrictions on Input Vectors for PKCP Operations*** table.

Note the following:

- The PKCP does not check input restrictions
- A_Len and B_Len indicate the size of vectors A and B in 32-bit words
- Max_Len equals 128 (32-bit) words, for example, the standard maximum vector size is 4096 bits

Table 40-3: Operational Restrictions on Input Vectors for PKCP Operations

Function	Requirement
Multiply	0 < A_Len, B_Len <= Max_Len
Add	0 < A_Len, B_Len <= Max_Len
Subtract	0 < A_Len, B_Len <= Max_Len Result must be positive (A>=B)
AddSub	0 < A_Len <= Max_Len (B and C operands have A_Len as length, B_Len ignored) Result must be positive ((A + C) >= B)
Right Shift	0 < A_Len <= Max_Len
Left Shift	0 < A_Len <= Max_Len
Divide, Modulo	1 < B_Len <= A_Len <= Max_Len Most significant 32-bit word of B operand cannot be zero
Compare	0 < A_Len <= Max_Len (B operand has A_Len as length, B_Len ignored)
Copy	0 < A_Len <= Max_Len

The host processor is responsible for allocating a block of contiguous memory in PKA RAM for the result vectors. The ***PKCP Result Vector Memory Allocation*** table indicates how much memory is allocated for the result vectors.

Table 40-4: PKCP Result Vector Memory Allocation

Function	Result Vector	Result Vector Length (in 32-bit words)
Multiply	C	A_Len + B_Len + 6 (the 6 'scratchpad' words should be discarded)
Add	C	Max(A_Len, B_Len) + 1
Subtract	C	Max(A_Len, B_Len)
AddSub	D	A_Len + 1
Right Shift	C	A_Len
Left Shift	C	A_Len + 1 (when Shift Value is non-zero) A_Len (when Shift Value is zero)
Divide	C	Remainder → B_Len + 1 (one 'scratchpad' word should be discarded)
	D	Quotient → A_Len – B_Len + 1
Modulo	C	Remainder → B_Len + 1 (one 'scratchpad' word should be discarded)
Compare	None	Compare updates the PKA_COMPARE register
Copy	C	A_Len

Input vectors for an operation are always allowed to overlap in memory (partially or completely). The ***PKCP Result Vector/Input Overlap Restrictions*** table gives restrictions for the overlap of output and input vectors of the operations.

Table 40-5: PKCP Result Vector/Input Overlap Restrictions

Function	Result Vector	Restrictions
Multiply	C	No overlap with A or B vectors allowed
Add, Subtract	C	May overlap with A and/or B vector, provided the start address of the C vector does not lie above the start address of the vectors with which it overlaps
AddSub	D	May overlap with A, B and/or C vector, provided the start address of the D vector does not lie above the start address of the vectors with which it overlaps
Right Shift, Left Shift	C	May overlap with A vector, provided the start address of the C vector does not lie above the start address of the A vector
Divide	C	No overlap with A, B, or D vectors allowed
	D	No overlap with A, B, or C vectors allowed
Modulo	C	No overlap with A or B vectors allowed
Compare	None	Compare does not write a result vector
Copy	None	Same restrictions as for right or left shift, copy of a vector to a lower address is always allowed even if source and destination overlap†

†The copy operation can be used to fill memory by breaking the overlap restrictions, but it requires setting up TWO initial (32-bit) words. To zero a block of memory, set the A vector pointer to the block start, set the C vector pointer two words higher and the A vector length to the block length minus two (words). Fill the first two words of the block with constant zero and perform a PKCP copy operation to zero the remainder of the block.

Modular Exponentiation Operations

The ***Summary of ExpMod Operations*** table summarizes the modular exponentiation operations that the PKA supports.

Table 40-6: Summary of ExpMod Operations

Function	Mathematical Operation	Vector A	Vector B	Vector C	Vector D
ExpMod-ACT2 ExpMod-ACT4 ExpMod-variable	$C^A \bmod B \rightarrow D$	Exponent, length = A_Len	Modulus, length = B_Len	Base, length = B_Len	Result and Workspace
ExpMod-CRT	See below	Exp P followed by Exp Q at next higher even word address†, both A_Len long	Mod P + buffer word followed by Mod Q at next higher even word address‡, both B_Len long	Q inverse, length = B_Len	Input, Result (both 2xB-Len long) and Workspace

† If A_Len is even, Exp Q follows Exp P immediately – if A_Len is odd, there is one empty word between Exp Q and Exp P.

‡ If B_Len is even, there are two empty words between Mod P and Mod Q – if B_Len is odd, there is one empty (buffer) word between Mod Q and Mod P. Note that the engine may zero the words following Mod P and Mod Q.

The ExpMod-CRT operation performs the following computation steps. (These steps implement Garner's recombination algorithm after the basic exponentiations.)

- X <- (Input mod Mod P)Exp P mod Mod P
- Y <- (Input mod Mod Q)Exp Q mod Mod Q
- Z <- ((((X – Y) mod Mod P) · Q inverse) mod Mod P) · Mod Q
- Result <- Y + Z

The ExpMod-ACT2, -ACT4, and -variable functions implement the same mathematical operation but with a differently sized table with pre-calculated *odd powers*. The ExpMod-ACT2 function uses a table with two entries whereas ExpMod-ACT4 uses a table with eight entries. The ACT4 version gives better performance but needs more memory. ExpMod-variable and ExpMod-CRT operations allow the selection of a variable number (from 1 up to and including 16) of odd powers through the register normally used to specify the number of bits to shift for shift operations.

The exponentiation functions are extensions of the set of PKA functions. Input and result vectors are passed the same way as basic PKCP operations. The ***Restrictions on Input Vectors for ExpMod Operations*** table shows the restrictions on the input and result vectors for the exponentiation operations.

Table 40-7: Restrictions on Input Vectors for ExpMod Operations

Function	Requirements
ExpMod-ACT2 ExpMod-ACT4 ExpMod-variable	0 < A_Len <= Max_Len 1 < B_Len <= Max_Len Modulus B must be odd (for example, the least significant bit must be ONE) Modulus B > 2^{32} Base C < Modulus B Vectors B and C must be followed by an empty 32-bit *buffer* word
ExpMod-CRT	0 < A_Len <= Max_Len 1 < B_Len <= Max_Len Mod P and Mod Q must be odd (for example, the least significant bits must be ONE) Mod P > Mod Q > 2^{32}(note that Mod P must be larger than Mod Q) Mod P and Mod Q must be co-prime (their GCD must be 1) 0 < Exp P < (Mod P – 1) 0 < Exp Q < (Mod Q – 1) (Q inverse · Mod Q) 1 (modulo Mod P) Input < (Mod P · Mod Q) Mod P and Mod Q must be followed by an empty 32-bit *buffer* word

The ***ExpMod Result Vector/Scratchpad Area Memory Allocation Starting at PKA_DPTR*** table shows the required scratchpad sizes for the exponentiation operations. These sizes depend on the PKA type. The 'M_Len' used in the table is the 'real' Modulus length in 32-bit words, for example, without trailing zero words at the end. (This description also applies to Mod P in an ExpMod-CRT operation and Modulus B in the other operations.) If the last word of the modulus vector as given is non-zero, 'M_Len' equals B_Len.

Table 40-8: ExpMod Result Vector/Scratchpad Area Memory Allocation Starting at PKA_DPTR

Function	Scratchpad Area Size (in 32-bit words), Result Vector is either M_Len or 2xM_Len 32-bit words long
ExpMod-ACT2	5 x (M_Len + 2)
ExpMod-ACT4	11 x (M_Len + 2)
ExpMod-variable	(# odd powers + 3) x (M_Len + 2)
ExpMod-CRT	(# odd powers + 3) x (M_Len + 2) + (M_Len + 2 – (M_Len MOD 2))

NOTE: During execution of an ExpMod-ACT2, -ACT4 or -variable operation, the last 34 bytes of the PKA RAM are used as the general scratchpad for the sequencer program execution. The ExpMod-CRT operation requires the last 72 bytes of the PKA RAM as the scratchpad. These (fixed location) areas may not overlap with any of the input vectors and/or the D vector scratchpad area. They can be used freely when executing basic PKCP operations.

Table 40-9: ExpMod Scratchpad Area / Input Vector Overlap Restrictions

Function	Result Vector	Restrictions
ExpMod-ACT2 ExpMod-ACT4 ExpMod-variable	D	Scratchpad area starting at D may not overlap with any of the other vectors, except that base C may be co-located with result vector D to save space (for example, `PKA_CPTR`= `PKA_DPTR` is allowed).
ExpMod-CRT	D	Scratchpad area starting at D may not overlap with any of the other vectors. This area is also the location of the main input vector (with length 2 x B_Len)

The ***Maximum Number of Odd Powers*** table indicates the maximum number of odd powers that can be used for different standard PKA RAM sizes and PKA types (non-CRT operations using `PKA_CPTR` = `PKA_DPTR`). As a rule of thumb, for optimal performance, use one odd power for *Verify* operations and 4 (or as many as the implemented PKA RAM size allows) for *Sign* operations. Note the following points about odd powers:

- Using more than eight odd powers is not advisable as the speed advantage for each extra odd power decreases rapidly (and can even become negative for short exponent vector lengths due to the extra pre-processing required).
- The maximum number of odd powers is 16 (limited by the firmware). All '16 odd powers' entries in the table above hit this limit – they are not limited by the PKA RAM size.

Table 40-10: Maximum Number of Odd Powers

Operation	Modulus and Exponent Sizes	Maximum Number of Odd Powers
Non-CRT	1024 bits	16
	2048 bits	10
	4096 bits	2
CRT	2 × 512 bits	16
	2 ×1024 bits	16
	2 × 2048 bits	6

The ***2K-bit Modular Exponentiation PKA RAM Allocation Examples*** table shows example PKA RAM vector allocations for modular exponentiation operations with and without using CRT. The *free space* start address is the first free byte following the vector workspace. The sequencer execution scratchpad of 34 bytes (non-CRT) or 72 bytes (using CRT) must fit between this address and the end of the PKA RAM. Note that the non-CRT operations use `PKA_CPTR` = `PKA_DPTR` to save space.

Table 40-11: 2K-bit Modular Exponentiation PKA RAM Allocation Examples

Operation	(sub-)vector	Start address (Byte Offset)	Size (words)	Buffer (words)
non-CRT (`PKA_ALEN` = 0x040, `PKA_BLEN` = 0x040, 4 odd-powers)	Exponent	0x000 (`PKA_APTR` = 0x000)	64	0
	Modulus	0x100 (`PKA_BPTR` = 0x040)	64	2
	Base	0x208 (`PKA_CPTR` = 0x082)	64	2
	Result	0x208 (`PKA_DPTR` = 0x082)	64	2
	Vector Workspace	0x208 (= Result)	7 × (64+2)=462	0
	Free space	0x940 (2368 bytes used)	-	-
using CRT (`PKA_ALEN` = 0x020, `PKA_BLEN` = 0x020, 4 odd-powers)	Exp P	0x000 (`PKA_APTR` = 0x000)	32	0
	Exp Q	0x080	32	0
	Mod P	0x100 (`PKA_BPTR` = 0x040)	32	2
	Mod Q	0x188	32	2
	Q inverse	0x210 (`PKA_CPTR` = 0x084)	32	0
	Input, Result	0x290 (`PKA_DPTR` = 0x0A4)	64	0
	Vector workspace	0x290 (= Result)	7 × (32+2)+32+2-0 = 272	0
	Free space	0x6D0 (1744 bytes used)	-	-

The following example in pseudo-code describes the execution of a non-CRT modular exponentiation operation using a 512-bit modulus and a 160-bit exponent, using actual test vectors:

```
// Perform a 512/160 bit
modular exponentiation without CRT (using 4 'odd-powers')
// Exponent equals value 0x8FD84098_8A0930CC_9CDC1E8A_B246EB46_2D39F064
// write as vector A to PKA

Modular Inversion

Besides modular exponentiation, the sequencer also controls modular inversion operations.

Table 40-12: Summary of ModInv Operation

Function	Mathematical Operation	Vector A	Vector B	Vector C	Vector D
ModInv	A^{-1} mod B → D	NumToInvert, length = A_Len	Modulus, length = B_Len	Not Used	Result and Workspace

The above function is an extension of the set of basic PKCP functions with the following exceptions:

- Vector D not only addresses the result, but also a workspace.
- The `PKA_SHIFT` register field is used to return information on the operation's result.

Table 40-13: PKA_SHIFT Result Values for ModInv Operation

Function	PKA_SHIFT Register Field Value At Conclusion
ModInv	0 → success; VectorD holds result 7 → no inverse exists (GCD(A, B) != 1, for example, A and B have common factors); result undefined 31 → error, modulus even; result undefined other values are reserved

The following tables list the restrictions on the input and result vectors for the ModInv operation.

Table 40-14: Operational Restrictions on Input Vectors for the ModInv Operation

Function	Requirements
ModInv	0 < A_Len <= Max_Len 0 < B_Len <= Max_Len Modulus B must be odd (for example, the least significant bit must be ONE) Modulus B may not have value 1 (result is undefined, no error indicated) The highest word of the modulus vector, as indicated by B_Len, may not be zero.

Table 40-15: ModInv Scratchpad Area/Input Vector Overlap Restrictions

Function	Result Vector	Restrictions
ModInv	D	Scratchpad area starting at D may not overlap with any of the other vectors

The following table shows the required scratchpad sizes for the ModInv Operation.

Table 40-16: ModInv Result Vector/Scratchpad Area Memory Allocation (Both Starting at PKA_DPTR)

Function	Scratchpad area size (in 32-bit words), Result Vector is B_Length 32-bit words long
ModInv	5 x (M + ε(M)), with M = Max(A_Length, B_Length) ε(n) = 2 + (n MOD 2), for example, 2 (for n even) or 3 (for n odd)

NOTE: During execution of a ModInv operation, the last 34 bytes of the PKA RAM are used as general scratchpad for the sequencer program execution. This (fixed location) area may not overlap with any of the input vectors and/or the D vector scratchpad area during execution.

Modular Inversion with an Even Modulus

The ModInv operation requires the modulus to be odd. At first, this requirement appears to make the operation useless in the case of RSA key generation where the private key exponent *d* is derived from a chosen public exponent *e* as follows:

d = ModInv(e, φ); where φ = (p-1) × (q-1) and *p* and *q* both prime

Note that φ is even. However, since *e* must be odd (otherwise no inverse exists), *d* can be calculated as:

d = (1 + (φ × (e – ModInv(φ, e))) / e

With four more basic PKCP operations, ModInv can also be used to find inverse values in case the modulus is even.

Modular Inversion with a Prime Modulus

Modular inversion can be performed with a modular exponentiation using the modulus value minus two as exponent, provided that the modulus value is a prime. This is due to the following:

(A^M) mod M = A =>

(A^{M-1}) mod M = 1 =>

(A^{M-2}) mod M = A–1 (mod M)

Under the constraint that M is a prime value.

Especially with the large PKA engines containing an LNME, it is worthwhile to check whether this method is faster than using the ModInv operation directly. The modulus values for the ECC curves supported by this PKA engine must be prime, so this method can be used in ECDSA operations.

ECC Operations

Besides modular exponentiation and modular inversion, the sequencer also controls ECC operations.

Table 40-17: Summary of ECC Operations

Function	Mathematical Operation	Vector A	Vector B	Vector C	Vector D
ECC-ADD	Point addition/doubling† on elliptic curve: $y^2 = x^3 + ax + b \pmod{p}$ pntA + pntC → pntD	pntA.x followed‡ by pntA.y both B_Len long (A_Len *not* used)	Curve parameter *p* followed‡ by *a* (*b* is not needed) all B_Len long	pntC.x followed by pntC.y both B_Len long	Result, for example, pntD.x followed‡ by pntD.y and workspace
ECC-MUL	Point multiplication on elliptic curve: $y^2 = x^3 + ax + b \pmod{p}$ *k* x pntC → pntD	Scalar *k* A_Len long	Curve parameter *p* followed‡ by *a*and *b* all B_Len long.	pntC.x followed‡ by pntC.y both B_Len long	Result, for example pntD.x followed‡ by pntD.y and workspace

† If pntA = pntC, a point doubling operation is performed automatically.

‡ All input components must be located on a 64-bit boundary and must have extra 'buffer' words (of 32 bits each) after their most significant word. ε must be 3 (B_Len odd) or 2 (B_Len even). Each result component (for example, pntD.x, pntD.y) is followed by ε buffer (zero) words.

The above functions are extensions of the set of PKCP basic functions with the following exceptions:

- Input and result vectors can now be composite (for example, consist of two or three equal-sized subvectors).
- Vector D not only addresses the result, but also a workspace.
- The `PKA_SHIFT` register is used to return information on the result of the operation.

Table 40-18: PKA_SHIFT Result Values for ECC Operations

Function	PKA_SHIFT Register Field Value at Conclusion
ECC-ADD ECC-MUL	0 → success; VectorD holds result point 7 → result is point-at-infinity; VectorD result point undefined 31 → error, (p not odd, p too short, etc); VectorD result point undefined Other values are reserved

The following tables below list the restrictions on the input and result vectors for the ECC operations.

Table 40-19: Operational Restrictions on Input Vectors for ECC Operations

Function	Requirements
ECC-ADD	1 < B_Len <= 24 (maximum vector length is 768 bits) Modulus p must be a prime > 2^{63} Effective modulus size (in bits) must be a multiple of 32† The highest word of the modulus vector, as indicated by B_Len, may not be zero. *a*< p and *b*< p pntA and pntC must be on the curve (this condition is not checked) Neither pntA nor pntC can be the point-at-infinity, although ECC-ADD can return this point as a result
ECC-MUL	0 < A_Len <= 24 (maximum vector length is 768 bits) 1 < B_Len <= 24 (maximum vector length is 768 bits) Modulus p must be a prime > 2^{63} Effective modulus size (in bits) must be a multiple of 32† The highest word of the modulus vector, as indicated by B_Len, may not be zero. *a*< p and *b*< p pntC must be on the curve (this condition is not checked) pntC cannot be the point-at-infinity, although ECC-MUL can return this point as a result

† Modulus lengths of 112 and 521 bits are exceptions to this rule.

Table 40-20: ECC Scratchpad Area/Input Vector Overlap Restrictions

Function	Result Vector	Restrictions
ECC-ADD ECC-MUL	D	Scratchpad area starting at D may not overlap with any of the other vectors

The ***>ECC Result Vector/Scratchpad Area Memory Allocation*** table shows the required scratchpad sizes for the ECC operations:

Table 40-21: ECC Result Vector/Scratchpad Area Memory Allocation (Both Starting at PKA_DPTR)

Function	Scratchpad area size (in 32-bit words), Result Vector is 2x(B_Length+ ε †(B_Length)) 32-bit words long
ECC-ADD	2 × L + 5 x M, where L = B_Length + ε(B_Length) M = B_Length + 1 + ε(B_Length + 1)
ECC-MUL	18 x L + Max(8, L), where L = (B_Length + ε(B_Length))

† ε(*n*) = 2 + (*n* MOD 2), for example, 2 (for *n* even) or 3 (for *n* odd)

NOTE: During execution of an ECC-ADD or ECC-MUL operation, the last 72 bytes of the PKA RAM are used as a general scratchpad for the sequencer program execution. These (fixed location) areas must not overlap with any of the input vectors and the D vector scratchpad area during execution.

The ***ECC Point Multiplication PKA RAM Allocation Examples*** table shows example PKA RAM vector allocations for ECC point multiplication operations. The *free space* start address is the first free byte following the vector scratchpad. The sequencer execution scratchpad of 72 bytes must fit between this address and the end of the PKA RAM. Because of this requirement, a 521-bit ECC point multiplication cannot be performed with 2K byte PKA RAM.

Table 40-22: ECC Point Multiplication PKA RAM Allocation Examples

Modulus Length	(sub-)vector	Start Address (byte offset)	Size (words)	Buffer (words)
192 bits (=6 words, PKA_ALEN=0x006, PKA_BLEN=0x006)	Scalar *k*	0x000 (PKA_APTR = 0x000)	6	0
	p	0x018 (PKA_BPTR = 0x006)	6	2
	a	0x038	6	2
	b	0x058	6	2
	PntC.x (base)	0x078 (PKA_CPTR = 0x01E)	6	2
	PntC.y (base)	0x098	6	2
	PntD.x (result)	0x0B8 (PKA_DPTR = 0x02E)	6	2
	PntD.y (result)	0x0D8	6	0
	Vector scratchpad	0x0B8 (= PntD.x)	(18 × 8) + 8 = 152	0
	Free space	0x318 (792 bytes used)	-	-
384 bits (=12 words, ALENGTH=0x00C, BLENGTH=0x00C)	Scalar *k*	0x000 (PKA_APTR = 0x000)	12	0
	p	0x030 (PKA_BPTR = 0x00C)	12	2
	a	0x068	12	2
	b	0x0A0	12	2
	PntC.x (base)	0x0D8 (PKA_CPTR = 0x036)	12	2
	PntC.y (base)	0x110	12	2
	PntD.x (result)	0x148 (PKA_DPTR = 0x052)	12	2
	PntD.y (result)	0x180	12	0
	Vector scratchpad	0x148 (= PntD.x)	(18 × 14) + 14 = 266	0
	Free space	0x570 (1392 bytes used)	-	-
521 bits (=17 words, ALENGTH=0x011, BLENGTH=0x011)	Scalar *k*	0x000 (PKA_APTR = 0x000)	17	1 (to align *p*)
	p	0x048 (PKA_BPTR = 0x012)	17	3
	a	0x098	17	3
	b	0x0E8	17	3
	PntC.x (base)	0x138 (PKA_CPTR = 0x04E)	17	3
	PntC.y (base)	0x188	17	3
	PntD.x (result)	0x1D8 (PKA_DPTR = 0x076)	17	3

Table 40-22: ECC Point Multiplication PKA RAM Allocation Examples (Continued)

Modulus Length	(sub-)vector	Start Address (byte offset)	Size (words)	Buffer (words)
	PntD.y (result)	0x228	17	0
	Vector scratchpad	0x1D8 (= PntD.x)	(18 × 20) + 20 = 380	0
	Free space	0x7C8 (1992 bytes used)	-	-

The following example in pseudo-code describes the execution of a 192 bits ECC point multiplication, using actual test vectors (the curve parameters and generator point are from standard curve 'secp192r1').

```
// Perform a 192 bits ECC point multiplication using PKA RAM layout from table
above.
// Scalar 'k' equals value 0x8D98D058_9EFD018A_C9BCF3CF_2C33AEC0_24867D7F_6ADACBFF
// write as vector A to PKA RAM Byte offset 0x000:

    Write PKA_RAM_BASE+0x000+0x00 0x6ADACBFF
    Write PKA_RAM_BASE+0x000+0x04 0x24867D7F
    Write PKA_RAM_BASE+0x000+0x08 0x2C33AEC0
    Write PKA_RAM_BASE+0x000+0x0C 0xC9BCF3CF
    Write PKA_RAM_BASE+0x000+0x10 0x9EFD018A
    Write PKA_RAM_BASE+0x000+0x14 0x8D98D058
// Curve parameter 'p' equals value
0xFFFFFFFF_FFFFFFFF_FFFFFFFF_FFFFFFFE_FFFFFFFF_FFFFFFFF
// write as 1st part of vector B immediately following vector A at PKA RAM Byte
offset 0x018
// (no buffer word needed after 'k' vector, 64-bit alignment is OK):

ADSP-2184x PKA Register Descriptions

Public Key Accelerator (PKA) contains the following registers.

Table 40-23: ADSP-2184x PKA Register List

Name	Description
PKA_ALEN	PKA Vector_A Length
PKA_APTR	PKA Vector_A Address
PKA_BLEN	PKA Vector_B Length
PKA_BPTR	PKA Vector_B Address
PKA_COMPARE	PKA Compare Result
PKA_CPTR	PKA Vector_C Address
PKA_DIVMSW	PKA Most-Significant-Word of Divide Remainder
PKA_DPTR	PKA Vector_D Address
PKA_FUNC	PKA Function
PKA_RAM	Start of PKA RAM space
PKA_RESULTMSW	PKA Most-Significant-Word of Result Vector
PKA_SHIFT	PKA Bit Shift Value

PKA Vector_A Length

During execution of basic PKCP operations, the PKA_ALEN register is double buffered and can be written with a new value for the next operation. When not written, the value remains intact. During the execution of sequencer controlled complex operations, the PKA_ALEN register may not be written and its value is undefined at the conclusion of the operation. The driver software cannot rely on the written value to remain intact.

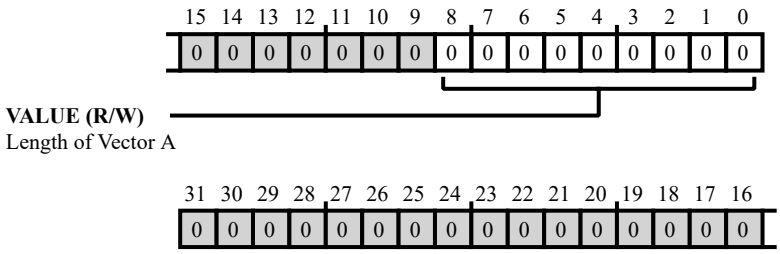

Figure 40-2: PKA_ALEN Register Diagram

Table 40-24: PKA_ALEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
8:0 (R/W)	VALUE	Length of Vector A. Length (in 32-bit words) of Vector A.

PKA Vector_A Address

During execution of basic PKCP operations, the PKA_APTR register is double buffered and can be written with a new value for the next operation. When not written, the value remains intact. During the execution of sequencer controlled complex operations, the PKA_APTR register may not be written and its value is undefined at the conclusion of the operation. The driver software cannot rely on the written value to remain intact.

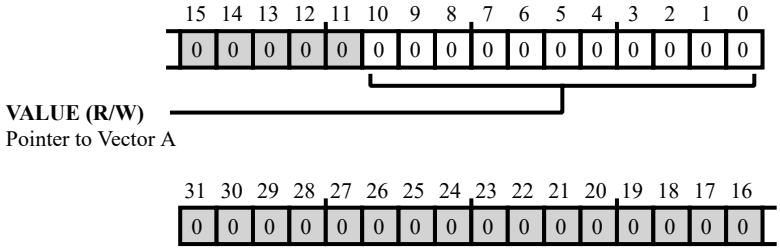

Figure 40-3: PKA_APTR Register Diagram

Table 40-25: PKA_APTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
10:0 (R/W)	VALUE	Pointer to Vector A. The PKA_APTR.VALUE bit field is the location of Vector A within the PKA RAM. Vectors are identified through the location of their least-significant 32-bit word. Note that bit [0] must be zero to ensure that the vector starts at an 8-byte boundary.

PKA Vector_B Length

During execution of basic PKCP operations, the PKA_BLEN register is double buffered and can be written with a new value for the next operation. When not written, the value remains intact. During the execution of sequencer controlled complex operations, the PKA_BLEN register may not be written and its value is undefined at the conclusion of the operation. The driver software cannot rely on the written value to remain intact.

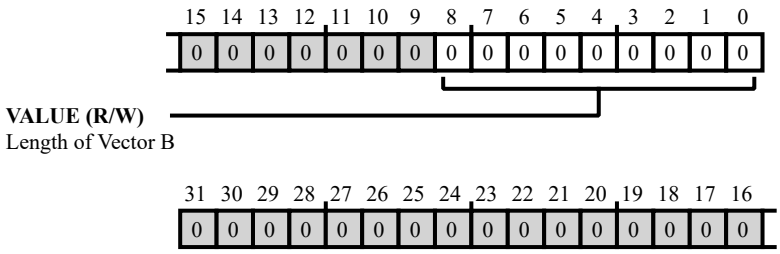

Figure 40-4: PKA_BLEN Register Diagram

Table 40-26: PKA_BLEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
8:0 (R/W)	VALUE	Length of Vector B. Length (in 32-bit words) of Vector B.

PKA Vector_B Address

During execution of basic PKCP operations, the PKA_BPTR register is double buffered and can be written with a new value for the next operation. When not written, the value remains intact. During the execution of sequencer controlled complex operations, the PKA_BPTR register may not be written and its value is undefined at the conclusion of the operation. The driver software cannot rely on the written value to remain intact.

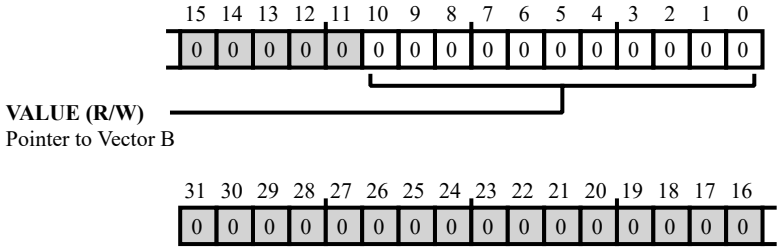

Figure 40-5: PKA_BPTR Register Diagram

Table 40-27: PKA_BPTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
10:0 (R/W)	VALUE	Pointer to Vector B. The PKA_BPTR.VALUE bit field is the location of Vector B within the PKA RAM. Vectors are identified through the location of their least-significant 32-bit word. Note that bit [0] must be zero to ensure that the vector starts at an 8-byte boundary.

PKA Compare Result

The PKA_COMPARE register provides the result of a basic PKCP Compare operation. It is updated when the PKA_FUNC.RUN bit is reset at the end of that operation. The status after a complex sequencer operation is unknown.

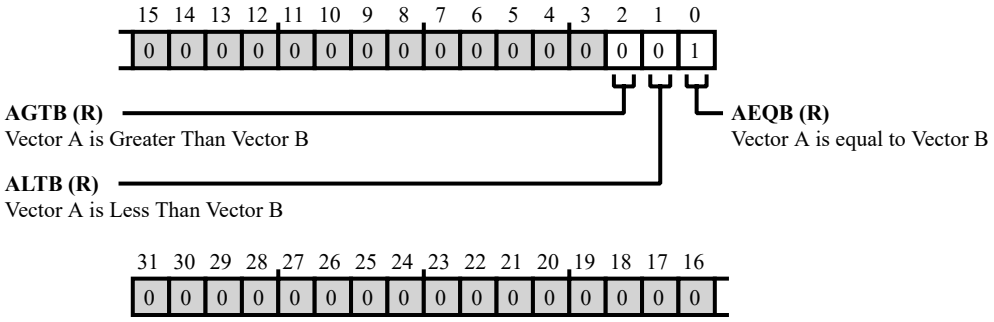

Figure 40-6: PKA_COMPARE Register Diagram

Table 40-28: PKA_COMPARE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
2 (R/NW)	AGTB	Vector A is Greater Than Vector B. The PKA_COMPARE.AGTB bit shows the result of the basic compare operation is PKCP Vector_A is greater than Vector_B.
1 (R/NW)	ALTB	Vector A is Less Than Vector B. The PKA_COMPARE.ALTB bit shows the result of the basic compare operation is Vector_A is less than Vector_B.
0 (R/NW)	AEQB	Vector A is equal to Vector B. The PKA_COMPARE.AEQB bit shows the result of the basic compare operation is Vector_A is equal to Vector_B.

PKA Vector_C Address

During execution of basic PKCP operations, the PKA_CPTR register is double buffered and can be written with a new value for the next operation. When not written, the value remains intact. During the execution of sequencer controlled complex operations, the PKA_CPTR register may not be written and its value is undefined at the conclusion of the operation. The driver software cannot rely on the written value to remain intact.

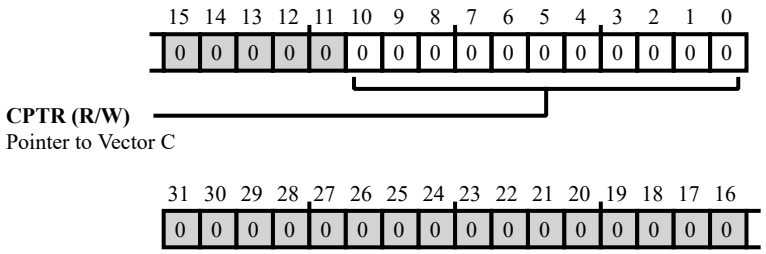

Figure 40-7: PKA_CPTR Register Diagram

Table 40-29: PKA_CPTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
10:0 (R/W)	CPTR	Pointer to Vector C. The PKA_CPTR.CPTR bit field is the location of Vector C within the PKA RAM. Vectors are identified through the location of their least-significant 32-bit word. Note that bit [0] must be zero to ensure that the vector starts at an 8-byte boundary.

PKA Most-Significant-Word of Divide Remainder

The PKA_DIVMSW register indicates the (32-bit word) address in the PKA RAM where the most significant non-zero 32-bit word of the Remainder result for the basic Divide and Modulo operations is stored. Bits [4:0] are loaded with the bit number of the most significant non-zero bit in the most significant non-zero word when MS one control bit is set. For Divide, Modulo and MS one reporting, this register is updated when the PKA_FUNC.RUN bit is reset at the end of the operation.

For the complex sequencer controlled operations, updating bits [4:0] of this register with the actual result's most significant bit location is done near the end of the operation. Note that the result is only meaningful if no errors were detected and that for ECC operations, the PKA_DIVMSW register provides information for the x-coordinate of the result point only.

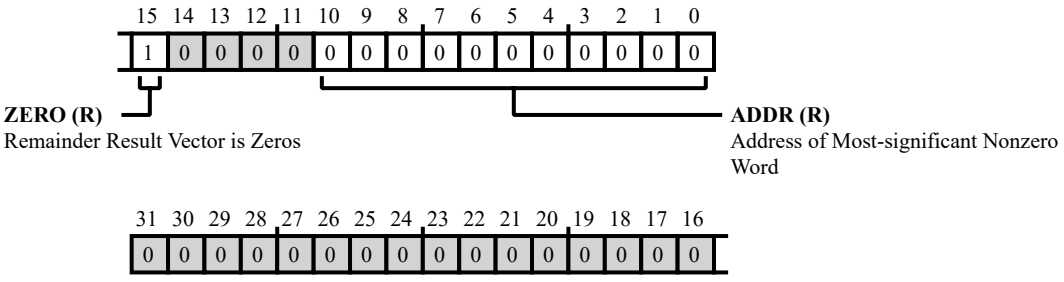

Figure 40-8: PKA_DIVMSW Register Diagram

Table 40-30: PKA_DIVMSW Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/NW)	ZERO	Remainder Result Vector is Zeros. The PKA_DIVMSW.ZERO bit shows the remainder result vector is all zeros, ignore the address returned in bits [10:0].
10:0 (R/NW)	ADDR	Address of Most-significant Nonzero Word. The PKA_DIVMSW.ADDR bit shows the address of the most significant non-zero 32-bit word of the remainder result vector in PKA RAM.

PKA Vector_D Address

During execution of basic PKCP operations, the PKA_DPTR register is double buffered and can be written with a new value for the next operation. When not written, the value remains intact. During the execution of sequencer controlled complex operations, the PKA_DPTR register may not be written and its value is undefined at the conclusion of the operation. The driver software cannot rely on the written value to remain intact.

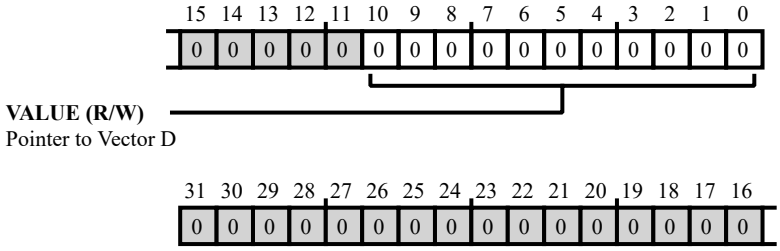

Figure 40-9: PKA_DPTR Register Diagram

Table 40-31: PKA_DPTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
10:0 (R/W)	VALUE	Pointer to Vector D. The PKA_DPTR.VALUE bit field is the location of Vector D within the PKA RAM. Vectors are identified through the location of their least-significant 32-bit word. Note that bit [0] must be zero to ensure that the vector starts at an 8-byte boundary.

PKA Function

The PKA_FUNC register contains the control bits to start basic PKCP as well as complex sequencer operations. The PKA_FUNC.RUN bit can be used to poll for the completion of the operation. Modifying bits [11:0] is made impossible during the execution of a basic PKCP operation.

During the execution of Sequencer controlled complex operations, this register is modified - the PKA_FUNC.RUN and PKA_FUNC.STALLRSLT bits are set to zero at the conclusion, but other bits are undefined.

Continuously reading this register to poll the PKA_FUNC.RUN bit is NOT allowed when executing complex sequencer operations (the sequencer cannot access the PKCP when this is done).

Leave at least one SCLK cycle between poll operations.

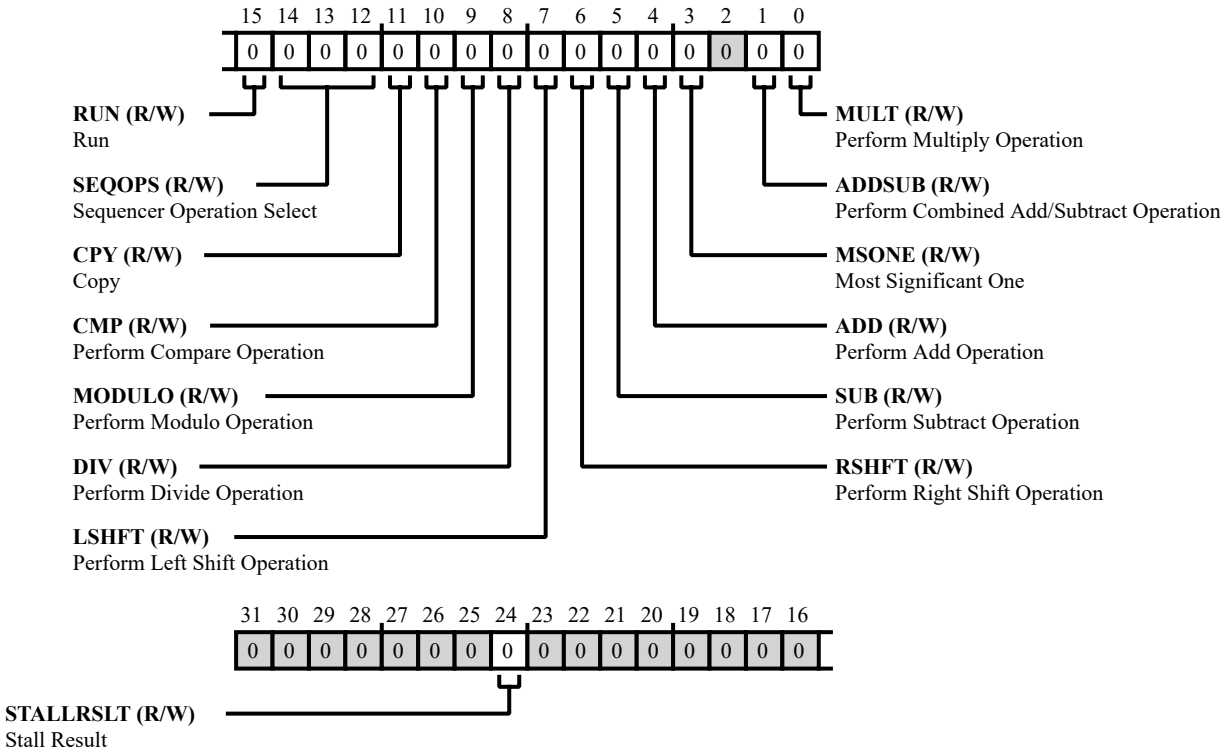

Figure 40-10: PKA_FUNC Register Diagram

Table 40-32: PKA_FUNC Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
24 (R/W)	STALLRSLT	Stall Result. When the PKA_FUNC.STALLRSLT bit is set, updating the PKA_COMPARE, PKA_RESULTMSW and PKA_DIVMSW registers, as well as resetting the run bit, is stalled beyond the point that a running operation is actually finished. Use this to allow software enough time to read results from a previous operation when the newly started operation is known to take only a short amount of time. If a result is waiting, the result registers is updated and the run bit is reset in the clock cycle following writing the stall result bit back to 0. The stall result function may only be used for basic PKCP operations.	
15 (R/W)	RUN	Run. Set the PKA_FUNC.RUN bit to instruct the PKA module to begin processing the basic PKCP or complex sequencer operation. This bit is reset low automatically when the operation is complete. The complement of this bit is output as the pkaint1 interrupt. After a reset, the run bit is always set to 1b but the first sequencer firmware instruction sets this bit to 0 immediately after the hardware reset is released. A few clock cycles are needed before the first instruction is executed and the run bit state has been propagated.	
14:12 (R/W)	SEQOPS	Sequencer Operation Select. The PKA_FUNC.SEQOPS bit field select the complex sequencer operation to perform.	
		0	None
		1	ExpMod-CRT
		2	ExpMod-ACT4
		3	ECC-ADD
		4	ExpMod-ACT2
		5	ECC-MUL
		6	ExpMod-variable
		7	ModInv
11 (R/W)	CPY	Copy. Setting the PKA_FUNC.CPY bit performs the copy operation. For more information, see the "PKCP Vector Operations" section.	
10 (R/W)	CMP	Perform Compare Operation. Setting the PKA_FUNC.CMP bit performs the compare operation. For more information, see the "PKCP Vector Operations" section.	

Table 40-32: PKA_FUNC Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
9 (R/W)	MODULO	Perform Modulo Operation. Setting the PKA_FUNC.MODULO bit performs the modulo operation. For more information, see the "PKCP Vector Operations" section.
8 (R/W)	DIV	Perform Divide Operation. Setting the PKA_FUNC.DIV bit performs the divide operation. For more information, see the "PKCP Vector Operations" section.
7 (R/W)	LSHFT	Perform Left Shift Operation. Setting the PKA_FUNC.LSHFT bit performs the left shift operation. For more information, see the "PKCP Vector Operations" section.
6 (R/W)	RSHFT	Perform Right Shift Operation. Setting the PKA_FUNC.RSHFT bit performs the right shift operation. For more information, see the "PKCP Vector Operations" section.
5 (R/W)	SUB	Perform Subtract Operation. Setting the PKA_FUNC.SUB bit performs the subtract operation. For more information, see the "PKCP Vector Operations" section.
4 (R/W)	ADD	Perform Add Operation. Setting the PKA_FUNC.ADD bit performs the add operation. For more information, see the "PKCP Vector Operations" section.
3 (R/W)	MSONE	Most Significant One. Setting the PKA_FUNC.MSONE bit loads the location of the most significant one bit within the result word indicated in the PKA_RESULTMSW register into bits [4:0] of the PKA_DIVMSW register; it can only be used with basic PKCP operations, except for divide, modulo and compare.
1 (R/W)	ADDSUB	Perform Combined Add/Subtract Operation. Setting the PKA_FUNC.ADDSUB bit performs the combined Add/Subtract operation. For more information, see the "PKCP Vector Operations" section.
0 (R/W)	MULT	Perform Multiply Operation. Setting the PKA_FUNC.MULT bit performs the multiply operation. For more information, see the "PKCP Vector Operations" section.

Start of PKA RAM space

The PKA_RAM register provides the starting location of the RAM space to hold the input, output and other vectors.

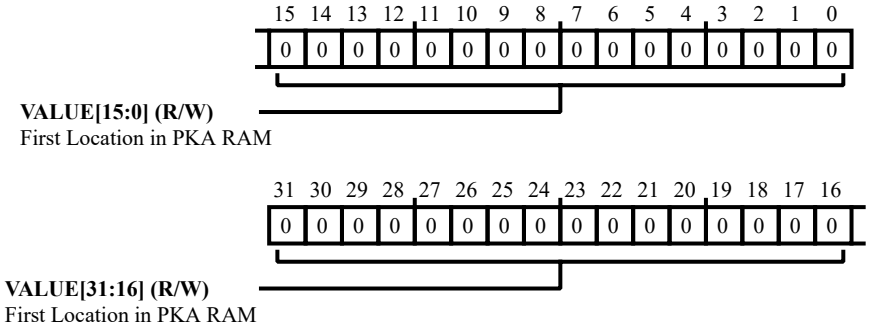

Figure 40-11: PKA_RAM Register Diagram

Table 40-33: PKA_RAM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	First Location in PKA RAM. The PKA_RAM.VALUE bit field provides the starting location of the RAM space to hold the input, output and other vectors.

PKA Most-Significant-Word of Result Vector

The PKA_RESULTMSW register indicates the (word) address in the PKA RAM where the most significant non-zero 32-bit word of the result is stored and should be ignored for modulo operations. For basic PKCP operations, the PKA_RESULTMSW register is updated when the PKA_FUNC.RUN bit is reset at the end of the operation.

For the complex sequencer controlled operations, updating the final value matching the actual result is done near the end of the operation. Note that the result is only meaningful if no errors are detected and that for ECC operations, the PKA_DIVMSW register provides information for the x-coordinate of the result point only.

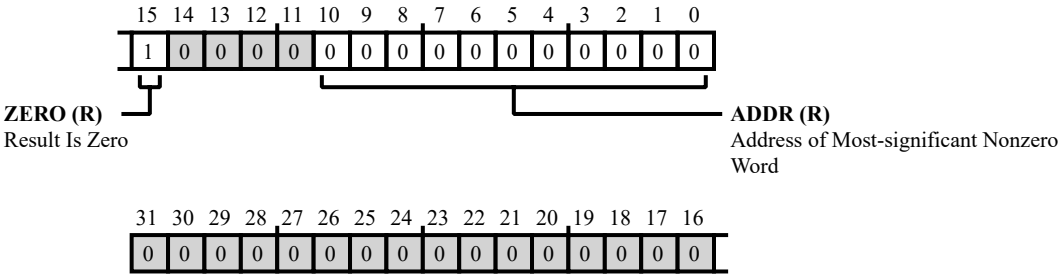

Figure 40-12: PKA_RESULTMSW Register Diagram

Table 40-34: PKA_RESULTMSW Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/NW)	ZERO	Result Is Zero. The PKA_RESULTMSW.ZERO bit indicates the result vector is all zeros, ignore the address returned in bits [10:0].
10:0 (R/NW)	ADDR	Address of Most-significant Nonzero Word. The PKA_RESULTMSW.ADDR bit is the address of the most significant non-zero 32-bit word of the result vector in PKA RAM.

PKA Bit Shift Value

For basic PKCP operations, modifying the contents of the PKA_SHIFT register is made impossible while the operation is being performed. For the ExpMod-variable and ExpMod-CRT operations, the PKA_SHIFT register is used to indicate the number of odd powers to use (directly as a value in the range 1-16). For the ModInv and ECC operations, this register is used to hold a completion code.

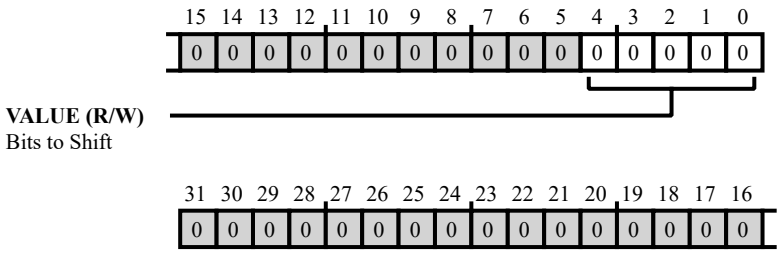

Figure 40-13: PKA_SHIFT Register Diagram

Table 40-35: PKA_SHIFT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
4:0 (R/W)	VALUE	Bits to Shift. The PKA_SHIFT.VALUE bit field is the number of bits to shift the input vector (in the range 0-31) during a Rshift or Lshift operation.

41 Public Key Interrupt Controller (PKIC)

The Public Key Accelerator (PKA) and the True Random Number Generator (TRNG) share a common interrupt controller, the Public Key Interrupt Controller (PKIC). The host processor configures the PKIC to generate interrupts when certain operations are complete, or interrupts are caused by errors.

PKIC Functional Description

The main purpose and function of the PKIC is to capture the interrupts from different sources, either from the PKA or the TRNG and combine them to one interrupt output. The interrupt controller is managed using the following register groups:

- Control for polarity, edge, and level detection and enabling of individual interrupts
- Acknowledgment (to clear edge detected interrupts)
- Status:
  - A raw source status register after edge detection, if edge selected.
  - A status register after masking with the interrupt enable control bits.

ADSP-2184x PKIC Register List

The Public Key Processor Interrupt Controller (PKIC) provides security-related features. A set of registers governs PKIC operations. For more information on PKIC functionality, see the PKIC register descriptions.

Table 41-1: ADSP-2184x PKIC Register List

Name	Description

PKIC Programming Model

The following sections provide information on how to program the PKIC.

Enabling/Disabling and Status

The PKIC_EN_STAT register provides the mask to which interrupt source is enabled. There are two status registers, PKIC_RAW_STAT and PKIC_EN_STAT. They allow the host processor to read the status of the interrupt source before and after the mask is applied.

Level or Edge

All of the interrupt sources are level or edge events. The PKIC_TYPE_CTL register configures each interrupt to either level or edge. The PKIC_POL_CTL register controls the polarity of the signal.

These interrupts are latched at both status registers in case edge detection is selected. The edge detectors are reset by clearing the interrupts using the PKIC_ACK registers.

PKIC Programming Concepts

The following concepts help with proper programming for the PKIC module.

Interrupt Handling

When an interrupt is triggered, the handler must first examine this module, the PKIC to determine what triggered the interrupt. By reading the PKIC_EN_STAT, the bits that are set are the pending interrupts of the ones that were not masked. After determining the source of the interrupt, the appropriate action must be taken to service the interrupt from the corresponding module, the PKA, or the TRNG. After handling the interrupt in a particular module, the corresponding interrupt must be acknowledged and cleared in the PKIC to allow further interrupts.

While handling an interrupt, any events that would cause another interrupt would happen without triggering another interrupt.

Overlapping Registers

There are two sets of overlapping registers in the PKIC. The PKIC_EN_STAT and PKIC_ACK registers share one address. If read, the register tells which enabled interrupts are pending. If written to (W1C), the interrupt is acknowledged and cleared. The PKIC_RAW_STAT and PKIC_EN_SET registers are another pair that share the address. When read, the register tells which interrupts are pending and if written to will enabled certain interrupts. This register cannot be used to disable any interrupts.

ADSP-2184x PKIC Register Descriptions

Public Key Processor Interrupt Controller (PKIC) contains the following registers.

Table 41-3: ADSP-2184x PKIC Register List

Name	Description
PKIC_ACK	Acknowledge Register
PKIC_EN_CLR	Enable Clear Register
PKIC_EN_CTL	Enable Control Register
PKIC_EN_SET	Enable Set Register
PKIC_EN_STAT	Enabled Status Register
PKIC_POL_CTL	Polarity Control Register
PKIC_RAW_STAT	Raw Status Register
PKIC_TYPE_CTL	Type Control Register

Acknowledge Register

The PKIC_ACK register is used to acknowledge the interrupt and clear the corresponding interrupt bit in the status register.

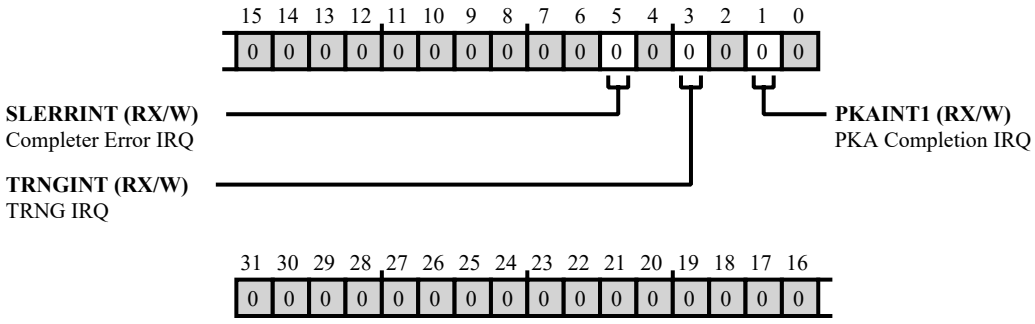

Figure 41-1: PKIC_ACK Register Diagram

Table 41-4: PKIC_ACK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (RX/W)	SLERRINT	Completer Error IRQ. The PKIC_ACK.SLERRINT bit is the acknowledge bit for the completer error interrupt. When set =1 the PKIC_ACK.SLERRINT bit acknowledges the interrupt signal and clears the status bit (and is cleared automatically).	
		0	Do not acknowledge interrupt and clear status bit
		1	Acknowledge interrupt and clear status bit
3 (RX/W)	TRNGINT	TRNG IRQ. The PKIC_ACK.TRNGINT bit is the acknowledge bit for the TRNG interrupt. When set =1 the PKIC_ACK.TRNGINT bit acknowledges the interrupt signal and clears the status bit (and is cleared automatically).	
		0	Do not acknowledge interrupt and clear status bit
		1	Acknowledge interrupt and clear status bit
1 (RX/W)	PKAINT1	PKA Completion IRQ. The PKIC_ACK.PKAINT1 bit is the acknowledge bit for the PKA completion interrupt. When set =1 the PKIC_ACK.PKAINT1 bit acknowledges the interrupt signal and clears the status bit (and is cleared automatically).	

Enable Clear Register

The PKIC_EN_CLR register allows the user to disable certain interrupts without enabling others. The disabled interrupts are also reflected in PKIC_EN_CTL register.

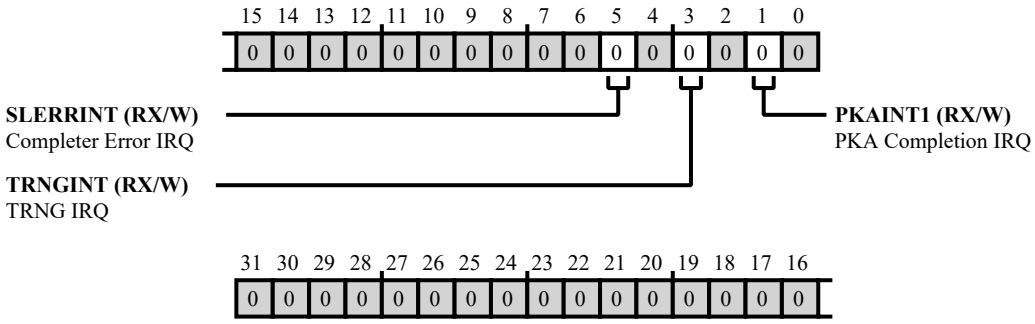

Figure 41-2: PKIC_EN_CLR Register Diagram

Table 41-5: PKIC_EN_CLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (RX/W)	SLERRINT	Completer Error IRQ. The PKIC_EN_CLR.SLERRINT bit is the individual disable for the completer error interrupt. When set =1 this bit clears/resets the corresponding bit in the PKIC_EN_CTL register to 0 (disables the interrupt). This bit is cleared automatically.	
		0	No action
		1	Clear/reset corresponding CTL bit
3 (RX/W)	TRNGINT	TRNG IRQ. The PKIC_EN_CLR.TRNGINT bit is the individual disable for the TRNG interrupt. When set =1 this bit clears/resets the corresponding bit in the PKIC_EN_CTL register to 0 (disables the interrupt). This bit is cleared automatically. 0= no effect.	
		0	No action
		1	Clear/reset corresponding CTL bit
1 (RX/W)	PKAINT1	PKA Completion IRQ. The PKIC_EN_CLR.PKAINT1 bit is the individual disable for the PKA Completion interrupt. When set =1 this bit clears/resets the corresponding bit in the PKIC_EN_CTL register to 0 (disables the interrupt). This bit is cleared automatically. 0= no effect.	
		0	No action
		1	Clear/reset corresponding CTL bit

Enable Control Register

The PKIC_EN_CTL register provides individual enable bits for the interrupt sources.

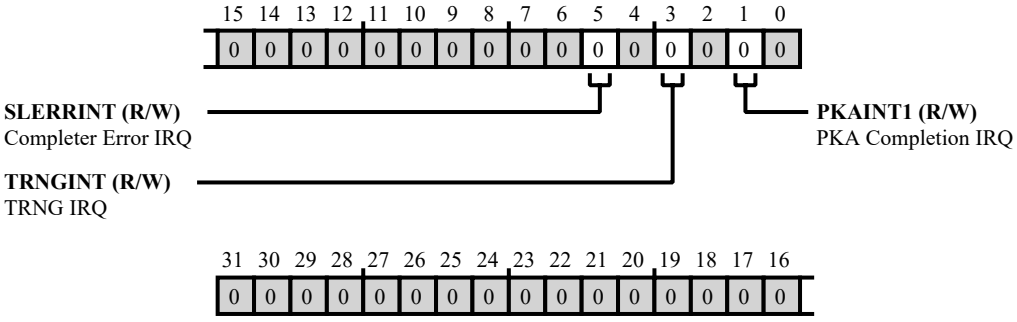

Figure 41-3: PKIC_EN_CTL Register Diagram

Table 41-6: PKIC_EN_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W)	SLERRINT	Completer Error IRQ. The PKIC_EN_CTL.SLERRINT bit enables control for the completer error interrupt.	
		0	Disable interrupt
		1	Enable interrupt
3 (R/W)	TRNGINT	TRNG IRQ. The PKIC_EN_CTL.TRNGINT bit enables control for the TRNG interrupt.	
		0	Disable interrupt
		1	Enable interrupt
1 (R/W)	PKAINT1	PKA Completion IRQ. The PKIC_EN_CTL.PKAINT1 bit enables control for the PKA completion interrupt.	
		0	Disable interrupt
		1	Enable interrupt

Enable Set Register

The PKIC_EN_SET register allows the user to only set certain interrupt sources without disabling any others. The enabled interrupts are reflected in PKIC_EN_CTL register.

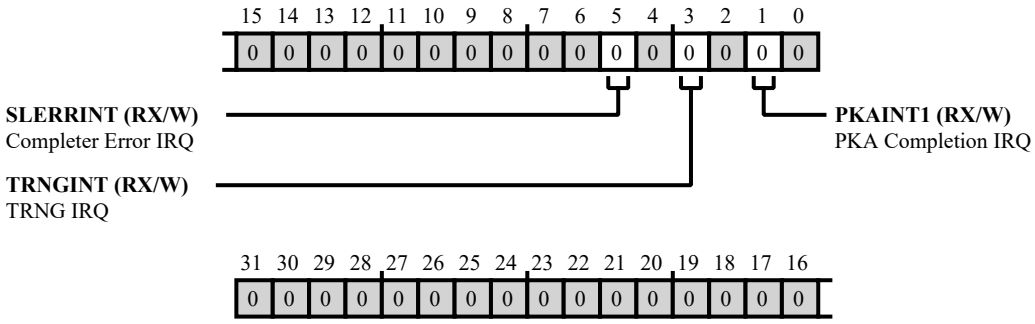

Figure 41-4: PKIC_EN_SET Register Diagram

Table 41-7: PKIC_EN_SET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (RX/W)	SLERRINT	Completer Error IRQ. The PKIC_EN_SET.SLERRINT bit is the individual enable for the completer error interrupt. If =1, sets the corresponding bit in the PKIC_EN_CTL register to 1 (enables interrupt). This bit is cleared automatically. 0=no effect	
		0	No effect
		1	Enable interrupt
3 (RX/W)	TRNGINT	TRNG IRQ. The PKIC_EN_SET.TRNGINT bit is the individual enable for the TRNG interrupt. If =1, sets the corresponding bit in the PKIC_EN_CTL register to 1 (enables interrupt). This bit is cleared automatically.	
		0	No effect
		1	Enable interrupt
1 (RX/W)	PKAINT1	PKA Completion IRQ. The PKIC_EN_SET.PKAINT1 bit is the individual enable for the PKA Completion interrupt. If =1, sets the corresponding bit in the PKIC_EN_CTL register to 1 (enables interrupt). This bit is cleared automatically.	
		0	No effect
		1	Enable interrupt

Enabled Status Register

The PKIC_EN_STAT register is used to tell the status of the interrupts after the gating with the PKIC_EN_CTL register.

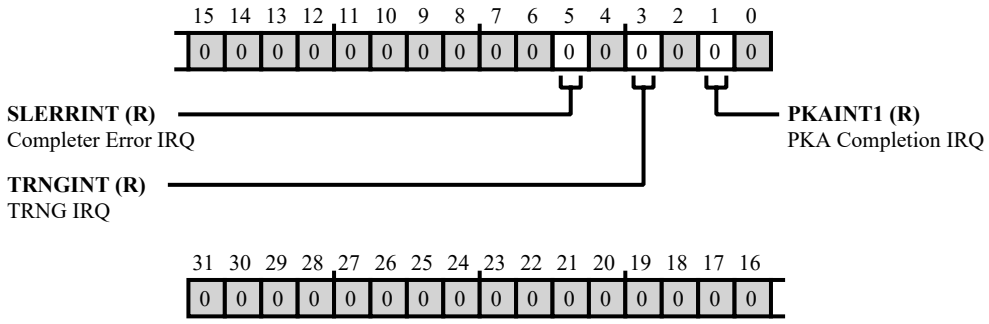

Figure 41-5: PKIC_EN_STAT Register Diagram

Table 41-8: PKIC_EN_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/NW)	SLERRINT	Completer Error IRQ. The PKIC_EN_STAT.SLERRINT bit provides the status of the completer error interrupt (after masking from the PKIC_EN_CTL register).	
		0	Interrupt is inactive
		1	Interrupt is pending
3 (R/NW)	TRNGINT	TRNG IRQ. The PKIC_EN_STAT.TRNGINT bit provides the status of the TRNG interrupt (after masking from the PKIC_EN_CTL register).	
		0	Interrupt is inactive
		1	Interrupt is pending
1 (R/NW)	PKAINT1	PKA Completion IRQ. The PKIC_EN_STAT.PKAINT1 bit provides the status of the PKA Completion interrupt (after masking from the PKIC_EN_CTL register).	
		0	Interrupt is inactive
		1	Interrupt is pending

Polarity Control Register

The PKIC_POL_CTL register is used to configure the signal polarity for each individual interrupt. During the initialization phase of the PKA the host processor must set each interrupt in this register to (high level/rising edge or low level/falling edge).

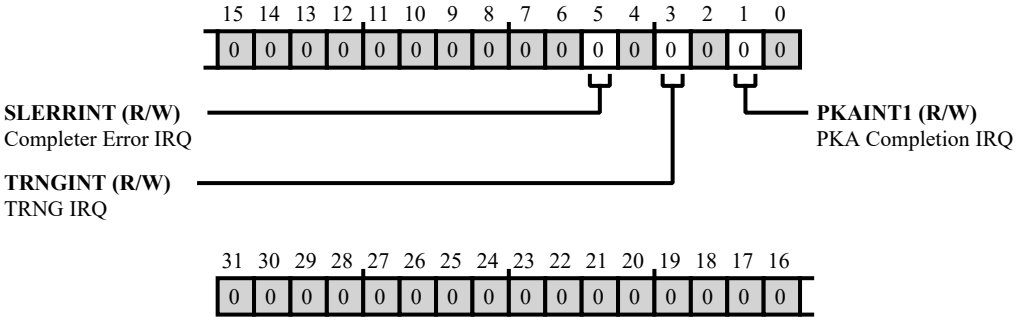

Figure 41-6: PKIC_POL_CTL Register Diagram

Table 41-9: PKIC_POL_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W)	SLERRINT	Completer Error IRQ. The PKIC_POL_CTL.SLERRINT bit provides polarity control for the completer error interrupt.	
		0	Low level/falling edge
		1	High level/rising edge
3 (R/W)	TRNGINT	TRNG IRQ. The PKIC_POL_CTL.TRNGINT bit provides polarity control for the TRNG interrupt.	
		0	Low level/falling edge
		1	High level/rising edge
1 (R/W)	PKAINT1	PKA Completion IRQ. The PKIC_POL_CTL.PKAINT1 bit provides polarity control for PKA completion interrupt.	
		0	Low level/falling edge
		1	High level/rising edge

Raw Status Register

The PKIC_RAW_STAT register reflects the status of the individual interrupts before masking with the PKIC_EN_CTL register.

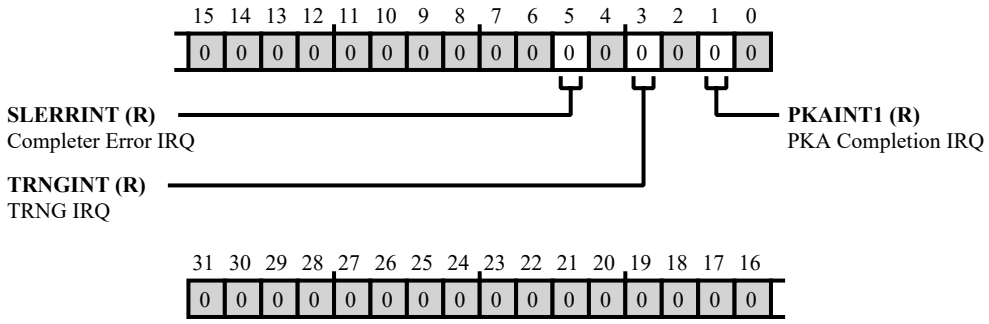

Figure 41-7: PKIC_RAW_STAT Register Diagram

Table 41-10: PKIC_RAW_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/NW)	SLERRINT	Completer Error IRQ. The PKIC_RAW_STAT.SLERRINT bit provides the raw status of the completer error interrupt.	
		0	Inactive interrupt
		1	Pending interrupt
3 (R/NW)	TRNGINT	TRNG IRQ. The PKIC_RAW_STAT.TRNGINT bit provides the raw status of the TRNG interrupt where 1=pending and 0=inactive.	
		0	Inactive interrupt
		1	Pending interrupt
1 (R/NW)	PKAINT1	PKA Completion IRQ. The PKIC_RAW_STAT.PKAINT1 bit provides raw status of the PKA completion interrupt where 1=pending and 0=inactive.	
		0	Inactive interrupt
		1	Pending interrupt

Type Control Register

The PKIC_TYPE_CTL register is used to configure the signal type for each individual interrupt. During the initialization phase of the PKA the host processor must set each interrupt in this register to level or edge.

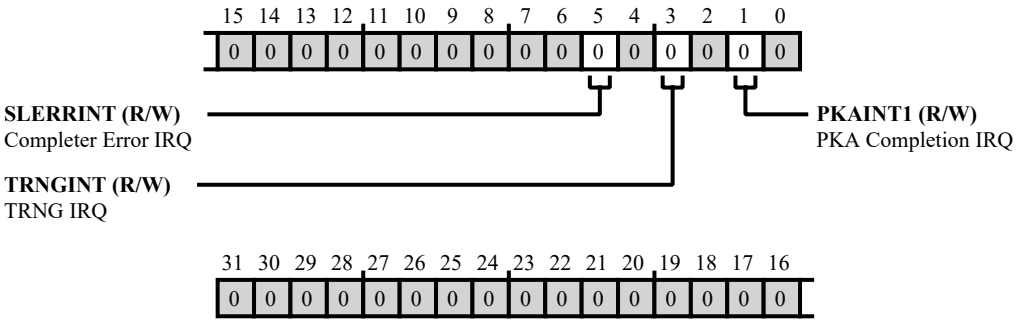

Figure 41-8: PKIC_TYPE_CTL Register Diagram

Table 41-11: PKIC_TYPE_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W)	SLERRINT	Completer Error IRQ. The PKIC_TYPE_CTL.SLERRINT bit provides signal type control for the completer error interrupt.	
		0	Level
		1	Edge

		0	Level
		1	Edge
1 (R/W)	PKAINT1	PKA Completion IRQ. The PKIC_TYPE_CTL.PKAINT1 bit provides signal type control for the PKA completion interrupt.	
		0	Level
		1	Edge

42 True Random Number Generator (TRNG)

The TRNG engine provides a true, non-deterministic, noise source for generating keys, Initialization Vectors (IVs), and other random number requirements. Other non-cryptographic purposes include statistical sampling, retry timers for communications protocols and noise generation.

TRNG Features

The TRNG features include:

- Hardware-based non-deterministic random number generator
- ANSI X9.31 postprocessing (depending on processor)
- Redundant 'fail-safe' design with self-test circuits
- Reliable shot noise oscillator implementation with auto-tuning
- Debug output to allow monitoring of internal operation
- Alarm count overflow and auto-tuning error interrupts
- Buffer to allow generation of large blocks of random data in the background

TRNG Functional Description

The following sections provide details on the function of the TRNG module.

ADSP-2184x TRNG Register List

The True Random Number Generator (TRNG) provides random number generation, intended mainly for security-related applications. A set of registers governs TRNG operations. For more information on TRNG functionality, see the TRNG register descriptions.

Table 42-1: ADSP-2184x TRNG Register List

Name	Description
TRNG_ALMCNT	TRNG Alarm Counter Register

Table 42-1: ADSP-2184x TRNG Register List (Continued)

Name	Description
TRNG_ALMMSK	TRNG Alarm Mask Register
TRNG_ALMSTP	TRNG Alarm Stop Register
TRNG_BLKCNT	TRNG Block Count Register
TRNG_CFG	TRNG Configuration Register
TRNG_CNT	Counter Register
TRNG_CTL	TRNG Control Register
TRNG_FRODETUNE	TRNG FRO De-tune Register
TRNG_FROEN	TRNG FRO Enable Register
TRNG_INPUT[n]	TRNG Input Registers
TRNG_INTACK	TRNG Interrupt Acknowledge Register
TRNG_KEY[n]	Post-Process Key Registers
TRNG_LFSR_H	TRNG LFSR Access Register
TRNG_LFSR_L	TRNG LFSR Access Register
TRNG_LFSR_M	TRNG LFSR Access Register
TRNG_MONOBITCNT	TRNG Monobit Test Result Register
TRNG_OUTPUT[n]	TRNG Output Registers
TRNG_POKER[n]	TRNG Poker Test Result Registers
TRNG_RUNCNT	TRNG Run Count Registers
TRNG_RUN[n]	TRNG Run Test State and Result Registers
TRNG_STAT	TRNG Status Register
TRNG_TEST	TRNG Test Register
TRNG_V[n]	TRNG Post-Process "V" Value Registers

Random Number Generation

The random numbers that the TRNG generates are produced by sampling Free Running Oscillators (FRO). The (TRNG_CTL.STARTUPCYC) bit field along with TRNG_CFG.MINREFCYC (minimum refill cycles) and TRNG_CFG.MAXREFCYC (maximum refill cycles) bit fields determine the number of samples taken to generate the first random value and subsequent random values.

1. After enabling the TRNG (TRNG_CTL.TRNGEN bit =1), a number of FRO output samples defined by the TRNG_CTL.STARTUPCYC bit field are gathered in the main linear-feedback shift register (LFSR) before taking a snapshot of the LFSR and storing that snapshot in the random data buffer (after optional post-processing).

2. After taking a snapshot of the LFSR, a number of FRO output samples defined by the TRNG_CFG.MINREFCYC bit field, are gathered in the main LFSR. If the random data buffer is full, sample-taking continues until the number of samples (counting from the snapshot) matches the number of samples defined by the TRNG_CFG.MAXREFCYC bit field. At that point, the TRNG switches off the FROs and powers down.
3. If, after the TRNG_CFG.MINREFCYC sampling period, the random data buffer is not completely filled, a new snapshot of the LFSR is taken and stored in the random data buffer (after optional postprocessing). Control branches back to point step 2 above and a new TRNG_CFG.MINREFCYC sample period starts.

Locking Detection and Prevention

Lock detection in functional mode uses the sampled outputs of the individual FROs. A FRO alarm event is declared when a repeating pattern (of up to four sample lengths) is detected continuously for the number of samples defined in the alarm threshold TRNG_ALMCNT.ALMTHRESH bit field. The alarm event is logged by setting the bit that corresponds to the FRO that caused the alarm in the TRNG_ALMMSK register. If that bit was already set, the corresponding bit in the TRNG_ALMSTP register is set. The FRO is switched off to prevent further alarm events from that FRO. If the TRNG_ALMMSK register bit was not yet set, the FRO is restarted automatically in an attempt to break locking.

The shutdown count field in the alarm count TRNG_ALMCNT.SHDNCNT register monitors the number of FROs switched off. (It counts the number of 1 bits in the TRNG_ALMSTP register.) The shutdown threshold field (TRNG_ALMCNT.SHDNTHRESH) can be configured to generate the shutdown overflow interrupt (TRNG_STAT.SHDNOVR). When the shutdown count in the TRNG_ALMCNT.SHDNCNT bit field exceeds the shutdown threshold in the TRNG_ALMCNT.SHDNTHRESH bit field, the shutdown overflow bit (TRNG_STAT.SHDNOVR) is set to 1 (which can be used to generate an interrupt).

Software can use two strategies for the TRNG operation:

- ***Monitored Operation***. Software checks the TRNG_ALMMSK register at regular intervals (on the order of seconds). If a bit is set in that register, then the program must also check the TRNG_ALMSTP register to determine if a FRO was shut down due to multiple alarm events. If no FROs are shut down, the program clears the TRNG_ALMMSK register to remove the incidental alarm events. If one or more FROs are shut down, the host processor can modify the delay selection of those FROs using the TRNG_FRODETUNE register to prevent further locking. For this type of operation, the shutdown threshold is normally set to a low value (two, for example). The shutdown overflow interrupt can then be used to signal abnormal operation conditions or the breakdown of FROs.
- ***Unmonitored Operation.*** Software sets the shutdown threshold to the acceptable number of FROs to be shut down before taking corrective actions. It then uses the shutdown overflow interrupt to initiate corrective actions (clearing the TRNG_ALMMSK and TRNG_ALMSTP registers, toggling bits in the TRNG_FRODETUNE register). The software must monitor the time interval between these interrupts. If they occur too often (for example, within a minute after each other), this frequency indicates abnormal operating conditions or the breakdown of FROs.

Run Testing

Run Test

The TRNG block counts the number of consecutive zeros and ones (runs) in the data stream shifted into the main LFSR. The run length and bit value is then used to increment a specific bucket counter for these values. After 20,000 bits, the bucket counters must be within specified limits for this test to pass. If not, a run fail interrupt (RUNFAIL) is generated.

Table 42-2: Allowable Limits on Runs of 0's and 1's

Run Count	Bit Value	Min (inclusive)	Max (inclusive)
1	0	2267	2733
	1	2267	2733
2	0	1079	1421
	1	1079	1421
3	0	502	748
	1	502	748
4	0	233	402
	1	233	402
5	0	90	223
	1	90	223
6 and up	0	90	233
	1	90	233

Long Run Test

The long run test fails immediately when a run longer than 33 bits is found and a long run fail (`TRNG_STAT.LRUNFAIL`) interrupt is generated.

Noise Source Test

A noise source failure is declared when a run of 48 or more identical bits is found and a noise fail interrupt (`TRNG_STAT.NOISEFAIL`) is generated.

The status and counts are stored in the `TRNG_RUNCNT` and `TRNG_RUN[n]` registers. Unless otherwise indicated, all counters and state bits in these registers are reset when writing a 1 to either the monobit fail acknowledge (`TRNG_INTACK.MBITFAIL`), the run fail acknowledge (`TRNG_INTACK.RUNFAIL`), or the poker fail acknowledge (`TRNG_INTACK.PKRFAIL`) bits.

Monobit Testing

The TRNG block performs the monobit test on blocks of 20,000 bits (in parallel with the run test and poker test). It monitors the number of zeros and ones in the data stream shifted into the main LFSR. At the start of the block,

the counter is initialized to 10,000. Each 1 value increments the counter, each 0 value decrements the counter. After 20,000 bits, the counter value must be within 9310–10690 (inclusive) for this test to pass. If not, a monobit fail interrupt (TRNG_STAT.MBITFAIL) is generated. The AIS-31 standard (test T1, ref 0) specifies this run time testing of the TRNG and the parameters.

NOTE: The actual limits stated here are different than the limits stated in the AIS-31 standard due to the implementation. The circuitry in the TRNG uses an up-down counter while the standard just evaluates the sum of the 20,000 bits.

When the continue poker (TRNG_TEST.CONTPKR) bit is set to 1, the test is not stopped after 20,000 bits. The counter keeps incrementing and decrementing (protected against overflow and underflow). But, no actual limit checking happens. The offset from starting value 10,000 indicates the balance of 0 and 1 bits that were checked since the start of the continuous test. The offset is twice the number of missing or extra 1 bits. (An extra 1 bit adds an increment operation and removes one decrement operation. So, having 10,001 1 bits in the block gives a counter value of 10,002.)

Poker Testing

The poker test is run in parallel with the monobit test and run test. Counters in the TRNG_POKER[n] registers are used to count the occurrences of one specific 4-bit value in the data stream fed into the main LFSR. All of the counters are decremented by one every 64 data bits and reset to their start value every 20,000 bits. All counters start at a value of –1 and are decremented 312 times during the 20,000-bit test run.

Each 8-bit counter holds a two's complement value and does not overflow past the range of –128 to +127. At the end of the 20,000-bits block, the values of the counters that contain a single 1 bit appended at the least significant bit side are individually squared and then added. The poker test fails with a poker fail (PKRFAIL) interrupt when:

- the resulting sum (accumulated in the TRNG_MONOBITCNT register) is outside the range 1288 – 71750 (inclusive), or
- one of the counters tries to increment or decrement outside its limit range

NOTE: The poker test fails when the 4-bit values of the data stream are distributed too evenly (with eight counters having incremented 312 times and the others incremented 313 times). This failure is intentional. The minimum mean deviation from the expected value of 312.5 is 4.5. Failure at counter overflow is not an official part of the poker test as specified in the AIS-31 standard (ref 0). It can be shown that the maximum deviation for one counter's value from the mean value of 312.5 (without the poker test failing) is 129.5. Since this deviation is more than 40% of the mean value, it indicates that something is wrong. Here, the counter overflow failure is combined with the official poker test failure.

When the continue poker (TRNG_TEST.CONTPKR) bit is set to 1, the test does not stop after 20,000 bits. The counters keep incrementing and decrementing (the latter every 64 bits). A PKRFAIL interrupt is generated when one of the counters tries to increment or decrement outside its limit range.

Data for Tests

For the monobit test, run test and poker test circuits self-test, the test data written to the TRNG_INPUT[n]0 register is used for the monobit test and run test bit-by-bit. It executes from bit 31 down to bit 0. For the poker test, the written test data is used in eight blocks of 4 bits, starting from bits 31:28 down to bits 3:0.

When the TRNG_TEST.CONTPKR bit =0 during run test and poker test circuits self-tests, the state of the poker and runs test status registers is frozen after all calculations are made and after inputting 20,000 test bits. This state allows time to read the test results. These calculations take around 20 clock cycles to complete. The status registers are reset to their starting states when the first word for the next test block of test bits is written to the TRNG_INPUT[n]0 register. Then, the contents of this word are processed.

X9.31 Postprocessing

Postprocessing is available on some parts using the TRNG. If available, the postprocessing block is situated after the main LFSRs and before the output buffer that stores the random numbers for consumption. The online test logic for monobit, run, and poker testing is before the postprocessor block. The bits used for testing are from the main LFSR.

The postprocessor is based on the ANSI X9.31 specification using 3-Key 3DES cipher algorithm. It does not provide any more entropy than is what is already achieved from sampling the Free Running Oscillators (FROs). The use of the postprocessor only helps with applications requiring the use of an X9.31 compliant RNG.

The following section is an example of postprocessing.

The variables include:

- DT is a 64-bit date/time vector. This value is the input coming from random bits from the main LFSR.
- I is an intermediate value, a 64-bit value
- R is the final result, a 64-bit value
- V is a 64-bit seed value that is to be kept secret
- K is the 3-key for 3DES, each being 64-bits

The postprocessing uses the steps:

1. The intermediate value I is calculated: I = $3DES_{EDE}$(K, DT) with 3DES.
2. The result R is calculated: R = $3DES_{EDE}$(K, I XOR V).
3. Finally, V is updated: V = $3DES_{EDE}$(K, R XOR I).

TRNG Block Diagram

The ***System Block Diagram of the TRNG*** diagram shows the system block for the TRNG. The system includes:

- Free Running Oscillators (FROs) that are the source of sampled bits
- A post-processing unit (processor dependent) for standards compliance

- Test circuitry to detect non-randomness due to failures in the system

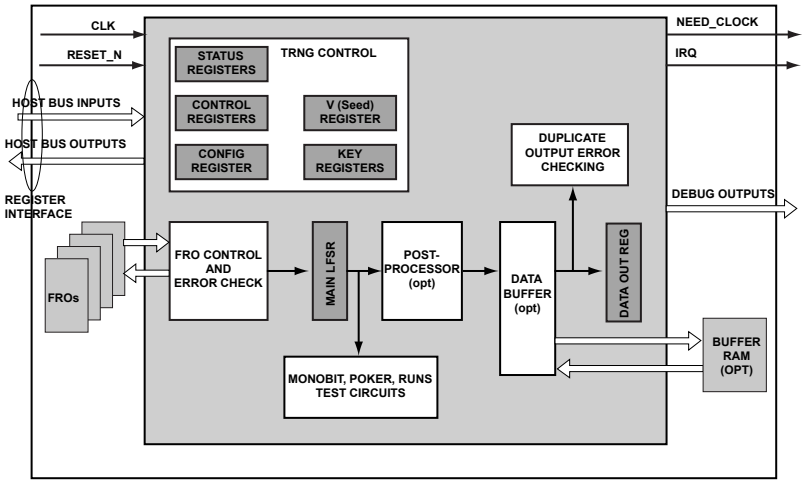

Figure 42-1: System Block Diagram of the TRNG

TRNG Architectural Concepts

The random numbers are accessible to the host processor in four 32-bit registers allowing a single burst read of a 128-bit random number. Acknowledging the data ready (interrupt) state causes the TRNG to move a new value (when available in the data buffer) to the TRNG output register. The TRNG always tries to keep the data buffer completely full. Pulling out data starts the regeneration of a new number by:

- Enabling the FROs
- Capturing their outputs in the LFSR, and
- Cryptographically postprocessing the values from the LFSR

The process produces new random values to replenish the buffer.

The major functional blocks of the TRNG module are:

- The actual TRNG core with control and test circuits, optional post-processor, and optional data buffer control logic
- Free Running Oscillators (FROs) instantiated outside the TRNG core
- A 128-byte buffer RAM instantiated outside the TRNG core

In the TRNG core, the true entropy source uses FROs as the basic building block. The accumulation of timing jitter, caused (for the largest part) by shot noise, creates uncertainty intervals for the output transitions of each FRO. Sampling within an uncertainty interval generates a single bit of entropy, which is ‘accumulated’ in a LFSR. As the uncertainty interval is very narrow compared to the cycle time of a FRO, the mean amount of entropy generated per sample is small (less than 1/100 bit per sample). To increase the entropy generation rate, multiple FROs are used in parallel.

The FROs are asynchronous to one another and asynchronous to the sampling clock to make their behavior truly non-deterministic.

The output signals of the FROs are sampled at regular intervals (in general, at the TRNG core module clock frequency). The samples feed into an error detection circuit that checks for repeating patterns coming out of a FRO. If a repeating pattern persists for a configurable number of samples, the FRO is suspect of having synchronized to (a harmonic of) the sampling interval. This activity drastically reduces the amount of entropy generated by that FRO. The error detection circuit signals this activity as a FRO error event.

Error events can occur during normal operation. The FRO control circuit attempts to restart a FRO that on a first error event. A second error event causes an automatic shutdown of the FRO. Because there are multiple FROs, shutting down a FRO reduces the amount of entropy generated, but it does not immediately jeopardize the TRNG operation. A limit can be configured below which the number of operational FROs does not drop. If this limit is crossed, an interrupt can be generated on the host processor. Software on the host processor can then attempt to prevent frequent locking of a FRO by *de-tuning* it to a slightly different frequency.

An XOR tree combines the sampled outputs and feeds them into an 81-bit LFSR to accumulate entropy and whiten the random bits stream.

NOTE: Here, *whitening* means balancing the number of one and zero bits in the stream.

TRNG Operating Modes

The TRNG has the following operating modes.

Normal Reading Mode

In normal reading mode, random data can only be read out of the output registers of the TRNG module when the ready bit (`TRNG_STAT.RDY`) =1. Acknowledging the data by writing a 1 to the ready acknowledge bit in the `TRNG_INTACK.RDY` register clears the ready bit from the status register and clears the output registers. The registers remain at zero until the next 128-bit data block is available.

Secure Reading Mode

An attacker can try to read the output registers (without acknowledging the data) to obtain a copy of data to be read later by an application. To block this attack, secure reading mode is used. In this mode, enable reading from the output registers (by writing 0x00 to the open read gate bits (`TRNG_INTACK.OPENRDGATE`) before it is possible to access the output registers. Enabling the reading starts a timeout (controlled by the `TRNG_CFG.RDTIMEOUT` bit field). When this timeout expires, reading is disabled, and the offered data is acknowledged so that it is not offered again. The host processor must set this timeout such that there is enough time to read the output registers and perform a normal data acknowledge (which stops the timeout).

Test Mode

In addition to the test circuitry that operates during normal operation, the TRNG has a test mode that allows further diagnosis when errors occur. In test mode, programs have access to the main LFSR through the

TRNG_LFSR_L, TRNG_LFSR_M, and TRNG_LFSR_H registers. Programs can also control the finite state machine sample counter using the TRNG_CNT register.

In test mode, the TRNG can be configured to test individual or a chosen set of FROs. It can also be configured to feed test patterns to the delay chain.

TRNG Data Transfer Modes

The host processor reads four 32-bit registers to access the random numbers. Once the registers are read and the data ready interrupt has been acknowledged, the TRNG moves more data from the internal buffer to the output registers (TRNG_OUTPUT[n]).

TRNG Event Control

There are eight events that the TRNG generates. The events are common error events from the run-time testing of the TRNG. While the TRNG is operating and generating random bits, test circuitry is also running statistical tests. The tests determine if the sources of the random bits have started to fail and are not truly producing random bits. There is also a single event to signal when data is ready in the output registers.

These events are captured in the TRNG_STAT register and can generate a single interrupt in the Public Key Interrupt Controller (PKIC). The individual events can be masked so the interrupt is not triggered. This configuration uses the TRNG_CTL register. The event and associated interrupt can be acknowledged in the TRNG_INTACK register.

The ***TRNG Interrupt Signals*** table lists all events or interrupts that the TRNG can generate.

TRNG Interrupt Signals

The TRNG provides a total of eight interrupts multiplexed into one output.

Table 42-3: TRNG Interrupt Signals

Interrupt	Name	Description
0	RDY	Ready. Random number is ready to be read from registers
1	SHDNOVR	Shutdown Overflow. The number of FRO's automatically shut down due to failures or errors have gone above the threshold specified in TRNG_ALMCNT.SHDNTHRESH.
2	STUCKOUT	Stuck Out. Logic circuitry around the output registers has detected the same output has been provided twice.
3	NOISEFAIL	Noise Fail. Logic circuitry monitoring the data shifted into the main LFSR detected 48 identical bits, which is considered a noise source failure.
4	RUNFAIL	Run Fail. Logic circuitry monitoring the data shifted into the main LFSR detected an out-of-bounds value for at least one of the TRNG_RUN[n] counters after checking 20,000 bits.

Table 42-3: TRNG Interrupt Signals (Continued)

Interrupt	Name	Description
5	LRUNFAIL	Long Run Fail. Logic circuitry monitoring the data shifted into the main LFSR detected 34 identical bits.
6	PKRFAIL	Poker Fail. Logic circuitry monitoring the data shifted into the main LFSR detected an out-of-bounds value in at least one of the 16 TRNG_POKER[n] counters or an out-of-bounds sum of squares values after checking 20,000 bits.
7	MBITFAIL	Monobit Fail. Logic circuitry monitoring the data shifted into the main LFSR detected an out-of-bounds number of 1's after checking 20,000 bits.

ADSP-2184x TRNG Register Descriptions

True Random Number Generator (TRNG) contains the following registers.

Table 42-4: ADSP-2184x TRNG Register List

Name	Description
TRNG_ALMCNT	TRNG Alarm Counter Register
TRNG_ALMMSK	TRNG Alarm Mask Register
TRNG_ALMSTP	TRNG Alarm Stop Register
TRNG_BLKCNT	TRNG Block Count Register
TRNG_CFG	TRNG Configuration Register
TRNG_CNT	Counter Register
TRNG_CTL	TRNG Control Register
TRNG_FRODETUNE	TRNG FRO De-tune Register
TRNG_FROEN	TRNG FRO Enable Register
TRNG_INPUT[n]	TRNG Input Registers
TRNG_INTACK	TRNG Interrupt Acknowledge Register
TRNG_KEY[n]	Post-Process Key Registers
TRNG_LFSR_H	TRNG LFSR Access Register
TRNG_LFSR_L	TRNG LFSR Access Register
TRNG_LFSR_M	TRNG LFSR Access Register
TRNG_MONOBITCNT	TRNG Monobit Test Result Register
TRNG_OUTPUT[n]	TRNG Output Registers
TRNG_POKER[n]	TRNG Poker Test Result Registers
TRNG_RUNCNT	TRNG Run Count Registers
TRNG_RUN[n]	TRNG Run Test State and Result Registers

Table 42-4: ADSP-2184x TRNG Register List (Continued)

Name	Description
TRNG_STAT	TRNG Status Register
TRNG_TEST	TRNG Test Register
TRNG_V[n]	TRNG Post-Process "V" Value Registers

TRNG Alarm Counter Register

The TRNG_ALMCNT register, together with the TRNG_ALMMSK and TRNG_ALMSTP registers, can be used by the host processor to determine if the FRO/sample cycle locking is a problem. Note that incidental alarm events are expected to occur during normal operation. This register also controls the way the monobit test and poker test circuits operate (using the standard 20,000 bit blocks or running continuously).

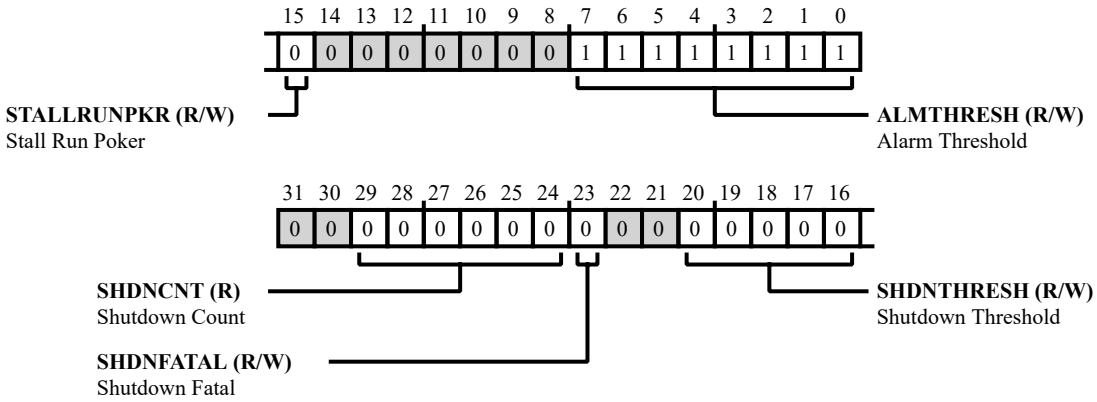

Figure 42-2: TRNG_ALMCNT Register Diagram

Table 42-5: TRNG_ALMCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:24 (R/NW)	SHDNCNT	Shutdown Count. This read-only field indicates the number of 1 bits in the TRNG_ALMSTP register, the number of FRO's that's been turned off.
23 (R/W)	SHDNFATAL	Shutdown Fatal. When the TRNG_ALMCNT.SHDNFATAL bit field is set, the shutdown overflow (SHDNOVR) interrupt is considered a fatal error requiring taking the complete TRNG engine off-line.
20:16 (R/W)	SHDNTHRESH	Shutdown Threshold. The TRNG_ALMCNT.SHDNTHRESH bit field provides the threshold setting for generating the shutdown overflow (SHDNOVR) interrupt, which is activated when the shutdown count (TRNG_ALMCNT.SHDNCNT) value in this register exceeds the threshold value set here.
15 (R/W)	STALLRUNPKR	Stall Run Poker. When the TRNG_ALMCNT.STALLRUNPKR bit is set, stalls the Monobit Test, Run Test and Poker Test circuits when either the TRNG_STAT.MBITFAIL, TRNG_STAT.RUNFAIL or TRNG_STAT.PKRFAIL bits =1. This allows inspection of the state of the result counters (which would otherwise be reset immediately for the next 20,000 bits block to test).

Table 42-5: TRNG_ALMCNT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	ALMTHRESH	Alarm Threshold. The `TRNG_ALMCNT.ALMTHRESH` bit field sets the alarm detection threshold for the repeating pattern detectors on each FRO. A FRO alarm event is declared when a repeating pattern (of up to four samples length) is detected continuously for the number of samples defined by this fields value. Reset value 255 (decimal) should keep the number of alarm events to a manageable level.

TRNG Alarm Mask Register

A set bit (=1) in the TRNG_ALMMSK register signifies an alarm event and is used by the host processor to determine which of the individual FROs generated the alarm. If a bit in this register is set, the corresponding bit in the TRNG_ALMSTP register is set and the FRO is turned off by clearing the corresponding bit in the TRNG_FROEN register. If a bit is not set, the FRO restarts automatically to try to break sample cycle locking that could have caused the alarm event.

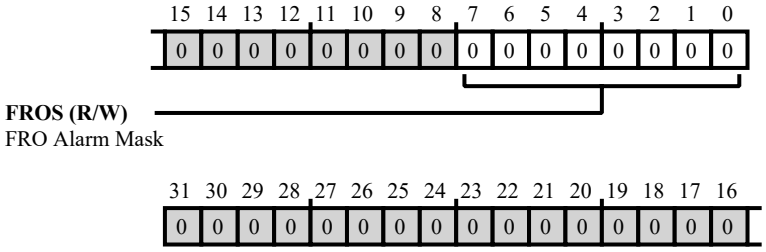

Figure 42-3: TRNG_ALMMSK Register Diagram

Table 42-6: TRNG_ALMMSK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	FROS	FRO Alarm Mask. The TRNG_ALMMSK.FROS bit field provides logging for the alarm events of individual FROs. A 1 in bit [n] indicates FRO n experienced an alarm event.

TRNG Alarm Stop Register

The TRNG_ALMSTP register is used by the host processor to determine which of the individual FROs generated more than one alarm event in quick succession. If a FRO generates an alarm event while a previous event is still logged in the TRNG_ALMMSK register, the corresponding bit in this register is set (=1) and the FRO is turned off by clearing (=0) the corresponding bit in the TRNG_FROEN register. The TRNG_ALMCNT.SHDNCNT bit field keeps track of the number of bits that are set in this register.

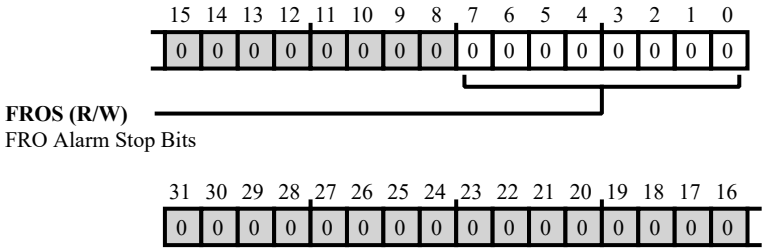

Figure 42-4: TRNG_ALMSTP Register Diagram

Table 42-7: TRNG_ALMSTP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	FROS	FRO Alarm Stop Bits. The TRNG_ALMSTP.FROS bit field provides logging for the alarm events of individual FROs. A 1 in bit [n] indicates FRO n experienced more than one alarm event in quick succession and has been turned off. A 1 in this field forces the corresponding bit in the TRNG_FROEN register to 0.

TRNG Block Count Register

The TRNG_BLKCNT register is the counter for the 128-bit blocks generated by the post-processor. These bits are forced to zero when the post-processor is disabled and are cleared to zero when an internal re-seed operation has finished. This register can be used by driver software to determine when to re-seed the post-processor.

The whole 32 bits of this register represent the amount of data (in bytes) generated since a re-seed. The TRNG_BLKCNT register is only present when a post-processor is available.

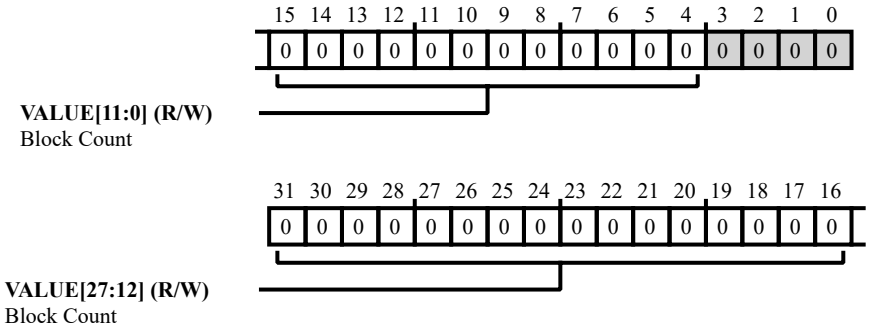

Figure 42-5: TRNG_BLKCNT Register Diagram

Table 42-8: TRNG_BLKCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:4 (R/W)	VALUE	Block Count. The TRNG_BLKCNT.VALUE bit field is the counter for the 128-bit blocks generated by the post-processor. These bits are forced to zero when the post-processor is disabled and are cleared to zero when an internal re-seed operation has finished.

TRNG Configuration Register

The TRNG_CFG register holds the lower and upper limits of the samples taken from the FROs in order to refill the random data buffer. This register also holds the time out value used for secure reading mode.

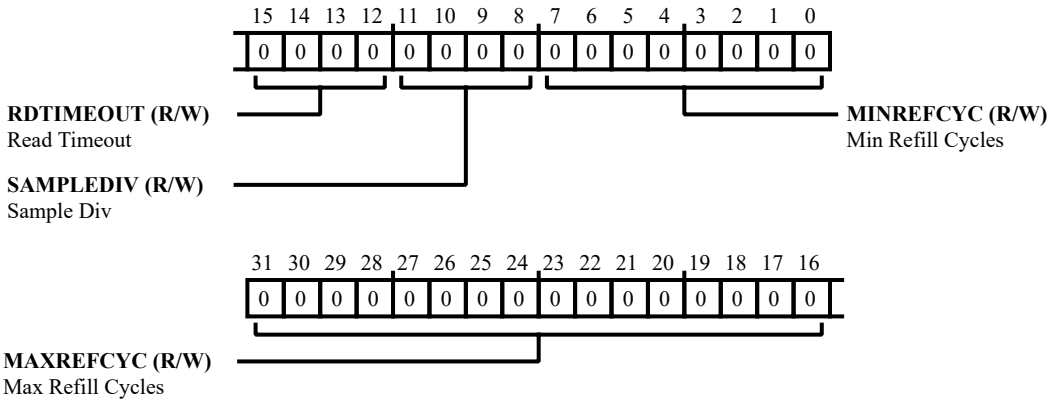

Figure 42-6: TRNG_CFG Register Diagram

Table 42-9: TRNG_CFG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	MAXREFCYC	Max Refill Cycles. The TRNG_CFG.MAXREFCYC bit field determines the maximum number of samples (between 2^8 and 2^{24}) taken to re-generate entropy from the FROs after reading out a 64-bit random number. If the written value of this field is zero, the number of samples is 2^{24}, otherwise the number of samples equals the written value times 2^8. This field can only be modified while the TRNG_CTL.TRNGEN bit =0.
15:12 (R/W)	RDTIMEOUT	Read Timeout. The TRNG_CFG.RDTIMEOUT bit field controls the secure reading mode. When this field is 0, secure reading mode is disabled. Values in the range 1-15 enable secure reading and set a read gate closure timeout of approximately (read_timeout + 1) x 16 clock input cycles. This field can only be modified while the TRNG_CTL.TRNGEN bit =0.

Table 42-9: TRNG_CFG Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
11:8 (R/W)	SAMPLEDIV	Sample Div. The TRNG_CFG.SAMPLEDIV bit field directly controls the number of input cycles between samples taken from the FROs. The default value 0 indicates that samples are taken every cycle, maximum value 15 (decimal) takes one sample every 16 cycles. This field must be set to a value such that the slowest FRO (even under worst-case conditions) has a cycle time less than twice the sample period. The default configuration of the FROs allows this field to remain 0. This field can only be modified while TRNG_CTL.TRNGEN=0. Note: In order to avoid oversampling the FRO, do not to use a TRNG_CFG.SAMPLEDIV value of 0.
7:0 (R/W)	MINREFCYC	Min Refill Cycles. The TRNG_CFG.MINREFCYC bit field determines the minimum number of samples (between 2^6 and 2^{24}) taken to re-generate entropy from the FROs after reading out a 64-bit random number. If the value of this field is zero, the number of samples is fixed to the value determined by the maximum refill cycles (TRNG_CFG.MAXREFCYC) field, otherwise the minimum number of samples equals the written value times 64 (which can be up to 2^{14}). The number of samples defined here cannot be higher than the number defined by the TRNG_CFG.MAXREFCYC field (i.e. that field takes precedence). This field can only be modified while the TRNG_CTL.TRNGEN bit =0.

Counter Register

The TRNG_CNT register is used to access the main control Finite State Machine's (FSM) sample counter while the TRNG_CTL.TSTMODE bit =1.

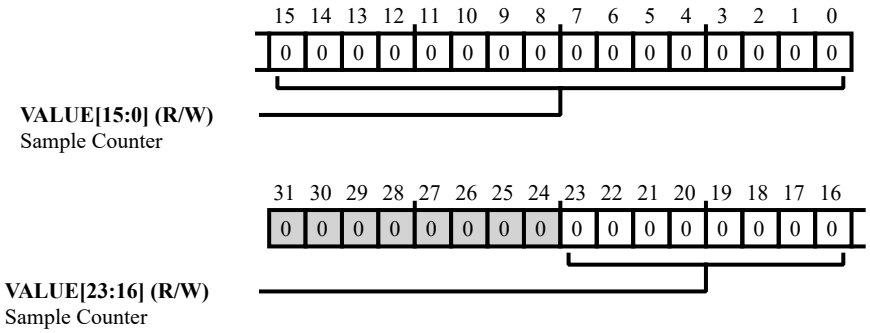

Figure 42-7: TRNG_CNT Register Diagram

Table 42-10: TRNG_CNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:0 (R/W)	VALUE	Sample Counter. The TRNG_CNT.VALUE bit field is the sample counter used by control finite state machine. This counter can only be accessed when the TRNG_CTL.TSTMODE bit =1.

TRNG Control Register

The TRNG_CTL register must be written to start accumulating entropy before random numbers can be generated. In most cases, the TRNG_CFG register must also be written prior to writing the TRNG_CTL register. To enable the TRNG, set the TRNG_CTL.TRNGEN bit. This register also controls post-processing (if available). Note that when the TRNG_CTL.TRNGEN bit =1, the start up cycles field (TRNG_CTL.STARTUPCYC) and the post-processing enable bit (if available) are locked. Any writes to these fields are ignored.

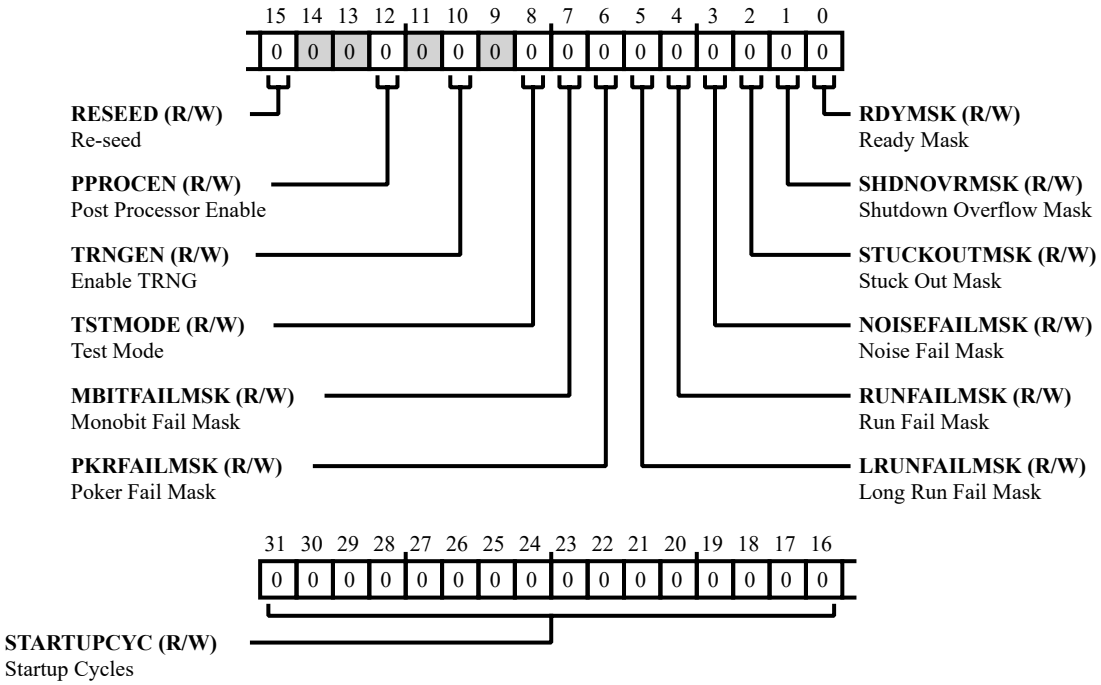

Figure 42-8: TRNG_CTL Register Diagram

Table 42-11: TRNG_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	STARTUPCYC	Startup Cycles. The TRNG_CTL.STARTUPCYC bit field determines the number of samples (between 2^8 and 2^{24}) taken to gather entropy from the FROs during startup. If the written value of this field is zero, the number of samples is 2^{24}, otherwise the number of samples equals the written value times 2^8 . This field can only be written when TRNG_CTL.TRNGEN=0 before the write.

Table 42-11: TRNG_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15 (R/W)	RESEED	Re-seed. The TRNG_CTL.RESEED bit is set-only, writing a 1 starts a re-seed cycle and writing a 0 has no effect. A re-seed cycle entails loading the TRNG_KEY[n] and TRNG_V[n] registers with random values generated internally; these values are not visible outside the TRNG core. This bit falls back to 0 automatically after the re-seed operation is complete; at that time the TRNG_BLKCNT register is reset to zero and the random data buffer is zeroized so that any new data read from the TRNG will use the new seed values. This bit is only present when post-processing is available and can only be set to 1 when TRNG_CTL.TRNGEN=1 before the write. Note that re-seeding can be done with the post-processor disabled (normally used to seed the post-processor before enabling it). When writing a 1 to this bit, all other bits in this register remain unchanged.
12 (R/W)	PPROCEN	Post Processor Enable. Setting the TRNG_CTL.PPROCEN bit enables the FIPS post-processor. If this bit is reset to 0, the post-processor is forced back into the idle state immediately. This bit is only present when post-processing is available and can only be changed when the TRNG_CTL.TRNGEN bit (enable TRNG) was 0 before the write. To change the TRNG_CTL.PPROCEN bit during operation, first put the TRNG into reset (TRNG_CTL.TRNGEN =0). If the post-processor is enabled, it can be disabled by a subsequent write of 0 to this bit (writing this bit when the TRNG_CTL.TRNGEN bit is still 1 has no effect). The post-processor then stops immediately. To enable it, this bit bit must be written with 1. Changing the enabled/disabled state does not affect the contents of the TRNG_KEY[n] and TRNG_V[n] registers. After changing the state, the TRNG must be started again by setting the TRNG_CTL.TRNGEN bit to 1. Note that it is required to re-gather entropy, so the same number of start-up cycles must be used as when starting the TRNG out of a system reset state.
10 (R/W)	TRNGEN	Enable TRNG. Setting the TRNG_CTL.TRNGEN bit to 1 starts the TRNG, gathering entropy from the FROs for the number of samples determined by the value in the TRNG_CTL.STARTUPCYC (Startup Cycles) field. Resetting this bit to 0 forces all TRNG logic back into the idle state immediately. Resetting this bit to 0 also performs the Un-instantiate operation, clearing all internal post-processor registers.
8 (R/W)	TSTMODE	Test Mode. When the TRNG_CTL.TSTMODE bit is set, access is enabled to the TRNG_CNT and TRNG_LFSR_L, TRNG_LFSR_M and TRNG_LFSR_H registers (the latter are cleared before enabling access) and sets the TRNG_STAT.NEEDCLK bit for testing purposes. This bit must be set to 1 before various test modes in the TRNG_TEST register can be enabled.

Table 42-11: TRNG_CTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
7 (R/W)	MBITFAILMSK	Monobit Fail Mask. When the TRNG_CTL.MBITFAILMSK bit is set, this mask allows the TRNG_STAT.MBITFAIL bit to activate the (active HIGH) interrupt output.
6 (R/W)	PKRFAILMSK	Poker Fail Mask. When the TRNG_CTL.PKRFAILMSK bit is set, this mask allows the TRNG_STAT.PKRFAIL bit to activate the (active HIGH) interrupt output.
5 (R/W)	LRUNFAILMSK	Long Run Fail Mask. When the TRNG_CTL.LRUNFAILMSK bit is set, this mask allows the TRNG_STAT.LRUNFAIL bit to activate the (active HIGH) interrupt output.
4 (R/W)	RUNFAILMSK	Run Fail Mask. When the TRNG_CTL.RUNFAILMSK bit is set, this mask allows the TRNG_STAT.RUNFAIL bit to activate the (active HIGH) interrupt output.
3 (R/W)	NOISEFAILMSK	Noise Fail Mask. When the TRNG_CTL.NOISEFAILMSK bit is set, this mask allows the TRNG_STAT.NOISEFAIL bit to activate the (active HIGH) interrupt output.
2 (R/W)	STUCKOUTMSK	Stuck Out Mask. When the TRNG_CTL.STUCKOUTMSK bit is set, this mask allows the TRNG_STAT.STUCKOUT bit to activate the (active HIGH) interrupt output.
1 (R/W)	SHDNOVRMSK	Shutdown Overflow Mask. When the TRNG_CTL.SHDNOVRMSK bit is set, this mask allows the TRNG_STAT.SHDNOVR bit to activate the (active HIGH) interrupt output.
0 (R/W)	RDYMSK	Ready Mask. When the TRNG_CTL.RDYMSK bit is set, this mask allows the TRNG_STAT.RDY bit to activate the (active HIGH) interrupt output.

TRNG FRO De-tune Register

The TRNG_FRODETUNE register is used by the host processor to change the frequencies of individual FROs. This can reduce the number of alarm events generated by a specific FRO.

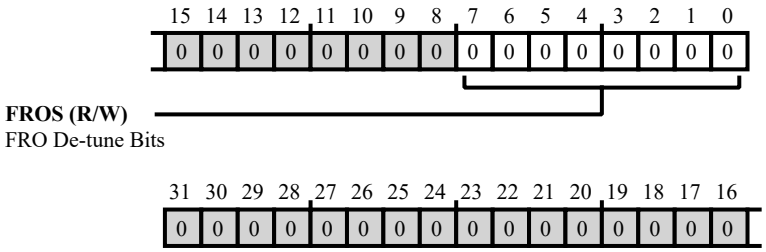

Figure 42-9: TRNG_FRODETUNE Register Diagram

Table 42-12: TRNG_FRODETUNE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	FROS	FRO De-tune Bits. The TRNG_FRODETUNE.FROS bits De-tune the FROs. A 1 in bit [n] lets FRO n run approximately 5% faster. The value of one of these bits may only be changed while the corresponding FRO is turned off (by temporarily writing a 0 in the corresponding bit of the TRNG_FROEN register).

TRNG FRO Enable Register

The TRNG_FROEN register can be used by the host processor to enable and disable FROs individually. Only enabled FROs contribute to entropy generation, but require power to do so. Disabled FROs cannot generate alarm events.

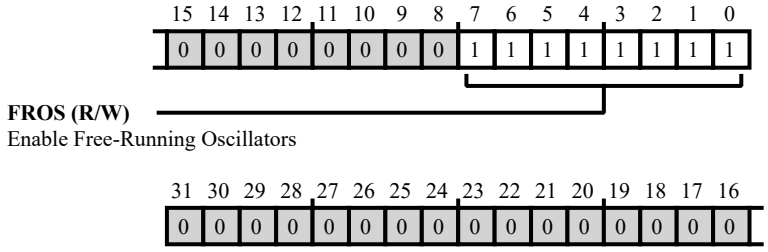

Figure 42-10: TRNG_FROEN Register Diagram

Table 42-13: TRNG_FROEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	FROS	Enable Free-Running Oscillators. The TRNG_FROEN.FROS bits are the enables for the individual FROs. A 1 in bit [n] enables FRO n. The default state is all ones to enable all FROs after power-up. Note that the FROs are not actually started up before the TRNG_CTL.TRNGEN bit is set to 1. These bits are automatically forced to 0 (and cannot be written to 1) when the corresponding bit in the TRNG_ALMSTP register has value 1.

TRNG Input Registers

The TRNG_INPUT[n] registers are used as input for post-processor testing (if post processing is available) and as input for Monobit Test, Run Test and Poker Test functionality tests (TRNG_INPUT0 only). They share their addresses with the corresponding TRNG_OUTPUT[n] registers. The least significant word is contained in the TRNG_INPUT0 register.

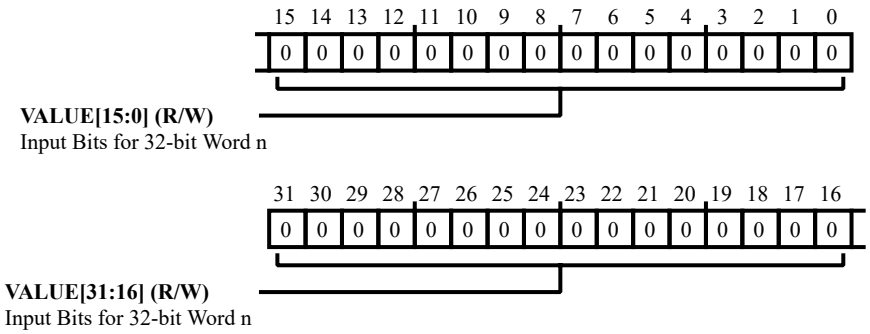

Figure 42-11: TRNG_INPUT[n] Register Diagram

Table 42-14: TRNG_INPUT[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Input Bits for 32-bit Word n. The TRNG_INPUT[n].VALUE bit field is used to hold 32-bits of the 64-bit word of test data for 3-DES post-processor (if available). Or, the TRNG_INPUT[n].VALUE bit field is used to hold 32-bit data word for Run Test and Poker Test circuits self test. Can only be written to when the TRNG_STAT.TSTRDY bit =1.

TRNG Interrupt Acknowledge Register

The TRNG_INTACK register is written to acknowledge interrupts indicated in bits [7:0] of the TRNG_STAT register. Writing a 1 to any of the bits [7:2] has side effects in resetting various parts of the TRNG core logic which can also be used even if no interrupts are actually active.

When acknowledging the interrupts, these bits are write '1' to clear the associated bit in TRNG_STAT register. The bit in this register will also automatically be reset to zero.

When secure reading mode is enabled, write bits [7:0] of this register with zeros to enable TRNG data reads from the TRNG_OUTPUT[n] registers. Writing bits [7:0] also starts the (configurable) timeout counter that automatically acknowledges the TRNG data (and disables reads) if the TRNG_INTACK.RDY bit is not written with a 1 within that timeout period.

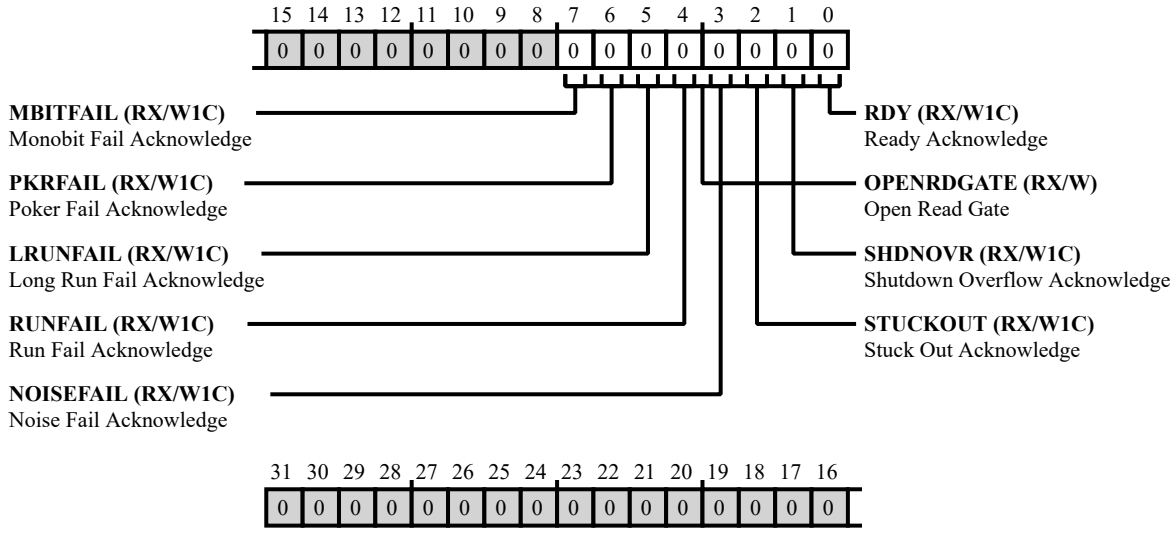

Figure 42-12: TRNG_INTACK Register Diagram

Table 42-15: TRNG_INTACK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7 (RX/W1C)	MBITFAIL	Monobit Fail Acknowledge. Set the TRNG_INTACK.MBITFAIL bit to acknowledge the Monobit Fail Interrupt. This also resets all counter and state bits in the TRNG_RUN[n], TRNG_MONOBITCNT and the TRNG_POKER[n] registers (except for the TRNG_RUNCNT.LENMAX field).
6 (RX/W1C)	PKRFAIL	Poker Fail Acknowledge. Set the TRNG_INTACK.PKRFAIL bit to acknowledge the Poker Fail Interrupt. This also resets all counter and state bits in the TRNG_RUN[n], TRNG_MONOBITCNT and the TRNG_POKER[n] registers (except for the TRNG_RUNCNT.LENMAX field).

Table 42-15: TRNG_INTACK Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
5 (RX/W1C)	LRUNFAIL	Long Run Fail Acknowledge. Set the TRNG_INTACK.LRUNFAIL bit to acknowledge the Long Run Fail Interrupt. Also clears the TRNG_RUNCNT.LENMAX field.
4 (RX/W1C)	RUNFAIL	Run Fail Acknowledge. Set the TRNG_INTACK.RUNFAIL bit to acknowledge the Run Fail Interrupt. Also resets all counter and state bits in the TRNG_RUN[n], TRNG_MONOBITCNT and the TRNG_POKER[n] registers (except for the TRNG_RUNCNT.LENMAX field).
3 (RX/W1C)	NOISEFAIL	Noise Fail Acknowledge. Set the TRNG_INTACK.NOISEFAIL bit to acknowledge the Noise Fail Interrupt. Setting this bit also clears the TRNG_RUNCNT.LENMAX (Run Length Max) field, the random data buffer, the TRNG_OUTPUT[n] registers and the TRNG_STAT.RDY bit.
2 (RX/W1C)	STUCKOUT	Stuck Out Acknowledge. Set the TRNG_INTACK.STUCKOUT bit to acknowledge the Stuck Out Interrupt. Setting this bit also clears the random data buffer, the TRNG_OUTPUT[n] registers and the TRNG_STAT.RDY bit.
1 (RX/W1C)	SHDNOVR	Shutdown Overflow Acknowledge. Set the TRNG_INTACK.SHDNOVR bit to acknowledge the Shutdown Overflow Interrupt.
0 (RX/W1C)	RDY	Ready Acknowledge. The TRNG_INTACK.RDY bit allows a new number (if it is ready in the random data buffer), to directly move into the result register. Once done, the TRNG_STAT.RDY bit is reset, after at most size clock cycles.
7:0 (RX/W)	OPENRDGATE	Open Read Gate. In Secure Reading Mode, the TRNG_INTACK.OPENRDGATE bit writes an all zeros value to bits [7:0] to enable reading of TRNG data from the TRNG_OUTPUT[n] registers. This starts the timeout counter that automatically acknowledges the TRNG data (and disables reading) if the TRNG_INTACK.RDY bit is not written with a 1 within that timeout period.

Post-Process Key Registers

The TRNG_KEY[n] registers are used to load the key used for post-processing (if available). These registers are write-only. Reads return the values of the other registers mapped at the same addresses.

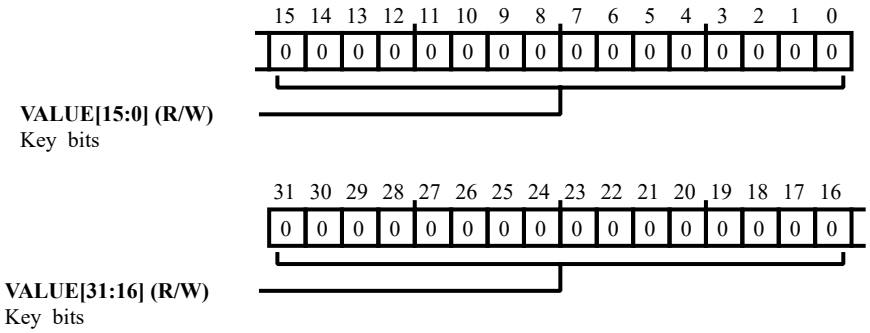

Figure 42-13: TRNG_KEY[n] Register Diagram

Table 42-16: TRNG_KEY[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Key bits. Bits for cipher key used in the post-processor.

TRNG LFSR Access Register

The TRNG_LFSR_H register is used to access bits [80:64] of the main entropy accumulation LFSR while in test mode (TRNG_CTL.TSTMODE =1).

For security reasons, the LFSR contents are zeroed before enabling access.

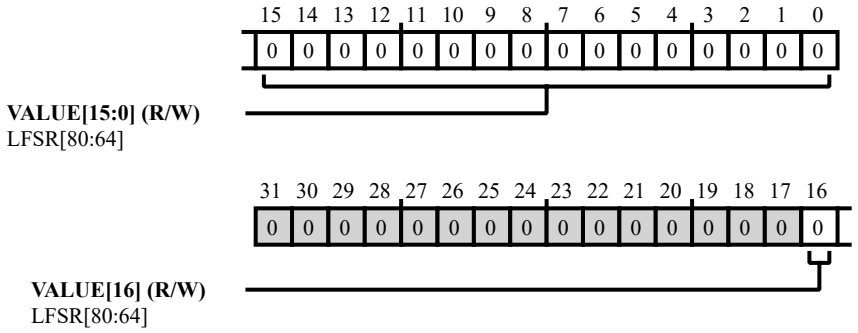

Figure 42-14: TRNG_LFSR_H Register Diagram

Table 42-17: TRNG_LFSR_H Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
16:0 (R/W)	VALUE	LFSR[80:64]. The TRNG_LFSR_H.VALUE bit field contains bits [80:64] of the main entropy accumulation LFSR. This field can only be accessed when the TRNG_CTL.TSTMODE bit =1. Contents are cleared (=0) before access is enabled.

TRNG LFSR Access Register

The TRNG_LFSR_L register is used to access bits [31:0] of the main entropy accumulation LFSR while in test mode (TRNG_CTL.TSTMODE =1).

For security reasons, the LFSR contents are zeroed before enabling access.

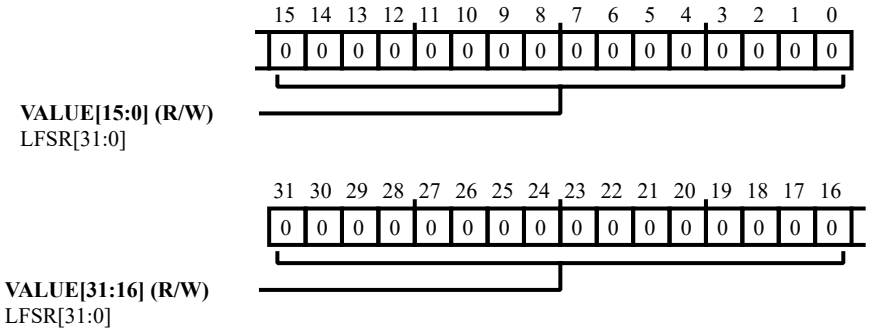

Figure 42-15: TRNG_LFSR_L Register Diagram

Table 42-18: TRNG_LFSR_L Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	LFSR[31:0]. The TRNG_LFSR_L.VALUE bit field contains bits [31:0] of the main entropy accumulation LFSR. This field can only be accessed when the TRNG_CTL.TSTMODE bit =1. Contents are cleared (=0) before access is enabled.

TRNG LFSR Access Register

The TRNG_LFSR_M register is used to access bits [63:32] of the main entropy accumulation LFSR while in test mode (TRNG_CTL.TSTMODE =1).

For security reasons, the LFSR contents are zeroed before enabling access.

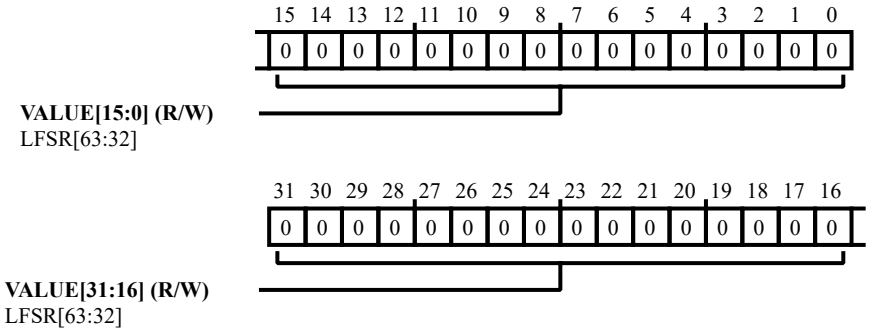

Figure 42-16: TRNG_LFSR_M Register Diagram

Table 42-19: TRNG_LFSR_M Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	LFSR[63:32]. The TRNG_LFSR_M.VALUE bit field contains bits [63:32] of the main entropy accumulation LFSR. This field can only be accessed when the TRNG_CTL.TSTMODE bit =1. Contents are cleared (=0) before access is enabled.

TRNG Monobit Test Result Register

The TRNG_MONOBITCNT register accesses the counter used perform a Monobit Test as specified by the AIS-31 standard (test T1, ref 4). This test is performed on blocks of 20,000 bits (in parallel to the run test and Poker Test).

Note: Immediately after performing the actual Monobit Test at the end of the 20,000 bits block, the counter is used to accumulate the Poker Test results. As a result, the actual Monobit Test count result value can only be read in the TRNG_MONOBITCNT register if the test fails and the stall run Poker (TRNG_ALMCNT.STALLRUNPKR) bit =1.

The monobit test result register is read-only; writing it accesses the registers mapped at the same address. The counter in this register is reset when writing a 1 to either the monobit fail acknowledge (TRNG_INTACK.MBITFAIL), run fail acknowledge (TRNG_INTACK.RUNFAIL) or the poker fail acknowledge (TRNG_INTACK.PKRFAIL) bits.

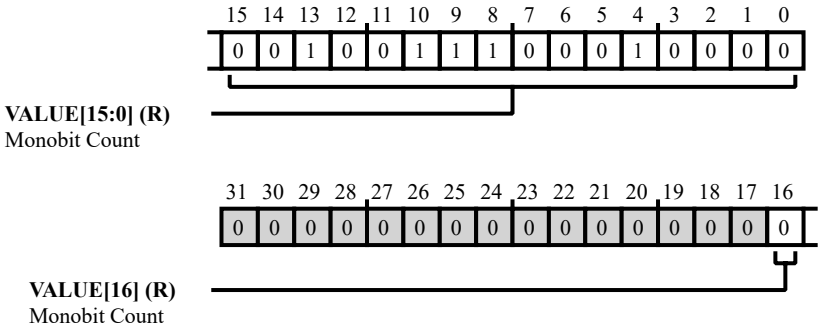

Figure 42-17: TRNG_MONOBITCNT Register Diagram

Table 42-20: TRNG_MONOBITCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
16:0 (R/NW)	VALUE	Monobit Count. The TRNG_MONOBITCNT.VALUE bit field is the up/down counter which monitors 1 and 0 bits. After 20,000 bits, this counter should have a value in the range 9310 through 10690 (inclusive) to pass the Monobit Test. This counter is protected against overflow and underflow.

TRNG Output Registers

The TRNG_OUTPUT[n] registers provide read access to the 128-bit random number output. A subset of these registers are also used as output for post-processor testing (if available). They share their addresses with the TRNG_INPUT0 through TRNG_INPUT3 registers. The least significant word is contained in the TRNG_OUTPUT0 register.

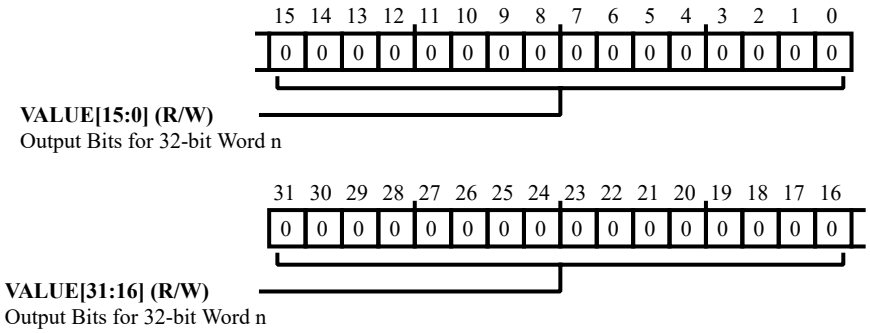

Figure 42-18: TRNG_OUTPUT[n] Register Diagram

Table 42-21: TRNG_OUTPUT[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Output Bits for 32-bit Word n. The TRNG_OUTPUT[n].VALUE bit field is used to holds 32 bits of the 128-bit word of random data. Only valid when the TRNG_STAT.RDY bit =1. Alternatively, this register holds the 32-bits of the 42-bit word of result data for 3-DES post-processing testing. Only valid when the TRNG_STAT.TSTRDY bit =1.

TRNG Poker Test Result Registers

The TRNG_POKER[n] registers are used to access the 16 counters used perform a poker test on blocks of 20,000 bits (in parallel to the monobit and run tests).

Poker test result registers are read-only; writing them accesses the registers mapped at these same addresses. All counters in these registers are reset when writing a 1 to either the monobit fail acknowledge (TRNG_INTACK.MBITFAIL), run fail acknowledge (TRNG_INTACK.RUNFAIL) or the poker fail acknowledge (TRNG_INTACK.PKRFAIL) bits.

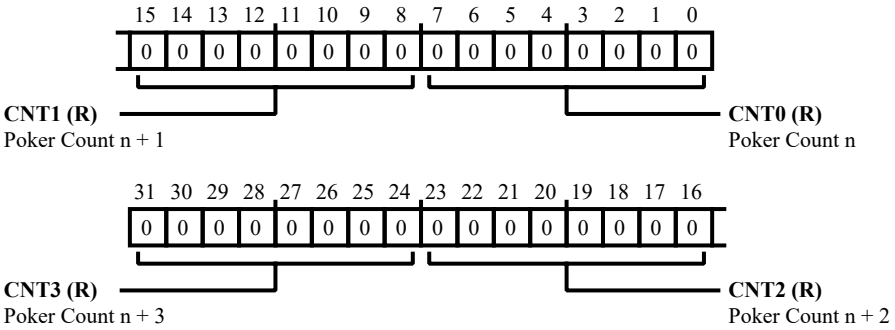

Figure 42-19: TRNG_POKER[n] Register Diagram

Table 42-22: TRNG_POKER[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/NW)	CNT3	Poker Count n + 3. The TRNG_POKER[n].CNT3 bit field provides the counter for 4-bit value 0x3, 0x7, 0xB, 0xF in TRNG_POKER0, TRNG_POKER1, TRNG_POKER2, TRNG_POKER3, respectively.
23:16 (R/NW)	CNT2	Poker Count n + 2. The TRNG_POKER[n].CNT2 bit field provides the counter for 4-bit value 0x2, 0x6, 0xA, 0xE in TRNG_POKER0, TRNG_POKER1, TRNG_POKER2, TRNG_POKER3, respectively.
15:8 (R/NW)	CNT1	Poker Count n + 1. The TRNG_POKER[n].CNT1 bit field provides the counter for 4-bit value 0x1, 0x5, 0x9, 0xD in TRNG_POKER0, TRNG_POKER1, TRNG_POKER2, TRNG_POKER3, respectively.
7:0 (R/NW)	CNT0	Poker Count n. The TRNG_POKER[n].CNT0 bit field provides the counter for 4-bit value 0x0, 0x4, 0x8, 0xC in the TRNG_POKER0, TRNG_POKER1, TRNG_POKER2, TRNG_POKER3, respectively.

TRNG Run Count Registers

The TRNG_RUNCNT registers are used to access the 10 counters that perform a run test and long run test as specified by the AIS-31 standard (tests T3 and T4, ref 4). They are also used to perform the noise source failure test proposed in section E.5 of that same standard.

The TRNG_RUNCNT registers are read-only; writing them accesses the other registers which are mapped at the same addresses. Unless otherwise indicated, all counters and state bits in these registers are reset when writing a 1 to either the Monobit Fail acknowledge (TRNG_INTACK.MBITFAIL), Run Fail acknowledge (TRNG_INTACK.RUNFAIL) or the Poker Fail acknowledge (TRNG_INTACK.PKRFAIL) bits.

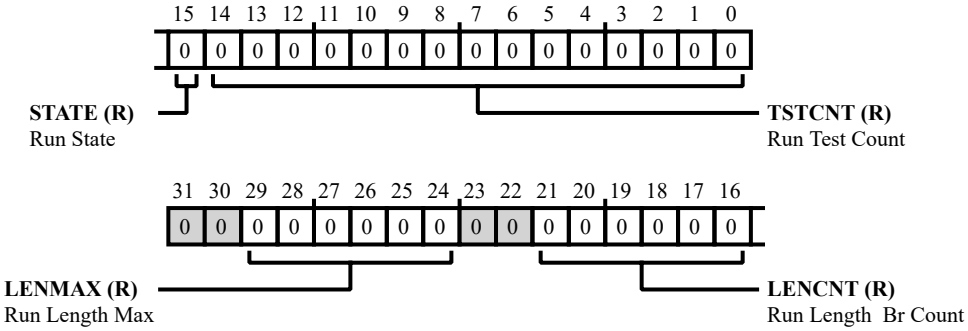

Figure 42-20: TRNG_RUNCNT Register Diagram

Table 42-23: TRNG_RUNCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:24 (R/NW)	LENMAX	Run Length Max. The TRNG_RUNCNT.LENMAX bit field configures the maximum run length count value encountered since start of test. This value is reset back to zero when writing a 1 to either the Noise Fail acknowledge (TRNG_INTACK.NOISEFAIL) or the Long Run Fail acknowledge (TRNG_INTACK.LRUNFAIL) bits.
21:16 (R/NW)	LENCNT	Run Length Br Count. The TRNG_RUNCNT.LENCNT bit field configures the counter for the current run of consecutive 0/1 bits; cannot increment past its maximum value of 63.
15 (R/NW)	STATE	Run State. The TRNG_RUNCNT.STATE bit field provides th state of bits in the current run.
14:0 (R/NW)	TSTCNT	Run Test Count. The TRNG_RUNCNT.TSTCNT bit field configures the block length counter for the run and poker tests - counts up for 20,000 tested bits and then controls testing of the run_X_count_... and poker_count_X counters to contain expected values, after which they - and this counter - are reset for the next block.

TRNG Run Test State and Result Registers

The TRNG_RUN[n] registers holds the counts for the associated run bucket for 1's and 0's.

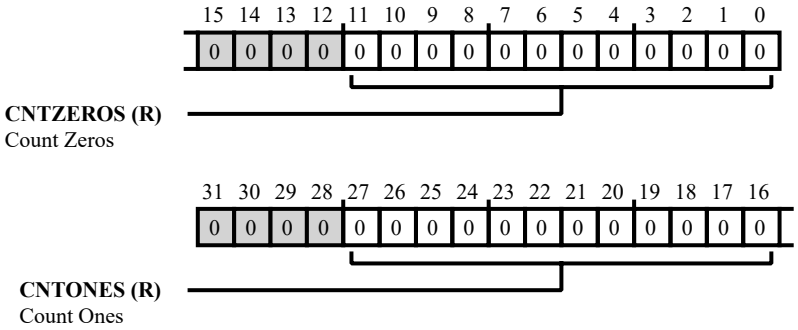

Figure 42-21: TRNG_RUN[n] Register Diagram

Table 42-24: TRNG_RUN[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
27:16 (R/NW)	CNTONES	Count Ones. In TRNG_RUN1, this counter is for single bit runs of value one bits. After 20,000 bits, this counter should have a value in the range 2267 to 2733 (inclusive) to pass the run test. This counter cannot increment past its maximum value of 4095. In TRNG_RUN2, this counter is for two bit runs of value one bits. After 20,000 bits, this counter should have a value in the range 1079 to 1421 (inclusive) to pass the run test. This counter cannot increment past its maximum value of 2047. In TRNG_RUN3, this counter is for three bit runs of value one bits. After 20,000 bits, this counter should have a value in the range 502 to 748 (inclusive) to pass the run test. This counter cannot increment past its maximum value of 1023. In TRNG_RUN4, this counter for four bit runs of value one bits. After 20,000 bits, this counter should have a value in the range 233 to 402 (inclusive) to pass the run test. This counter cannot increment past its maximum value of 511. In TRNG_RUN5, this counter is for five bit runs of value one bits. After 20,000 bits, this counter should have a value in the range 90 to 223 (inclusive) to pass the run test. This counter cannot increment past its maximum value of 255. In TRNG_RUN6, this counter for six and higher bit runs of value one bits. After 20,000 bits, this counter should have a value in the range 90 to 233 (inclusive) to pass the run test. This counter cannot increment past its maximum value of 255.

Table 42-24: TRNG_RUN[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
11:0 (R/NW)	CNTZEROS	Count Zeros. In TRNG_RUN1, this counter is for single bit runs of value zero bits. After 20,000 bits, this counter should have a value in the range 2267 to 2733 (inclusive) to pass the run test. This counter cannot increment past its maximum value of 4095. In TRNG_RUN2, this counter is for two bit runs of value zero bits. After 20,000 bits, this counter should have a value in the range 1079 to 1421 (inclusive) to pass the run test. This counter cannot increment past its maximum value of 2047. In TRNG_RUN3, this counter is for three bit runs of value zero bits. After 20,000 bits, this counter should have a value in the range 502 to 748 (inclusive) to pass the run test. This counter cannot increment past its maximum value of 1023. In TRNG_RUN4, this counter is for four bit runs of value zero bits. After 20,000 bits, this counter should have a value in the range 233 to 402 (inclusive) to pass the run test. This counter cannot increment past its maximum value of 511. In TRNG_RUN5, this counter is for five bit runs of value zero bits. After 20,000 bits, this counter should have a value in the range 90 to 223 (inclusive) to pass the run test. This counter cannot increment past its maximum value of 255. In TRNG_RUN6, this counter is for six and higher bit runs of value zero bits. After 20,000 bits, this counter should have a value in the range 90 to 233 (inclusive) to pass the run test. This counter cannot increment past its maximum value of 255.

TRNG Status Register

The TRNG_STAT register provides status results. This register shares the same address as the Interrupt Acknowledge (TRNG_INTACK) register.

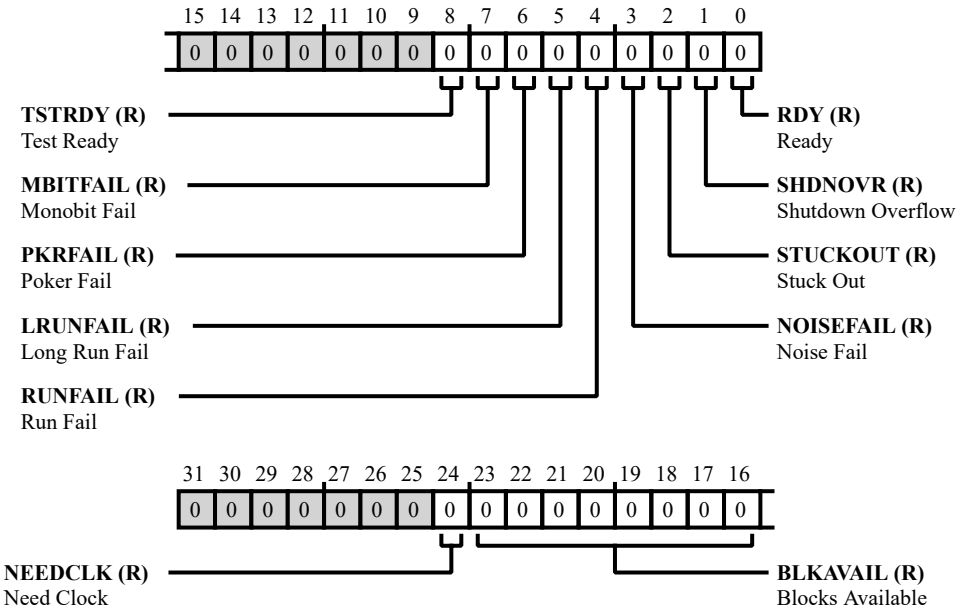

Figure 42-22: TRNG_STAT Register Diagram

Table 42-25: TRNG_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
24 (R/NW)	NEEDCLK	Need Clock. When the TRNG_STAT.NEEDCLK bit is set, it indicates that the TRNG is busy generating entropy or is in one of its test modes; the module clock may not be turned off.
23:16 (R/NW)	BLKAVAIL	Blocks Available. This field indicates the number of 128-bit blocks of random data that are available in the random data buffer. If this value is non-zero, the output registers will be refilled from the random data buffer immediately after acknowledging the TRNG_STAT.RDY by writing a 1 to TRNG_INTACK.RDY.
8 (R/NW)	TSTRDY	Test Ready. When the TRNG_STAT.TSTRDY bit is set, it indicates that data for known-answer tests on the monobit test, run test, poker test and post-processor functions can be written to the TRNG_INPUT[n] registers. When testing the post-processor, result data can be read from those same registers when this bit has become 1 again (after dropping to 0).

Table 42-25: TRNG_STAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
7 (R/NW)	MBITFAIL	Monobit Fail. When the TRNG_STAT.MBITFAIL bit is set, the monobit test logic monitoring data, shifted into the main LFSR, detected an out-of-bounds number of 1s after checking 20,000 bits (test T1 as specified in the AIS-31 standard).
6 (R/NW)	PKRFAIL	Poker Fail. When the TRNG_STAT.PKRFAIL bit is set, the poker test logic monitoring data shifted into the main LFSR detected an out-of-bounds value in at least one of the 16 poker counters or an out of bounds "sum of squares" value after checking 20,000 bits (test T2 as specified in the AIS-31 standard).
5 (R/NW)	LRUNFAIL	Long Run Fail. When the TRNG_STAT.LRUNFAIL bit is set, the run test logic monitoring data shifted into the main LFSR detected a sequence of 34 identical bits (test T4 as specified in the AIS-31 standard).
4 (R/NW)	RUNFAIL	Run Fail. When the TRNG_STAT.RUNFAIL bit is set, the run test logic monitoring data shifted into the main LFSR detected an out-of-bounds value for at least one of the TRNG_RUN[n].CNTZEROS or TRNG_RUN[n].CNTONES counters after checking 20,000 bits (test T3 as specified in the AIS-31 standard).
3 (R/NW)	NOISEFAIL	Noise Fail. When the TRNG_STAT.NOISEFAIL bit is set, the Run Test logic monitoring data shifted into the main LFSR detected a sequence of 48 identical bits, which is considered a noise source failure as proposed in section E.5 of the AIS-31 standard.
2 (R/NW)	STUCKOUT	Stuck Out. When the TRNG_STAT.STUCKOUT bit is set, the logic around the output data registers detected that the TRNG generates the same value twice in a row.
1 (R/NW)	SHDNOVR	Shutdown Overflow. When the TRNG_STAT.SHDNOVR bit is set, the number of FROs shut down after a second error event (the number of 1 bits in the TRNG_ALMSTP register) has exceeded the threshold set by the TRNG_ALMCNT.SHDNTHRESH bit field.
0 (R/NW)	RDY	Ready. When the TRNG_STAT.RDY bit is set, data is available in the TRNG_OUTPUT0 to TRNG_OUTPUT3 registers. If a new number is already available in the random data buffer, that number is directly moved into the result register. In this case the ready status bit is asserted again, after at most six module clock cycles.

TRNG Test Register

The TRNG_TEST register can be used by the host processor to perform a number of tests on the TRNG logic including:

- Register controlled characterization by connecting the tst_fro_clk_out output to a selected FRO clock output
- FRO logic connectivity and error event detection checking by feeding known patterns through the FRO delay line and error event detection circuits
- Direct XOR-ed FRO outputs capture by disabling the main LFSR feedback logic
- Extend the Monobit Test and Poker Test by not resetting the Monobit count and Poker Test X counters after each 20,000 bits block
- Perform known answer tests on the Run Test, Poker Test and post-processor functions.

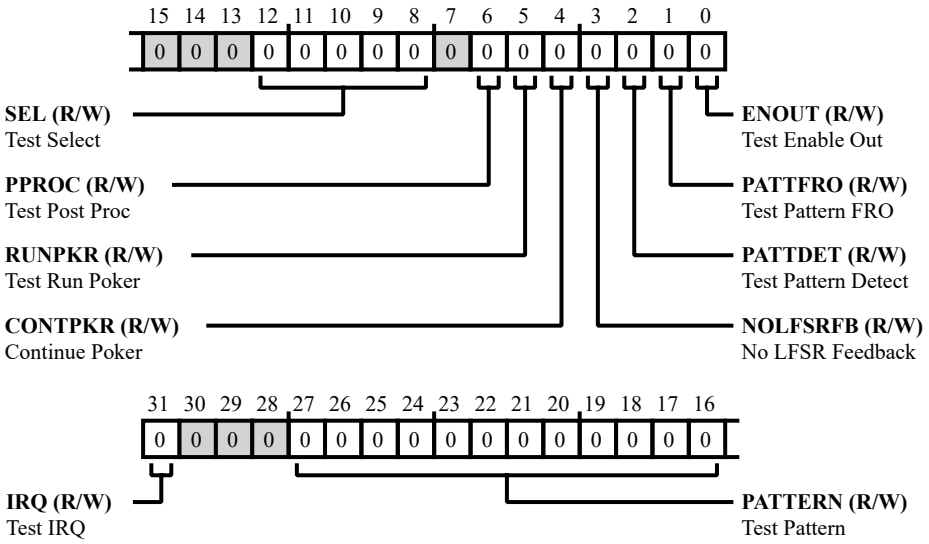

Figure 42-23: TRNG_TEST Register Diagram

Table 42-26: TRNG_TEST Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	IRQ	Test IRQ. When the TRNG_TEST.IRQ bit is set force irq output HIGH for interrupt signal connectivity testing.	
		0	Do not force IRQ high
		1	Force IRQ output high

Table 42-26: TRNG_TEST Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
27:16 (R/W)	PATTERN	Test Pattern. The TRNG_TEST.PATTERN bit field sets up a repeating sequence of bits to be fed into the selected FRO delay chain TRNG_TEST.PATTFRO =1 and/or the selected FRO error detection circuit TRNG_TEST.PATTDET =1. This field is rotated right over one bit, once every sample period, when either of these control bits is 1. Therefore, bit [16] is the actual pattern bit fed into the test target.	
12:8 (R/W)	SEL	Test Select. The TRNG_TEST.SEL bit field configures the number of the FRO to be tested, the value should be in the range of 0 to 7.	
6 (R/W)	PPROC	Test Post Proc. When the TRNG_TEST.PPROC bit is set, it provides direct access to the post-processor for known-answer tests (writing input data to the TRNG_INPUT[n] registers). While this bit is set, the TRNG can continue to generate entropy in the main LFSR and any buffered random data is preserved, to be loaded into the output registers as soon as this bit is reset to 0 again. The need clock output is forced active while this bit is set. For X9.31 post-processors, it is advisable to re-seed the post-processor after running known-answer tests as the original key and V values are modified to known values. This bit is only present when post-processing is available and can only be set to 1 when the TRNG_CTL.PPROCEN bit =1 and the test run poker (TRNG_TEST.RUNPKR) bit in this register is 0.	
5 (R/W)	RUNPKR	Test Run Poker. When the TRNG_TEST.RUNPKR bit is set, it provides direct access to the inputs of the Monobit, Run and Poker Test circuits (writing input data in chunks of 32 bits to the TRNG_INPUT0 register). While this bit is 1, the TRNG is not allowed to generate entropy but any buffered random data is preserved, to be loaded into the output registers as soon as this bit is reset to 0 again. The TRNG_STAT.NEEDCLK bit is forced active while this bit is 1. The Monobit, Run and Poker Test circuits are reset to their initial states on any change of this bit.	
4 (R/W)	CONTPKR	Continue Poker. When the TRNG_TEST.CONTPKR bit is set, Monobit Test and Poker Test keep running continuously by not resetting the Monobit count (TRNG_MONOBITCNT) and poker counters (TRNG_POKER[n] register) at the end of each 20,000 bits test block. This bit can only be set to 1 when TRNG_CTL.TSTMODE =1.	
		0	Do not continue poker test
		1	Continue poker test

Table 42-26: TRNG_TEST Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3 (R/W)	NOLFSRFB	No LFSR Feedback. When the TRNG_TEST.NOLFSRFB bit is set, it removes XNOR feedback from the main LFSR, converting it into a normal shift register for the XOR-ed outputs of the FROs (shifting data in on the LSB side). A 1 also forces the LFSR to sample continuously. This bit can only be set to 1 when TRNG_CTL.TSTMODE =1.	
		0	Keep XNOR feedback
		1	Remove XNOR feedback
2 (R/W)	PATTDET	Test Pattern Detect. When the TRNG_TEST.PATTDET bit is set, it repeatedly feeds test pattern (PATTERN) into the error detection circuit of the FRO selected by the test select (TRNG_TEST.SEL) field. This bit can only be set to 1 when TRNG_CTL.TSTMODE =1.	
		0	Do not repeat feed test pattern
		1	Repeat feed test pattern
1 (R/W)	PATTFRO	Test Pattern FRO. When the TRNG_TEST.PATTFRO bit is set, it repeatedly feeds test pattern (PATTERN) into the delay chain of the FRO selected by the test select (TRNG_TEST.SEL) field by forcing the corresponding FRO enable (FROEN) output LOW. This bit can only be set to 1 when TRNG_CTL.TSTMODE =1.	
		0	Do not repeat feed test pattern
		1	Repeat feed test pattern
0 (R/W)	ENOUT	Test Enable Out. When the TRNG_TEST.ENOUT bit is set, it enables the tst_fro_clk_out output, connecting to the FRO selected by the test select (TRNG_TEST.SEL) field. This bit can only be set to 1 when TRNG_CTL.TSTMODE =1.	
		0	Disable tst_fro_clk_out
		1	Enable tst_fro_clk_out

TRNG Post-Process "V" Value Registers

The TRNG_V[n] registers are used to load the V value used for post-processing (if available). These registers are write-only. Reads return the values of the other registers mapped at the same addresses.

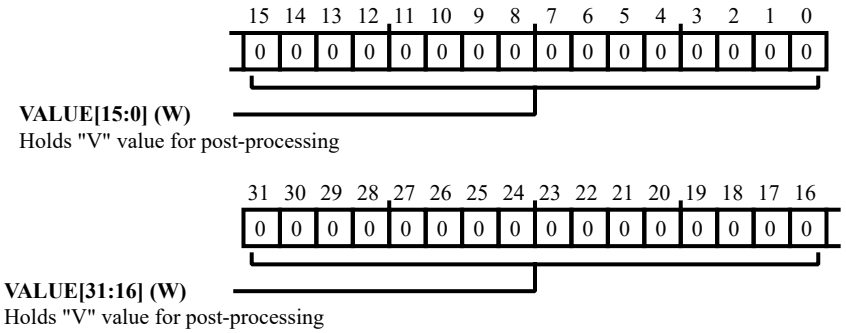

Figure 42-24: TRNG_V[n] Register Diagram

Table 42-27: TRNG_V[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (RX/W)	VALUE	Holds "V" value for post-processing. Bits of the post-processing 'V' value.

43 FIR Accelerator (FIR)

Finite Impulse Response (FIR) filters are frequently used in digital signal processing applications. The FIR accelerator is a dedicated hardware interface used to perform filter processing to reduce the instruction processing load on the core. FIR filters are used in a wide array of applications including multi-rate processing with an interpolator or decimator.

Features

This hardware module can perform FIR filters without core intervention. This allows programs to use the core to implement complex algorithms, effectively adding more bandwidth to the processor.

The FIR supports the following features:

- Fixed-point and 32-bit IEEE floating-point format
- Four SHARC+ core compatible MAC units that operate in parallel
- Rounding modes compatible with SHARC+ core MACs
- Single rate or multi-rate window processing
- Programmable rates with decimation or interpolation mode
- Up to 32 filter channels available in TDM in legacy mode
- Burst transfers on data or coefficient loads

NOTE: The FIR accelerator module has a local memory that the core cannot access during regular operation. Unlike previous SHARC processors, the FIR accelerator modules each have access to the system memory (on-chip or off-chip).

Also, unlike the previous SHARC processors, where only one of the FIR or IIR accelerators can be used at a time, the SHARC+ processor can use both accelerators simultaneously.

Clocking

The FIR accelerator runs at the speed of the core clock frequency (CCLK).

Functional Description

The ***FIR Block Diagram*** shows the 1024-TAP FIR hardware accelerator. The accelerator consists of a 1024 word coefficient memory, a 1024 deep delay line for data, and four MAC units. The accelerator runs at /CCLK frequency.

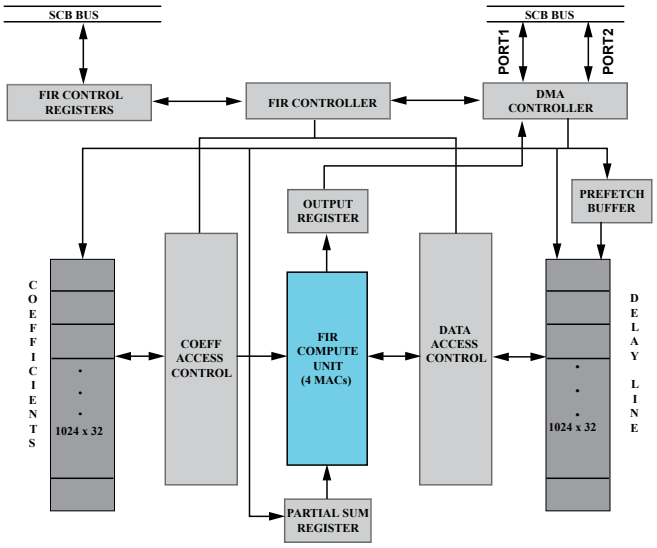

Figure 43-1: FIR Block Diagram

The FIR accelerator has the following logical sub blocks:

- A datapath unit that consists of:
  - A 1024 deep coefficient memory
  - A 1024 deep delay line for the data
  - Four 32-bit floating-point and fixed-point multiplier and adder units
  - One 32-bit prefetch buffer that operates in a pipelined fashion
  - One 32-bit buffer to hold the previous partial sum
  - One 32-bit buffer to hold the output
- Configuration registers for the number of TAPs, number of channels, filter enable, interrupt control, DMA enable, up sample or down sample control, and ratios.
- Core access interface for writing to the DMA and filter configuration registers and reading the status register.
- DMA bus interface for transferring data and coefficients to and from the accelerator.
- DMA configuration registers including chain pointer, input, output, and coefficient registers.

ADSP-2184x FIR Register List

The FIR accelerator is a dedicated hardware interface used to perform filter processing to reduce the instruction processing load on the core.

Table 43-1: ADSP-2184x FIR Register List

Name	Description
FIR_CHNPTR	FIR Chain Pointer Register
FIR_COEFCNT	FIR Coefficient Count Register
FIR_COEFIDX	FIR Coefficient Index Register
FIR_COEFMOD	FIR Coefficient Modifier Register
FIR_CTL1	FIR Global Control Register
FIR_CTL2	FIR Channel Control Register

99	FIR1_TRGI	FIR1 Core 1 FIR Wait on Trigger Input	Pulse

Compute Block

The MAC unit, shown in the ***FIR MAC Unit*** figure, has four multiply accumulators. The accumulators operate simultaneously on a single filter as described below.

- The MAC unit operates on the data and coefficient fetched from the data and coefficient RAMs
- Each MAC can perform 32-bit floating-point or 32-bit fixed-point MAC operations
- Floating-point format is IEEE-compliant
- Multiply and accumulation operation (addition) are pipelined
- A 32-bit floating-point MAC operation generates 32-bit multiply results
- A 32-bit fixed-point operation generates 80-bit results (64-bit result + 16 guard bits)

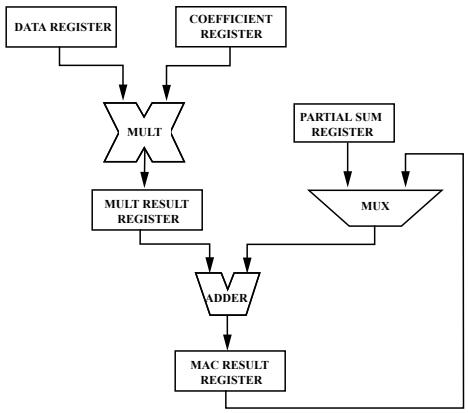

Figure 43-2: FIR MAC Unit

Partial Sum Register

The partial sum register is useful for Floating-point Multi-Iteration mode. For a particular channel, the intermediate MAC result is written to the output buffer of the system memory (on-chip or off-chip). If the same channel is requested again, the partial result register is updated with the intermediate MAC result through DMA from the output buffer of the system memory. The result is added to the current MAC result after each iteration. This process repeats until all iterations complete (the entire soft filter length is processed).

Delay Line Memory

The accelerator has a 1024 TAP delay line to hold the data locally. The DMA controller fetches the data from system memory and loads it into the delay line. Four read accesses can be made to the delay line simultaneously.

Coefficient Memory

The accelerator has a 1024 deep coefficient memory to store the coefficients. The DMA controller loads the coefficients from system memory into coefficient memory. Four coefficients can be fetched from the coefficient memory simultaneously. If the soft filter length is more than 1024, processing happens in multi-iteration mode.

Prefetch Data Buffer

The prefetch data buffer enables pipeline operation. One data sample is prefetched when the compute unit is operating on the delay line corresponding to the current sample. The data prefetched in this buffer is later used to update the delay line for the next sample. This operation happens in parallel again when the compute unit is not accessing the delay line. In other words, it happens when the compute unit is adding the output from the four MACs and the partial sum register.

Table 43-5: Pipeline Operation for Window Size = 1

Cycles	1	2	3	4	5	6
Output DMA			N	N1	N2	N3
Compute		N	N1	N2	N3	

Table 43-5: Pipeline Operation for Window Size = 1 (Continued)

Cycles	1	2	3	4	5	6
Input DMA	N	prefetch N1	prefetch N2	prefetch N3		

Processing Output

The accelerator uses all four MACs simultaneously to calculate one output sample as shown in the ***Multi-Iteration Filtering Flow*** figure and the following procedure.

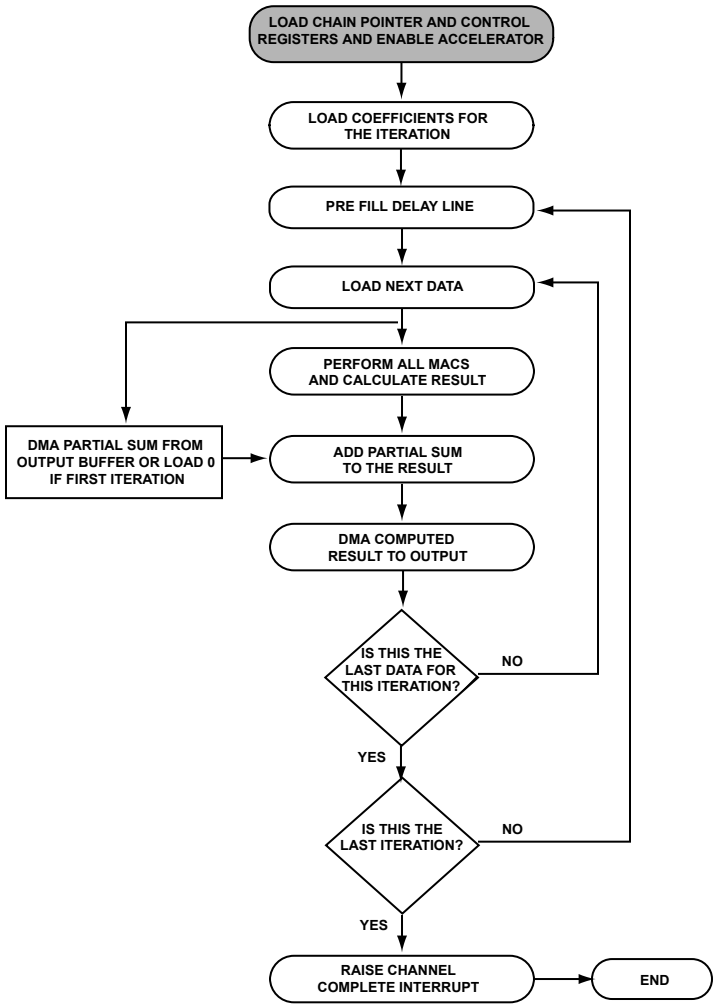

Figure 43-3: Multi-Iteration Filtering Flow

1. The accelerator fetches four input data from the delay line and four corresponding coefficients from the coefficient memory and feeds them to the MAC units for multiply and accumulation operations.
2. The accelerator repeats the procedure with the next four input data and coefficients until all the TAPs complete. For example, this procedure happens N/4 times for an N TAP filter.

3. When all the TAPs are complete, the accelerator adds the four MAC outputs together to the previous partial sum (if any) to calculate the final result.
4. Finally, that output sample is stored back in system memory.

System Memory Storage

The following sections describe the storage format for the accelerator.

CAUTION: Store all data in memory aligned to the word address boundaries. Any other programmed addresses do not flag an error.

Coefficients and Input Buffer Storage

For any N TAP filter with coefficients:

```
C[i] i = 0,1,
...
N - 1
```

store the coefficients in system memory buffer in the order:

```
C[N - 1], C[N - 2]
...
C[1],C[0]
```

and CI should point to `C(N - 1)`.

Single Rate Input Filtering

The total size of the input buffer must at least be equal to `N - 1 + W`. If the input buffer that needs to be processed is:

```
 x[n],x[n+1],x[n+2]
 ...
 x[n+W-1]
```

store it in the memory as

```
x[n-(N-1)], x[n-(N-2)]
...
x[n-1], x[n], x[n+1]
...
x[n+W-1]
```

and the `FIR_INIDX` register value should point to `x[n - (N - 1)]`

Decimation

Assuming M = decimation ratio, the total size of the input buffer should at least be equal to `N - 1 + W x M`. If the input buffer that needs to be processed is:

```
x[n],x[n+1],x[n+2]....x[n+WxM-1],
```

store it in the memory as:

```
x[n-(N-1)], x[n-(N-2)]....x[n-1],
x[n], x[n+1]....x[n+WxM-1]
```

and the FIR_INIDX register value should point to x[n-(N-1)].

Interpolation

Assuming L= interpolation ratio, the total size of the input buffer should be at least equal to:

Ceil ((N-1)/L)+W/L.

If the input buffer that needs to be processed is:

```
x[n], x[n+1], x[n+2]....x[n+W/L-1],
and K = Ceil((N-1)/L)
```

store it in the memory as:

```
x[n-k], x[n-(K-1)], x[n-(K-2)]....x[n-1],
x[n], x[n+1].... x[n+W/L-1]
```

and the FIR_INIDX register value should point to x[n-K].

Operating Modes

The FIR core performs a sum-of-products operation to compute the convolution sum. It supports single-rate, decimation, and interpolation functions.

Single Rate Processing

In a single-rate filter, the output result rate is equal to the input sample rate. The filter output Y(n) is computed according to following equation where N is the number of filter coefficients: c(k) k = 0 to N – 1 are the filter coefficients and x(n) represents the input time-series.

$$Y(n)= \sum_{k=0}^{N-1} c(k) \cdot x(n-k)$$

Figure 43-4: Filter Output Calculation

Single Iteration

Results are computed in a single iteration when the soft filter length is less than or equal to 1024.

Floating-point Multi-Iteration

Results are computed in multiple iterations when the soft filter length is greater than 1024 (for example, 2048 TAPs on a 1024 hard filter length). In this mode, the accelerator implements two iterations of 1024 TAPs.

NOTE: If the soft filter length is not a multiple of the hard filter length, the accelerator iterates until the soft filter length is satisfied.

Example: 550 taps on a 256 tap filter. In this example, the FIR accelerator implements two iterations of 256 taps and one iteration of 38 taps.

NOTE: Multi-iteration mode is not supported in fixed-point format.

Window Processing

In window-based mode, multiple output samples (up to 1024) equal to the window size of that channel are calculated. After these calculations are complete, the accelerator begins processing the next channel. A configurable window size parameter is provided to specify the length of the window.

To select sample-based processing mode, configure the window size to 1. In this mode, one sample from a particular channel is processed through all the taps of that channel and the final output sample is calculated.

Multi-Rate Processing

Multi-rate filters change the sampling rate of a signal—they convert the input samples of a signal to a different set of data that represents the same signal sampled at a different rate.

Decimation

A decimation filter provides a single output result for every M input samples, where M is the decimation ratio. The output rate is 1/M th of the input rate. The filter implementation exploits the low output sample rate by not starting a computation until a new set of M input samples is available.

In this mode, after low-pass filtering (for anti-aliasing), FIR logic discards the ratio – 1 samples of output data. For performance optimization, FIR logic skips the computation of output samples, which are discarded.

The input buffer size for decimation filters is N – 1 + (W × M) where:

- N is the number of taps
- W is the window size
- M is the decimation ratio

The window size (`FIR_CTL2.WINDOW` bits) must be programmed with the number of output samples.

To start this mode, programs set the `FIR_CTL2.RATIO` and `FIR_CTL2.UPSAMP` bits (along with normal filter setting). Also, the `FIR_CTL2.TAPLEN` bit field value should be greater than or equal to the `FIR_CTL2.RATIO` bit field value for the decimation filter.

Interpolation

An interpolation filter provides L output results for each new input sample, where L is the interpolation ratio. The output rate is L times the input rate.

In this mode, according to the ratio specified in configuration register, FIR logic inserts L – 1 zeros between any two input samples (upsampling). It then performs the interpolation (through the FIR filter).

Both upsampling and downsampling do not support multi-iteration mode. Therefore, the filtering operation only happens on up to 1024 TAPs and the ratio of up and downsampling can only be an integer value.

In an interpolation filter, FIR logic inserts L – 1 zeros between each sample. The program must ensure that these zeros fully shift out of the delay line before moving on to the next channel. This operation puts a restriction on window size in terms of L – *the sample ratio* as showing in the expression:

WINDOWSIZE = *n* × *SAMPLERATIO*, where *n* is the number of input samples.

The input buffer size is smallest integer greater than or equal to (N – 1 + W) L for interpolation filters where:

- N is the number of taps
- W is the window size
- L is the interpolation ratio

To start the mode, programs configure the `FIR_CTL2.RATIO` and `FIR_CTL2.UPSAMP` bits (along with filter settings).

Floating-Point Data Format

The FIR accelerator treats data and coefficients in 32-bit floating-point format as the default functional mode.

Fixed-Point Data Format

In fixed-point mode, the 32-bit input data or coefficient is treated as fixed-point. A 32-bit fixed-point MAC operation generates an 80-bit result. Fixed-point data or coefficients can be unsigned integer, unsigned fractional and signed integer.

NOTE: In fixed-point mode, the entire 80-bit result register is always written back in bursts of 3 × 32 bits. The first word is the LSW, the second word is the MSW, and the third word is a 16-bit overflow. The remaining 16 bits are padded with zeros. Therefore, for fixed-point mode: WINDOWSIZE = WINDOWSIZE × 3.

If the signed fractional format is used, the output must be scaled by 2. The MAC does not right shift to remove the redundant sign bit. A final routine must decimate the output buffer to the desired samples.

Multi-iteration mode is not supported in this format. Therefore, the maximum TAP length is 1024.

Auto Configuration Mode (ACM)

The accelerator can be operated in legacy mode or Auto Configuration Mode (ACM), controlled by the `FIR_CTL1.ACM` bit. The default functional mode is legacy mode. The accelerator mode can only be changed when the accelerator is disabled.

The ACM provides the following additional features:

- Halt and queuing

The core may pause the current Transfer Control Block (TCB) chain being processed by setting the FIR_CTL1.HALT bit. The accelerator acknowledges the core by setting the FIR_DMASTAT.HALT_STAT bit. The core can appropriately take action to submit/insert new TCB's. After the core acts, the accelerator processing can be resumed by clearing the FIR_CTL1.HALT bit. Before halting the accelerator, if the initial TCB chain is processed, the accelerator comes to the idle state. In this case, the accelerator has to be disabled and enabled by toggling the FIR_CTL1.EN bit and the FIR_CTL1.HALT bit must be cleared to resume processing.

- No channel number limitation

  Unlike legacy mode, there is no fixed channel number limitation and, therefore, the accelerator ignores the value programmed in the FIR_CTL1.CH field. The application can queue an unlimited number of channels/TCBs dynamically and the accelerator keeps processing the TCBs until the chain pointer becomes null.

- Selective interrupt

  The core can enable/mask interrupt generation for each channel using the FIR_CTL2.IMASK bit. If the bit is cleared, an interrupt is generated after completion of the channel.

- Selective controller / target trigger

  The core can enable/mask trigger generation by the accelerator after the end of processing of each channel using the FIR_CTL2.TMASK bit. The accelerator can also wait for a trigger after loading the TCB and coefficients and before processing a channel for which the FIR_CTL2.TWAIT bit is set.

In addition to the above features, there are three additional fields as part of the TCB FIR_SCTL1, FIR_SCTL2, and FIR_SGCTL registers. The FIR_SGCTL register can be used to change the FIR_CTL1 parameters such as rounding mode and fixed-point mode for each channel. The FIR_SCTL1 and FIR_SCTL2 registers can be used as general-purpose registers.

Data Transfer

The FIR filter works exclusively through DMA.

Chain Assignment

The structure of a TCB is conceptually the same as a traditional linked list. Each TCB has several data values and a pointer to the next TCB. Further, the chain pointer of a TCB can point to itself to continuously re-run the same DMA. The FIR accelerator reads each word of the TCB and loads it into the corresponding register. The end of the chain (no further TCBs are loaded) is indicated by a TCB with a chain pointer register value of zero.

The FIR accelerator DMA supports circular buffer chained DMA. The FIR accelerator does not support circular buffering for the coefficient buffer.

Table 43-6: TCBs for Chained DMA in Legacy Mode

Address	Register
TCB	FIR_CHNPTR
TCB + 0x1	FIR_COEFCNT
TCB + 0x2	FIR_COEFMOD
TCB + 0x3	FIR_COEFIDX
TCB + 0x4	FIR_OUTBASE
TCB + 0x5	FIR_OUTCNT
TCB + 0x6	FIR_OUTMOD
TCB + 0x7	FIR_OUTIDX
TCB + 0x8	FIR_INBASE
TCB + 0x9	FIR_INCNT
TCB + 0xA	FIR_INMOD
TCB + 0xB	FIR_INIDX
TCB + 0xC	FIR_CTL2

Table 43-7: TCBs for Chained DMA in Auto Configuration Mode

Address	Register
TCB	FIR_CHNPTR
TCB + 0x1	FIR_SCTL1
TCB + 0x2	FIR_SCTL2
TCB + 0x3	FIR_SGCTL
TCB + 0x4	FIR_COEFCNT
TCB + 0x5	FIR_COEFMOD
TCB + 0x6	FIR_COEFIDX
TCB + 0x7	FIR_OUTBASE
TCB + 0x8	FIR_OUTCNT
TCB + 0x9	FIR_OUTMOD
TCB + 0xA	FIR_OUTIDX
TCB + 0xB	FIR_INBASE
TCB + 0xC	FIR_INCNT
TCB + 0xD	FIR_INMOD
TCB + 0xE	FIR_INIDX
TCB + 0xF	FIR_CTL2

The FIR_COEFCNT register is loaded with the values in the FIR_COEFCNT TCB field and is decremented from that value onwards. However, coefficient loading continues until the number of coefficients, equal to the tap length, are read. This condition is true even if the FIR_COEFCNT register reaches zero as in the case of a tap length = 10, and the FIR_COEFCNT bit field in the TCB is initialized to 0. The value in the FIR_COEFCNT register is –10 after all coefficients are loaded.

NOTE: Initialize the FIR_CHNPTR register to TCB + 12 in legacy mode and TCB + 15 in ACM mode.

DMA Access

The FIR accelerator has two DMA channels (accelerator input and output) to connect to the system memory. The DMA controller fetches the data and coefficients from memory and stores the result.

Burst Access Support

Burst access enhances the throughput of the DMA channel and reduces the overall load on the system fabric. Burst support is provided for TCB, data, and coefficient loads on the DMA channel. The FIR module supports burst transfers of size SINGLE, INCR4 INCR8 and INCR16. The DMA access are automatically split into these four types of burst by the FIRA accelerator for optimum performance. For a TCB load, a burst access of length 16 is issued which reduces the TCB load time.

An additional bit (FIR_CTL1.BURSTEN) enables the burst feature. Burst transfers are always of size SINGLE when the modifier is other than 1. In cases of burst transfers around the circular buffer boundary, the design ensures that the burst does not cross the buffer boundary.

Data and Coefficient Load in Parallel

To reduce the overall loading time of data and coefficients, the operation occurs over separate channels. After the TCB load, both data and coefficients are loaded in parallel over two DMA channels (CH0 and CH1). If there is no conflict in the system when accessing the data and coefficients, the loading time is significantly improved over when loaded sequentially using a single channel. This mode is enabled by default and can be disabled by setting the FIR_CTL1.DCP_DIS bit. When disabled, coefficient load and data load occur sequentially over a single channel (CH0).

Prefetch Buffer for DMA Channels

An access latency exists in every burst transfer for the address issued for the first data to arrive. To reduce the latency, both channels of the FIR contain a prefetch buffer. When one burst access is in-progress, the FIR prefetch buffer receives the next burst, which reduces the latency for consecutive accesses. The FIR prefetch buffer is disabled by default. Setting the FIR_CTL1.PFB_EN bit enables the prefetch buffer.

Accelerator TCB

The location of the DMA parameters for the next sequence comes from the chain pointer register that points to the next set of DMA parameters stored in the internal memory of the processor. In chained DMA operations, the

accelerator automatically initializes and starts another DMA transfer when the current DMA transfer is complete. Each new set of parameters is stored in a user-initialized memory buffer or TCB for a chosen peripheral.

Chain Pointer DMA

The DMA controller supports circular buffer chain pointer DMA. One TCB must be configured for each channel. The DMA controller contains the following:

- A control register value to configure the filter parameters (such as filter tap length, window size, sample rate conversion settings) for each channel. In ACM mode, additional parameters such as interrupt mask, trigger mask, and trigger wait are also available.
- Software control register values in ACM mode for each channel.
- Secondary control register value to configure rounding mode, fixed-point mode, and two's complement for each channel.
- DMA parameter register values for the input data (delay line).
- DMA parameter register values for coefficient load.
- DMA parameter register values for output data.

Intermediate results in multi-iteration mode are saved in the output buffer.

As shown in the ***Circular Buffer Addressing*** figure, the accelerator loads the TCB into its internal registers and uses these values to fetch coefficients and data and to store results. After processing a window of data for any channel, the accelerator writes back the appropriate values to the `FIR_INIDX` and `FIR_OUTIDX` bit fields of the TCB in memory. Then, data processing can begin from where it left off during the next time slot of that channel.

The write-back value for input buffer is:

- `FIR_INIDX` + W for single rate filtering
- `FIR_INIDX` + W × M for decimation (M = decimation ratio)
- `FIR_INIDX` + W/L for interpolation (L = interpolation ratio)
- The write-back value for output buffer in floating point mode is: `FIR_OUTIDX` + W
- The write-back value for output buffer in fixed-point mode is: `FIR_OUTIDX` + 3 × W

NOTE: The `FIR_CTL2` register is part of the FIR TCB. This configuration allows programming individual FIR channels with different control attributes.

The above index updates are valid only for legacy mode. In ACM mode, the `FIR_INIDX` and `FIR_OUTIDX` bit fields of the TCB in memory are updated to 0x00000000 and 0xFFFFFFFF by the accelerator after processing a window of data.

In ACM mode, when the `FIR_CTL1.SMQ_LIUPS_EN` bit is set, the accelerator updates the `FIR_INIDX` and `FIR_OUTIDX` bit fields of the TCB in memory after processing a window of data

and according to the circular buffer scheme. When the FIR_CTL1.SMQ_LIUPS_EN bit is cleared, the accelerator updates the FIR_INIDX and FIR_OUTIDX bit fields of the TCB in memory to 0x00000000 and 0xFFFFFFFF after processing a window of data. The FIR_CTL1.SMQ_LIUPS_EN bit is only valid in ACM mode.

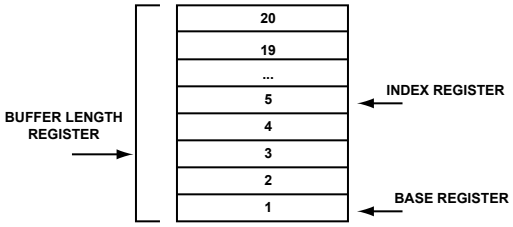

Figure 43-5: Circular Buffer Addressing

Programming Model

The following sections provide general programming information for the FIR accelerator.

Legacy Mode

The ***Wait for Core Intervention ≥ Idle (if auto channel iterate bit = 0)*** figure shows the diagram for multichannel filtering. Multiple channels are processed in a time division multiplexed (TDM) format. After completing all the channels, the accelerator can either repeat the slots or wait for core intervention.

For multichannel filtering, use the following steps.

1. Program the number of channels using the FIR_CTL1.CH bits.
2. Configure the TCBs in system memory with one channel's TCB pointing to the next channel's TCB.
3. Write the first TCB value into the FIR_CHNPTR register and enable the accelerator.
    a. The accelerator fetches the first channel's TCB and, using it as pointer, prefills the delay line and coefficient memory and loads the FIR_CTL2 register to configure the filter parameters corresponding to that channel.
    b. The accelerator then calculates output samples corresponding to one window and stores the data back in internal memory.
    c. At the end of the window the accelerator updates the FIR_INIDX and FIR_OUTIDX registers in the TCB of system memory and moves to the next channel.
    d. When all the channels are finished and the auto channel iterate bit (FIR_CTL1.CAI) =1, the accelerator processes the first channel again and iterates through the channels. If the FIR_CTL1.CAI bit =0, the accelerator waits for core intervention.

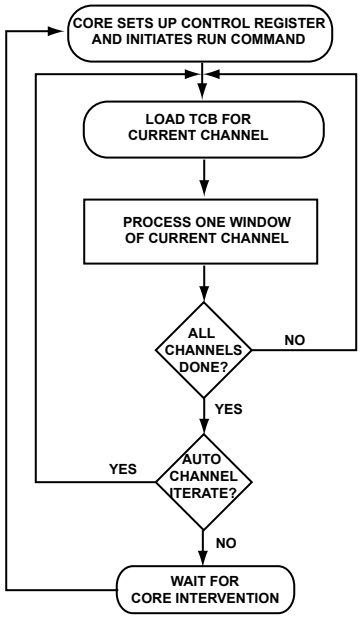

Figure 43-6: Wait for Core Intervention ≥ Idle (if auto channel iterate bit = 0)

NOTE: All the addresses programmed in the TCB correspond to 32-bit address boundaries and should not contain the lower 2 bits (assumed as zeros).

Auto Configuration Mode (ACM)

The figure shows multi-channel filtering in ACM. Multiple channels are processed in a time multiplexed format (TDM).

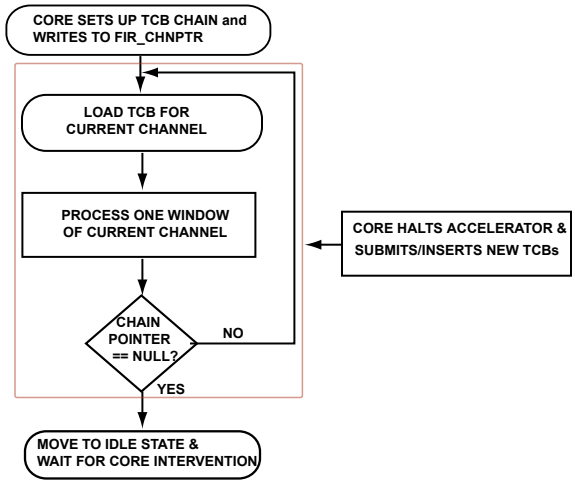

Figure 43-7: Multi-Channel Filtering in Auto Configuration Mode

For multi-channel filtering:

1. Configure the Transfer Control Blocks (TCBs) in system memory with one channel's TCB pointing to the next channel's TCB. There is no limit on the number of channels to be configured.

2. Write the first TCB value to the FIR_CHNPTR register and enable the accelerator.

   The accelerator fetches the first channel's TCB. Using it as pointer, it prefills the delay line and coefficient memory and loads the FIR_CTL2 and FIR_SGCTL registers to configure the filter parameters corresponding to that channel.

   When the FIR_CTL2.TWAIT bit is set, the accelerator waits for a input trigger to start the window processing for the channel.

   The accelerator then calculates output samples corresponding to one window and stores the data back in internal memory. When the FIR_CTL2.TMASK bit is cleared the accelerator sends an output trigger after completion of processing of the channel.

   When the FIR_CTL2.IMASK bit is cleared, the accelerator interrupts the core after completion of processing of a particular channel.

   At the end of the window, the accelerator updates the FIR_INIDX and FIR_OUTIDX registers to 0x00000000 and 0xFFFFFFFF in the TCB of system memory and moves to the next channel.

3. At any instant, as required, the core halts the accelerator. It sets the FIR_CTL1.HALT bit and appropriately takes action to submit or insert new TCBs and clears the FIR_CTL1.HALT bit to resume channel processing.

   If the FIR_CHNPTR register is zero (last channel is being processed or channel processing is complete) after halting the accelerator, the FIR_CHNPTR register is appropriately written before resuming the accelerator channel processing.

   When the accelerator is idle after halting, FIR_CTL1.EN bit is toggled to disable and re-enable the accelerator and the FIR_CTL1.HALT bit is cleared, and the accelerator resumes channel processing.

4. The accelerator continues processing until all the channels are complete. Repeat *Step 3* (if required) to submit/insert new channels.

NOTE: Channel auto iterate (FIR_CTL1.CAI) is not supported in ACM.

Debug Mode

The next sections show the steps required for reading and writing local memory in debug mode.

Write to Local Memory

1. Clear the FIR_CTL1.DMAEN bit.
2. Set the FIR_DBG_CTL.EN, FIR_DBG_CTL.MEM, and FIR_DBG_CTL.HLD bits.
3. Set the FIR_DBG_CTL.ADRINC bit for address auto increment.
4. Write the start address to the FIR_DBG_ADDR register.

   NOTE: If bit 11 in the FIR_DBG_ADDR register is set, coefficient memory is selected.

5. Write data to the FIR_DBG_WRDAT register.

Read from Local Memory

1. Clear the FIR_CTL1.DMAEN bit.
2. Set the FIR_DBG_CTL.EN, FIR_DBG_CTL.MEM, and FIR_DBG_CTL.HLD bits.
3. Set the FIR_DBG_CTL.ADRINC bit for address auto increment.
4. Write the start address to the FIR_DBG_ADDR register.

   NOTE: If bit 11 in the FIR_DBG_ADDR register is set, coefficient memory is selected.

5. Read data from the FIR_DBG_RDDAT register.

Single-Step Mode

Single-step mode can be used for debug purposes. An extra debug register is used in this mode.

1. Enable stop DMA during breakpoint hit in the emulator settings.
2. Clear the FIR_DBG_CTL.HLD bit and enable the FIR_DBG_CTL.EN and FIR_DBG_CTL.RUN bits.
3. Program the FIR module according to the application.
4. In single-step mode, each iteration is updated in the emulator session.

Computing FIR Output, Tap Length Greater than 4096

With little core intervention, the FIR accelerator can also be used to calculate output for a tap length greater than 4096 taps. The section demonstrates the calculation with an example of 8192 taps.

1. Divide the transfer function of an 8192 FIR filter into two 4096 FIR filters:

   $H(Z) = b_0 + b_1Z^{-1} + b_2Z^{-2} + ...b_{4095}Z^{-4095} + b_{4096}Z^{-4096}b_{4097}Z^{-4097} + ...b_{8191}Z^{-8191}$

   $= b_0 + b_1Z^{-1} + b_2Z^{-2} + ...b_{4095}Z^{-4095} + Z^{-4096}(b_{4096} + b_{4097} + ...b_{8191}Z^{-4096})$

2. Divide the filter coefficients of an 8192 tap filter among two 4096 tap FIR filters:

   Filter 1

   Coefficients = b0, b1, b2,……, b4095

   Input data = x[n], x [n – 1],…….x[n – 4095]

   Filter 2

   Coefficients = b4096, b4097,……..,b8191

   Input data = x[n – 4096], x[n – 4097],……x[n – 8191]

The accelerator can be used in two-channel mode where:

- channel 1 operates on x[n]…x[n – 4095] input data with the filter coefficients of filter 1 and

- channel 2 operates on x[n – 4096]…x[n – 8191] with the filter coefficients of filter 2.

Once both the channels are processed, add the partial sum output of both the channels to get the final output. Implement this approach (tap length = TAPS = 8192, window size = WINDOW) using the following programming steps.

1. Create a circular input data buffer in system memory (IBUF). The buffer must be large enough to avoid overwriting data before the accelerator processes it. Ideally, the input buffer size for a channel is TAPS + WINDOW – 1.
2. Create a coefficient buffer of size TAPS (8192) (CBUF).
3. Create one output buffer of size WINDOW (OBUF) and another temporary output buffer (OBUF1) to store the partial sum.
4. Create two TCBs in system memory with first TCB chained to the second and second chained to the first in a circular manner.
    a. Point the `FIR_COEFIDX` bit field of the first TCB to the start address of the coefficient buffer (CBUF) and that of the second TCB to 4096 offset from the start of the coefficient buffer (CBUF + 4096).
    b. Point the `FIR_OUTBASE` and `FIR_OUTIDX` bit fields of the first TCB to the start address of OBUF and that of the second TCB to the start address of OBUF1.
    c. Point the `FIR_INIDX` bit field of the first TCB to the start address of IBUF and that of the second TCB to 4096 offset from the start address of IBUF.
    d. Configure the `FIR_CTL2` bit field of both the TCB for tap length = TAP/2 = 4096 and window size = WINDOW.
5. Initialize the `FIR_CHNPTR` register to point to the first TCB.
6. Program the `FIR_CTL1` register to initiate the accelerator processing by setting the `FIR_CTL1.EN` and `FIR_CTL1.DMAEN` bits and the number of channels configured as 2.
7. Wait for the FIR all channels done interrupt (`FIR_DMASTAT.ACDONE`) to occur. Inside the ISR, add the partial sum results using the core from both the output buffers (OBUF and OBUF1) to get the final output. To save memory, replace the contents of the buffer OBUF with the final output result.

Debug Features

The following sections provide information for debugging the FIR accelerator.

Local Memory Access

The contents of FIR delay line and coefficient memories are made observable for debug by setting the `FIR_DBG_CTL.EN`/`FIR_DBG_CTL.MEM` and `FIR_DBG_CTL.HLD` bits. The debug address register (`FIR_DBG_ADDR`) and two data registers are provided for debug operations. Bit 11 of the `FIR_DBG_ADDR` register selects coefficient memory when set (=1) and selects delay line memory when cleared (=0).

In the debug mode, the read data register (FIR_DBG_RDDAT) returns the contents of the memory location pointed to by the address register. Data can be written into any memory location using FIR_DBG_WRDAT register writes. If the address auto-increment bit (FIR_DBG_CTL.ADRINC) is set, the address register auto-increments on FIR_DBG_WRDAT writes and FIR_DBG_RDDAT reads. During auto-increment the FIR_DBG_ADDR register cannot cross the data memory or coefficient memory boundary.

Single-Step Mode

Programs can single step through the MAC operations and observe the memory contents after each step. The FIR_DBG_CTL.EN, FIR_DBG_CTL.HLD, and FIR_DBG_CTL.MEM bits control the FIR MAC units.

Emulation Considerations

In FIR debug mode, the DMA operations are not observable.

Interrupts

The ***FIR Interrupt Overview*** table provides the source of interrupt and service instructions for the FIR interrupts.

Table 43-8: FIR Interrupt Overview

Accelerator Mode	Default Programmable Interrupt	Sources	Masking	Service
Legacy Mode	FIR_DMA	Window Complete	N/A	ROC from FIR_DMASTAT + RTI instruction
		All channels complete		
	FIR_STAT	MAC IEEE floating point exceptions	N/A	ROC from FIR_MACSTAT + RTI instruction
		MAC fixed point overflow		
Auto Configuration Mode	FIR_DMA	Window Complete	FIR_CTL2.IMASK	ROC from FIR_DMASTAT + RTI instruction
	FIR_STAT	MAC IEEE floating point exceptions	N/A	ROC from FIR_MACSTAT + RTI instruction
		MAC fixed point overflow	N/A	

Sources

The FIR module drives two interrupt signals: FIR_DMA for the DMA status and FIR_STAT for the MAC status. The FIR module generates interrupts as described in the following sections.

Window Complete

This interrupt is generated at the end of each channel when all the output samples are calculated corresponding to a window and updated index values are written back.

In legacy mode, if the FIR_CTL1.CCINTR bit is set, an interrupt is generated after completion of window processing of each channel. In ACM, the interrupt generation can be selectively masked using the FIR_CTL2.IMASK bit for each channel.

All Channels Complete

This interrupt is generated when all the channels are complete or when one iteration of time slots completes. Note that the interrupt follows the access completion rule, where the interrupt is generated when all data are written back to system memory.

The all channels complete interrupt source is only applicable in legacy mode. If the FIR_CTL1.CCINTR bit is not set in legacy mode, the all channel complete interrupt is generated. In ACM mode, interrupt generation for each channel is controlled using the FIR_CTL2.IMASK bit.

NOTE: The FIR_CTL1.CCINTR bit is valid only in legacy mode. In ACM mode, interrupt generation for each channel is controlled using the FIR_CTL2.IMASK bit.

MAC Status

A MAC status interrupt is generated under the following conditions and is reflected in the FIR_MACSTAT register.

- Multiplier result zero – Set if multiplier result is zero
- Multiplier result infinity – Set if multiplier result is infinity
- Multiply invalid – Set if multiply operation is invalid
- Adder result zero – Set if adder result is zero
- Adder result infinity – Set if adder result is infinity
- Adder invalid – Set if addition is invalid
- Adder overflow – for fixed-point operation

Service

The DMA interrupt status bits are sticky and are cleared when the DMA status register is read. When a MAC status interrupt occurs, programs can find this state by reading the MAC status register (FIR_MACSTAT). The read of the register clears the (sticky) MAC interrupt status bits.

The status interrupt sources are derived from the FIR_MACSTAT register. A status interrupt can occur due to the last set of MAC operations of a processing iteration that correspond to a particular channel. The interrupt is generated continuously and cannot be stopped, even after disabling the accelerator. The interrupt can only be stopped when another processing iteration results in a non-zero or valid multiply or add result.

ADSP-2184x FIR Register Descriptions

The FIR accelerator (FIR) contains the following registers.

Table 43-9: ADSP-2184x FIR Register List

Name	Description
FIR_CHNPTR	FIR Chain Pointer Register
FIR_COEFCNT	FIR Coefficient Count Register
FIR_COEFIDX	FIR Coefficient Index Register
FIR_COEFMOD	FIR Coefficient Modifier Register
FIR_CTL1	FIR Global Control Register
FIR_CTL2	FIR Channel Control Register
FIR_DBG_ADDR	Debug Address Register
FIR_DBG_CTL	FIR Debug Control Register
FIR_DBG_RDDAT	FIR Debug Data Read Register
FIR_DBG_WRDAT	FIR Debug Data Write Register
FIR_DMASTAT	FIR DMA Status Register
FIR_INBASE	FIR Input Data Base Register
FIR_INCNT	FIR Input Data Count Register
FIR_INIDX	FIR Input Data Index Register
FIR_INMOD	FIR Input Data Modifier Register
FIR_MACSTAT	FIR MAC Status Register
FIR_OUTBASE	FIR Output Data Base Register
FIR_OUTCNT	FIR Output Data Count Register
FIR_OUTIDX	FIR Output Data Index Register
FIR_OUTMOD	FIR Output Data Modifier Register
FIR_SCTL1	Software Control Register 1
FIR_SCTL2	Software Control Register 2
FIR_SGCTL	Secondary Global Control Register

FIR Chain Pointer Register

The FIR_CHNPTR register contains the chain pointer address.

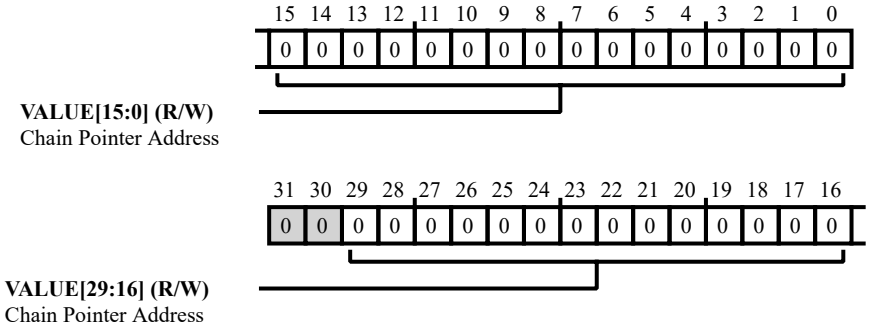

Figure 43-8: FIR_CHNPTR Register Diagram

Table 43-10: FIR_CHNPTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:0 (R/W)	VALUE	Chain Pointer Address. The FIR_CHNPTR.VALUE bit field contains the chain pointer address.

FIR Coefficient Count Register

The FIR_COEFCNT register contains the 16-bit coefficient buffer count.

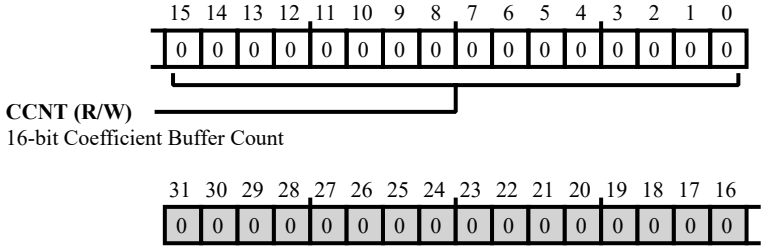

Figure 43-9: FIR_COEFCNT Register Diagram

Table 43-11: FIR_COEFCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	CCNT	16-bit Coefficient Buffer Count. The FIR_COEFCNT.CCNT bit field contains the 16-bit coefficient buffer count.

FIR Coefficient Index Register

The FIR_COEFIDX register contains the coefficient index word address with the lower two bits removed.

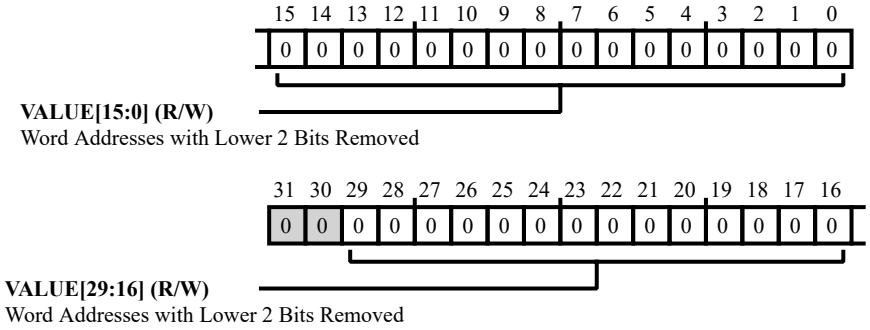

Figure 43-10: FIR_COEFIDX Register Diagram

Table 43-12: FIR_COEFIDX Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:0 (R/W)	VALUE	Word Addresses with Lower 2 Bits Removed. The FIR_COEFIDX.VALUE bit field contains the word addresses with the lower 2 bits removed.

FIR Coefficient Modifier Register

The FIR_COEFMOD register contains the 16-bit coefficient index modifier.

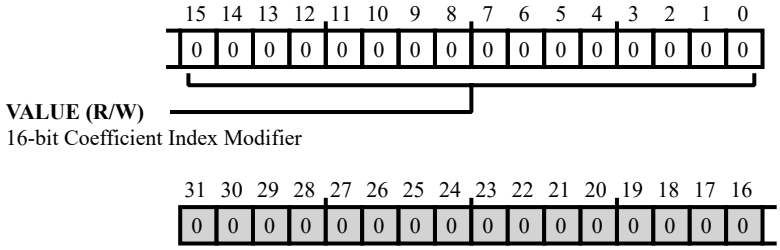

Figure 43-11: FIR_COEFMOD Register Diagram

Table 43-13: FIR_COEFMOD Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	16-bit Coefficient Index Modifier. The FIR_COEFMOD.VALUE bit field contains the 16-bit coefficient index modifier.

FIR Global Control Register

The FIR_CTL1 register is used to configure the global parameters for the accelerator. These parameters include the number of channels, channel auto iterate, DMA enable, and accelerator enable.

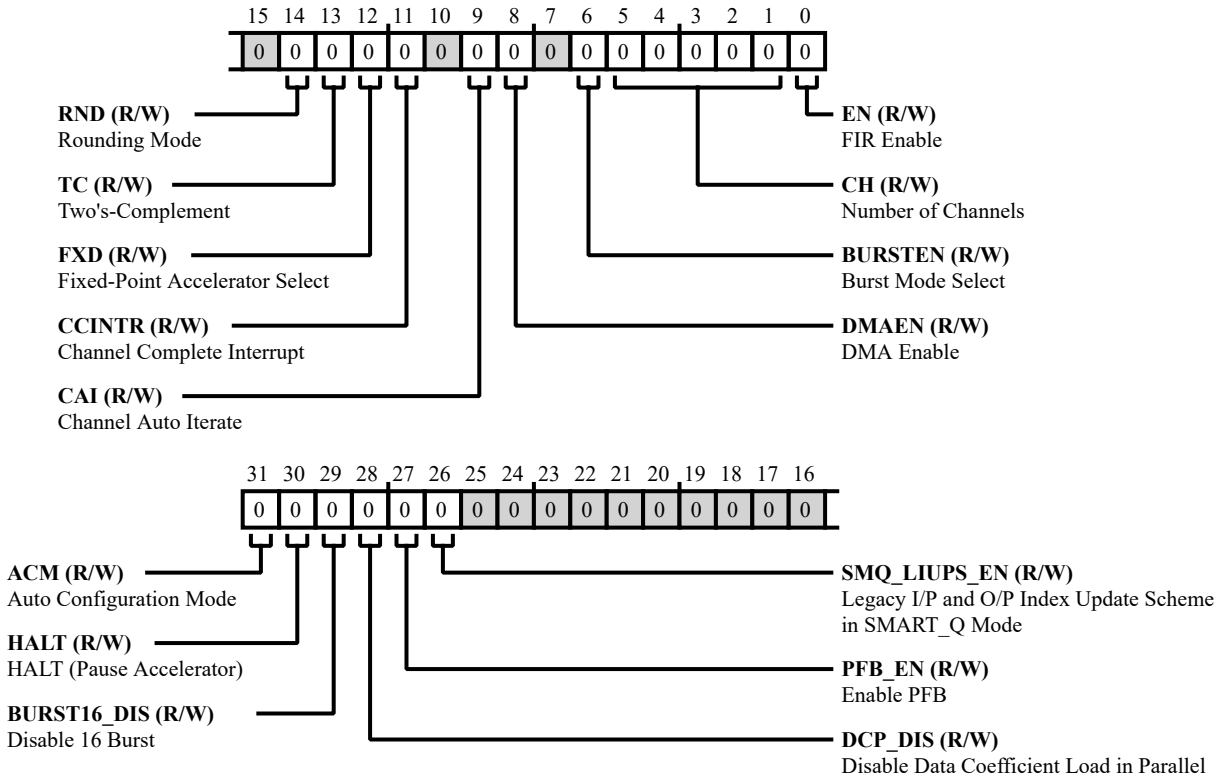

Figure 43-12: FIR_CTL1 Register Diagram

Table 43-14: FIR_CTL1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	ACM	Auto Configuration Mode. The FIR_CTL1.ACM bit configures the mode for loading the TCB.	
		0	Legacy Mode. Load TCB without the FIR_CTL1 register. Core intervention may be required.
		1	Auto Configuration Mode. Load TCB with the FIR_CTL1 register. Core intervention is not required.

Table 43-14: FIR_CTL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
30 (R/W)	HALT	HALT (Pause Accelerator). This bit is only valid in Auto Configuration mode (ACM)	
		0	Release. Release accelerator for further processing of data.
		1	Pause. Pause accelerator for core to check status and modify or submit jobs.
29 (R/W)	BURST16_DIS	Disable 16 Burst. The `FIR_CTL1.BURST16_DIS` bit configures the accelerator to disable 16 burst when in burst mode.	
		0	Maximum burst of INCR16 in burst mode for DMA and TCB
		1	Maximum burst of INCR8 in burst mode for DMA and non-burst for TCB
28 (R/W)	DCP_DIS	Disable Data Coefficient Load in Parallel. The `FIR_CTL1.DCP_DIS` bit enables data and coefficient loading to occur in parallel.	
		0	Enable
		1	Disable
27 (R/W)	PFB_EN	Enable PFB. When set (=1), the `FIR_CTL1.PFB_EN` bit enables the prefetch buffer on both FIR channels.	
		0	Disable
		1	Enable
26 (R/W)	SMQ_LIUPS_EN	Legacy I/P and O/P Index Update Scheme in SMART_Q Mode. The `FIR_CTL1.SMQ_LIUPS_EN` bit configures the scheme the accelerator uses to update the input index (II) and output index (OI). This bit is only valid in ACM.	
		0	Update the II with all '0' and the OI with all 'F', respectively
		1	Update II and OI after circular buffer scheme
14 (R/W)	RND	Rounding Mode. The `FIR_CTL1.RND` bit configures the accelerator to use a rounding mode.	
		0	Round to Nearest
		1	Truncate (round towards zero)

Table 43-14: FIR_CTL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
13 (R/W)	TC	Two's-Complement. The FIR_CTL1.TC bit configures the accelerator to use either unsigned integer or signed integer	
		0	Unsigned Integer
		1	Signed Integer
12 (R/W)	FXD	Fixed-Point Accelerator Select. The FIR_CTL1.FXD bit configures the accelerator to use either 32-bit IEEE floating-point or 32-bit fixed-point.	
		0	32-bit IEEE Floating-Point
		1	32-bit Fixed Point
11 (R/W)	CCINTR	Channel Complete Interrupt. The FIR_CTL1.CCINTR bit configures the accelerator to generate an interrupt when each or all channels are done. This bit is only valid in Legacy Mode. In Auto Configuration Mode (ACM), interrupt generation for each channel is controlled using the FIR_CTL2.IMASK bit.	
		0	Interrupt is Generated Only When All Channels are Done
		1	Interrupt is Generated After Each Channel is Done
9 (R/W)	CAI	Channel Auto Iterate. The FIR_CTL1.CAI bit, if cleared, causes the TDM processing to stop (idle) once all channels are done. If set, processing moves to the first channel and continues TDM processing in a loop when all channels are done. Channel Auto Iterate is not available in Auto Configuration Mode (ACM).	
		0	TDM Processing Stops (IDLE) Once All Channels are Over
		1	Moves to First Channel and Continues TDM Processing in a Loop When All Channels are Over
8 (R/W)	DMAEN	DMA Enable. The FIR_CTL1.DMAEN bit enables and disables DMA on the FIR accelerator.	
		0	DMA Disabled
		1	DMA Enabled
6 (R/W)	BURSTEN	Burst Mode Select. When the FIR_CTL1.BURSTEN bit is set, burst mode is enabled for coefficient loads and data loads. When cleared, burst mode is disabled. By default, burst mode is disabled.	

Table 43-14: FIR_CTL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5:1 (R/W)	CH	Number of Channels. The `FIR_CTL1.CH` bit field configures the number of channels and is programmable from 0 to 31. This bit field is only valid in Legacy Mode. There is no channel number limitation in Auto Configuration Mode (ACM) as the accelerator keeps processing the TCBs until the chain pointer becomes null.	
		0	Channel 1
		1-30	Channel 2-31
		31	Channel 32
0 (R/W)	EN	FIR Enable. The `FIR_CTL1.EN` bit enables and disables the FIR accelerator.	
		0	Disable FIR
		1	Enable FIR

FIR Channel Control Register

The FIR_CTL2 register is used to configure the channel specific parameters such as filter TAP length, window size, sample rate conversion, up/down sampling and ratio. In Auto Configuration Mode(ACM), this register is also used to configure additional channel specific parameters like interrupts and triggers.

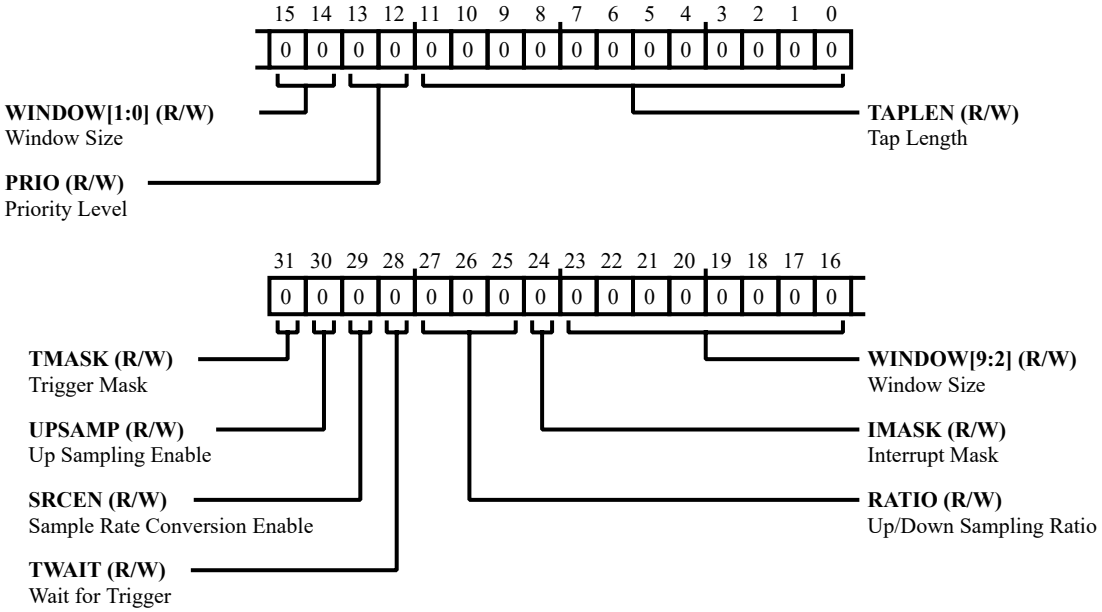

Figure 43-13: FIR_CTL2 Register Diagram

Table 43-15: FIR_CTL2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	TMASK	Trigger Mask. The FIR_CTL2.TMASK bit enables trigger generation for the channel. It is only valid in Auto Configuration Mode (ACM).	
		0	Enable
		1	Mask
30 (R/W)	UPSAMP	Up Sampling Enable. The FIR_CTL2.UPSAMP bit enables up sampling.	
		0	Down Sampling
		1	Up Sampling

Table 43-15: FIR_CTL2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R/W)	SRCEN	Sample Rate Conversion Enable. The `FIR_CTL2.SRCEN` bit field enables sample rate conversion.	
		0	Disabled
		1	Enabled
28 (R/W)	TWAIT	Wait for Trigger. The `FIR_CTL2.TWAIT` bit disables the wait for the trigger. It is only valid in Auto Configuration Mode (ACM).	
		0	Disable wait for trigger for the channel
		1	Enable wait for the external trigger assertion
27:25 (R/W)	RATIO	Up/Down Sampling Ratio. The `FIR_CTL2.RATIO` bit field sets the sampling ratio (`FIR_CTL2.RATIO` + 1).	
24 (R/W)	IMASK	Interrupt Mask. The `FIR_CTL2.IMASK` bit enables interrupt generation for the channel. This bit is only valid in Auto Configuration Mode (ACM).	
		0	Enable
		1	Mask
23:14 (R/W)	WINDOW	Window Size. The `FIR_CTL2.WINDOW` bit field sets the window size which specifies the number of sample/block to process (sample based processing = window size of 0).	
13:12 (R/W)	PRIO	Priority Level. The `FIR_CTL2.PRIO` bit field indicates the priority.	
		0	Level 0 (lowest)
		1	Level 1
		2	Level 2
		3	Level 3 (highest)
11:0 (R/W)	TAPLEN	Tap Length. The `FIR_CTL2.TAPLEN` bit field sets the tap length which is programmable between 0-4095 (Tap Length = `FIR_CTL2.TAPLEN` + 1).	

Debug Address Register

The FIR_DBG_ADDR register holds the debug address.

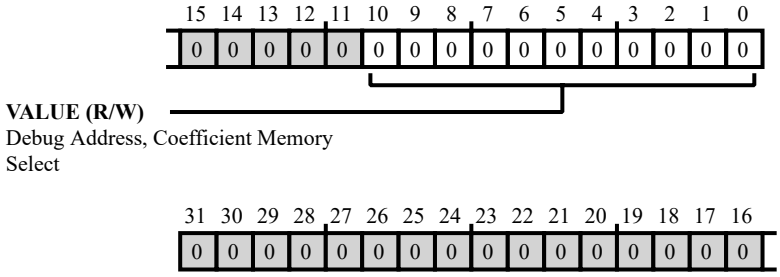

Figure 43-14: FIR_DBG_ADDR Register Diagram

Table 43-16: FIR_DBG_ADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
10:0 (R/W)	VALUE	Debug Address, Coefficient Memory Select. The FIR_DBG_ADDR.VALUE bit field holds the debug address (bits 0-10). Bit 11 configures whether the memory access is to coefficient memory (=0) or to delay line memory (=1).

FIR Debug Control Register

The FIR_DBG_CTL register controls debugging operations such as enabling debug mode running, hold or single stepping.

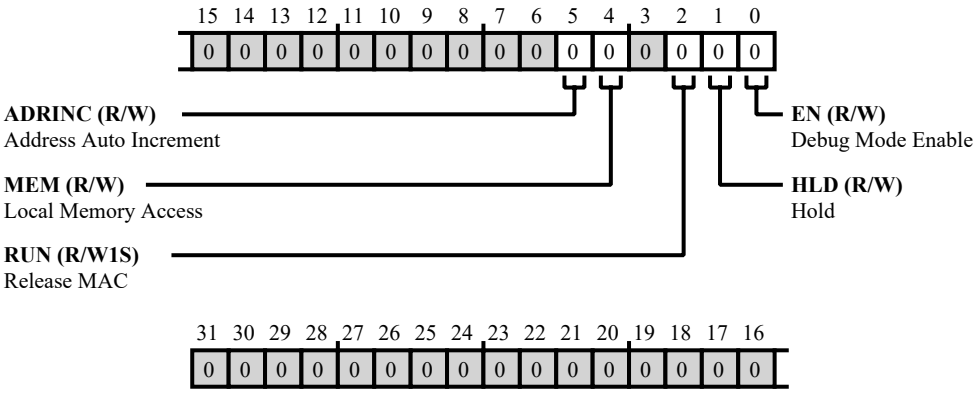

Figure 43-15: FIR_DBG_CTL Register Diagram

Table 43-17: FIR_DBG_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W)	ADRINC	Address Auto Increment. The FIR_DBG_CTL.ADRINC bit bit allows the address register to auto-increment on FIR_DBG_WRDAT writes and FIR_DBG_RDDAT reads.	
4 (R/W)	MEM	Local Memory Access. When the FIR_DBG_CTL.MEM bit is set, the data and coefficients memory can be indirectly accessed.	
2 (R/W1S)	RUN	Release MAC. The FIR_DBG_CTL.RUN bit releases the MAC. This bit is self-clearing after one FIR clock cycle.	
1 (R/W)	HLD	Hold. The FIR_DBG_CTL.HLD bit holds or single-steps through the FIR.	
		0	Hold
		1	Single-step
0 (R/W)	EN	Debug Mode Enable. The FIR_DBG_CTL.EN bit enables debug mode. For local memory access, the FIR_CTL1 register can be cleared.	
		0	Disable Debug Mode
		1	Enable Debug Mode

FIR Debug Data Read Register

The FIR_DBG_RDDAT register hold the debug read data.

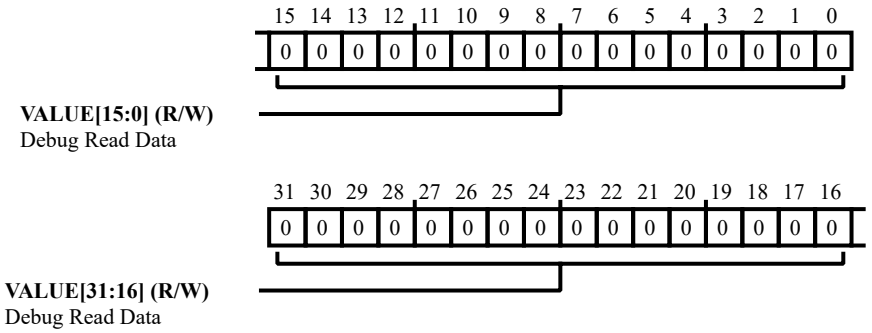

Figure 43-16: FIR_DBG_RDDAT Register Diagram

Table 43-18: FIR_DBG_RDDAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Debug Read Data. The FIR_DBG_RDDAT.VALUE bit field holds the debug read data.

FIR Debug Data Write Register

The FIR_DBG_WRDAT register holds the debug write data.

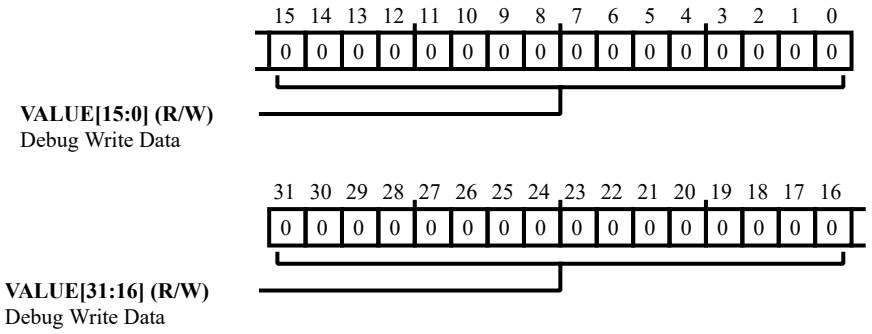

Figure 43-17: FIR_DBG_WRDAT Register Diagram

Table 43-19: FIR_DBG_WRDAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Debug Write Data. The FIR_DBG_WRDAT.VALUE bit field holds the debug write data.

FIR DMA Status Register

The FIR_DMASTAT register provides information about chain pointer loading, coefficient DMA, data preload DMA, processing in progress, window complete, all channels complete.

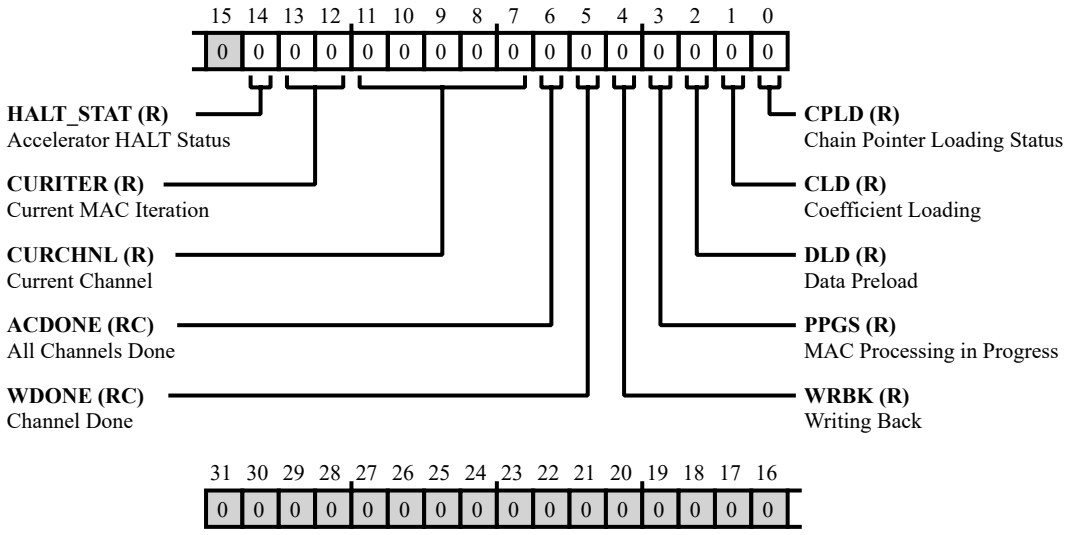

Figure 43-18: FIR_DMASTAT Register Diagram

Table 43-20: FIR_DMASTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/NW)	HALT_STAT	Accelerator HALT Status. Accelerator HALT status. 1 - Acknowledge to core that acceleration is in halt state. 0 - Not in halt state
13:12 (R/NW)	CURITER	Current MAC Iteration. The FIR_DMASTAT.CURITER bit indicates the current MAC iteration in multi-iteration mode. Zero indicates the final iteration.
11:7 (R/NW)	CURCHNL	Current Channel. The FIR_DMASTAT.CURCHNL bit indicates the channel that is being processed in the TDM slot. Zero indicates the last slot.
6 (RC/NW)	ACDONE	All Channels Done. The FIR_DMASTAT.ACDONE bit indicates the accelerator that processing all channels is complete. This is a sticky bit and is cleared on a register read. The FIR_CTL1.CCINTR bit does not affect the FIR_DMASTAT.ACDONE bit.
5 (RC/NW)	WDONE	Channel Done. The FIR_DMASTAT.WDONE bit indicates the accelerator that processing the current channel is complete. This is a sticky bit and is cleared on a register read. The FIR_CTL1.CCINTR bit does not affect the FIR_DMASTAT.WDONE bit.

Table 43-20: FIR_DMASTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
4 (R/NW)	WRBK	Writing Back. The `FIR_DMASTAT.WRBK` bit indicates the accelerator is writing back the updated index registers.
3 (R/NW)	PPGS	MAC Processing in Progress. The `FIR_DMASTAT.PPGS` bit indicates MAC processing in progress.
2 (R/NW)	DLD	Data Preload. The `FIR_DMASTAT.DLD` bit indicates data preloading.
1 (R/NW)	CLD	Coefficient Loading. The `FIR_DMASTAT.CLD` bit indicates coefficient loading.
0 (R/NW)	CPLD	Chain Pointer Loading Status. The `FIR_DMASTAT.CPLD` bit indicates the state machine is in chain pointer load state.

FIR Input Data Base Register

The FIR_INBASE register contains the input word base address with the lower two bits removed.

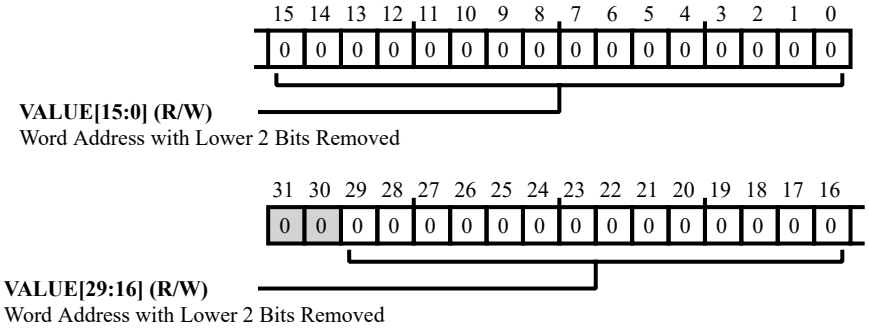

Figure 43-19: FIR_INBASE Register Diagram

Table 43-21: FIR_INBASE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:0 (R/W)	VALUE	Word Address with Lower 2 Bits Removed. The FIR_INBASE.VALUE bit field contains the word address with the lower 2 bits removed.

FIR Input Data Count Register

The FIR_INCNT register contains the 16-bit input data count.

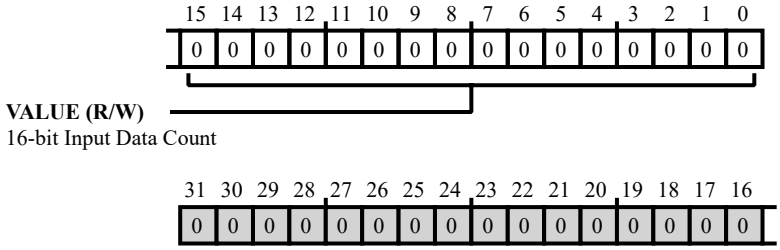

Figure 43-20: FIR_INCNT Register Diagram

Table 43-22: FIR_INCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	16-bit Input Data Count. The FIR_INCNT.VALUE bit field contains the 16-bit input data count.

FIR Input Data Index Register

The FIR_INIDX register contains the input word address with the lower two bits removed.

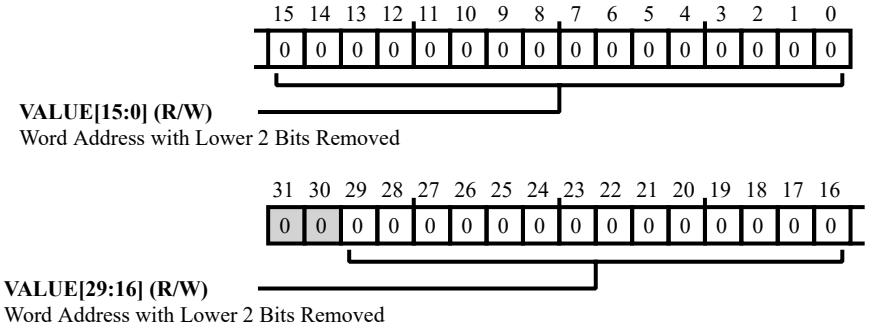

Figure 43-21: FIR_INIDX Register Diagram

Table 43-23: FIR_INIDX Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:0 (R/W)	VALUE	Word Address with Lower 2 Bits Removed. The FIR_INIDX.VALUE bit field contains the input word address with the lower two bits removed.

FIR Input Data Modifier Register

The FIR_INMOD register contains the 16-bit input data buffer modifier.

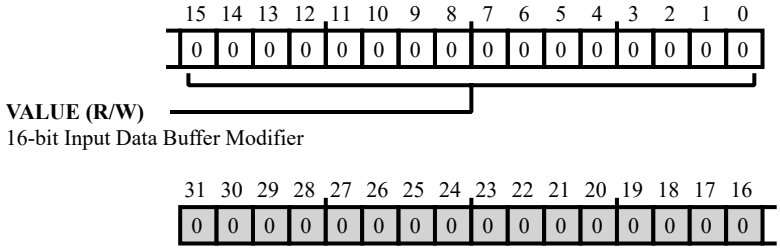

Figure 43-22: FIR_INMOD Register Diagram

Table 43-24: FIR_INMOD Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	16-bit Input Data Buffer Modifier. The FIR_INMOD.VALUE bit field contains the 16-bit input data buffer modifier.

FIR MAC Status Register

The FIR_MACSTAT register provides the status of MAC operations. The status of all four multipliers/adders are available separately for programs to poll. In fixed-point mode only, the ARIx bits are used (all other bits are reserved).

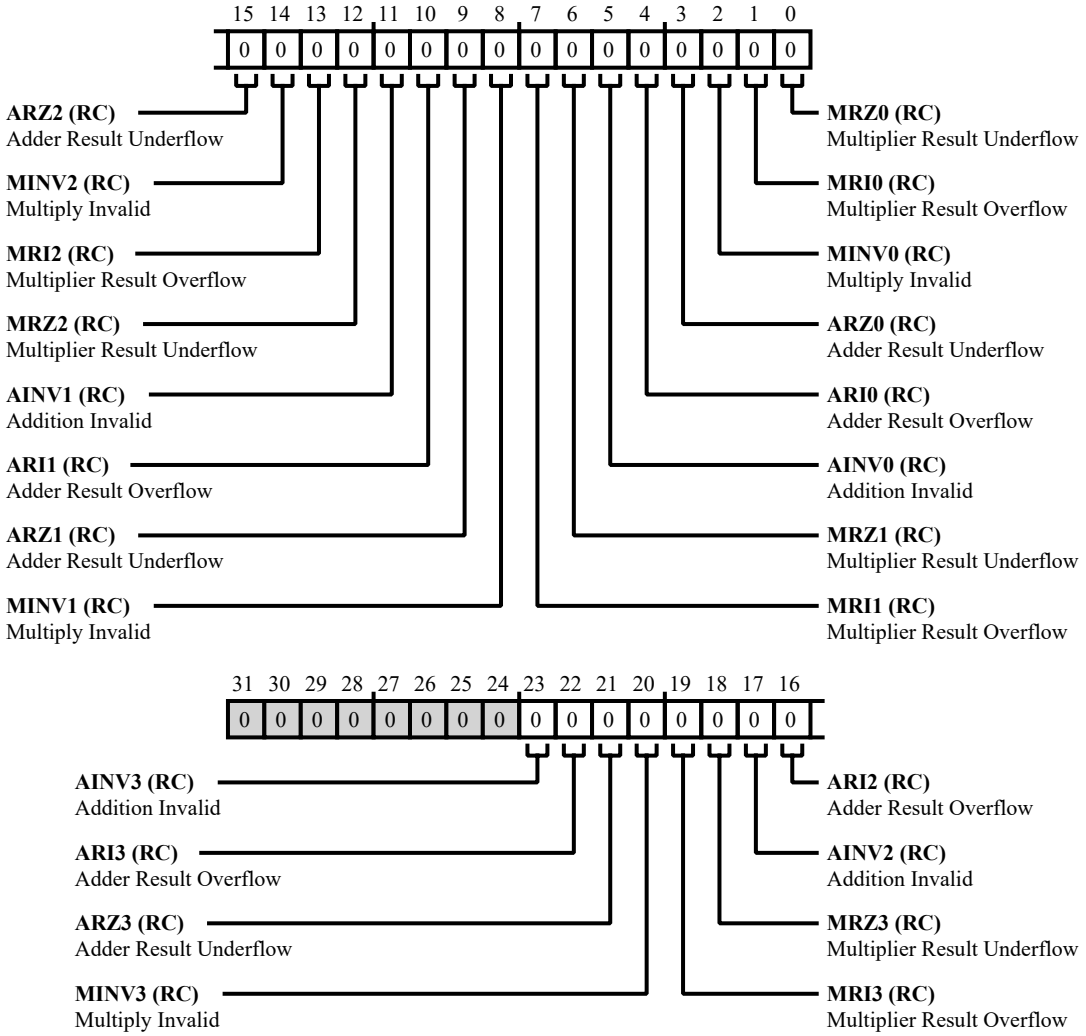

Figure 43-23: FIR_MACSTAT Register Diagram

Table 43-25: FIR_MACSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23 (RC/NW)	AINV3	Addition Invalid. The FIR_MACSTAT.AINV3 bit is set if the adder 3 addition is invalid.

Table 43-25: FIR_MACSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
22 (RC/NW)	ARI3	Adder Result Overflow. The `FIR_MACSTAT.ARI3` bit is set if the adder 3 result is infinity. Indicates overflow in fixed-point mode.
21 (RC/NW)	ARZ3	Adder Result Underflow. The `FIR_MACSTAT.ARZ3` bit is set if the adder 3 result is zero.
20 (RC/NW)	MINV3	Multiply Invalid. The `FIR_MACSTAT.MINV3` bit is set if the multiplier 3 multiply operation is invalid.
19 (RC/NW)	MRI3	Multiplier Result Overflow. The `FIR_MACSTAT.MRI3` bit is set if the multiplier 3 result is infinity.
18 (RC/NW)	MRZ3	Multiplier Result Underflow. The `FIR_MACSTAT.MRZ3` bit is set if the multiplier 3 result is zero.
17 (RC/NW)	AINV2	Addition Invalid. The `FIR_MACSTAT.AINV2` bit is set if the adder 2 addition is invalid.
16 (RC/NW)	ARI2	Adder Result Overflow. The `FIR_MACSTAT.ARI2` bit is set if the adder 2 result is infinity. Indicates overflow in fixed-point mode.
15 (RC/NW)	ARZ2	Adder Result Underflow. The `FIR_MACSTAT.ARZ2` bit is set if the adder 2 result is zero.
14 (RC/NW)	MINV2	Multiply Invalid. The `FIR_MACSTAT.MINV2` bit is set if the multiplier 2 multiply operation is invalid.
13 (RC/NW)	MRI2	Multiplier Result Overflow. The `FIR_MACSTAT.MRI2` bit is set if the multiplier 2 result is infinity.
12 (RC/NW)	MRZ2	Multiplier Result Underflow. The `FIR_MACSTAT.MRZ2` bit is set if the multiplier 2 result is zero.
11 (RC/NW)	AINV1	Addition Invalid. The `FIR_MACSTAT.AINV1` bit is set if the adder 1 addition is invalid.
10 (RC/NW)	ARI1	Adder Result Overflow. The `FIR_MACSTAT.ARI1` bit is set if the adder 1 result is infinity. Indicates overflow in fixed-point mode.
9 (RC/NW)	ARZ1	Adder Result Underflow. The `FIR_MACSTAT.ARZ1` bit is set if the adder 1 result is zero.

Table 43-25: FIR_MACSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
8 (RC/NW)	MINV1	Multiply Invalid. The `FIR_MACSTAT.MINV1` bit is set if the multiplier 1 multiply operation is invalid.
7 (RC/NW)	MRI1	Multiplier Result Overflow. The `FIR_MACSTAT.MRI1` bit is set if the multiplier 1 result is infinity.
6 (RC/NW)	MRZ1	Multiplier Result Underflow. The `FIR_MACSTAT.MRZ1` bit is set if the multiplier 1 result is zero.
5 (RC/NW)	AINV0	Addition Invalid. The `FIR_MACSTAT.AINV0` bit is set if the adder 0 addition is invalid.
4 (RC/NW)	ARI0	Adder Result Overflow. The `FIR_MACSTAT.ARI0` bit is set if the adder 0 result is infinity. Indicates overflow in fixed-point mode.
3 (RC/NW)	ARZ0	Adder Result Underflow. The `FIR_MACSTAT.ARZ0` bit is set if the adder 0 result is zero.
2 (RC/NW)	MINV0	Multiply Invalid. The `FIR_MACSTAT.MINV0` bit is set if the multiplier 0 multiply operation is invalid.
1 (RC/NW)	MRI0	Multiplier Result Overflow. The `FIR_MACSTAT.MRI0` bit is set if the multiplier 0 result is infinity.
0 (RC/NW)	MRZ0	Multiplier Result Underflow. The `FIR_MACSTAT.MRZ0` bit is set if multiplier 0 result is zero.

FIR Output Data Base Register

The FIR_OUTBASE register contains the output word base address with the lower two bits removed

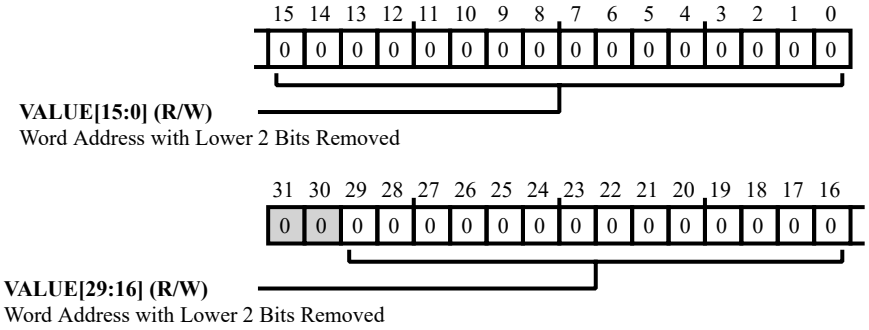

Figure 43-24: FIR_OUTBASE Register Diagram

Table 43-26: FIR_OUTBASE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:0 (R/W)	VALUE	Word Address with Lower 2 Bits Removed. The FIR_OUTBASE.VALUE bit field contains the word address with the lower 2 bits removed.

FIR Output Data Count Register

The FIR_OUTCNT register contains the 16-bit output buffer count.

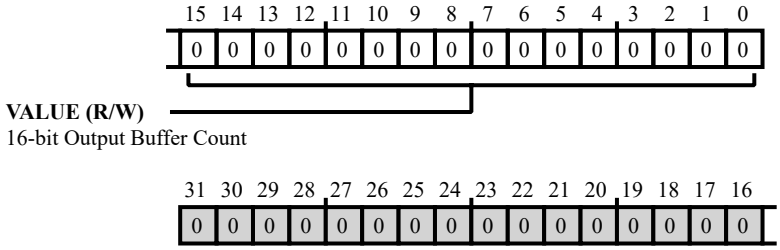

Figure 43-25: FIR_OUTCNT Register Diagram

Table 43-27: FIR_OUTCNT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	16-bit Output Buffer Count. The FIR_OUTCNT.VALUE bit field contains the 16-bit output buffer count.

FIR Output Data Index Register

The FIR_OUTIDX register contains the output word address with the lower two bits removed.

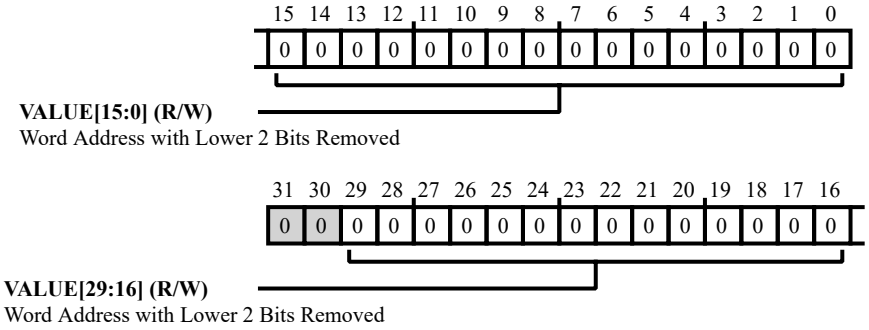

Figure 43-26: FIR_OUTIDX Register Diagram

Table 43-28: FIR_OUTIDX Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:0 (R/W)	VALUE	Word Address with Lower 2 Bits Removed. The FIR_OUTIDX.VALUE bit field contains the word address with the lower 2 bits removed.

FIR Output Data Modifier Register

The FIR_OUTMOD register contains the 16-bit output data buffer modifier.

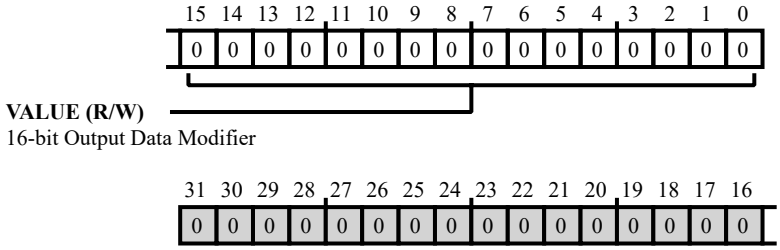

Figure 43-27: FIR_OUTMOD Register Diagram

Table 43-29: FIR_OUTMOD Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	16-bit Output Data Modifier. The FIR_OUTMOD.VALUE bit field contains the 16-bit output data modifier.

Software Control Register 1

The FIR_SCTL1 register is used to control software.

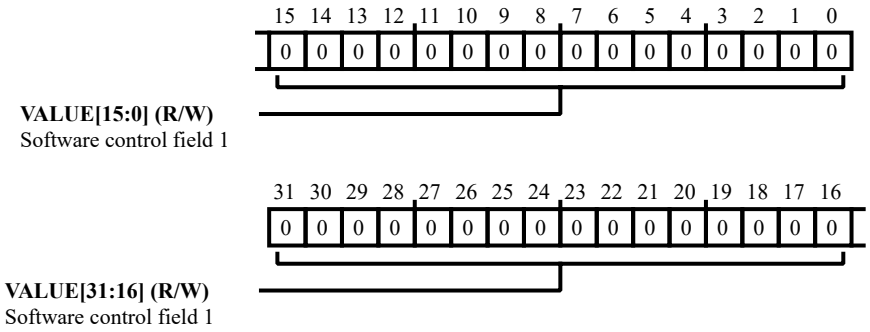

Figure 43-28: FIR_SCTL1 Register Diagram

Table 43-30: FIR_SCTL1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Software control field 1.

Software Control Register 2

The FIR_SCTL2 register is used to control software.

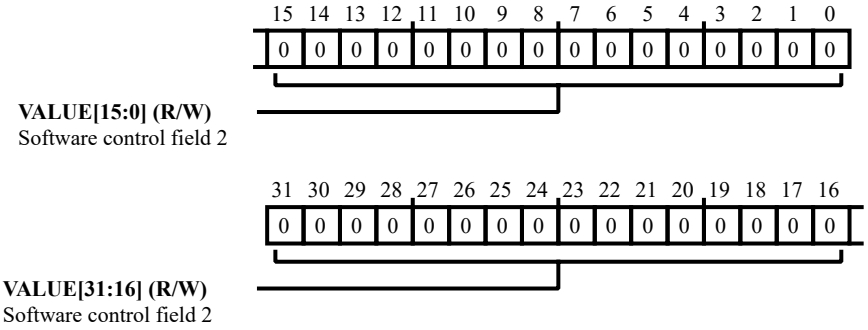

Figure 43-29: FIR_SCTL2 Register Diagram

Table 43-31: FIR_SCTL2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Software control field 2.

Secondary Global Control Register

The FIR_SGCTL register is used to configure the global parameters for the accelerator in ACM mode for loading CTL1 register bits as part of TCB.

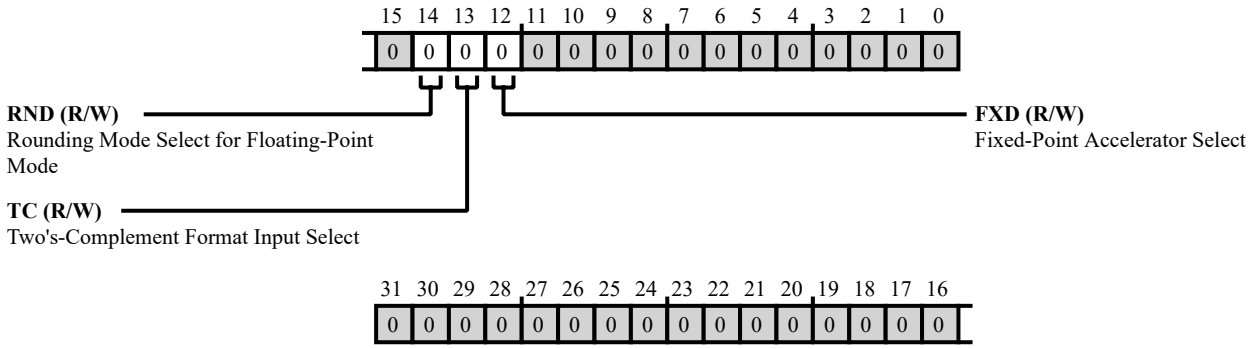

Figure 43-30: FIR_SGCTL Register Diagram

Table 43-32: FIR_SGCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
14 (R/W)	RND	Rounding Mode Select for Floating-Point Mode. The FIR_SGCTL.RND bit indicates whether the rounding mode is to the nearest or truncated (round towards zero).	
		0	Round to nearest
		1	Truncate
13 (R/W)	TC	Two's-Complement Format Input Select. The FIR_SGCTL.TC bit indicates the two's complement format input for fixed-point mode.	
		0	Unsigned integer
		1	Signed integer
12 (R/W)	FXD	Fixed-Point Accelerator Select. When set (=1), the FIR_SGCTL.FXD bit indicates a 32-bit fixed point accelerator. When cleared (=0), the bit indicates a 32-bit floating-point compatible with SHARC-XI.	
		0	32-bit floating-point
		1	32-bit fixed point

44 IIR Accelerator (IIR)

The processor includes an Infinite Impulse Response (IIR) filter accelerator implemented in hardware that reduces the processing load on the core, freeing it up for other tasks.

Features

The accelerator supports a maximum of 32 channels in legacy mode. In Auto Configuration Mode (ACM), there is no limit on number of channels. The accelerator locally stores all the biquad coefficients of 32 channels in legacy mode. Window size can be configured from 1 (sample-based) to 1024.

The IIR has the following features:

- Supports IEEE floating point format 32/40-bit
- Rounding modes compatible with SHARC+ core MACs
- Sample-based or window-based processing
- Up to 64 cascaded biquads per channel
- Up to 32 filter channels available in TDM
- Allows biquad save state storage
- Supports real-time coefficient slewing using a dedicated hardware slewing engine

NOTE: The IIR accelerator module has local memory that is not accessible by the core during regular operation mode. Unlike in the previous SHARC processors, the IIR accelerator modules each have access to the system memory (on-chip/off-chip).

Unlike in the previous SHARC processors, where only one of the IIR or FIR accelerators can be enabled at a time, the processor can simultaneously use both the IIR and the FIR accelerators.

IIR Definitions

The following definitions are helpful when using the IIR filter and calculating slewing coefficients.

Infinite Impulse Response (IIR) filter

A recursive filter calculates its output by using current and previous inputs, along with previous outputs. IIR filters are digital filters that have an infinite impulse response.

Automatic Configuration Mode (ACM)

The IIR accelerator loads biquad coefficients for only the current channel before processing the current channel.

Legacy Mode

The IIR accelerator loads biquad coefficients for all channels before processing the first channel.

Task Control Block (TCB)

A method to store task-specific parameters and calculation states in a user-initialized memory buffer and permitting user tasks to directly access the values. The reduction of the amount of time required for context switching can lessen the execution time for user tasks.

Biquad (biquadratic)

A second-order recursive digital linear filter, containing two poles and two zeros. In the Z domain, its transfer function consists of the ratio of two quadratic functions. The biquad form II implements the equation in two parts with difference equations and two less storage delay components.

Multiply and Accumulate (MAC) Unit

The IIR subblock with a pipelined multiplier and accumulator that performs floating-point calculations on data and fetches coefficients. Can perform 32-bit or 40-bit operations.

Window-based Processing Mode

Includes using a window size of one or greater (maximum of 1024) for a channel.

Save Biquad State Mode

The mode where the IIR filter stores the current biquad states in local memory when it must switch to another high-priority accelerator task. After resuming, these states can be reloaded, and IIR processing continued.

Slewing

Computation of IIR filter coefficients in real time and in parallel with IIR filtering. The slewing engine calculates coefficients using a slew rate, slew frequency (number of samples), and slewing time (number of iterations).

Slew Rate (α)

A 32-bit floating-point number ($0 \leq \alpha \leq 1$) that indicates the slewing process rate. Alpha (α) values approximating zero indicates a rapidly changing slew process. Values approximating one indicate a slow changing slew.

Slew Frequency (n)

Determines the number of samples (n+1) that pass before the IIR coefficients are slewed.

Slew Time (N)

Determines the number of iterations of coefficient slewing performed by the slewing engine.

Slew Mode

To achieve multiple target values for each coefficient, change the slew rate (either constant or linear) or set the slewing parameters for each channel.

Clocking

The IIR accelerator runs at the speed of core clock.

Functional Description

The ***IIR Accelerator Block Diagram*** shows the blocks of the IIR hardware accelerator.

The accelerator has:

- a coefficient memory size of 1440 × 40 bits (288 biquads x 5 coefficients).
- a data memory size of 576 × 40 bits (288 biquads x 2 states).
- one SHARC+ core compatible MAC unit with an input data buffer to supply data to the MAC.

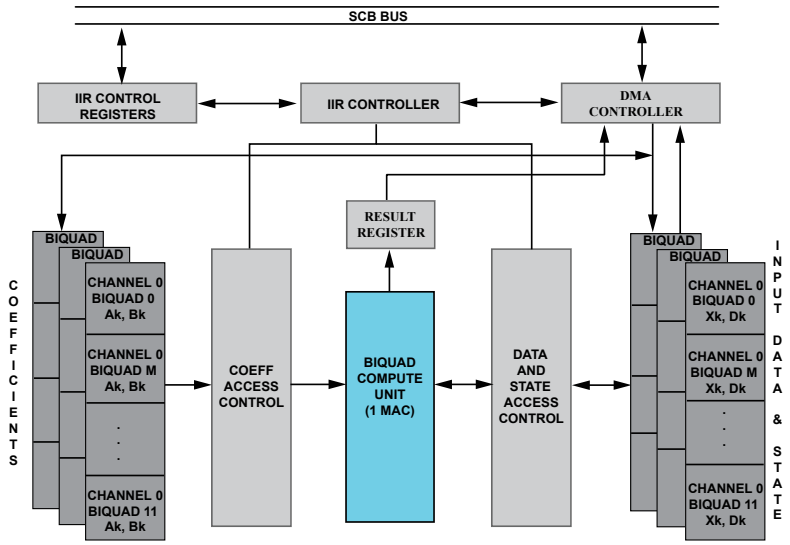

Figure 44-1: IIR Accelerator Block Diagram

A transposed direct form II biquadratic is used to implement the IIR accelerator, which reduces coefficient sensitivity. The ***Transposed Direct Form II Biquad*** figure shows the signal flow graph for the biquad structure.

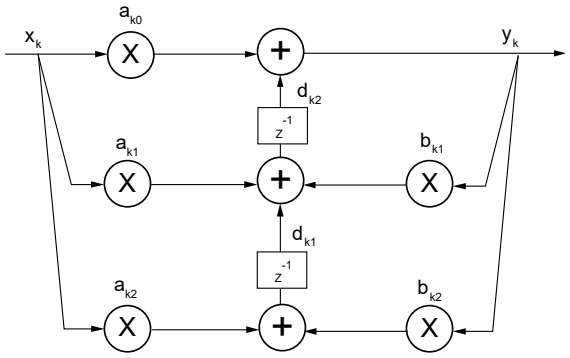

Figure 44-2: Transposed Direct Form II Biquad

The accelerator has the following logical subblocks.

- A data path unit with the following elements:
  - 32/40-bit coefficient memory (Ak, Bk) for storing biquad coefficients
  - 32/40-bit input data (Xk) and state (Dk)
  - One 40/32-bit floating-point multiplier and adder (MAC) unit
  - An input data buffer to efficiently supply data to MAC
  - One 40-bit result register to hold result of the biquad
- Configuration registers for controlling various parameters such as the number of biquads, the number of channels, interrupt control, and DMA control.

- A core access interface for writing the DMA/filter configuration registers and for reading the status registers.
- A DMA bus interface for transferring data to and from the accelerator. This interface also preloads the coefficients (Ak, Bk) and state (Dk) at startup.
- DMA configuration registers for the transfer of input data, output data, and coefficients.

ADSP-2184x IIR Register List

The IIR module reduces the processing load on the core. For more information on IIR functionality, see the IIR register descriptions.

Table 44-1: ADSP-2184x IIR Register List

Name	Description
IIR_ALPHA[n]	Channel n Alpha
IIR_CHNPTR	Chain Pointer Register
IIR_COEFIDX	Coefficient Buffer Index Register
IIR_COEFLEN	Coefficient Buffer Length Register
IIR_COEFMOD	Coefficient Index Modifier Register
IIR_CTL1	Global Control Register
IIR_CTL2	Channel Control Register
IIR_DBG_ADDR	IIR Debug Address Register
IIR_DBG_CTL	IIR Debug Control Register
IIR_DBG_RDDAT_HI	IIR Debug Read Data High Register
IIR_DBG_RDDAT_LO	IIR Debug Read Data Low Register

Multiply and Accumulate (MAC) Unit

The ***IIR MAC Unit*** figure shows a pipelined multiplier and accumulator unit that operates on the data and coefficients fetched from the data and coefficient memory. The MAC can perform 32-bit floating-point or 40-bit floating-point MAC operations. The 32-bit floating-point operations generate 32-bit results and the 40-bit floating-point operations generate 40-bit results.

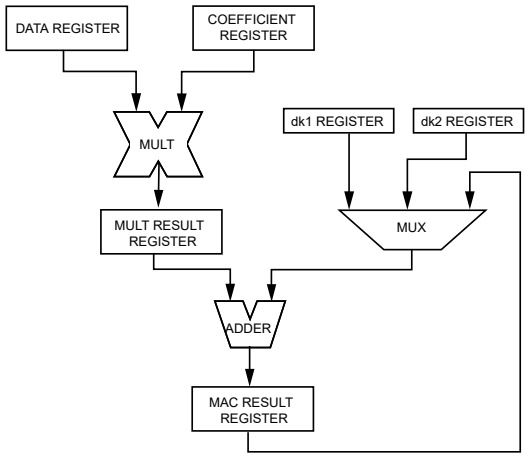

Figure 44-3: IIR MAC Unit

Input Data and Biquad State

The size of the data memory is 576 × 40 bits and locally holds the dk1 and dk2 state of all biquads. The DMA controller fetches the sample data from internal memory and calculates the output plus the dk1 and dk2 values for each biquad and stores them in local data memory.

Coefficient Memory

The size of coefficient memory is 1440 × 40 bits and stores all the coefficients for all biquads. At startup, the DMA loads the coefficients from system memory into local coefficient memory.

Internal Memory Storage

This section describes the required storage model for the IIR accelerator.

Coefficient Memory Storage

Store the coefficients and Dk values for a specific biquad BQD[k] in internal memory in the following order: Ak0, Ak1, Bk1, Ak2, Bk2, Dk2, and Dk1.

NOTE: The naming convention for the filter coefficients used here is different from the one used in MATLAB. The following conversion should be used when using MATLAB generated coefficients:

(Akx = bx and Bkx = -ax).

Store the coefficients for each biquad in the order:

```
b0, b1, -a1, b2, -a2, dk2, dk1
```

For N biquad stages, store the coefficients in the order:

```
b01, b11, -a11, b21, -a21, dk21, dk11,
b02, b12, -a12, b22, -a22, dk22, dk12,
,......
b0N, b1N, -a1N, b2N, -a2N, dk2N, dk1N.
```

where bxN and axN are the coefficients ([b, a]) for the Nth biquad stage.

Target Coefficient Memory Storage

For coefficient slewing, the structure of the target coefficient array is like the coefficient memory storage. The first five coefficient of each biquad are stored in internal memory with the order: Ak0, Ak1, Bk1, Ak2, and Bk2. Following the five coefficients, two zeroes replace the initial state values Dk1 and Dk2.

IMPORTANT: The naming convention used in this hardware reference and that used in MATLAB follows the same conversion rule described for the Coefficient Memory Storage (Akx = bx and Bkx = -ax).

Operating Modes

The accelerator operates:

- In Window Processing Mode, that also includes sample-based processing mode
- In 40-Bit Floating-Point Mode
- In Save Biquad State Mode
- In Auto Configuration Mode (ACM)
- Calculates Coefficient Slewing

Window Processing Mode

Select the sample-based processing mode by configuring window size to one. All biquads for a particular channel process one sample, and then calculate a final output sample in this mode.

In window-based mode, multiple output samples (maximum of 1024, equal to the window size) of that channel are calculated. After these calculations are complete, the accelerator begins processing the next channel. A register field provides a window size parameter to specify the length of the window.

40-Bit Floating-Point Mode

In 40-bit floating-point mode, the accelerator treats input data and coefficients as a 40-bit floating-point numbers. The 40-bit floating-point MAC operations generate 40-bit results. This mode can be selected by setting the `IIR_CTL1.FORTYBIT` bit.

In ACM mode, 40-bit floating-point mode can be selected by setting the `IIR_SGCTL.FORTYBIT` bit field for each channel.

As the DMA bus width is 32 bits, in 40-bit mode the IIR accelerator performs two packed 32-bit accesses to the memory to:

- fetch one 40-bit input or coefficient data
- store one 40-bit output word

The first 32-bit word provides the lower 32 bits and the 8 LSBs of the second 32-bit word provides rest of the upper 8 bits of the complete 40-bit word. The ***32-Bit to 40-Bit Packing*** figure shows the 32– to 40–bit packing used by the accelerator.

NOTE: Overhead time may be required to pack the input 40-bit data into the format acceptable by the IIR accelerator and for unpacking the output of accelerator to a format acceptable to the rest of the application.

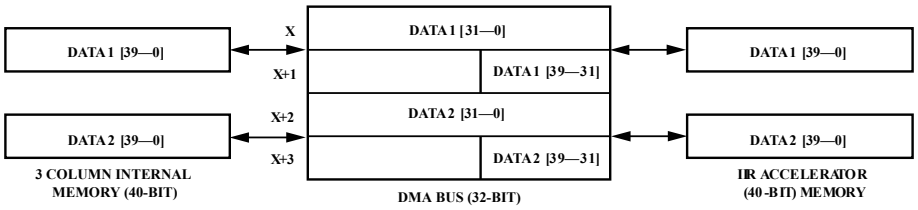

Figure 44-4: 32-Bit to 40-Bit Packing

Save Biquad State Mode

The `IIR_CTL1.SS` bit stores the current biquad states in local memory (writes all the Dk1 and Dk2 states back into the system memory states). This is useful for applications that require fast switching to another high-priority accelerator task—a required IIR to FIR processing transition for example. After resuming, these states can be reloaded and IIR processing can be continued. DMA status is automatically stored after each iteration.

NOTE: In legacy mode, the accelerator loads the biquad coefficients for all the channels before processing the first channel. After processing the last channel, when the `IIR_CTL1.SS` bit is set, the accelerator stores the biquad states of all the channels in local memory (writes all the Dk1 and Dk2 states back into the system memory states). In ACM mode, the accelerator loads the biquad coefficients for only the current channel

before starting to process the current channel. When the IIR_SGCTL.SS bit is set, the accelerator stores the biquad states of the current channel in local memory before starting calculations for the next channel.

NOTE: During the save state operation, it is not permitted to have write access to any of the IIR accelerator registers that are loaded by chaining. Attempted writes to these registers can result in the blocking of IOP core reads until the save state operation completes.

Auto Configuration Mode (ACM)

The accelerator can be operated in legacy mode or Auto Configuration Mode (ACM). ACM is configured by setting the IIR_CTL1.ACM bit. The default functional mode is legacy mode. The accelerator must be disabled before changing the accelerator mode.

The ACM provides the following features:

- Halt and Queuing

  The core can pause processing the current Transfer Control Block (TCB) chain by setting the IIR_CTL1.HALT bit. The accelerator acknowledges the core by setting the IIR_DMASTAT.HALT_STAT bit. The core can then submit or insert new TCBs. After the core acts, the accelerator resumes processing by clearing the IIR_CTL1.HALT bit. Before halting the accelerator, when the initial TCB chain is processed, the accelerator goes to the idle state. To do this, disable the accelerator and then enable it by toggling the IIR_CTL1.EN. Clear the IIR_CTL1.HALT bit to resume processing.

- No Channel Number Limitation

  Unlike in legacy mode, there is no fixed channel number limitation, and the accelerator ignores the value programmed in the IIR_CTL1.CH field. The application can queue an unlimited number of channels and TCBs dynamically, plus the accelerator keeps processing the TCBs until the chain pointer is null.

- Selective Interrupt

  The core can enable and mask interrupt generation for each channel by setting the IIR_CTL2.IMASK bit. When the bit is cleared, an interrupt generates after the channel completes.

- Selective Controller/Target Trigger

  The core can enable/mask trigger generation by the accelerator after the end of processing of each channel using the IIR_CTL2.TMASK bit. The accelerator can also wait for a trigger after loading the TCB and coefficients and before processing a channel for which the IIR_CTL2.TWAIT bit is set.

  This feature can also be enabled in legacy mode by setting the IIR_CTL1.L_TIMASK_EN and IIR_CTL1.L_TWAIT_EN bits. In legacy mode, when the IIR_CTL1.L_TIMASK_EN and IIR_CTL1.L_TWAIT_EN bits are set, then the IIR_CTL2.TMASK and IIR_CTL2.TWAIT bits can be used to enable/mask trigger generation and wait for a trigger for each channel respectively.

Additionally, use the IIR_CTL1 register to change parameters such as rounding mode, 40-bit mode, and save state for each channel. The IIR_SCTL1 and IIR_SCTL2 registers can be used as general-purpose registers.

Coefficient Slewing

The following sections describe the features, parameters, and real-time processing for coefficient slewing.

- Coefficient Slewing Features
- Coefficient Slewing Parameters
- Coefficient Real-time Slewing

Coefficient Slewing Features

Enable the slewing feature by setting `IIR_CTL1.SLEW_EN` bit. When this bit is cleared, the IIR operates in legacy mode. Once set, this bit should not be cleared until the `IIR_CTL1.EN` bit is cleared.

The slewing feature does not support the ACM operating mode.

The slewing feature can be enabled in burst/non-burstmode, 40-bit or 32-bit mode, and in the channel auto interate (CAI) mode.

The IIR instances IIR0 and IIR1 each have one slewing engine.

Slewing calculations happen in parallel to its biquad execution within the IIR block. When slewed coefficients are needed for the next sample calculation, slewing of coefficients happens during the current sample.

Coefficients can be slewed for each sample (sample -based) or after a configured interval of samples.

Slew parameters can be configured on a per channel basis using the:

- Slewing Rate (α)
- Slewing Frequency (n)
- Slewing Time (N)

These parameters are part of the TCB for each channel. The TCB length is increased by three for legacy mode when the coefficient slewing is enabled.

With appropriate values of α, n and N, the user can ensure that the coefficients approximate their target values at the end of the slewing process for each channel. Without proper values, the user may observe audio glitches after slewing completion because of the differences in target and final coefficients.

A separate memory for storing the Target Coefficients (C_T) resides inside the IIR accelerator.

The slewing rate (α) can be kept constant or can be linearly changing from one to zero. The `IIR_CTL2.SLEW_LALPHA_MODE` control bit defines the alpha configuration (constant or varying) operating for each channel.

Whenever the slewing saturates or slewing time expires (that is, after N iterations), C[n] either remains at the last iterated value or attains C_T, based on the `IIR_CTL2.SLEW_SAT_EN` bit set for each channel.

Slewing parameters (α, N, n) and target coefficients (C_T) can be updated during the slewing process by enabling the `IIR_CTL1.SLEW_PARAMS_UPDATE` bit and by disabling and reenabling the DMA.

During channel switching, the slewing engine remembers the state of slewing in the current channel and restores the state once the channel comes back.

Coefficient Slewing Parameters

Slewing Rate (α)

The slewing rate (α) is 32-bit floating-point number with a value zero through one. When α approximates one, it indicates a slow slewing process. When α approximates zero, it indicates a fast slewing process. The slewing rate provides a 32-bit floating-point number as the sixth element in the task control block (that is, `TCB+0x5` or the `IIR_ALPHA[n]` register for the nth channel).

Slewing Frequency (n)

The slewing frequency (n) determines after how many samples the slew calculation for the IIR coefficients happens. When n = 0, beginning from the second sample every sample output is calculated using the updated slewed coefficients (see the *IIR Coefficient Slewing (constant alpha mode) n=0 and n=3 Examples* figure). For n > 0, the accelerator coefficients are slewed after every n+1 samples and output of n+1 samples are calculated using last slewed coefficients. An internal counter keeps track of the number of samples completed to take a decision on performing the slewing for the next sample.

For instance, when n = 3, starting from the 5th sample, every fourth sample (N+1) output is calculated using new coefficients (that is, fifth through eighth samples). Coefficients are slewed again at the nineth sample and every fourth sample thereafter.

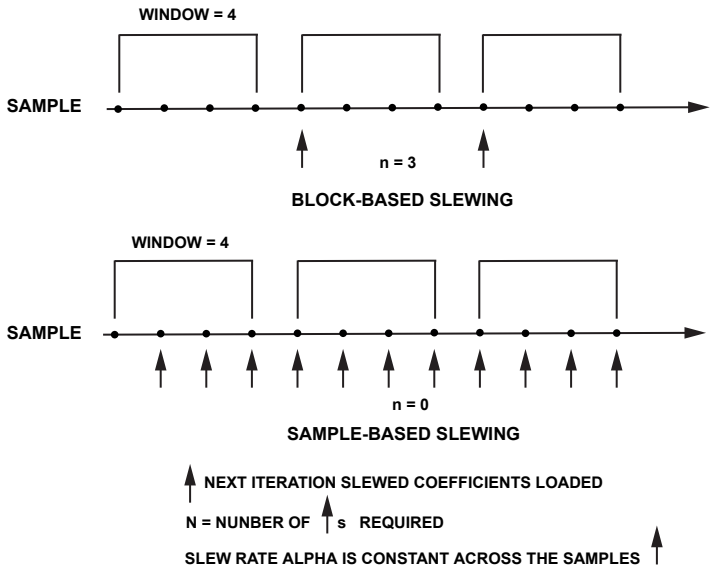

Figure 44-5: IIR Coefficient Slewing (constant alpha mode) n=0 and n=3 Examples

Slewing Time (N)

The slewing time (N) indicates the number of iterations of coefficient slewing performed by the slewing engine. This parameter is defined for each channel and decremented inside the slewing engine after each slewing iteration.

Once it reaches zero, the slewing stops. The total number of samples processed during an entire slewing interval is (n*N) samples.

Coefficient Real-time Slewing

This processor has a dedicated hardware to slew the IIR coefficients in real time and in parallel to the IIR filtering. Typically, slewing done through software takes up significant core MIPS and DMA overhead for loading slewed coefficients. The dedicated hardware engine placed inside the IIR filter can slew IIR biquad coefficients in real time and avoids using the core. Slewing ensures a smooth transition of IIR coefficients during the change of IIR parameters, that can otherwise result in audio click noises.

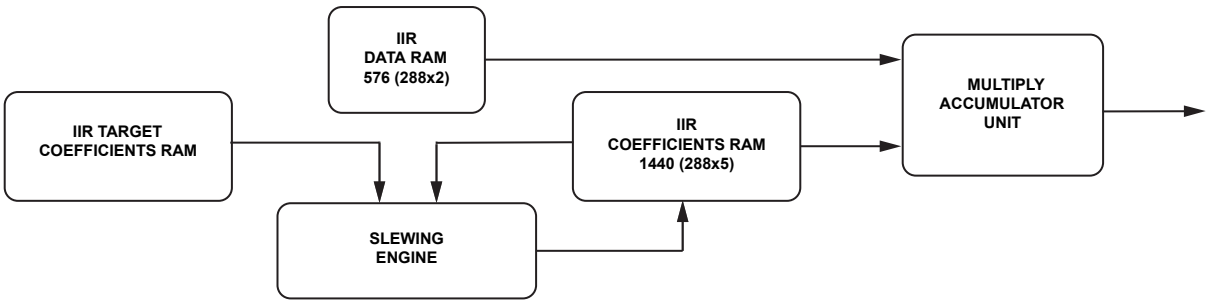

Figure 44-6: IIR Slewing Block Diagram

One slewing engine connects to each of the IIR filters. The coefficient slewing is done based on the following recursive equation:

$C[n] = (1-\alpha) * C_T + \alpha * C[n-1]$, where $C = \{Ak0, Ak1, Bk1, Ak2, Bk2\}$ and $0 \leq \alpha \leq 1$
where C_T is the target coefficient, α is the slewing rate, and n is sample number.

Data Transfers

The IIR filter works exclusively through DMA.

IIR Accelerator TCB

The location of the DMA parameters for the next sequence comes from the chain pointer register. This register points to the next set of DMA parameters stored in the system memory of the processor known as the Task Control Block (TCB). In chained DMA operations, the processor automatically initializes and then begins another DMA transfer once the current DMA transfer completes. Each new set of parameters is stored in a user-initialized memory buffer or TCB for a chosen peripheral.

Chain Assignment

The structure of a TCB is conceptually the same as the structure of a linked list. Each TCB has several data values and a pointer to the next TCB. The chain pointer of a TCB can point to itself to re-run the same DMA continuously. The IIR accelerator reads each word of the TCB and loads it into the corresponding register. A TCB with a chain pointer register value of zero indicates the end of the chain (no further TCBs to load). The IIR

accelerator supports circular buffer chained DMA. The following tables show the required TCBs for chained DMA in Legacy Mode and ACM. TCB refers to the start address of the TCB array.

NOTE: The IIR accelerator DMA has two available TCB loading sequences:

- Loads five parameters for the coefficients (IIR_CTL2, IIR_COEFIDX, IIR_COEFMOD, IIR_COEFLEN, and IIR_CHNPTR).
- Loads 10 parameters for the data (IIR_CTL2, IIR_INIDX, IIR_INMOD, IIR_INLEN, IIR_INBASE, IIR_OUTIDX, IIR_OUTMOD, IIR_OUTLEN, IIR_OUTBASE, and IIR_CHNPTR).

Initialize IIR_CHNPTR to TCB+12 in legacy mode and TCB+15 in ACM.

DMA Access

The IIR accelerator has two DMA channels (accelerator input and output) to connect to the system memory. The DMA controller fetches the data and coefficients from memory and stores the result.

Burst Mode Access

Burst mode enhances the throughput of the DMA channel and reduces the overall load on the system. When the `IIR_CTL1.BURSTEN` bit is set, it loads all the biquads for all the channels with burst enabled. The IIR module supports only INCR8 burst.

Chain Pointer DMA

The DMA controller supports a circular buffer chain pointer DMA. One transfer control block (TCB) must be configured for each channel. The TCB contains:

- A control register value to configure the filter parameters (such as number of biquads, window size) for each channel. For ACM, additional parameters such as an interrupt mask, trigger mask, and trigger wait exist.
- Software control register values in ACM for each channel.
- Secondary control register value in ACM to configure rounding mode, 40-bit mode, and save state for each channel.
- DMA parameter register values for the input data.
- DMA parameter register values for coefficient load.
- DMA parameter register values for output data.

In legacy mode, The chain pointer (`IIR_CHNPTR`) field of the last channel TCB should point to the first channel TCB. This configuration exists so that when the IIR accelerator is enabled, the module:

1. Loads the coefficients (Ak, Bk) and state variables (Dk) for all the channels into the local coefficient memory of the IIR.
2. Loops back to the first channel again to start fetching the input data for processing.

In ACM, the chain pointer field of the last channel TCB need not point to the first channel TCB.

When the accelerator is enabled, the module:

1. Only loads the coefficients (Ak, Bk) and state variables (Dk) for the current channel being processed.
2. Starts fetching input data for processing.
3. After processing the current channel, when the `IIR_SGCTL.SS` bit is set, it saves the biquad states of the current channel in local memory and moves to the next channel.

In ACM, the accelerator keeps processing the TCBs until the chain pointer becomes null.

The accelerator loads the TCB into its internal registers and uses these values to fetch coefficients, fetch data, and store results. After processing a window of data for any channel, the accelerator writes back the `IIR_INIDX` (input

index register) and IIR_OUTIDX (output index register) values to the TCB in memory. Data processing can then begin from where it left off during the next time slot of that channel.

For 32-bit mode, the write-back values for the index registers are equal to IIRII + W and IIROI + W.

For 40-bit mode, the write-back values are: IIR_INIDX + 2 × W and IIR_OUTIDX + 2 × W.

Accelerator input and output channels connect to system memory.

NOTE: The IIR_CTL2 register is part of the IIR TCB. This configuration allows software to program individual IIR channels having different control attributes.

In ACM, when the IIR_CTL1.SMQ_LIUPS_EN bit is set, the accelerator updates the IIR_INIDX and IIR_OUTIDX bit fields of the TCB in memory after processing a window of data and according to the circular buffer scheme. When the IIR_CTL1.SMQ_LIUPS_EN bit is cleared, the accelerator updates the IIR_INIDX and IIR_OUTIDX bit fields of the TCB in memory to 0x00000000 and 0xFFFFFFFF after processing a window of data. The IIR_CTL1.SMQ_LIUPS_EN bit is only valid in ACM.

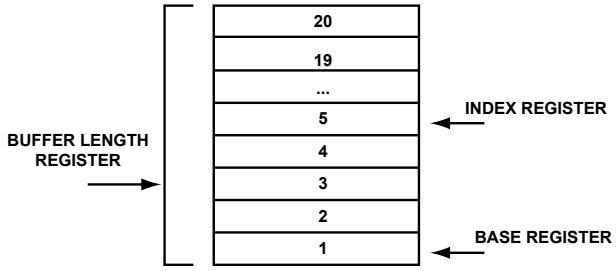

Figure 44-7: Circular Buffer Addressing

Interrupts

The ***IIR Interrupt Overview*** table provides the source of interrupt and service instructions for the IIR interrupts.

Table 44-8: IIR Interrupt Overview

Accelerator Mode	Default Programmable Interrupt	Sources	Masking	Service
Legacy Mode	IIR_DMA	Window Complete	N/A	ROC from IIR_DMASTAT + RTI instruction
		All channels complete		
	IIR_STAT	MAC IEEE floating point exceptions	N/A	ROC from IIR_MACSTAT + RTI instruction
		MAC fixed point overflow		

Table 44-8: IIR Interrupt Overview (Continued)

Accelerator Mode	Default Programmable Interrupt	Sources	Masking	Service
Auto Configuration Mode	IIR_DMA	Window Complete	IIR_CTL2.IMASK	ROC from IIR_DMASTAT + RTI instruction
	IIR_STAT	MAC IEEE floating point exceptions	N/A	ROC from IIR_MACSTAT + RTI instruction
		MAC fixed point overflow	N/A	

Sources

The IIR module drives two interrupt signals, IIR_DMA for the DMA status and IIR_STAT for the MAC status. The IIR module generates interrupts as described in the following sections.

Window Complete

This interrupt generates at the end of each channel when all the output samples are calculated for a window and the channel writes back updated index values.

In legacy mode, when the IIR_CTL1.CCINTR bit is set, an interrupt generates after completion of window processing of each channel. In ACM, the interrupt generation can be selectively masked using the IIR_CTL2.IMASK bit for each channel.

Interrupt masking for each channel can be enabled in legacy mode by setting the IIR_CTL1.L_TIMASK_EN bit. In legacy mode, when the IIR_CTL1.L_TIMASK_EN bit is set, interrupt generation for each channel is controlled using the IIR_CTL2.IMASK bit.

All Channels Complete

This interrupt generates when all the channels are complete or when one iteration of time slots completes. The interrupt follows the access completion rule, where the interrupt generates when all data are written back to system memory.

The All Channels Complete interrupt source only applies in legacy mode. When the IIR_CTL1.CCINTR and IIR_CTL1.L_TIMASK_EN bits are not set in Legacy Mode, the all channel complete interrupt generates. In ACM, interrupt generation for each channel is controlled using the IIR_CTL2.IMASK bit.

NOTE: In ACM, the Output DMA complete interrupt can be generated after the Save State completes for the channel by clearing the IIR_SGCTL.SSESEL bit . When this bit is set, the Output DMA interrupt generates before the Save State completes for the channel.

In Legacy Mode, when the IIR_CTL1.CCINTR and IIR_CTL1.SSESEL bits are cleared, the All Channels Done Interrupt generates after the Save State operation completes for all the channels.

MAC Status

A MAC status interrupt generates under the following conditions:

- Multiplier result zero–set when multiplier result is zero
- Multiplier result infinity–set when multiplier result is infinity
- Multiply invalid–set when multiply operation is invalid
- Adder result zero–set when adder result is zero
- Adder result infinity–set when adder result is infinity
- Adder invalid–set when addition is invalid

The slewing engine inside IIR accelerator has a floating-point subtractor, multiplier, and adder for calculating the next iteration of coefficients. The slewing engine interrupts are ORed with the previous IIR MAC Status interrupt and only sampled when slewing is enabled (set the `IIR_CTL1.SLEW_MAC_INT_EN` bit). A MAC status interrupt generates for any of the following conditions:

- Adder output is infinity, invalid, or zero
- Multiplier output is infinity, invalid, or zero
- Subtractor output is infinity or invalid

Service

The DMA interrupt status bits are sticky and are cleared when the DMA status register is read. When a MAC status interrupt occurs, programs can find this state (and clear) by reading the MAC status register (`IIR_MACSTAT`). The MAC interrupt status bits are sticky.

The status interrupt sources are derived from the `IIR_MACSTAT` register. A status interrupt can occur due to the last set of MAC operations of a processing iteration that correspond to a particular channel. The interrupt is generated continuously and cannot be stopped, even after disabling the accelerator. The interrupt can only be stopped when another processing iteration results in a non-zero or valid multiply or add result.

Programming Model

The following sections provide programming examples for legacy and auto configuration modes.

The Coefficient Slewing Programming section provides detailed programming steps for the different modes to calculate slewing coefficients.

Programming Legacy Mode and ACM

- Legacy Mode Programming
- Auto Configuration Mode Programming

Legacy Mode Programming

The IIR accelerator supports up to 32 channels which are time division multiplexed (TDM). Each channel can have a maximum of 64 biquads. The window size for each channel is configurable using the control registers. The maximum configured window size is 1024 samples.

For programming multi-channel filtering in Legacy Mode:

1. Program the number of channels using the `IIR_CTL1.CH` bits.
2. Configure the TCBs in system memory with one channel TCB pointing to the next channel TCB. The TCB of the last channel should point to the TCB of the first channel.
3. Write the first TCB value into the `IIR_CHNPTR` register and enable the accelerator.
4. When the `IIR_CTL1.BURSTEN` bit is set, ensure that the coefficient buffer end address plus seven words does not fall outside the valid address range and the buffer is initialized. When the burst feature is enabled, the IIR module issues an INCR8 burst. When the data count % 8== 7, the extra seven words are always read, but ignored by the IIR module.

NOTE: Data count = ∑(Bn*7) or ∑(Bn*14); where Bn is number of biquads for channel N. Each biquads contains 7 words for 32-bit mode or 14 words in 40-bit mode.

The ***Biquad Processing Program Flow*** figure shows the biquad processing program flow.

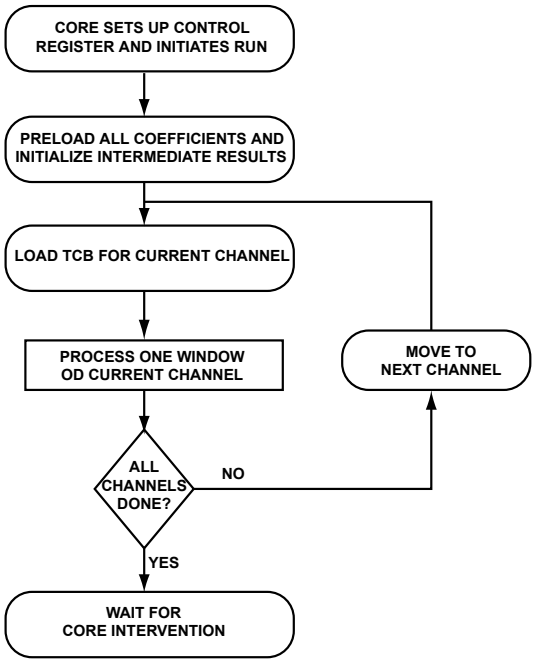

Figure 44-8: Biquad Processing Program Flow

The accelerator uses the following procedure to process biquads.

1. The controller loads all coefficients of all the channels into local storage.

2. Once all the coefficients are loaded, the controller goes to the first biquad of the first channel and calculates the output of the first biquad and updates the intermediate results for that biquad. When the `IIR_CTL1.L_TWAIT_EN` bit is set and the `IIR_CTL2.TWAIT` bit is set for the channel, the accelerator waits for the input trigger to start the computation.
3. The accelerator then moves to the next biquad of that channel and repeats the process until all the biquads for that channel are completed and the results are stored to memory.
4. The procedure is repeated for the next sample until processing completes for one window of the corresponding channel.
5. After one channel window is processed, the accelerator moves to the next channel and computes the results.

NOTE: All the addresses must be aligned on 32-bit address boundaries and must not contain the lower two bits (assumed to be zeros).

Auto Configuration Mode Programming

For ACM, there is no limit on the number of channels the accelerator can process. The accelerator keeps processing the TCBs until the chain pointer becomes null. Each channel can have a maximum of 64 biquads. The maximum configured window size is 1024 samples.

The Multi-channel Filtering in Auto Configuration Mode figure shows multi-channel filtering in ACM. Multiple channels are processed in a time division multiplexed (TDM) format.

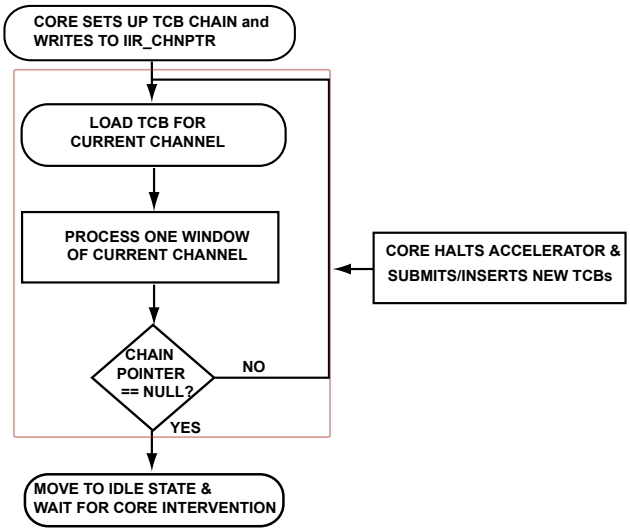

Figure 44-9: Multi-channel Filtering in Auto Configuration Mode

To program and understand the multi-channel filtering in ACM:

1. Configure the TCBs in system memory with the one channel TCB pointing to the next channel TCB. There is no limit on the number of channels to be configured. The TCB of the last channel does not need to point to the TCB of the first channel.

2. Write the first TCB value to the IIR_CHNPTR register and enable the accelerator.

   The accelerator fetches the first channel TCB. Using it as pointer, loads the biquad coefficients and biquad states for that channel into the IIR local memory and loads the IIR_CTL2 and IIR_SGCTL registers to configure the filter parameters corresponding to that channel.

   When the IIR_CTL2.TWAIT bit is set, the accelerator waits for a input trigger to start the window processing for the channel.

   The accelerator computes the output of the first biquad and updates the intermediate results for that biquad. Then, the accelerator moves to the next biquad of that channel and repeats the process until all the biquads for that channel are completed and the results are stored to memory. The process is repeated with the next sample until one window of the corresponding channel is processed. When the IIR_CTL1.SS bit is set, the accelerator saves the states of the biquads of the channel into system memory. If the IIR_CTL2.TMASK bit is cleared the accelerator sends an output trigger after completion of processing the channel.

   When the IIR_CTL2.IMASK bit is cleared, the accelerator interrupts the core after completion of processing a particular channel.

   At the end of the window, the accelerator updates the IIR_INIDX and IIR_OUTIDX registers to 0x00000000 and 0xFFFFFFFF in the TCB of system memory and moves to the next channel.

3. At any instant, the core can halt the accelerator as needed. It sets the IIR_CTL1.HALT bit and appropriately takes action to submit/insert new TCBs and clears the IIR_CTL1.HALT bit to resume channel processing.

   When the IIR_CHNPTR register is zero (last channel is being processed or channel processing is complete) after halting the accelerator, the IIR_CHNPTR register is written before resuming the accelerator channel processing.

   When the accelerator is idle after halt, IIR_CTL1.EN bit is toggled to disable and re-enable the accelerator and the IIR_CTL1.HALT bit is cleared and the accelerator resumes channel processing.

4. The accelerator continues processing until all the channels are complete. Repeat *Step 3* (as required) to submit or insert new channels.

Coefficient Slewing Programming

- Coefficient Slewing Program Flow
- Programming Constant Alpha Slewing Mode
- Programming Linear Changing Alpha Slewing Mode
- Programming Intermediate Target Coefficient Update Mode

NOTE: The save state bit should be disabled (IIR_CTL1.SS =0) when the coefficient slewing bit is enabled (IIR_CTL1.SLEW_EN =1).

Coefficient Slewing Program Flow

The *Slewing Operation Program Flow* figure captures the coefficient slewing program flow that is common for all slewing modes described:

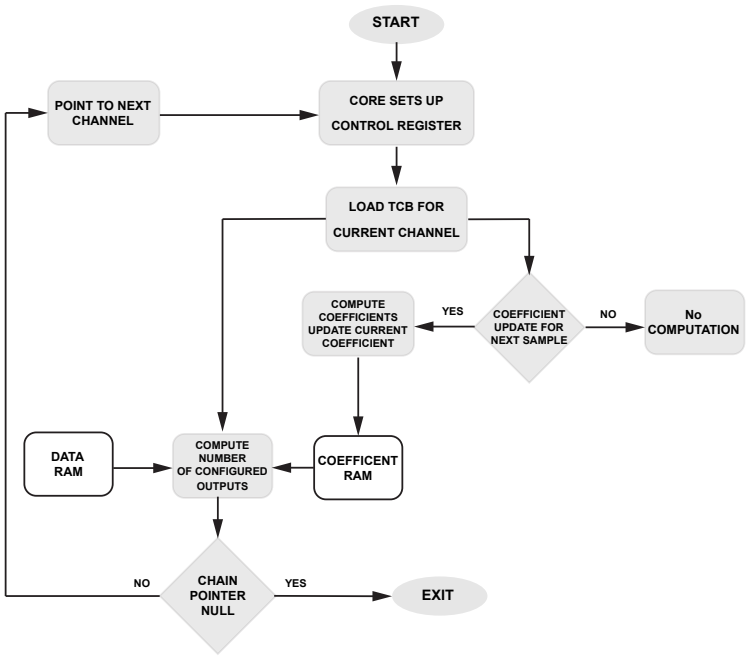

Figure 44-10: Slewing Operation Program Flow

Programming Constant Alpha Slewing Mode

To program slewing engine in constant alpha (α) mode, follow the below mentioned steps:

1. Enable coefficient slewing by setting the `IIR_CTL1.SLEW_EN` bit.
2. Provide the pointer to the target coefficient memory (`TCB+0x4`, IIR_CTIDX) along with current coefficient memory pointer (`TCB+0x3`, `IIR_COEFIDX`).
3. Set slewing rate (α) for the current channel using the 32-bit float format (`TCB+0x5`, `IIR_ALPHA[n]`).
4. Program the slewing frequency (n) and slewing time (N) values at (`TCB+0x6`, IIR_Nn) using the format in the `IIR_SLEW_CNFG[n]` register. Bits[0:7] should hold the value of slewing frequency (n) and bits[23:8] should hold the value of slewing time (N). The remaining bits must be zero.
5. Clear the `IIR_CTL2.SLEW_LALPHA_MODE` bit (`TCB+0xF`) to configure the slewing engine for constant alpha slewing mode.
6. When exact target coefficients are required after N iterations of slewing, set the `IIR_CTL2.SLEW_SAT_EN` bit to one.

NOTE: In constant alpha slewing mode, the window size should be a multiple of the slewing frequency (n+1).

Programming Linear Changing Alpha Slewing Mode

In this mode, the slewing rate (α) changes along with the coefficients after every iteration of slewing. During N slewing iterations, the value of alpha changes as (N-1)/N, (N-2)/N, … ,1/N, 0/N. Because α=0 for the last iteration of slewing, exact target coefficients are reached for each biquad.

To program the slewing engine in linearly changing alpha (α) mode, follow these steps:

1. Enable coefficient slewing by setting the `IIR_CTL1.SLEW_EN` bit.
2. Provide the pointer to the target coefficient memory (`TCB+0x4`, IIR_CTIDX) along with current coefficient memory pointer (`TCB+0x3`, `IIR_COEFIDX`).
3. Set slewing rate (α) for the current channel using the 32-bit float format (`TCB+0x5`, `IIR_ALPHA[n]`).
4. Program the slewing frequency (n) and slewing time (N) values at (`TCB+0x6`, IIR_Nn) using the format in the `IIR_SLEW_CNFG[n]` register. Bits[0:7] should hold the value of slewing frequency (n) and bits[23:8] should hold the value of slewing time (N). The remaining bits must be zero.
5. Set the `IIR_CTL2.SLEW_LALPHA_MODE` bit to enable linear varying alpha mode for this channel.
6. Program the slewing rate (α) in (`TCB+0x5`, `IIR_ALPHA[n]`) as 1/N in 32-bit float format. The slewing engine internally calculates the actual alpha to be used for each iteration.
7. The value of alpha is only updated at the start of the window. This restricts the slewing frequency (n) to a multiple of the window sample size. That is, `n = p*(window size-1)`, where p=1, 2, 3…

Programming Intermediate Target Coefficient Update Mode

Use Intermediate Target Coefficient Update Mode for achieving multiple target values for each coefficient after each slewing interval.

To program the slewing engine in Coefficient Update Mode, follow these steps:

1. Enable coefficient slewing by setting the `IIR_CTL1.SLEW_EN` bit.
2. Provide the pointer to the target coefficient memory (`TCB+0x4`, IIR_CTIDX) along with current coefficient memory pointer (`TCB+0x3`, `IIR_COEFIDX`).
3. Set slewing rate (α) for the current channel using the 32-bit float format (`TCB+0x5`, `IIR_ALPHA[n]`).
4. Program the slewing frequency (n) and slewing time (N) values at (`TCB+0x6`, IIR_Nn) using the format in the `IIR_SLEW_CNFG[n]` register. Bits[0:7] should hold the value of slewing frequency (n) and bits[23:8] should hold the value of slewing time (N). The remaining bits must be zero.
5. The slewing parameters slew rate(α), C_T, slewing time (N), and slewing frequency (n) can be updated during the slewing process.
6. When servicing a DMA interrupt, toggle the `IIR_CTL1.DMAEN` and `IIR_CTL1.SLEW_MAC_INT_EN` bits from zero to one to enable this mode.
7. When this mode is enabled, the IIR loads updated values of alpha, N, n, and the target coefficients.

ADSP-2184x IIR Register Descriptions

The IIR filter accelerator (IIR) contains the following registers.

Table 44-9: ADSP-2184x IIR Register List

Name	Description
IIR_ALPHA[n]	Channel n Alpha
IIR_CHNPTR	Chain Pointer Register
IIR_COEFIDX	Coefficient Buffer Index Register
IIR_COEFLEN	Coefficient Buffer Length Register
IIR_COEFMOD	Coefficient Index Modifier Register
IIR_CTL1	Global Control Register
IIR_CTL2	Channel Control Register
IIR_DBG_ADDR	IIR Debug Address Register
IIR_DBG_CTL	IIR Debug Control Register
IIR_DBG_RDDAT_HI	IIR Debug Read Data High Register
IIR_DBG_RDDAT_LO	IIR Debug Read Data Low Register
IIR_DBG_WRDAT_HI	IIR Debug Write Data High Register
IIR_DBG_WRDAT_LO	IIR Debug Write Data Low Register
IIR_DMASTAT	DMA Status Register
IIR_INBASE	Input Buffer Base Register
IIR_INIDX	Input Data Index Register
IIR_INLEN	Input Data Buffer Length Register
IIR_INMOD	Input Data Index Modifier Register
IIR_MACSTAT	MAC Status Register
IIR_OUTBASE	Output Buffer Base Register
IIR_OUTIDX	Output Data Buffer Index Register
IIR_OUTLEN	IIR Output Data Buffer Length Register
IIR_OUTMOD	IIR Output Data Index Modifier Register
IIR_SCTL1	Software Control Register1
IIR_SCTL2	Software Control Register2
IIR_SGCTL	Secondary Global Control Register
IIR_SLEW_CNFG[n]	Channel 0 Slewing Duration and Frequency

Channel n Alpha

The `IIR_ALPHA[n]` register gives access to Alpha, which is in 32-bit floating-point format. The register has both read and write access. However, a write to this register cannot be performed during non-IDLE state of DMA.

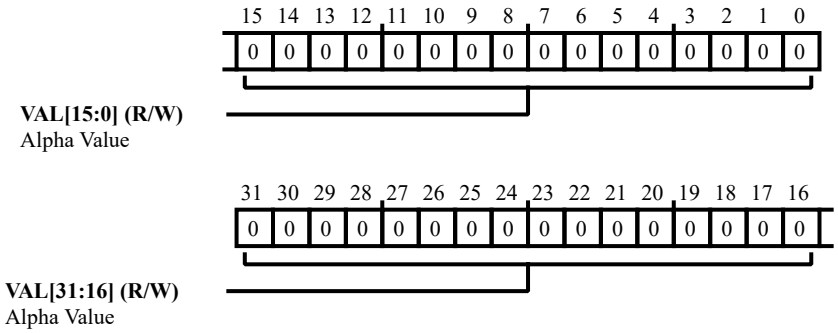

Figure 44-11: IIR_ALPHA[n] Register Diagram

Table 44-10: IIR_ALPHA[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VAL	Alpha Value. The `IIR_ALPHA[n].VAL` bit field indicates the alpha value for channel n in slewing mode.

Chain Pointer Register

The `IIR_CHNPTR` register should be written with word address without the lower 2 bits.

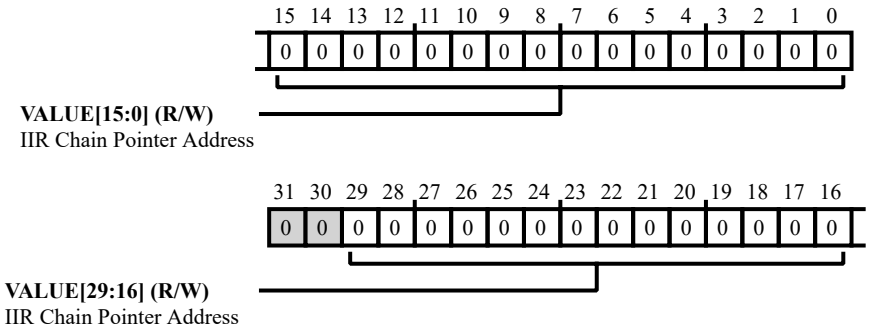

Figure 44-12: IIR_CHNPTR Register Diagram

Table 44-11: IIR_CHNPTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:0 (R/W)	VALUE	IIR Chain Pointer Address. The `IIR_CHNPTR.VALUE` bit field contains the chain pointer address.

Coefficient Buffer Index Register

The IIR_COEFIDX register contains the word address with the lower 2 bits removed.

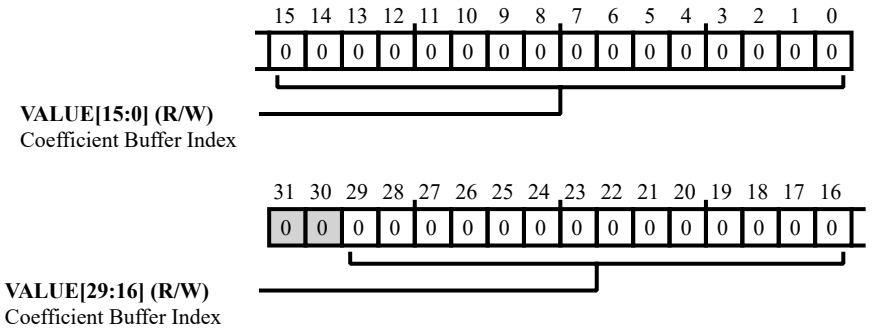

Figure 44-13: IIR_COEFIDX Register Diagram

Table 44-12: IIR_COEFIDX Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:0 (R/W)	VALUE	Coefficient Buffer Index. The IIR_COEFIDX.VALUE bit field provides the coefficient buffer index.

Coefficient Buffer Length Register

The `IIR_COEFLEN` register provides the coefficient buffer length.

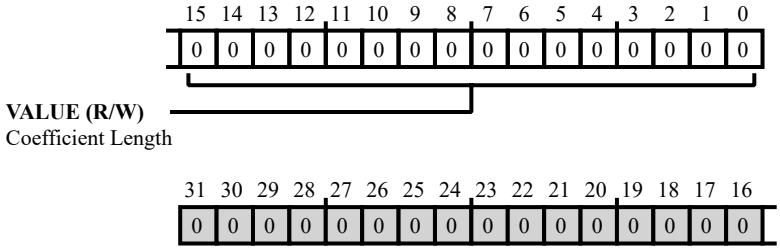

Figure 44-14: IIR_COEFLEN Register Diagram

Table 44-13: IIR_COEFLEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Coefficient Length. The `IIR_COEFLEN.VALUE` bit field provides the coefficient buffer length.

Coefficient Index Modifier Register

The `IIR_COEFMOD` register provides the coefficient index modifier.

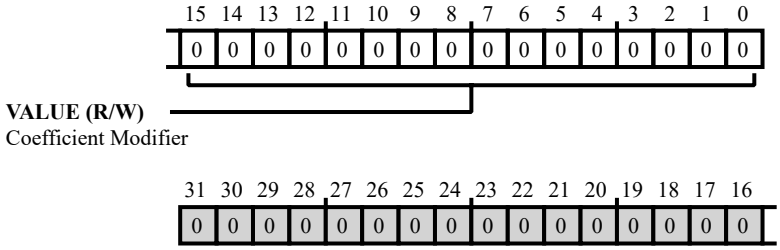

Figure 44-15: IIR_COEFMOD Register Diagram

Table 44-14: IIR_COEFMOD Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Coefficient Modifier. The `IIR_COEFMOD.VALUE` bit field provides the coefficient modifier.

Global Control Register

The `IIR_CTL1` register is used to configure the global parameters for the accelerator. These parameters include the number of channels, channel auto iterate, DMA enable, and accelerator enable.

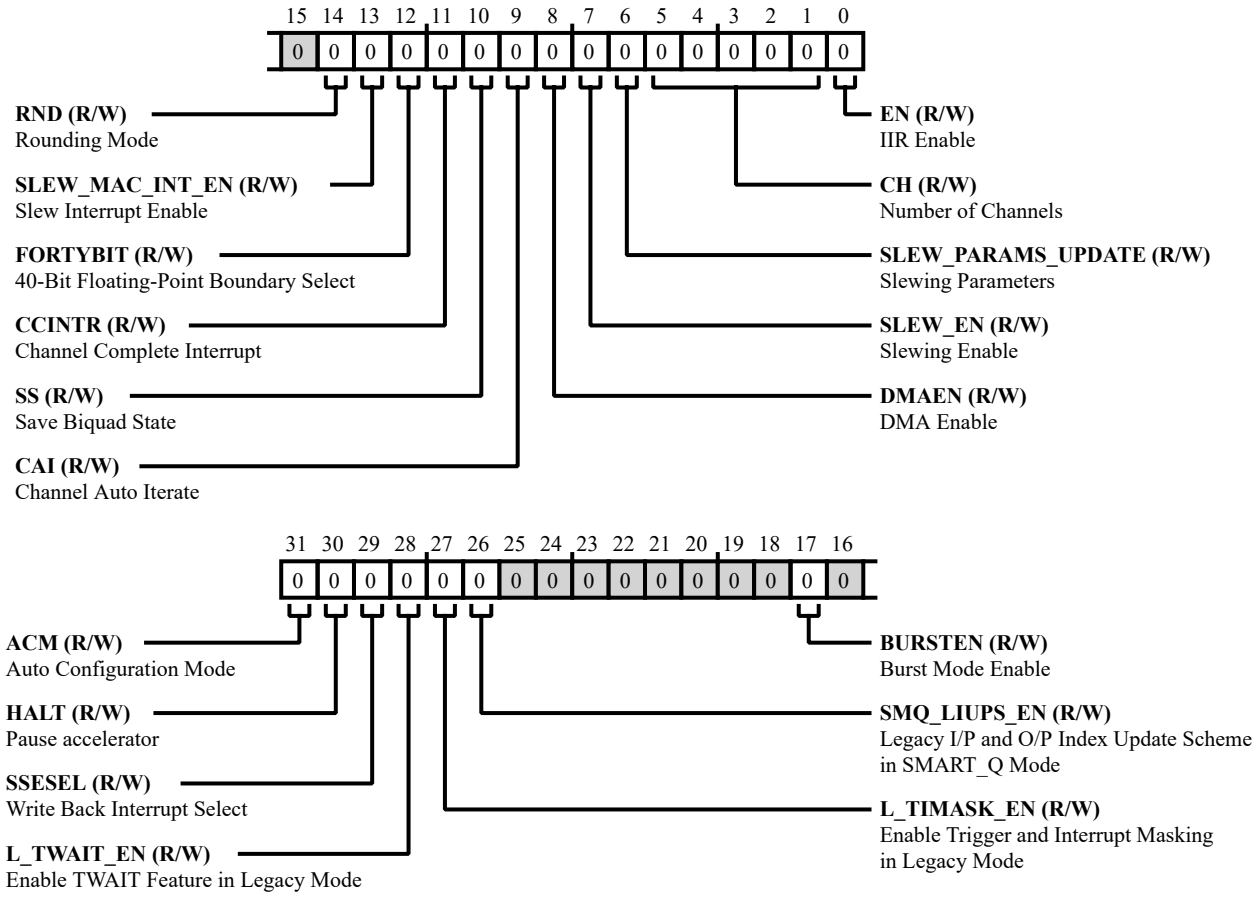

Figure 44-16: IIR_CTL1 Register Diagram

Table 44-15: IIR_CTL1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	ACM	Auto Configuration Mode. The `IIR_CTL1.ACM` bit configures the mode for loading the TCB.	
		0	Legacy Mode
		1	Auto Configuration Mode

Table 44-15: IIR_CTL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
30 (R/W)	HALT	Pause accelerator. The `IIR_CTL1.HALT` bit determines whether the accelerator pauses so that the core can check the status and modify or submit a job or the accelerator is released for further processing of data. This bit is only valid in Auto Configuration Mode (ACM).	
		0	Release accelerator
		1	Pause accelerator
29 (R/W)	SSESEL	Write Back Interrupt Select. The `IIR_CTL1.SSESEL` bit selects whether to generate an interrupt after the write back or after save state completion.	
		0	Generate Interrupt after save state completion
		1	Generate interrupt after write back completion
28 (R/W)	L_TWAIT_EN	Enable TWAIT Feature in Legacy Mode. The `IIR_CTL1.L_TWAIT_EN` bit indicates whether the TWAIT feature is available in legacy mode. This bit is only valid in legacy mode.	
		0	Not Available
		1	Available
27 (R/W)	L_TIMASK_EN	Enable Trigger and Interrupt Masking in Legacy Mode. The `IIR_CTL1.L_TIMASK_EN` bit enables trigger and interrupt masking in legacy mode. This bit is only valid in legacy mode.	
		0	Disable
		1	Enable
26 (R/W)	SMQ_LIUPS_EN	Legacy I/P and O/P Index Update Scheme in SMART_Q Mode. The `IIR_CTL1.SMQ_LIUPS_EN` bit configures the scheme the accelerator uses to update the input index (II) and output index (OI). This bit is only valid in ACM.	
		0	Update the II with all '0' and the OI with all 'F', respectively
		1	Update II and OI after circular buffer scheme
17 (R/W)	BURSTEN	Burst Mode Enable. The `IIR_CTL1.BURSTEN` bit field is set, burst access is enabled.	
		0	Disable burst mode
		1	Enable burst mode

Table 44-15: IIR_CTL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
14 (R/W)	RND	Rounding Mode. The `IIR_CTL1.RND` bit field selects the rounding mode for floating-point format.	
		0	Round to nearest (even)
		1	Truncate (Round towards zero)
13 (R/W)	SLEW_MAC_INT_EN	Slew Interrupt Enable. The `IIR_CTL1.SLEW_MAC_INT_EN` bit enables interrupts from slewing floating point units.	
12 (R/W)	FORTYBIT	40-Bit Floating-Point Boundary Select. The `IIR_CTL1.FORTYBIT` bit selects between 32-bit IEEE floating-point format or 40-bit IEEE floating-point format.	
		0	32-bit IEEE floating-point
		1	40-bit IEEE floating-point
11 (R/W)	CCINTR	Channel Complete Interrupt. The `IIR_CTL1.CCINTR` bit configures the channel complete interrupt to generate when all channels are done or after each channel is done. This bit is only valid in legacy mode when the IIR_CTL1.L_TIMASK_EN bit is cleared (=0). In Auto Configuration Mode (ACM) or when the IIR_CTL1.L_TIMASK_EN is set (=1), interrupt generation for each channel is controlled using IIR_CTL2.IMASK bit.	
		0	Interrupt is generated only when all channels are done (default)
		1	Interrupt is generated after each channel is done (default)
10 (R/W)	SS	Save Biquad State. The `IIR_CTL1.SS` bit configures the accelerator to store the Dk register settings into the internal memory. This can be used to save the biquad states before switching to another high priority accelerator task. This bit is only valid in legacy mode. In Auto Configuration Mode (ACM), the save state for each channel is controlled using the IIR_SGCTL.SS bit	

Table 44-15: IIR_CTL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
9 (R/W)	CAI	Channel Auto Iterate. The `IIR_CTL1.CAI` bit sets whether TDM processing stops (idle) once all channels complete processing or moves to first channel and continues TDM processing in a loop when all channels complete processing. Channel Auto Iterate is not available in Auto Configuration Mode (ACM). The accelerator keeps processing the TCBs until the chain pointer becomes null in ACM.	
		0	TDM processing stops (idle) once all channels complete processing
		1	Moves to first channel and continues TDM processing in a loop when all channels complete processing
8 (R/W)	DMAEN	DMA Enable. The `IIR_CTL1.DMAEN` bit enables DMA on the accelerator.	
		0	Disable
		1	Enable
7 (R/W)	SLEW_EN	Slewing Enable. The `IIR_CTL1.SLEW_EN` bit enables control of IIR coefficients slewing engine.	
		0	Disable Slewing Engine (default)
		1	Enable Slewing Engine
6 (R/W)	SLEW_PARAMS_UP-DATE	Slewing Parameters. Slewing parameters (alpha, slewing duration, slewing frequency) and target coefficients can be updated during the process of slewing by enabling this `IIR_CTL1.SLEW_PARAMS_UPDATE` bit and by disabling and re-enabling the DMA.	
5:1 (R/W)	CH	Number of Channels. The `IIR_CTL1.CH` bit field configures the number of channels and is programmable between 0-31 (channels = NCH + 1). This bit field is only valid in legacy mode. In Auto Configuration Mode (ACM), there is no limit on the number of channels. the accelerator keeps processing the TCBs until the chain pointer becomes null.	
0 (R/W)	EN	IIR Enable. The `IIR_CTL1.EN` bit enables or disables the IIR accelerator.	
		0	IIR disabled
		1	IIR enabled

Channel Control Register

The `IIR_CTL2` register is used to configure the channel specific parameters. These parameters include the number of biquads and window size. In Auto Configuration Mode (ACM), this register is also used to configure additional channel specific parameters like interrupts and triggers.

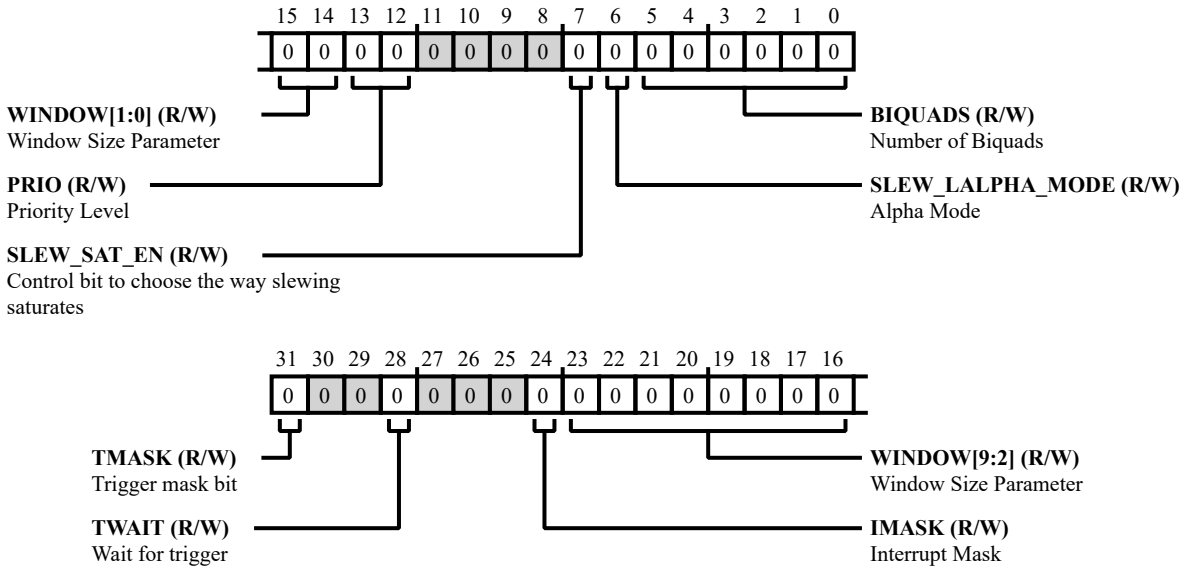

Figure 44-17: IIR_CTL2 Register Diagram

Table 44-16: IIR_CTL2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	TMASK	Trigger mask bit. The `IIR_CTL2.TMASK` bit enables trigger generation for the channel. It is valid in Auto Configuration Mode (ACM) or if CTL1.L_TIMASK_EN is set.	
		0	Enable
		1	Mask
28 (R/W)	TWAIT	Wait for trigger. The `IIR_CTL2.TWAIT` bit disables the wait for the trigger. It is valid in Auto Configuration Mode (ACM) or if CTL1.L_TIMASK_EN is set.	
		0	Disable wait for the trigger for the channel
		1	Enable wait for external trigger input assertion for the channel

Table 44-16: IIR_CTL2 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
24 (R/W)	IMASK	Interrupt Mask. The `IIR_CTL2.IMASK` bit enables interrupt generation for the channel. This bit is valid in Auto Configuration Mode (ACM) or if CTL1.L_TIMASK_EN is set.	
		0	Enable
		1	Mask
23:14 (R/W)	WINDOW	Window Size Parameter. The `IIR_CTL2.WINDOW` bit field configures the window size which specifies the number of samples/blocks to process (sample based processing = window size of 1). This bit field should be programmed to "actual window size required -1". For example, for sample based processing this bit field should be programmed to 0.	
13:12 (R/W)	PRIO	Priority Level. The `IIR_CTL2.PRIO` bit field indicates the priority.	
		0	Level 0 (lowest)
		1	Level 1
		2	Level 2
		3	Level 3 (highest)
7 (R/W)	SLEW_SAT_EN	Control bit to choose the way slewing saturates. `IIR_CTL2.SLEW_SAT_EN` bit field is set to HIGH to assume target coefficients after slewing duration. If this bit is not set, coefficients will remain at the last iteration values	
6 (R/W)	SLEW_LALPHA_MODE	Alpha Mode. The `IIR_CTL2.SLEW_LALPHA_MODE` bit controls whether to slew in constant alpha mode or linearly changing alpha mode. Program `IIR_CTL2.SLEW_LALPHA_MODE` bit field as, 0: Default setting; Constant alpha mode 1: Linearly changing alpha mode	
		0	Constant Alpha Mode (default)
		1	Linearly Changing Alpha Mode
5:0 (R/W)	BIQUADS	Number of Biquads. The `IIR_CTL2.BIQUADS` bit field configures the number of biquads and is programmable between 0-63 (number of Biquads = BIQUADS + 1).	

IIR Debug Address Register

The `IIR_DBG_ADDR` register holds the debug address. If bit 11 is set, coefficient memory is selected.

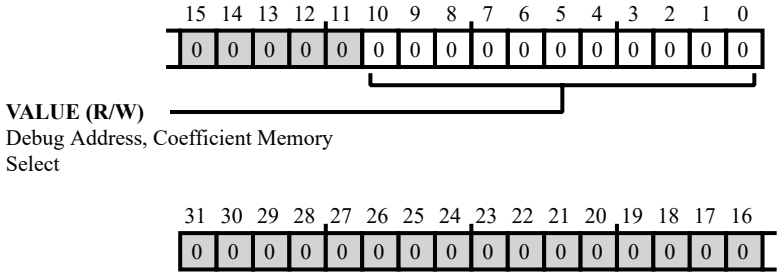

Figure 44-18: IIR_DBG_ADDR Register Diagram

Table 44-17: IIR_DBG_ADDR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
10:0 (R/W)	VALUE	Debug Address, Coefficient Memory Select. The `IIR_DBG_ADDR.VALUE` bit field holds the debug address (bits 0-10). Bit 11 configures whether the memory access is to coefficient memory (=0) or to delay line memory (=1).

IIR Debug Control Register

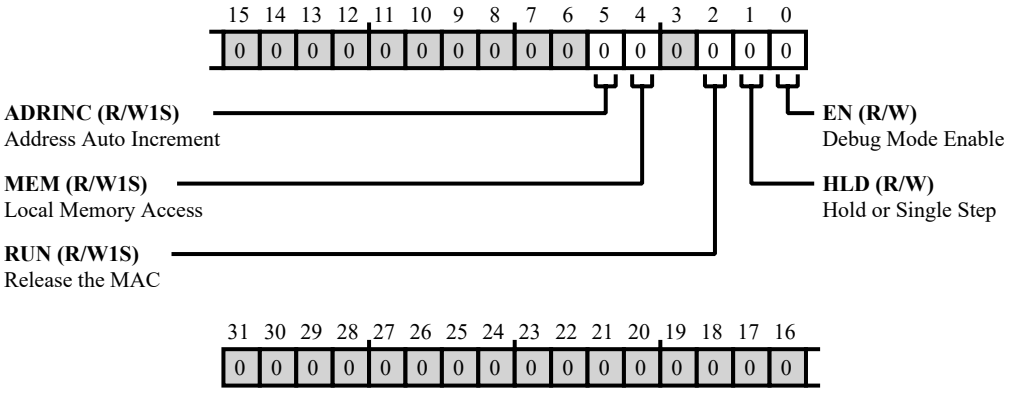

Figure 44-19: IIR_DBG_CTL Register Diagram

Table 44-18: IIR_DBG_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
5 (R/W1S)	ADRINC	Address Auto Increment. The `IIR_DBG_CTL.ADRINC` bit allows the address register to auto increment on `IIR_DBG_WRDAT_HI`/`IIR_DBG_WRDAT_LO` writes and `IIR_DBG_RDDAT_HI`/`IIR_DBG_RDDAT_LO` reads.	
4 (R/W1S)	MEM	Local Memory Access. The `IIR_DBG_CTL.MEM` bit allows the data and coefficients memory to be indirectly accessed.	
2 (R/W1S)	RUN	Release the MAC. The `IIR_DBG_CTL.RUN` bit releases the MAC; it is is self clearing after one IIR clock cycle.	
1 (R/W)	HLD	Hold or Single Step. The `IIR_DBG_CTL.HLD` bit function is based on the `IIR_DBG_CTL.MEM` bit setting. For `IIR_DBG_CTL.MEM` = 0 this bit sets single step. For `IIR_DBG_CTL.MEM` = 1 this bit sets hold data.	
		0	No effect
		1	Single step (IIR_DBGMEM=0) or Hold data (IIR_DBGMEM=1)
0 (R/W)	EN	Debug Mode Enable. The `IIR_DBG_CTL.EN` bit enables debug mode. For local memory access, the `IIR_CTL1` register can be cleared.	
		0	Disable
		1	Enable

IIR Debug Read Data High Register

The `IIR_DBG_RDDAT_HI` register is part of the 40-bit wide debug mode read data register and holds the upper 8 bits.

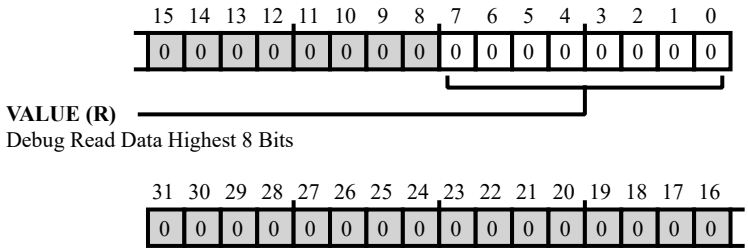

Figure 44-20: IIR_DBG_RDDAT_HI Register Diagram

Table 44-19: IIR_DBG_RDDAT_HI Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/NW)	VALUE	Debug Read Data Highest 8 Bits. The `IIR_DBG_RDDAT_HI.VALUE` bit field holds the upper 8-bit read data.

IIR Debug Read Data Low Register

The IIR_DBG_RDDAT_LO register is part of the 40-bit wide debug mode read data register and holds the lower 32 bits.

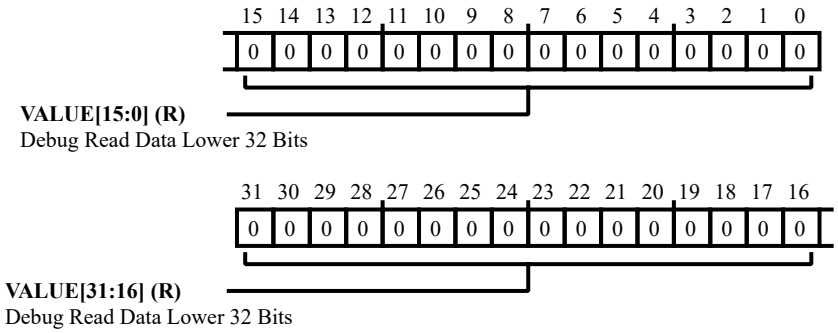

Figure 44-21: IIR_DBG_RDDAT_LO Register Diagram

Table 44-20: IIR_DBG_RDDAT_LO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	Debug Read Data Lower 32 Bits. The IIR_DBG_RDDAT_LO.VALUE bit field holds the lower 32-bit read data.

IIR Debug Write Data High Register

The `IIR_DBG_WRDAT_HI` register is part of the 40-bit wide debug mode write data register and holds the upper 8 bits.

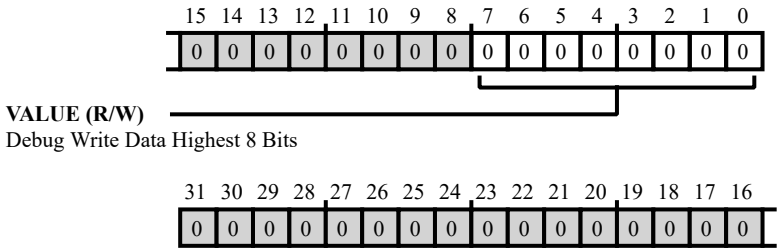

Figure 44-22: IIR_DBG_WRDAT_HI Register Diagram

Table 44-21: IIR_DBG_WRDAT_HI Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/W)	VALUE	Debug Write Data Highest 8 Bits. The `IIR_DBG_WRDAT_HI.VALUE` bit field holds the upper 8-bit write data.

IIR Debug Write Data Low Register

The IIR_DBG_WRDAT_LO register is part of the 40-bit wide debug mode write data register and holds the lower 32 bits.

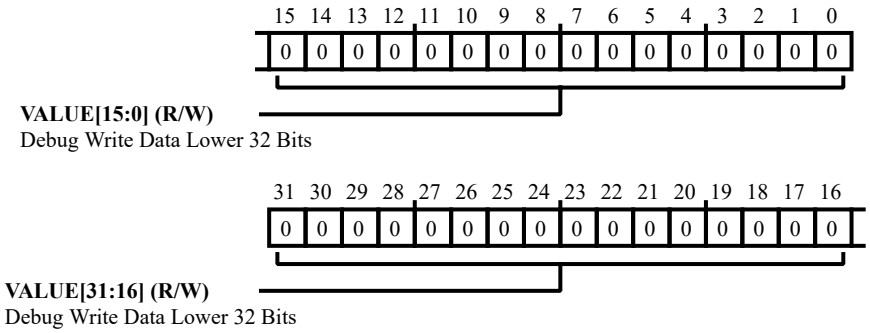

Figure 44-23: IIR_DBG_WRDAT_LO Register Diagram

Table 44-22: IIR_DBG_WRDAT_LO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Debug Write Data Lower 32 Bits. The IIR_DBG_WRDAT_LO.VALUE bit field holds the lower 32-bit write data.

DMA Status Register

The IIR_DMASTAT registers indicate the status of DMA operations.

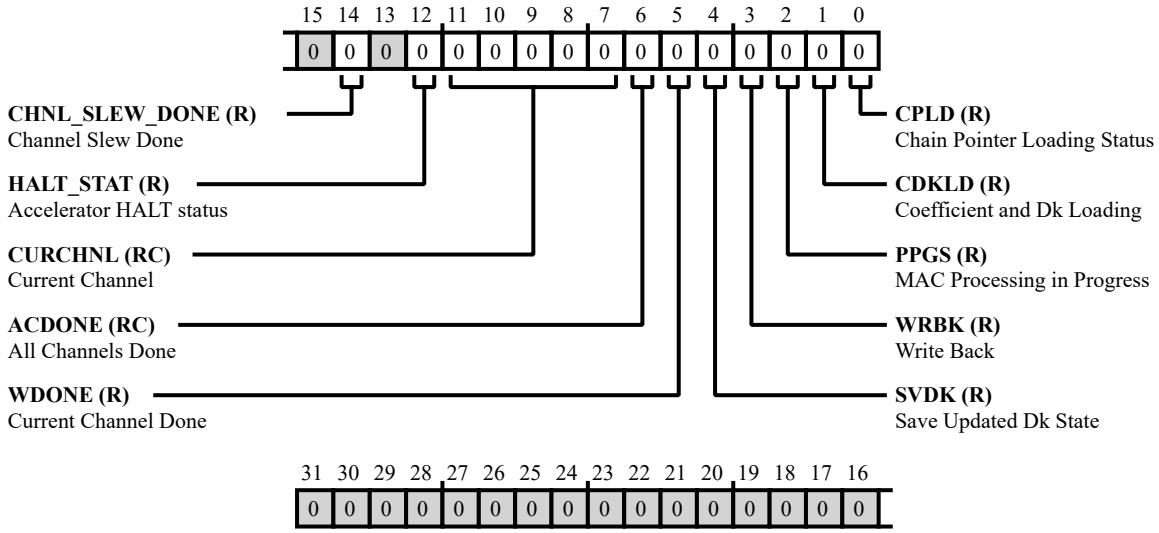

Figure 44-24: IIR_DMASTAT Register Diagram

Table 44-23: IIR_DMASTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/NW)	CHNL_SLEW_DONE	Channel Slew Done. The IIR_DMASTAT.CHNL_SLEW_DONE bit field indicates the completion of slewing (N iterations) in the current channel.
12 (R/NW)	HALT_STAT	Accelerator HALT status. Acknowledge to core that accelerator is in halt state, if set.
11:7 (RC/NW)	CURCHNL	Current Channel. The IIR_DMASTAT.CURCHNL bit field indicates the channel that is being processed in the TDM slot. Zero indicates the last slot.
6 (RC/NW)	ACDONE	All Channels Done. The IIR_DMASTAT.ACDONE bit indicates all channels are done processing. Note that the IIR_CTL1.CCINTR bit does not affect this status bit. This bit is sticky and is cleared on register read.
5 (R/NW)	WDONE	Current Channel Done. The IIR_DMASTAT.WDONE bit indicates the processing of the current channel is complete. Note that the IIR_CTL1.CCINTR bit does not affect this status bit. This bit is sticky and is cleared on register read.

Table 44-23: IIR_DMASTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
4 (R/NW)	SVDK	Save Updated Dk State. If there is more than one channel (`IIR_CTL1.CH`>0), the `IIR_DMASTAT.SVDK` bit toggles between 0 and 1 as it starts and completes the save state operation on one channel at a time.	
3 (R/NW)	WRBK	Write Back. The `IIR_DMASTAT.WRBK` bit indicates the accelerator is writing back updated index registers.	
2 (R/NW)	PPGS	MAC Processing in Progress. The `IIR_DMASTAT.PPGS` bit indicates MAC processing is in progress.	
1 (R/NW)	CDKLD	Coefficient and Dk Loading. The `IIR_DMASTAT.CDKLD` bit indicates the coefficient and Dk are loading.	
0 (R/NW)	CPLD	Chain Pointer Loading Status. The `IIR_DMASTAT.CPLD` bit indicates the IIR is in the chain pointer load state.	
		0	State machine not in chain pointer load state
		1	State machine in chain pointer load state

Input Buffer Base Register

The IIR_INBASE register contains the word address with the lower 2 bits removed.

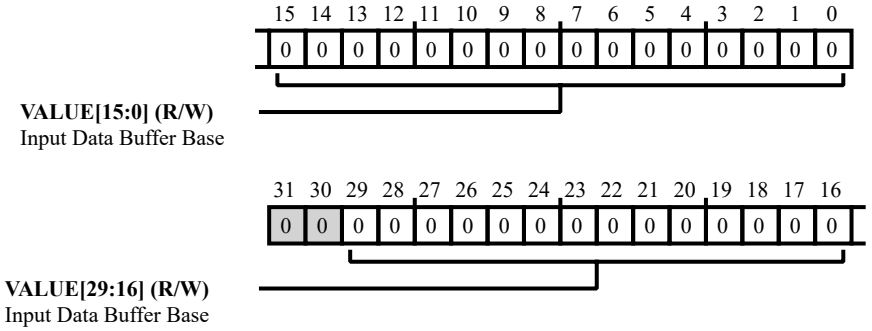

Figure 44-25: IIR_INBASE Register Diagram

Table 44-24: IIR_INBASE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:0 (R/W)	VALUE	Input Data Buffer Base. The IIR_INBASE.VALUE bit field value is the input data buffer base address.

Input Data Index Register

The IIR_INIDX register contains a word address with the lower 2 bits removed.

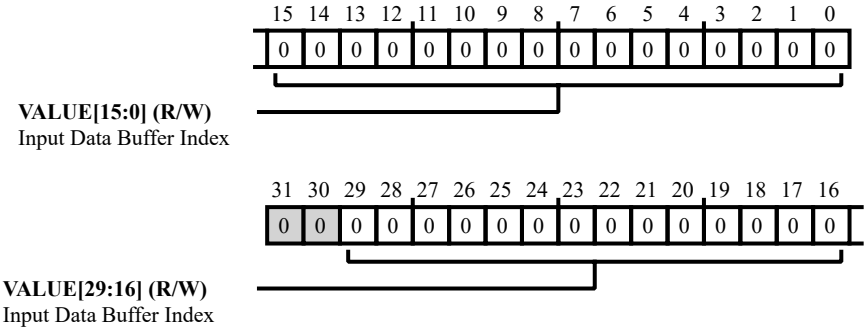

Figure 44-26: IIR_INIDX Register Diagram

Table 44-25: IIR_INIDX Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:0 (R/W)	VALUE	Input Data Buffer Index. The IIR_INIDX.VALUE bit field value is the input data buffer index.

Input Data Buffer Length Register

The `IIR_INLEN` register provides the input data buffer length.

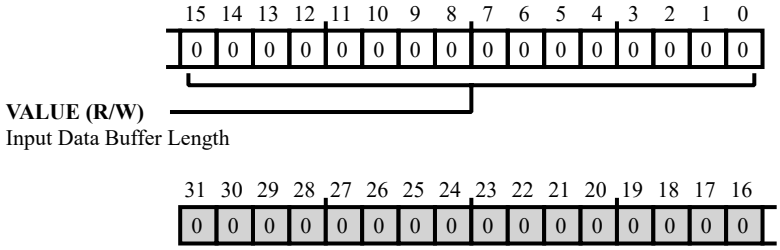

Figure 44-27: IIR_INLEN Register Diagram

Table 44-26: IIR_INLEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	Input Data Buffer Length. The `IIR_INLEN.VALUE` bit field value is the input data buffer length.

Input Data Index Modifier Register

The IIR_INMOD register provides the 16-bit input data buffer index modifier.

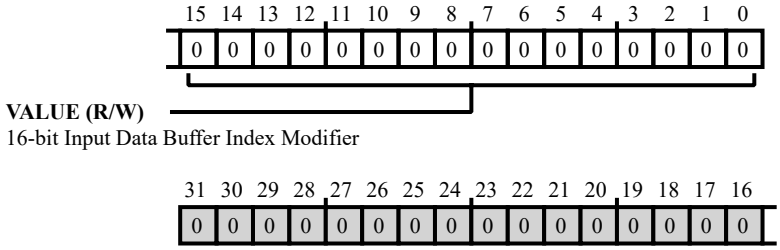

Figure 44-28: IIR_INMOD Register Diagram

Table 44-27: IIR_INMOD Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	16-bit Input Data Buffer Index Modifier. The IIR_INMOD.VALUE bit field value is the 16-bit input data buffer modifier.

MAC Status Register

The IIR_MACSTAT register indicates the status of MAC operations.

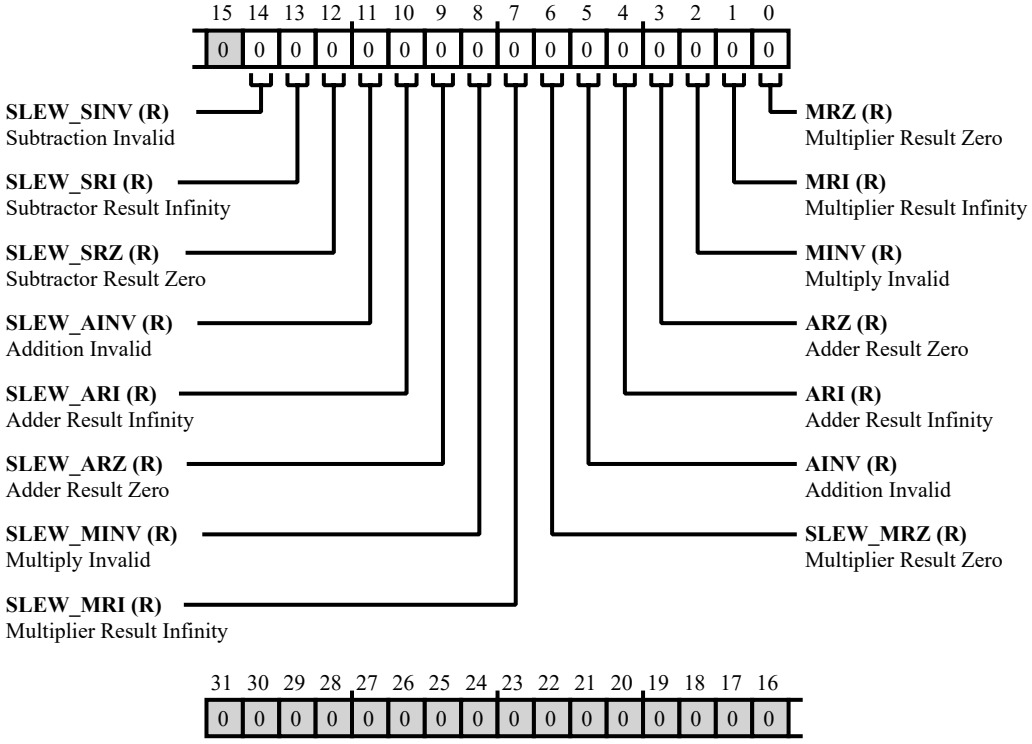

Figure 44-29: IIR_MACSTAT Register Diagram

Table 44-28: IIR_MACSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
14 (R/NW)	SLEW_SINV	Subtraction Invalid. The IIR_MACSTAT.SLEW_SINV bit indicates the subtraction is invalid.
13 (R/NW)	SLEW_SRI	Subtractor Result Infinity. The IIR_MACSTAT.SLEW_SRI bit indicates the subtractor result is infinity.
12 (R/NW)	SLEW_SRZ	Subtractor Result Zero. The IIR_MACSTAT.SLEW_SRZ bit indicates the subtractor result is zero.
11 (R/NW)	SLEW_AINV	Addition Invalid. The IIR_MACSTAT.SLEW_AINV bit indicates the addition is invalid.
10 (R/NW)	SLEW_ARI	Adder Result Infinity. The IIR_MACSTAT.SLEW_ARI bit indicates the adder result is infinity.

Table 44-28: IIR_MACSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
9 (R/NW)	SLEW_ARZ	Adder Result Zero. The `IIR_MACSTAT.SLEW_ARZ` bit indicates the adder result is zero.
8 (R/NW)	SLEW_MINV	Multiply Invalid. The `IIR_MACSTAT.SLEW_MINV` bit indicates the multiply operation is invalid.
7 (R/NW)	SLEW_MRI	Multiplier Result Infinity. The `IIR_MACSTAT.SLEW_MRI` bit indicates the multiplier result is infinity.
6 (R/NW)	SLEW_MRZ	Multiplier Result Zero. The `IIR_MACSTAT.SLEW_MRZ` bit indicates the multiplier result is zero.
5 (R/NW)	AINV	Addition Invalid. The `IIR_MACSTAT.AINV` bit indicates the addition is invalid.
4 (R/NW)	ARI	Adder Result Infinity. The `IIR_MACSTAT.ARI` bit indicates the adder result is infinity.
3 (R/NW)	ARZ	Adder Result Zero. The `IIR_MACSTAT.ARZ` bit indicates the adder result is zero.
2 (R/NW)	MINV	Multiply Invalid. The `IIR_MACSTAT.MINV` bit indicates the multiply operation is invalid.
1 (R/NW)	MRI	Multiplier Result Infinity. The `IIR_MACSTAT.MRI` bit indicates the multiplier result is infinity.
0 (R/NW)	MRZ	Multiplier Result Zero. The `IIR_MACSTAT.MRZ` bit indicates the multiplier result is zero.

Output Buffer Base Register

The `IIR_OUTBASE` register contains the word address with the lower 2 bits removed.

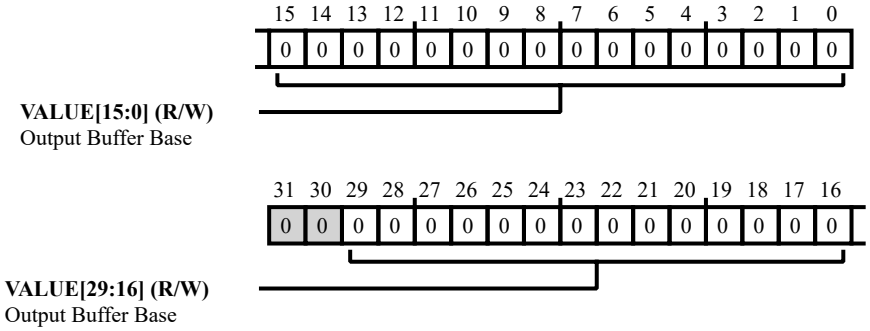

Figure 44-30: IIR_OUTBASE Register Diagram

Table 44-29: IIR_OUTBASE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:0 (R/W)	VALUE	Output Buffer Base. The `IIR_OUTBASE.VALUE` bit field provides the output buffer base address.

Output Data Buffer Index Register

The IIR_OUTIDX register is written with word address without the lower 2 bits.

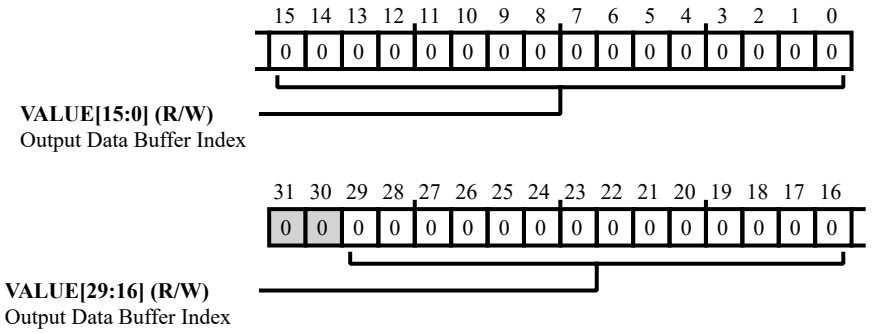

Figure 44-31: IIR_OUTIDX Register Diagram

Table 44-30: IIR_OUTIDX Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
29:0 (R/W)	VALUE	Output Data Buffer Index. The IIR_OUTIDX.VALUE bit field provides the output data buffer index.

IIR Output Data Buffer Length Register

The `IIR_OUTLEN` register provides the output data buffer length.

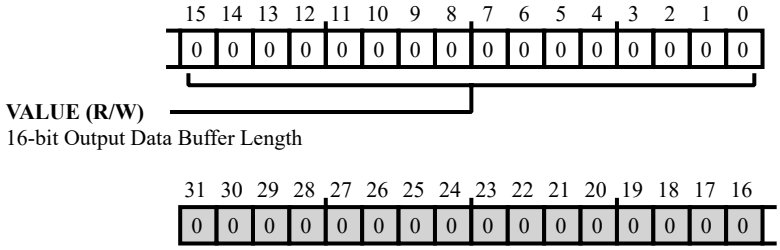

Figure 44-32: IIR_OUTLEN Register Diagram

Table 44-31: IIR_OUTLEN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	16-bit Output Data Buffer Length. The `IIR_OUTLEN.VALUE` bit field provides the output data buffer length.

IIR Output Data Index Modifier Register

The `IIR_OUTMOD` register provides the output data index modifier.

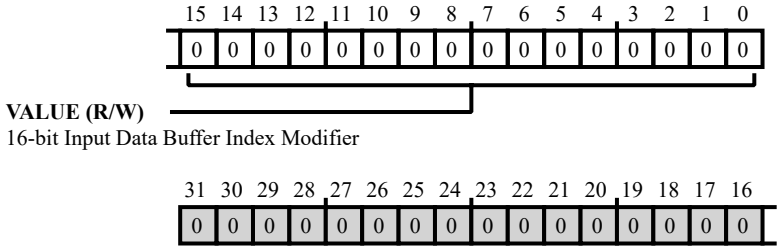

Figure 44-33: IIR_OUTMOD Register Diagram

Table 44-32: IIR_OUTMOD Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	VALUE	16-bit Input Data Buffer Index Modifier. The `IIR_OUTMOD.VALUE` bit field provides the output data buffer index modifier.

Software Control Register1

The `IIR_SCTL1` register is used by Smart Queuing APIs in ACM mode to exchange relevant job information amongst APIs.

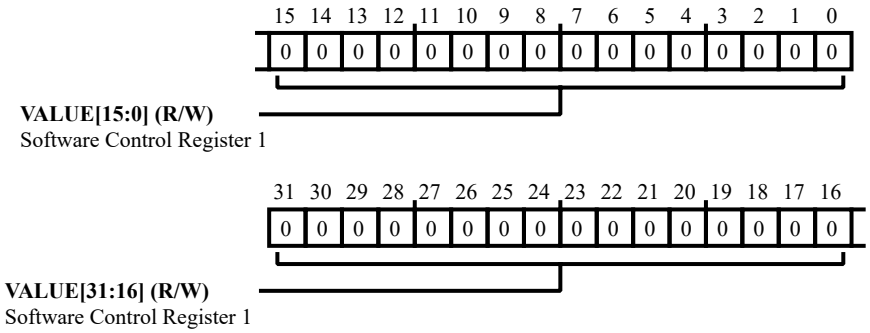

Figure 44-34: IIR_SCTL1 Register Diagram

Table 44-33: IIR_SCTL1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Software Control Register 1.

Software Control Register2

The `IIR_SCTL2` register is used by Smart Queuing APIs in ACM mode to exchange relevant job information amongst APIs.

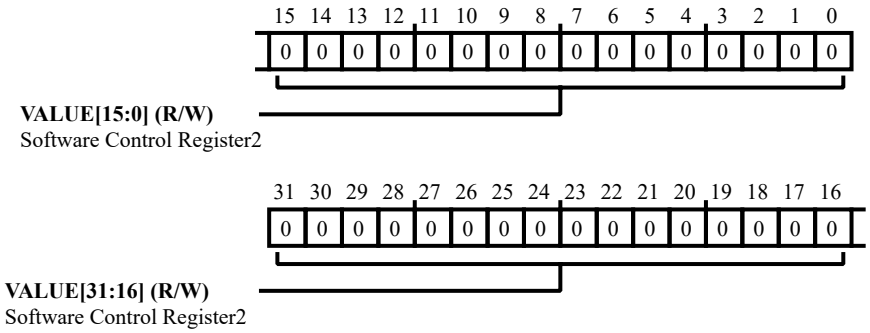

Figure 44-35: IIR_SCTL2 Register Diagram

Table 44-34: IIR_SCTL2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	VALUE	Software Control Register2.

Secondary Global Control Register

The `IIR_SGCTL` register configures the global parameters for the accelerator in ACM mode for loading CTL1 register as part of TCB.

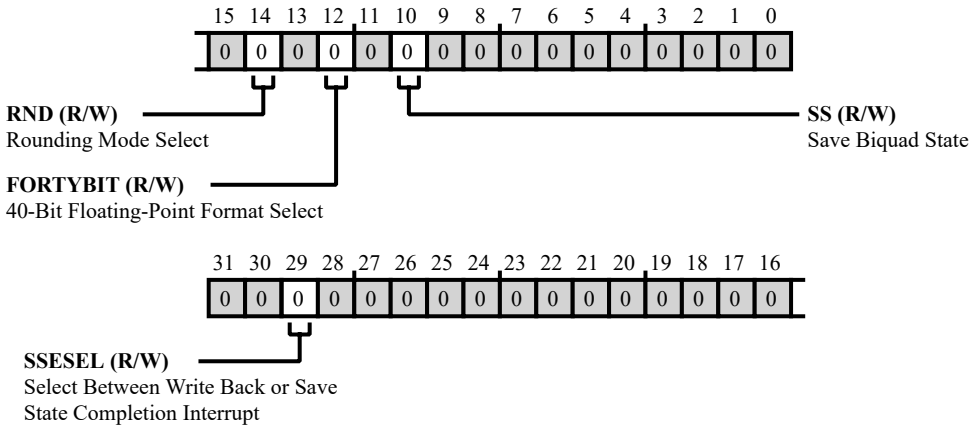

Figure 44-36: IIR_SGCTL Register Diagram

Table 44-35: IIR_SGCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
29 (R/W)	SSESEL	Select Between Write Back or Save State Completion Interrupt.	
14 (R/W)	RND	Rounding Mode Select. The `IIR_SGCTL.RND` bit selects the rounding mode for a floating-point mode compatible with SHARC+.	
		0	Round to nearest (even)
		1	Truncate (Round towards zero)
12 (R/W)	FORTYBIT	40-Bit Floating-Point Format Select. The `IIR_SGCTL.FORTYBIT` bit selects the floating point format.	
		0	32-bit floating point
		1	40-bit floating point
10 (R/W)	SS	Save Biquad State. The `IIR_SGCTL.SS` bit configures the accelerator to store the Dk register settings into the internal memory. This can be used to save the biquad states before switching to another high priority accelerator task.	

Channel 0 Slewing Duration and Frequency

The `IIR_SLEW_CNFG[n]` registers give access to the slewing duration, slewing frequency, and counter values of the particular channel. The register has both read and write access. However, a write to this register cannot be performed during non-IDLE state of DMA.

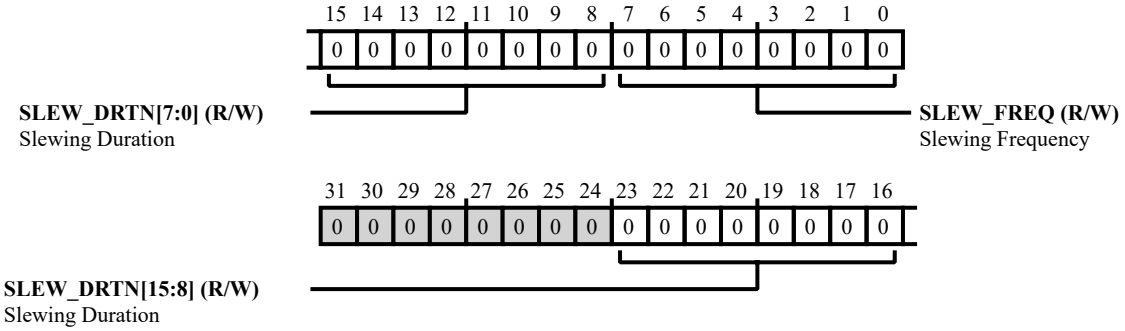

Figure 44-37: IIR_SLEW_CNFG[n] Register Diagram

Table 44-36: IIR_SLEW_CNFG[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
23:8 (R/W)	SLEW_DRTN	Slewing Duration. The `IIR_SLEW_CNFG[n].SLEW_DRTN` bit field programs number of samples processing during which slewing is done.
7:0 (R/W)	SLEW_FREQ	Slewing Frequency. The `IIR_SLEW_CNFG[n].SLEW_FREQ` bit field indicates the number of samples after which coefficients slewing is performed.

45 System Crossbars (SCB)

A modern system on a chip (SoCs) contains multi-cores, memory controllers, security blocks, and other high speed peripherals. As system integration increases, SoCs need to provide bus connectivity that allows better throughput to reduce performance bottlenecks. While traditional point-to-point connection buses have performed well in smaller systems, there is a need to use advanced switching based bus architectures for efficient handling of data transfer between multiplicity of data sources and sinks in the system. Additionally, mixing various traffic types in the same SoC (for example control, communication over peripherals and computing) while sharing the same bus resources, create different requirements from the Quality of Service (QoS) perspective.

The system crossbars (SCB) are the fundamental building blocks of a switch-fabric style for (on-chip) system bus interconnection. The SCBs connect system bus requesters to system bus completers, providing concurrent data transfer between multiple bus requesters and multiple bus completers. The SCB architecture addresses the challenges described above. The SCB provides sustainable throughput for simultaneous transactions in the system with configurable quality of service for each type of transaction (traffic) as required. A hierarchical model, built from multiple SCBs, provides a power and area efficient system interconnect, which satisfies the performance and flexibility requirements of a specific system.

SCB Features

The SCBs provide the following features:

- Efficient, pipelined bus transfer protocol for sustained throughput
- Full-duplex bus operation for flexibility and reduced latency
- Concurrent bus transfer support to allow multiple bus requesters to access bus completers simultaneously
- Simple priority-based QoS based arbitration model
- Programmable quality of service

SCB Functional Description

The following sections provide a functional description of the SCB.

- SCB Architectural Concepts

SCB Architectural Concepts

This section describes the components of the SCB and the modules connected to it. The basic elements in the SCB are SCB requesters, completers, requester interfaces, and completer interfaces.

Requesters

The system bus requesters include the peripheral Direct Memory Access (DMA) channels. These include the Serial Port (SPORT) DMA, SPI DMAs, Memory-to-Memory DMA channels (MDMA), the L1 code fill block, and the processor cores.

Completers

Completers are SCB connections that are responding to transfer requests. Completers include MMR registers, memory units, and various peripherals depending upon individual configurations. Each system completer has its own latencies and response times.

SCB Block Diagram

The SCB architectural model is shown in the ***SCB Overview*** figure. This figure shows a high level representation of a basic SCB connecting n completers to x requesters. A variable number of requesters connect to a variable number of completers in each SCB. In this example, all SIs connect to all MIs as indicated by the lines connecting them.

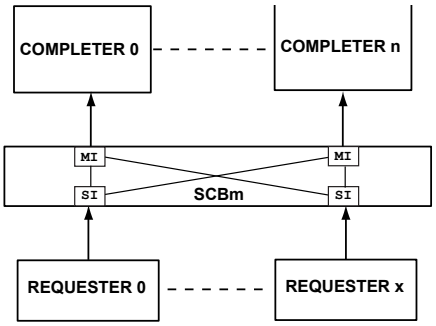

Figure 45-1: SCB Overview

Hierarchy Block Diagram

A system interconnect built from multiple SCBs in a hierarchical model is illustrated in the ***SCB Hierarchy Overview*** figure. The system requester node level SCBs requester connects multiple SIs to a single MI, which in turn connects to an SI of the system completer level node SCB.

As discussed above, all the requesters in the system are distributed across different SCBs. A given SCB at system requester node level connects directly to the system requesters. These SCBs connect to SCB0 through its SIs forming a hierarchical structure. While a requester must access any completer, its first access goes through the SCB it is connected to, and then through SCB0, to reach its intended completer. This simplifies the connecting hardware in the basic SCB block by limiting the requesters. Care must be taken when sharing requesters to allow adequate throughput for their individual data transfer requirements.

In this example, all SIs are connected to all MIs.

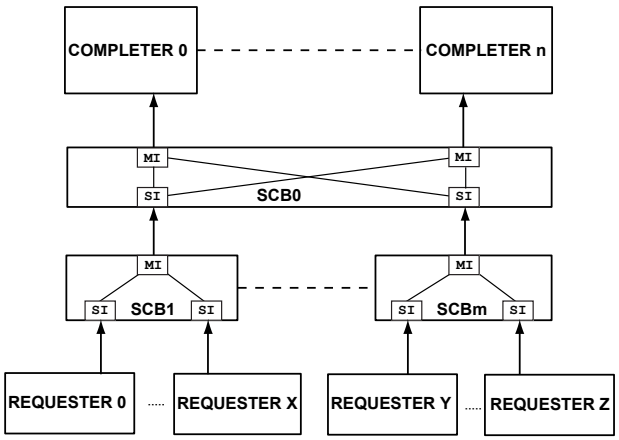

Figure 45-2: SCB Hierarchy Overview

NOTE: For an overall diagram of all SCB interconnections, see the SCB Block Diagram.

SCB Block Diagram

The ***SCB Block Diagram*** shows the functional blocks of the SCB module.

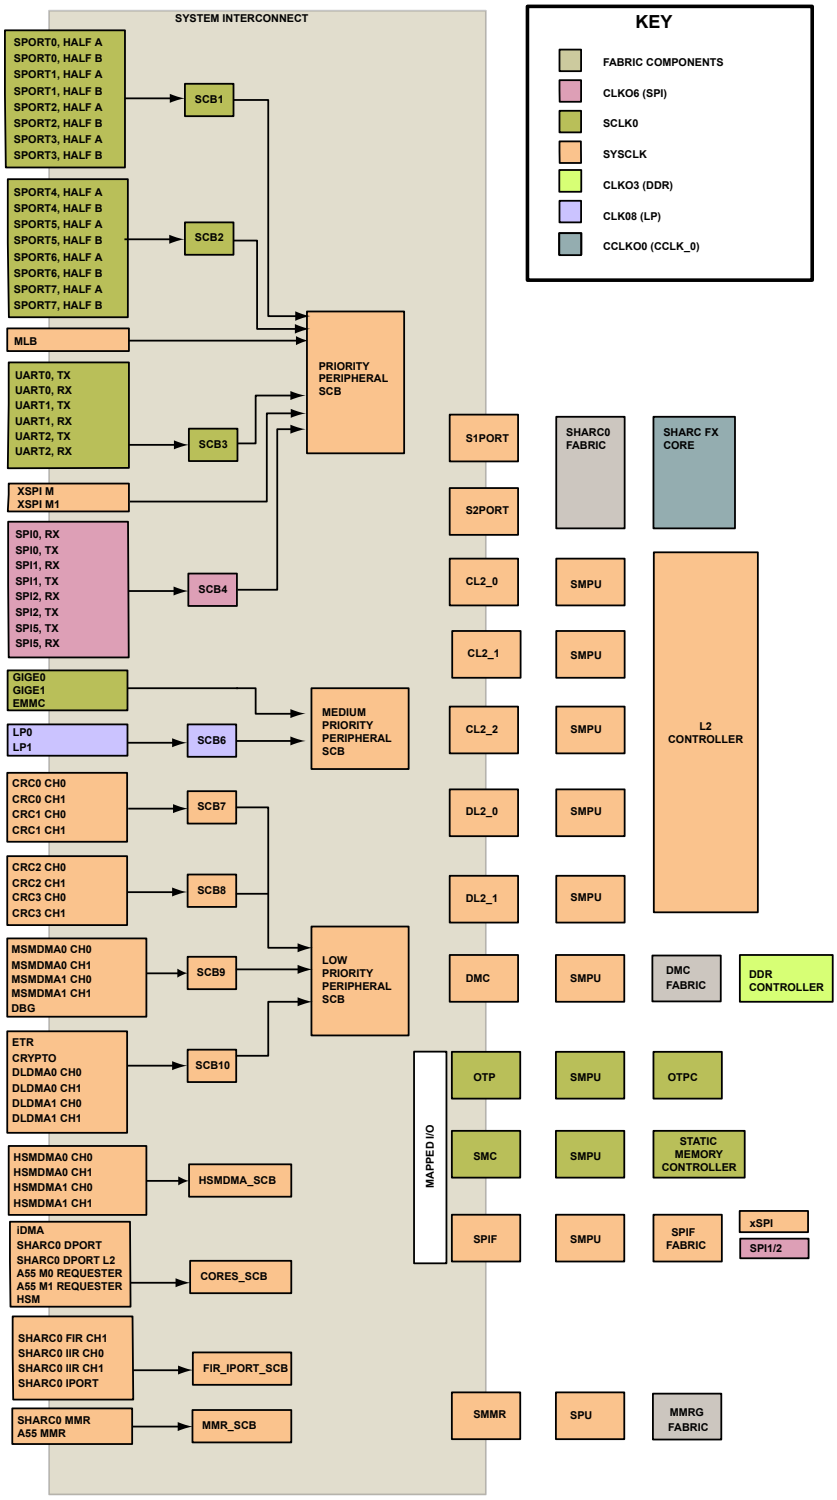

Figure 45-3: SCB Block Diagram

The following are important points related to the system fabric on the ADSP-SC84x processors.

- The hierarchy of SCBs manages the system bus interconnections, multiplexing, and arbitration among the peripherals on the processor.
- The SCBs connections support DMA channels for some peripherals and support dedicated connections for others. The connections also support memory-mapped register access for internal memory (L1 and L2) and for external memory.

  The completer interface of the crossbar where requesters such as DMA connect to performs two functions. The first function is arbitration. SCBx handles arbitration. The second function is clock conversion. The programmable QoS registers can be viewed as being associated with the SCBx.
- Most of the peripherals and the SCBs are in the *SCLK0* domain. MDMA0-7, EMDMA0/1, Crypto, FIR/IIR accelerators, MLB, DBG, ETR, SHARCFX and Arm cores and their SCBs are in the *SYSCLK* domain. The link port is in the CLK08 domain. SPI is in the CLK06 domain.
- MSMDMA0, MSMDMA1, HSMDMA0 and HSMDMA1 channels are unidirectional. For example, MSMDMA0 CH0 is read only and MSMDMA0 CH1 is write only.
- Access to the GPV (Global Programmers View) space is allowed only in secure mode. This space has registers for programming the QoS and CDC relationships and the remapping of various requesters.
- The S2 completer port of SHARC0 is intended primarily for MDMA. Hence, only the HSMDMA0 (MDMA3) and HSMDMA1 (MDMA7) is given access to S2 ports while all other requesters are given access to S1 port. This arrangement also means that S1 and S2 port share the same address space.
- LP to SPI2/xSPI access is allowed.

IMPORTANT: The following points are important changes from ADSP-2159x processors:

- SHARC-FX DPORT accesses L2 RAM and ROM over CL2_0 and CL2_1 are through a dedicated requester interface (SHARC0 DPORT L2); accesses to the rest of the system are over SHARC0 DPORT L2.
- Other new requesters are iDMA (from FX core), A55 data requester ports (a55_m0s_axi, a55_m1_axi), A55 MMR requester port (a55_mmr), SPI5(TX), SPI5(RX), xSPI requester port (xspi_m, xspi_m1), HSM, and eMSI.
- All requesters that can access DMC have been given access to SPI/xSPI.
- The SPIF completer in the system fabric has remapping options in the SPIF fabric for SPI[n] and xSPI in the same address space. The address map configuration is programmable using the remap registers.
- SH0_FIR_CH0 is moved to the HSMDMA SCB, and access to L2 is through dl2_0.

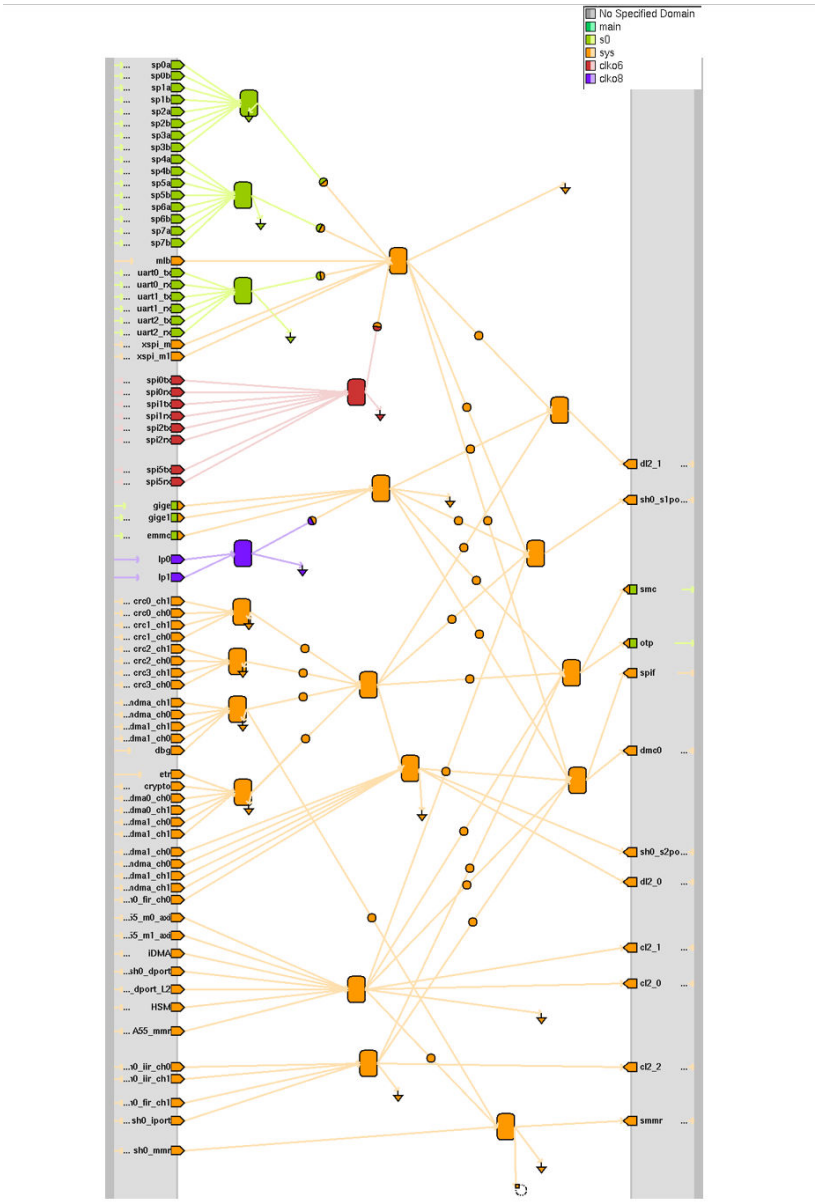

Figure 45-4: SCB Interconnections

The following acronyms are used in the ***SCB Interconnections*** figure.

SCB0-10

Indicate SCB interfaces, connecting the system bus requesters and completers

SCLK0, SYSCLK, CLK02, CLK06, CLK08

Indicate clock domains in which the specific SCBs operate. For more information on clock domains, see the Clock Generation Unit (CGU) chapter and the product data sheet.

iDMA

Indicates the integrated DMA in the SHARC-FX core

xSPI

Indicates the SPI hyperbus

A55

Indicates the ARM Coretex A55 microprocessor

Hardware Security Module CMRT-641

Indicates a 128-bit L2 completer

DL2_0, DL2_1

Indicates a 128-bit L2 completer

L1C0_S1

Indicates the S1 completer of the SHARC0 processor

L1C0_S2

Indicates the S2 completer of the SHARC0 processor

SHARC0_DPORT

Indicates the SHARC0 processor instruction requester port

SHARC0_IPORT

Indicates the SHARC0 processor instruction requester port

SHARC0_MMR

Indicates the SHARC0 processor MMR interface

MSMDMA

Indicates medium speed memory to memory DMA

HSMDMA

Indicates high speed memory to memory DMA

SHARC0, SHARC, SHARCFX

Indicates the SHARC-FX core (used interchangeably)

QoS

Indicates quality of service

SHARC Fabric with FIR/IIR Accelerator

The accelerator block on the SHARC core of the processor has two FIR and four IIR accelerators. All instances of the FIR and IIR accelerators operate at the core clock (CCLK) frequency. Accelerator requester ports can directly access the SHARC L1 memory with reduced latency. The access does not go through the system fabric. The SHARC core can also directly access the MMR registers of its accelerator.

The ***SHARC Fabric Connectivity*** figure shows a block diagram of the SHARC fabric with FIR/IIR accelerators integrated closely with the SHARC core.

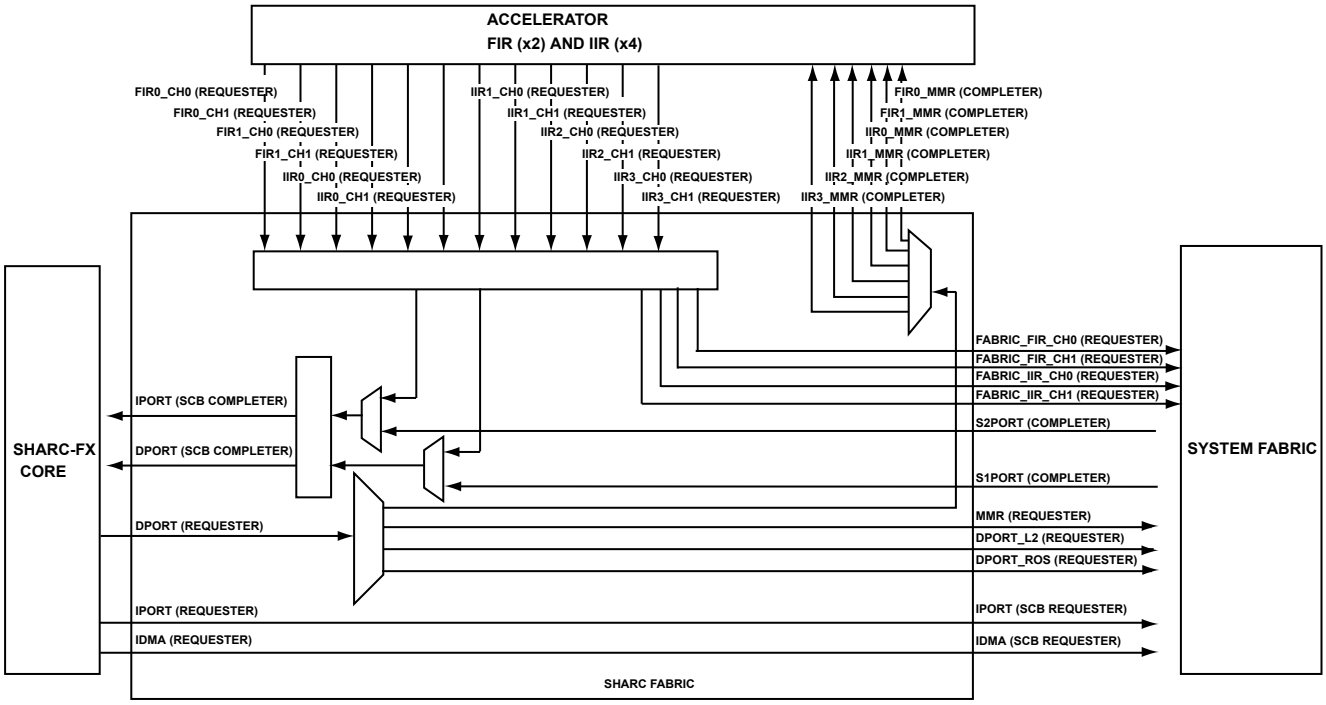

Figure 45-5: SHARC Fabric Connectivity

Port list and Parameters

Requester Ports (AXI-M)

- Data-Requester

  Inst-Requester

- iDMA

Completer Ports (AXI-S)

- DRAM-Completer
- IRAM-Completer

To ensure complete bandwidth utilization and optimal performance of the L2 ports, the controllers are allocated as shown in ***L2 Port Requester Allocation*** table.

Table 45-1: L2 Port Requester Allocation

Requesters	CL2_0	CL2_1	CL2_2	DL2_0	DL2_1
SHARC0 DPORT	✓	✓			
SHARC0 iDMA	✓	✓			
SHARC0 IPORT			✓		
A55 M0 AXI		✓			
A55 M1 AXI	✓				
HSM	✓	✓			
SHARC0_FIR_CH0				✓	
SHARC0_FIR_CH1			✓		
SHARC0_IIR_CH0			✓		
SHARC0_IIR_CH1			✓		
HSMDMA0				✓	
HSMDMA1				✓	
Peripherals					✓

Note the following:

- To reduce the probability of port conflict in a multicore system, FX, A55, HSM, and iDMA are connected on the CL2_0 and CL2_1 ports of L2. CL2_0 has access only to the first 2MB of L2. CL2_1 has access to second 2MB of L2
- For these requesters, access to the initial 2MB of L2 RAM and ROM goes through the CL2_0 port; the later 2MB of L2 RAM goes through the CL2_1 port
- SHARC-FX IPORT and Acceelerators (FIRs and IIRs) are connected over CL2_2 port.
- To increase FIR B/w from L2, FIR_CH0 is connected to DL2_0.

The addressable range for each of the ports is shown in the ***L2 Port Address Allocation*** table. SMPU 2 and 4 support exclusive access over CL2_0 and CL2_1 respectively, between SHARC FX DPORT and A55.

Table 45-2: L2 Port Address Allocation

SMPU Instance	Memory Address Range		EX- Acc	Comments
	Start Address	End Address		
CL2_0	0x2020_0000	0x2022_FFFF	Yes	ROM
	0x2040_0000	0x205F_FFFF	Yes	RAM
DL2_0	0x2000_0000	0x2022_FFFF	No	ROM
	0x2040_0000	0x207F_FFFF	No	RAM
CL2_1	0x2060_0000	0x207F_FFFF	Yes	RAM
CL2_2	0x2020_0000	0x2022_FFFF	No	ROM
	0x2040_0000	0x207F_FFFF	No	RAM
DL2_1	0x2020_0000	0x2022_FFFF	No	ROM
	0x2040_0000	0x207F_FFFF	No	RAM

Table 45-3: SCB Controlled DMA Channel Peripherals

	A55 M1 Controller	N/A	N/A
	iDMA	N/A	TBD

Table 45-3: SCB Controlled DMA Channel Peripherals (Continued)

	Requesters	DDE DMA Channels	Non DDE DMA Channels
	SH0 DPORT	N/A	N/A
	SH0 DPORT L2	N/A	N/A
	HSM	N/A	N/A
FIR_IPORT_SCB	SH0 FIR CH1	N/A	CH1
	SH0 IIR CH0	N/A	CH0
	SH0 IIR CH1	N/A	CH1
	SH0 IPORT	N/A	N/A
MMR_SCB	SHARC0 MMR	N/A	N/A
	A55_MRR	N/A	N/A

There are two types of peripherals that use DMA. The first have dedicated DMA channels controlled by the Dedicated DMA Engine (DDE) and have the same operating modes (see DMA Operating Modes) and use the same programming model (DMA Channel Programming Model). The second type is not controlled by the DDE module. These peripherals have their own operating modes and programming models (see the peripheral chapter for this information). The peripheral types are shown in the ***SCB-Controlled DMA Channel Peripherals*** table.

Address Remapping for Backwards Compatibility

To maintain backwards compatibility of the address map to the 21xxx processors, address remapping must occur at the integration level of the SHARC-FX core in SHARC + subsystems.

Address Translation for IPORT to L2 (Boot) ROM 0 and 1

The SHARC-FX reset vector 0x0010_0000 is mapped to the L2 (Boot) ROM. Native addresses issued by the IPORT are remapped/translated to reach the L2 ROM as shown in the following table.

Table 45-4: IPORT to L2 ROM Address Translation

Memory	Native Address Map		Converted Address Map	
	Start	End	Start	End
Boot ROM 0 (64kB	0010_0000	0010_FFFF	2020_0000	2020_FFFF
Boot ROM 1 (64kB)	0011_0000	0011_FFFF	2021_0000	2021_FFFF

S1/S2 to IRAM/DRAM Mapping

Other requesters in a system can access L1 over the bus completer port of the core. The SHARC+ core has two bus completer ports: S1 and S2. The system requester can access the entire L1 over either S1 or S2 port (depending on the grouping). In comparison, the SHARC-FX core has two bus completer ports, I-completer and D-completer, that allow and limit access to IRAM and DRAM, respectively. A bridge has been implemented to allow all system

requesters to access both IRAM and DRAM over I-completer and D-completer. The ***L1 Access Bridge Routing*** table shows the routing source to destination through the bridge. The ***X Bridge to Map Fabric*** figure shows the S1/S2 and accelerator access to IRAM and DRAM through the bridge.

NOTE: Accelerator accesses are also routed through the bridge.

Table 45-5: L1 Access Bridge Routing

Source	Range (SYS_ADDR)		Destination
S1	0x28240000	0x282BFFFF	DRAM/D-Completer
S1	0x282C0000	0x282CFFFF	IRAM/I-Completer
S2	0x28240000	0x282BFFFF	DRAM/D-Completer
S2	0x282C0000	0x282CFFFF	IRAM/I-Completer

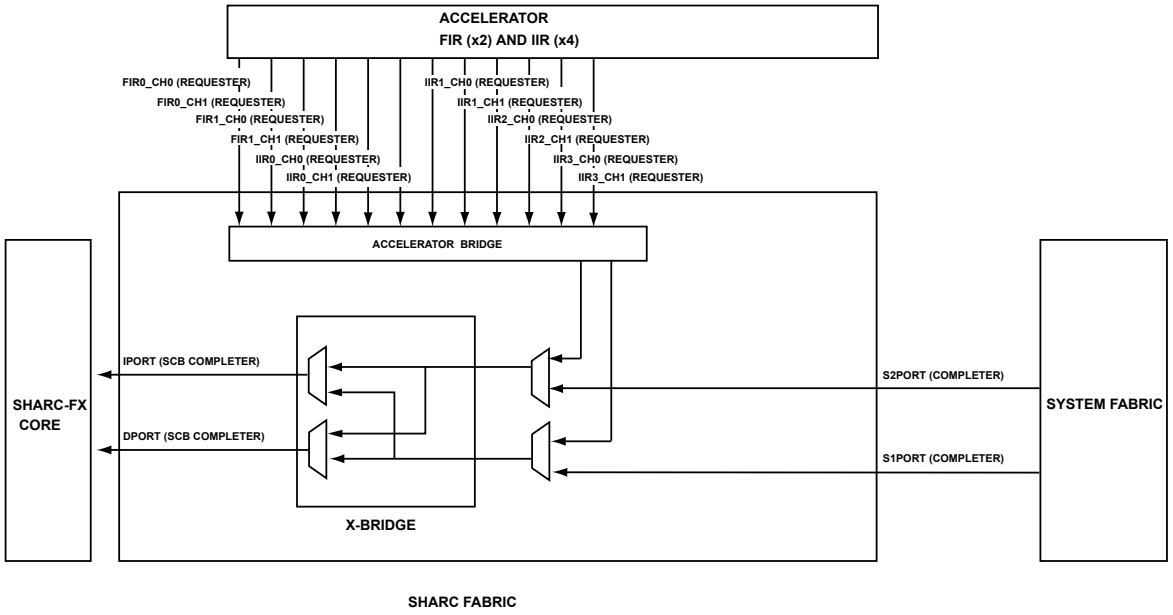

Figure 45-6: X-Bridge to Map Fabric

SHARC-FX Bus Completer Port Remapping

The SHARC-FX core accepts only its native address map on its bus completer port. To maintain SHARC+ backwards compatibility of the L1 bus completer address or multi-processor address, an address remapping or offset adjustment occurs on the incoming addresses to I-completer and D-completer before being forwarded to the SHARC-FX core. The *Bus Completer Port Address Remapping* table shows the remapping of addresses.

Table 45-6: Bus Completer Port Address Remapping

Destination	SYS_ADDR/MP_ADDR		Mapped Native ADDR	
DRAM/D-Completer	0x28240000	0x282BFFFF	0x2F780000	0x2F7FFFFF
IRAM/I-Completer	0x282C0000	0x282CFFFF	0x2F800000	0x2F80FFFF

NOTE:
- Byte and half word accesses to IRAM are not allowed by either the core or DMAs (over I-completer). Only 32-, 64- and 128-bit accesses are allowed. If an 8- or 16-bit access is attempted:
  - the core hits an exception
  - DMAs over I-completer do not receive an error response
- There are no restrictions for DRAM; 8-, 16-, 32-, 64- and128-bit accesses are allowed.
- Unaligned accesses to IRAM are not allowed; the address must always be 32-bit aligned. Unaligned 64- and 128-bit accesses around the 32-bit boundary are valid. The address does not need to be 64- or 28-bit aligned.
- Unaligned accesses to DRAM are allowed for any size.

Port Security

The SHARC-FX core has three requester ports: the instruction requester port, the data requester port, and iDMA. These ports interface with the rest of the system. The SHARC-FX core does not assign any security privileges on accesses from its requester ports. It uses SPU-based security privilege control.

Bus Completer Port Security

The SHARC-FX core has two bus completer ports: IRAM and DRAM. Requesters in the system use these ports to access the IRAM and DRAM of the SHARC-FX processor. These ports interface with the rest of the system. The security privileges of incoming accesses from other requesters in the system are overwritten or passed. The bus completer port security is based on the security privilege of the core (core SPU settings). As secure accesses pass the first stage and enter the second stage, the addresses of incoming accesses are remapped from the system address to the allowed address range supported by SHARC-FX core. If the accesses are not secure, the SHARC-FX processor generates an error response due to an invalid address.

System Crossbars

The System Crossbars (SCB) are the fundamental building blocks of the system bus interconnect. The SCB (often referred to as the system interconnect fabric), is a collection of inter-connection units connecting system requesters to completer memory spaces. The SCB connects one or more requester devices to one or more memory-mapped completer devices. Each connected requester can be a core that originates an SCB transaction, or a requester interface of an upstream SCB cascaded interconnect. Each connected completer can be the final completer of an SCB transaction or a completer interface of a downstream cascaded SCB interconnect (forming a hierarchy of SCBs).

Each SCB that has multiple requesters and completers share the total bandwidth of the SCB. (In a M:N configuration where M requesters are connected to N completers through the SCBx.)

The SCB provides separate channels for reads and writes. Read and write accesses through a given SCB do not share bandwidth. Only SCB0, which is the major SCB in the SCB hierarchy, has the multiple paths between multiple requester and completer interfaces.

All other SCBs in the chip connect to SCB0 through different completer interfaces. Other primary requesters (DMAs, cores, and so on) in the system are distributed across these small SCBs. For a given SCB, all the requester and completers share the total bandwidth of the SCB. (Only SCB0 is the exception). Since different DMA channels are scattered across different SCBs (SCB1, SCB2 SCB3, and so on), they do not conflict for the bandwidth when they are in different SCBs and accessing different completers. SCB0 allows for concurrent data transfer between multiple bus requesters and multiple bus completers, providing flexibility, and full-duplex operation.

If system accesses are carefully architected, SCB has a potential of providing sufficient sustained bandwidth in the end system.

Since the SCBs support burst transfers, it is important to configure the requesting requester appropriately to make best use of available SCB bandwidth. For a DMA requester, choosing the appropriate `DMA_CFG.MSIZE` value, is important from both a functional and a performance perspective. The value in the `DMA_CFG.PSIZE` bit field determines the width of the peripheral bus in use. It can be configured to 1-byte, 2-bytes, or 4-bytes. The `DMA_CFG.MSIZE` value determines the actual size of the SCB bus in use. It also determines the minimum number of bytes which are transferred from or to memory corresponding to a single DMA request or grant. The transfer can be 1-, 2-, 4-, 8-, 16-, or 32-bytes. If the `DMA_CFG.MSIZE` value is greater than the SCB bus width, the SCB performs burst transfers according to the width defined in `DMA_CFG.MSIZE`. When `DMA_CFG.MSIZE` is less than the SCB bus width, bursting is not supported and partial bus use results.

Each of the SCB unit in the fabric consists of N completer interfaces (MSTn). Each of these interfaces has controls for read quality of service, write quality of service, and functional mode. A subset of these matrices includes controls for IB (Interface Block) sync mode, and bus functional mode. For more details on IB, see the clock domain synchronization section.

SCB Bus Requester IDs

The SCB ***Bus Requester IDs*** table indicates which requesters are connected to each of the completer ports of SCB0. The tables also indicate the precise value of the ID as seen by the completer. These values are useful for SWU programming.

NOTE: For an overall diagram of all SCB interconnections, see the SCB Block Diagram.

Table 45-7: Bus Requester IDs

Requester	Hex ID Values	Binary Values
DMA0 (SPORT0, HALF A)	0x0000, 0x0100	13'b0000x00000000
DMA1 (SPORT0, HALF B)	0x0010, 0x0090	13'b00000x0010000

Table 45-7: Bus Requester IDs (Continued)

Requester	Hex ID Values	Binary Values
DMA2 (SPORT1, HALF A)	0x0020, 0x00A0	13'b00000x0100000
DMA3 (SPORT1, HALF B)	0x0030, 0x00B0	13'b00000x0110000
DMA4 (SPORT2, HALF A)	0x0040, 0x00C0	13'b00000x1000000

SCB Programming Model

The following sections provide information for programming the SCB properly.

Programming SCB Arbitration

Each completer interface has a QoS value (priority) associated with both read and write channels. These values are 4 bits present in the `SCB0_MSTx_RQOS` and `SCB0_MSTx_WQOS` registers. At the entry point to the infrastructure, all transactions are allocated this programmable local QoS value. The arbitration of the transaction throughout the infrastructure uses this QoS. At any arbitration node, a fixed priority exists for transactions with a different QoS. The highest value has the highest priority.

If there are coincident transactions at an arbitration node with the same QoS that require arbitration, then the network uses a Least Recently Granted (LRG) algorithm. At each switch, the requester with the highest QoS acquires access and that switch output takes the QoS value of the winner for that transaction. At the next switch completer interface, the requester uses the QoS value of the winner. QoS can have values from 0 (lowest priority) to 15 (highest priority).

For example in the following figure, ***SCB Arbitration***:

1. At SCB1, requesters (1, 2, 3) have RQOS values of (6, 4, 2)
2. At SCB2, requesters (4, 5, 6) have RQOS values of (12, 13, 1)

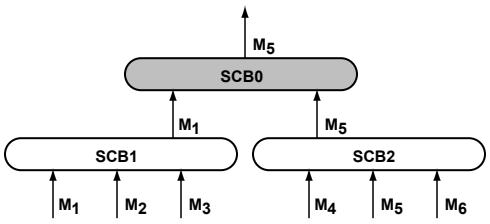

Figure 45-7: SCB Arbitration

In this case, requester 1 wins at SCB1, and requester 5 wins at SCB2. However, in a perfect competition at SCB0, requesters 4 and 5 had the highest overall RQOS values. requesters 4 and 5 would have fought for arbitration directly at SCB0. However, because of the mini*SCBs, requester 1, at a much lower RQOS value, is able to win against requester 4 and make it all the way to SCB0.

Programming Clock Domain Crossing Registers

The ***Clock Domain Crossing Options*** table shows the various clock domain crossings that are available on the processor. The clocking relationships are defined with respect to SYSCLK. The followng clock domains are programmable: CLKO3: SYSCLK, CLKO4: SYSCLK and CLKO8: SYSCLK CDC. The registers to configure the CDC mode are present within the GPV space of the respective fabric. For example: To program the CLKO3: SYSCLK relationship, program the GPV registers within the DMC_CDC fabric and the MMRG fabric.

Table 45-8: Clock Domain Crossing Options

		Clocking Relationships with respect to SYSCLK					
Functional Clocks	**Possible Completers**	**System Fabric**	**MMRG Fabric**	**DMC Fabric**	**SHARC Fabric**	**Arm Fabric**	**SPIF Fabric**
SYSCLK	System Fabric and Infrastructure Modules	1:1	1:1	*1	*1	*1	*1
SCLK0	SCLK0 Clock Doamin	Synchronous (m:1)	Synchronous (m:1)	*1	*1	*1	*1
CLKO0	SHARC0 and its Accelerators	*1	*1	*1	Programmable	*1	*1
CLKO1	A55	*1	*1	*1	*1	Programmable	*1
CLKO3	DMC	*1	Programmable	Programmable	*1	*1	*1
CLKO4	CAN	*1	Programmable	*1	*1	*1	*1
CLKO6	SPI	Synchronous (m:n) (except SPIF completer)	Synchronous (m:n)	*1	*1	*1	Synchronous (m:n)
CLKO8	LP	Programmable	Programmable	*1	*1	*1	*1

*1 Either the interface is not present or CDC is not required.

NOTE: Consider the following points in the *Clock Domain Crossing Options* table:

- For DMC fabric, the sync mode register should be programmed for m:n or async (default). Only for sysclk:CLKO3 = 500:500MHz, sync mode can be 1:1.
- For system MMRG fabric – CLKO8/LP sync mode register should be programmed for m:n or async (default).

Table 45-9: Sync Mode Bit Field Description

Sync Mode	Description
0	sync 1:1
1	sync n:1
2	sync 1:n
3	sync m:n
4	async

To change the clock domain crossing mode, follow the actions described in the ***Changing Clock Domain Crossing Modes*** table.

Table 45-10: Changing Clock Domain Crossing Modes

Original Mode	Required Mode	Action
ASYNC	Any other mode	Change the clocks, then change the MMR register
Any mode	ASYNC	Change the MMR register, then change clocks to ASYNC.
m:n	1:1	Change the clocks, then change the register.
1:1	m:n	Change the register, then change the clocks.

SCB Programming Concepts

The SCB arbitration model among requester or completer SCBs of the processor is fixed (not programmable). But, each completer does have a quality of service (QoS) programmable feature that affects arbitration.

The arbitration of transactions in SCB is based on the QoS value or the priority of the transaction. All requesters with the same priority form a priority group. Arbitration is granted to the highest priority group from which a member is trying to win access, and within that group, to the highest requester at that time. When a requester wins arbitration, it is relegated to the bottom of its group to ensure that it cannot prevent other requesters in its group from accessing the completer.

If you configure all requester priorities to different levels, the arbiter implements a fixed priority scheme. This scheme occurs because each requester is in a group of its own, and therefore, requesters maintain their ordering.

The LRG and fixed priority modes concurrently exist when the requester priority value registers are programmed with a combination of identical and unique values.

NOTE: The SCB arbitration hierarchy is fixed (for example, SCB1 requester to SCB1 completer). However, multiple requester inputs to the same completer permit QoS programming.

The *LRG Arbitration Example* figure shows three groups with different QoS values. Requesters in the same group share a QoS value. The arbitration occurs using an LRG scheme.

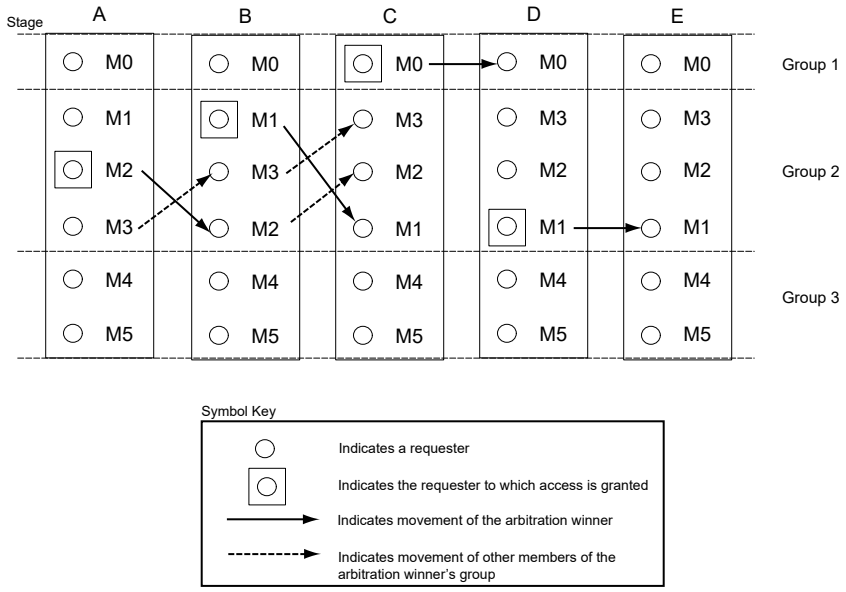

Figure 45-8: LRG Arbitration Example

The QoS value assigned to a transaction at entry point is carried forward by the transaction as it passes through all arbitration stages in the SCB. QoS for all requesters is configured as programmable in the system fabric interconnect.

The priority of the requesters fits into three groups:

- Group A - Peripherals with an external interface, without flow control and with real-time processing requirements
- Group B - Cores, peripherals with flow control, and offload engines
- Group C - MDMAs

Group A: Peripherals with external interface, without flow control and with real-time processing requirements

These requesters are assigned the highest priority. They are latency-critical – a large increase in latency could potentially result in data corruption and catastrophic failure. This high priority SCB group includes requesters connected to SCB1, SCB2, SCB3, SCB4, MLB and XSPI M. Requesters in this group are assigned the QOS reset value of 12.

Group B: Cores, peripherals with flow control, and offload engines

Core is latency-sensitive. Once a core requests data, it typically waits for the data without performing anything else in parallel. An increase in the latency has a direct impact on the performance of the core. This group is assigned medium priority and a QOS reset value of 7. Group B requesters are connected to SCB6, GIGE, CORES_SCB, FIR_IPORT_SCB, and MMR_SCB.

Group C: MDMAs

These requesters are assigned the lowest priority. MDMAs are data intensive and do not have any external interface. Requesters in this group are assigned the QOS reset value of 1. The Group C requesters are connected to SCB7, SCB8, SCB9, and SCB10.

QoS Programming

Adhere to the following guidelines if software is modifying the reset value of QoS:

- The highest QoS of any requester in a low priority SCB group must be less than the lowest QoS of any requester in a medium priority SCB group
- The highest QoS of any requester in medium priority SCB group must be less than the lowest QoS of any requester in high priority SCB group

Reset values of QoS have been spaced out to allow software to lower or higher the priority of a few requesters without having to modify the priority all the requesters. For example, the QoS of the SPI can be reduced from 12 to 11 without violating the two guidelines outlined above.

ADSP-2184x SCB0 Register Descriptions

Your module description, here. (SCB0) contains the following registers.

46 System Watchpoint Unit (SWU)

The system watchpoint unit (SWU) is a single module used for transaction monitoring. The SWU is attached to each system completer through the system crossbar interface and provides ports for all address channel signals for the system crossbar. The SWU does not have ports for the read/write data channel signals or the low-power interface signals.

Each SWU contains four match groups of registers with associated hardware. These four SWU match groups operate independently, but share common event (interrupt and trigger) outputs. Each match group can monitor either the write or read address channel and can operate in either watchpoint mode or bandwidth mode.

In this chapter, the naming convention for registers omit the numeric reference to any of the SWUs or it's groups. For example, SWU_GCTL represents registers SWU1_GCTL, SWU2_GCTL, and so on. Similarly, SWU_CUR[n] represents SWU1_CUR0/CUR1/CUR2/CUR3, SWU2_CUR0/CUR1/CUR2/CUR3 and so on.

SWU Features

The system watchpoint unit has the following features.

- Four independent match groups for each SWU
- Each match group can operate in either bandwidth mode or watchpoint mode

SWU Functional Description

This section describes the function of the SWU match block, interface block, and MMR block.

NOTE: In the *SWU Interrupt List* table, there are three SWUs, SWU1 (CL2_0), SWU3 (CL2_1) and SWU5 (CL2_2) for L2 Memory Core access and two SWUs, SWU2 (DL2_0) and SWU4 (DL2_1) for L2 Memory DMA access. CL2_2, DL2_0 and DL2_1 have access to the entire L2 range. CL2_0 has access to first 1MB and CL2_1 has access to second 1MB of L2.

ADSP-2184x SWU Register List

The System Watchpoint Unit (SWU) provides debug and development support through flexible transaction level and bandwidth monitoring and associated event triggering. The SWU can generate events based on monitoring transactions at the system targets through watchpoint-match groups. The SWU also provides watchpoint event

status reporting, a global lock, and processor reset capability. A set of registers governs SWU operations. For more information on SWU functionality, see the SWU register descriptions.

Table 46-1: ADSP-2184x SWU Register List

SWU Definitions

The following definitions are helpful when using the SWU module.

Watchpoint Mode

Mode in which transactions are recognized on an exact match. Actions can be configured to be taken after a specified number of matches have occurred.

Bandwidth Mode

Mode in which transactions are recognized and counted inside sampling window.

SWU Architectural Concepts

The information in this section provides basic module design concepts.

SWU-to-SCB Interface

The SWU system crossbar interface block latches all transactions on the system crossbar read and write address channels when the SWU_GCTL.EN register enable bit is set.

SWU Block Diagram

The *System Watchpoint Unit Top-Level Block Diagram* figure shows the SWU block diagram.

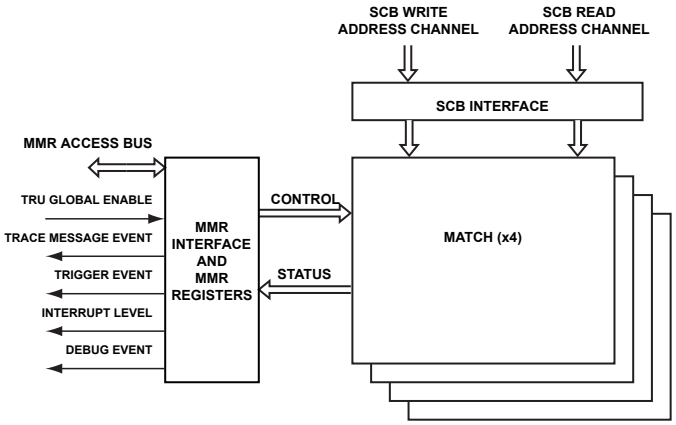

Figure 46-1: System Watchpoint Unit Top-Level Block Diagram

SCB Interface Block

The SWU system crossbar (SCB) latches all transactions on the SCB read and write address channels when the `SWU_GCTL.EN` bit is set.

MMR Interface Block

The SWU MMR block contains the peripheral bus interface and the SWU MMR registers. It also merges all interrupt requests and events from each match block into common outputs.

SWU Operating Modes

There are two operating modes supported by the SWU: bandwidth mode and watchpoint mode.

Bandwidth Mode

In bandwidth mode, the SWU module counts transactions which match the properties specified in the `SWU_CTL[n]` register during a sampling window determined by the respective `SWU_CNT[n]` register. At the end of the sampling window, the SWU stores results in the `SWU_HIST[n]` register. If the sampled bandwidth falls outside a programmed range, then the programmed action occurs.

Watchpoint Mode

In watchpoint mode, if the `SWU_CTL[n].CNTEN` bit is set, the SWU module decrements the `SWU_CUR[n]` register for each match, until it equals zero, at which point any programmed actions occur. The `SWU_CUR[n]` register is then reloaded from the `SWU_CNT[n]` register (if the `SWU_CTL[n].CNTRPTEN` bit is set), and the cycle repeats. If the `SWU_CTL[n].CNTRPTEN` bit is not set, any programmed actions happen on every match.

Match Block

There are four match blocks for each SWU. Each SWU match block can monitor either the read or write address channel, selected by the `SWU_CTL[n].DIR` bit. The SWU match block can operate in either watchpoint or bandwidth mode, as selected by the `SWU_CTL[n].BWEN` bit.

Scaling

Scaling allows the SWU to count more transactions by scaling the number of transactions and the number of clock cycles in bandwidth window (CNTn register) by 10,100 or 1000. This functionality is applicable only in bandwidth mode (SWU_CTL[n].BWEN==1).

Consider a case where the SWU_TARG[n].BWMAX bit field is programmed to 2. In the absence of any scaling, bandwidth overflow occurs when the SWU_CUR[n].CURBW bit field value > the SWU_TARG[n].BWMAX bit field value (2). With scaling set to 1:100 and after 275 transactions, the SWU_CUR[n].CURBW value is still 2 and equal to SWU_TARG[n].BWMAX. This event triggers a bandwidth overflow as the actual number of transactions is greater than 200 (2 × 100). The code can be rerun with a smaller scaling selected to analyze the cause for the overflow.

The counter increments after every group of N transactions with scaling enabled, where N is either 10,100 or 1000. (For N = 10, 0–9 transactions == 0 scaled transaction, 10–19 transactions == 1 scaled transaction, 20–29 transactions == 2 scaled transactions, and so on).

Fractional counts with scaling enabled are discarded and not rolled over from one bandwidth window to the next. For example, consider a case where scaling by 1000 is configured and the first window has 1200 transactions. The second window has 2800 transactions. The bandwidth for the first window is read as 1 and the second as 2. The 200 transactions from the first window do not get carried forward to the next window.

Do not use scaling by 10 with the SWU_CTL[n].BLENINC bit enabled if any of the requesters accessing the completer can launch a transaction of burst length 16.

SWU Event Control

The SWU can generate the following events when a match occurs and when the event is enabled by configuring the proper bits in the control register.

1. Trace Message
2. Trigger
3. Interrupt request
4. Debug

SWU Interrupts

All interrupt requests and events from each match block are merged into common outputs.

SWU Status and Errors

SWU status and errors are reported in the SWU_GSTAT register. The SWU records an address error when a write or read attempt is made to the MMR address space of the SWU and the register does not exist. This error is the only one the SWU records. The register contains bits that perform the following functions.

- Indicate whether a particular match group sampled a transaction that is below a minimum target or above a maximum target in bandwidth mode.
- Indicate whether a watchpoint match occurred for each match group.
- Indicate whether an interrupt request was triggered due to a match event from one of the match groups.

Triggers

The SWU can be either a trigger generator or a trigger receiver depending on the trigger routing unit (TRU) configuration. As a trigger generator, programs must set the `SWU_CTL[n].TRGEN` bit so that when a match condition is met, a trigger event is generated. Each SWU in the system can also be a trigger receiver when mapped as one in the TRU.

When the SWU is a receiver, a trigger event activates the SWU by automatically setting the `SWU_GCTL.EN` bit. Since the SWU can be automatically enabled through a trigger event, programs must pre-configure the SWU before enabling the TRU. Furthermore, although a trigger event can enable the SWU as a generator, to disable the SWU, programs must manually clear the `SWU_GCTL.EN` bit.

SWU Programming Model

Program the appropriate registers to use the SWU. Each control register configures aspects such as:

- The direction of monitoring (reads or writes)
- Whether SWU uses bandwidth mode or watchpoint mode
- The setup of events that are triggered when a condition is met while monitoring using the SWU

Configure supplemental registers such as the lower (`SWU_LA[n]`) and upper (`SWU_UA[n]`) address boundaries before enabling the SWU.

Once the SWU has been enabled and the monitoring conditions are met, events are generated when configured.

The global status register (`SWU_GSTAT`) can be read to observe the status of the units.

The ***SWU Logical Flow*** diagram shows the logical program flow of the SWU.

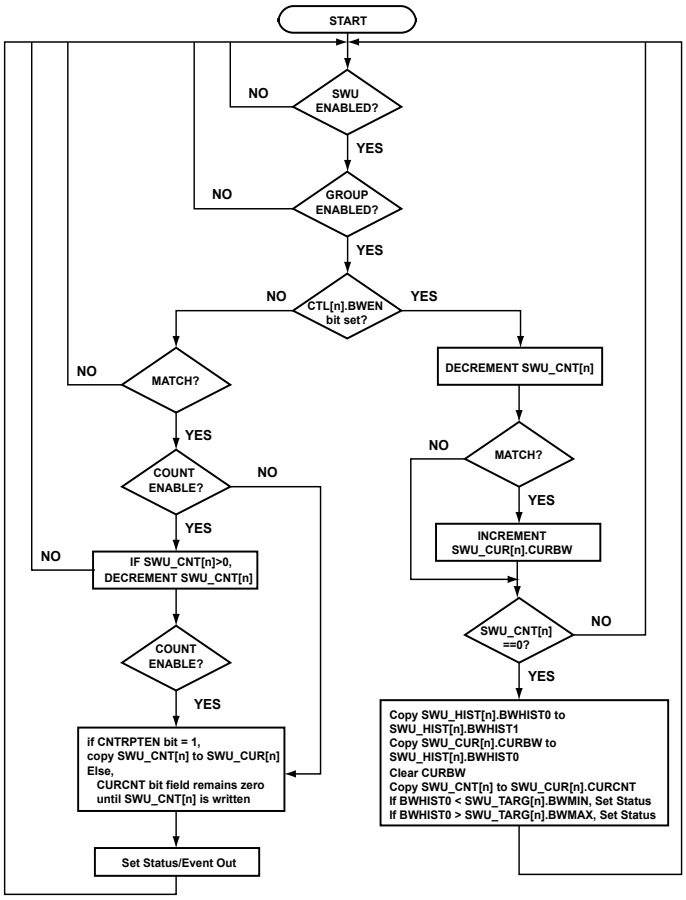

Figure 46-2: SWU Logical Flow

SWU Mode Configuration

The following sections show the steps for configuring SWU bandwidth mode and watchpoint mode.

Configuring the SWU for Bandwidth Mode

In bandwidth mode, the SWU counts transactions which match during a sampling window. At the end of the sampling window, the SWU stores the results. An action can be taken if the sampled bandwidth goes above or falls below a programmed range.

1. Configure the `SWU_CTL[n].DIR` bit to test the match on writes or reads.
2. Configure the `SWU_CTL[n].ACMPM` bits to address comparisons, exact match, matches inside a range or matches outside a range.
3. If ID comparison is desired, set the `SWU_CTL[n].IDCMPEN` bit.
4. Set the `SWU_CTL[n].BLENINC` bit to increment by burst length or clear it to increment by 1.
5. Configure the `SWU_CTL[n].MAXACT` and `SWU_CTL[n].MINACT` bits to enable actions taken when the bandwidth goes above the maximum, or falls below the minimum, respectively.

6. Set the SWU_CTL[n].BWEN=1 to enable bandwidth mode.
7. Program the lower address register, SWU_LA[n], and upper address register, SWU_UA[n], to define the memory range for comparison.
8. If ID comparison is enabled, program the ID register, SWU_ID[n].
9. Program the count register, SWU_CNT[n], with the number of clock cycles for which the SWU counts the number of matches.
10. If the SWU is set to respond when the bandwidth measurement underflows or overflows, program the min and max values into the SWU_TARG[n] register.
11. Enable the SWU

The SWU counts the number of matches in a pre-defined number of clock cycles as programmed. As an option, it can define lower and upper limits. If the matches fall outside the limits, an action can be taken.

Configuring the SWU for Watchpoint Mode

In watchpoint mode, the SWU can trigger a programmed action after every match or after a number of matches. This sequence can be automatically reset.

1. Set the SWU_CTL[n].DIR bit to test the match on writes or reads.
2. Configure the SWU_CTL[n].ACMPM bits for address comparisons, exact match, matches inside a range or matches outside a range.
3. If ID comparison is desired, set the SWU_CTL[n].IDCMPEN.
4. Set the SWU_CTL[n].CNTEN bit to enable the events to be triggered when the count decrements to zero.
5. If needed, set the SWU_CTL[n].CNTRPTEN bit to automatically reload the counter after it has decremented to zero to start another match sequence.
6. Clear the SWU_CTL[n].BWEN = 0 to configure watchpoint mode.
7. Configure the lower address register, SWU_LA[n], and upper address register, SWU_UA[n], to define the memory range for comparison.
8. If ID comparison is enabled, configure the ID register, SWU_ID[n].
9. Configure the count register, SWU_CNT[n], to determine how many matches occur before the watchpoint group responds.
10. Enable the SWU.

The SWU detects and counts down the number of match occurrences. When the counter expires, an action is taken.

ADSP-2184x SWU Register Descriptions

System Watchpoint Unit (SWU) contains the following registers.

Table 46-5: ADSP-2184x SWU Register List

Name	Description
SWU_CNT[n]	Count Register n
SWU_CTL[n]	Control Register n
SWU_CUR[n]	Current Register n
SWU_GCTL	Global Control Register
SWU_GSTAT	Global Status Register
SWU_HIST[n]	Bandwidth History Register n
SWU_ID[n]	ID Register n
SWU_LA[n]	Lower Address Register n
SWU_TARG[n]	Target Register n
SWU_UA[n]	Upper Address Register n

Count Register n

The SWU count registers (SWU_CNT[n]) contain a 16-bit count field (SWU_CNT[n].COUNT) whose usage differs depending on the mode of the watchpoint group. In bandwidth mode, the SWU_CNT[n].COUNT field value defines the number of clock cycles in a bandwidth period. In watchpoint mode, when the cycle count is enabled, the SWU_CNT[n].COUNT field value determines how many matches occur before the watchpoint group takes action.

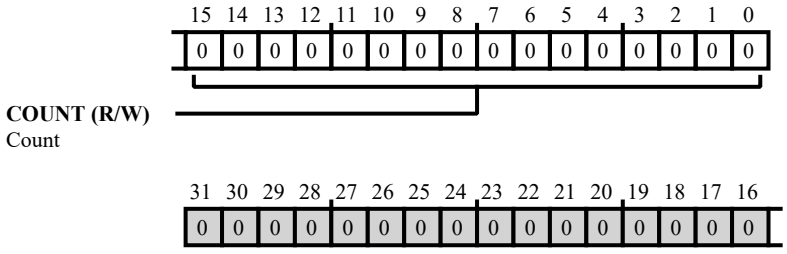

Figure 46-3: SWU_CNT[n] Register Diagram

Table 46-6: SWU_CNT[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
15:0 (R/W)	COUNT	Count. The SWU_CNT[n].COUNT field value defines the number of clock cycles in a bandwidth period. In watchpoint mode, when the cycle count is enabled, the SWU_CNT[n].COUNT field value determines how many matches occur before the watchpoint group takes action.

Control Register n

The SWU control registers (SWU_CTL[n]) contain watchpoint attribute controls for all four watchpoint groups. These controls include enabling watchpoints, selecting the transaction direction for match, selecting address comparison mode, enabling ID comparison, enabling security comparison, enabling cycle count, enabling count repeat, enabling debug events, enabling interrupts, enabling triggers, enabling trace messages, enabling bandwidth mode, selecting the burst length increment, and enabling bandwidth underflow and overflow detection.

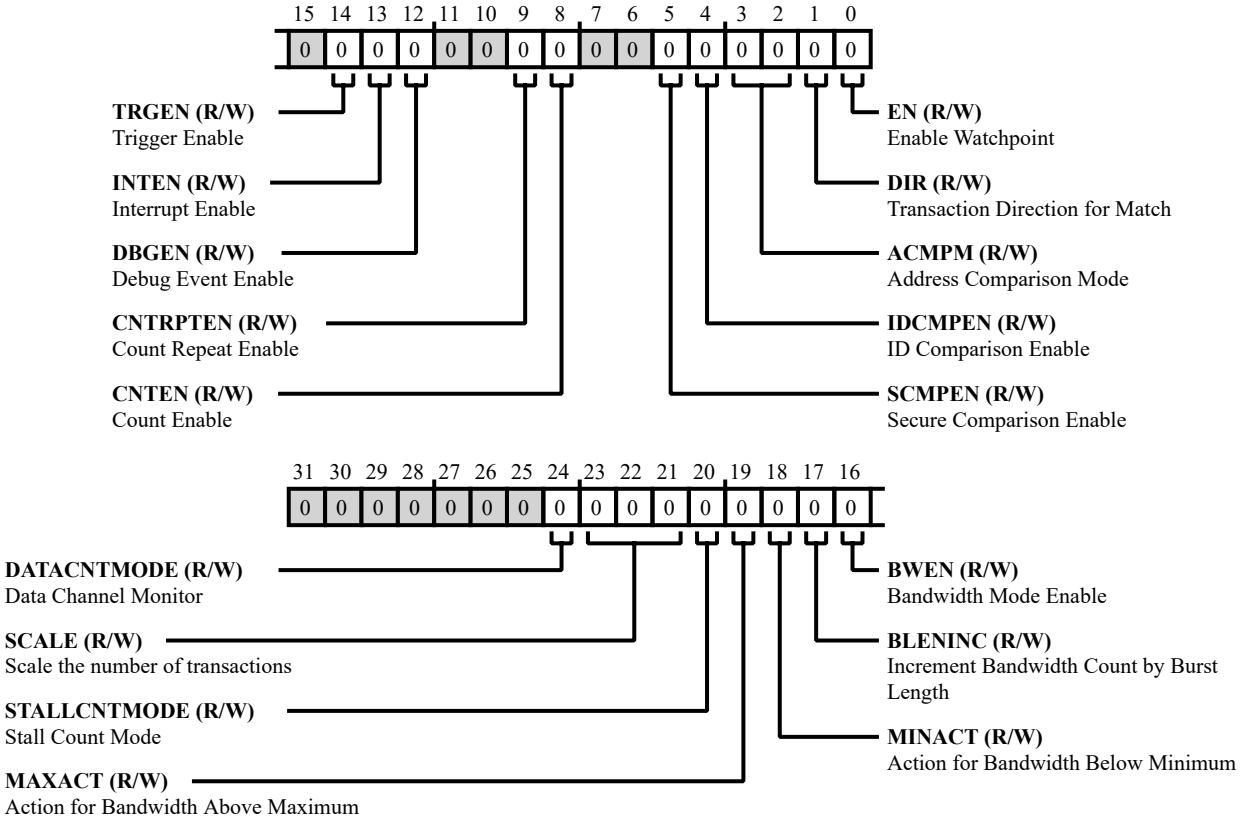

Figure 46-4: SWU_CTL[n] Register Diagram

Table 46-7: SWU_CTL[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
24 (R/W)	DATACNTMODE	Data Channel Monitor. The SWU_CTL[n].DATACNTMODE bit determines whether an address channel or a data channel is monitored. Note that in data channel only ID,READY and VALID signals are monitored and hence other comparisons (Address, Lock, Secure) will be ignored even if enabled. SWU_CTL[n].STALLCNTMODE and SWU_CTL[n].DIR can be used in conjunction with this bit	
		0	Monitor address channel
		1	Monitor data channel
23:21 (R/W)	SCALE	Scale the number of transactions. The SWU_CTL[n].SCALE bit field allows a program to count more transactions by scaling the number of transactions and also the number of clock cycles in the bandwidth window (SWU_CNT[n] register) by 10,100 or 1000. This is applicable only in bandwidth mode (SWU_CTL[n].BWEN==1).	
		0	No scaling
		1	1:10
		2	1:100
		3	Reserved
		4	1:1000
		5-7	Reserved
20 (R/W)	STALLCNTMODE	Stall Count Mode. The SWU_CTL[n].STALLCNTMODE bit determines whether the number of stalls are counted or whether the number of transactions are counted. This feature is only valid in bandwidth mode.	
		0	Count number of transactions
		1	Count number of stalls
19 (R/W)	MAXACT	Action for Bandwidth Above Maximum. Each SWU_CTL[n].MAXACT bit determines whether a watchpoint group takes action on bandwidth overflow. This feature is only valid in bandwidth mode.	
		0	No Action
		1	Take Action
18 (R/W)	MINACT	Action for Bandwidth Below Minimum. Each SWU_CTL[n].MINACT bit determines whether a watchpoint group takes action on bandwidth underflow. This feature is only valid in bandwidth mode.	
		0	No Action
		1	Take Action

Table 46-7: SWU_CTL[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
17 (R/W)	BLENINC	Increment Bandwidth Count by Burst Length. Each SWU_CTL[n].BLENINC bit controls how a watchpoint group's bandwidth count is incremented in the SWU_CUR[n] register's SWU_CUR[n].CURBW field. If the SWU_CTL[n].BLENINC bit is cleared (= 0), the SWU increments the bandwidth count by 1 for each matching transaction. If the SWU_CTL[n].BLENINC bit is set (=1), the SWU increments the bandwidth count by the burst length of the transaction for each matching transaction. This feature is only valid for bandwidth mode (SWU_CTL[n].BWEN bit == 1). Note that if the address range match is enabled (SWU_CTL[n].ACMPM bits) and if any address of a burst falls within the address range, the SWU_CUR[n].CURBW field is incremented by the burst length even if some of the burst address fall outside of the range. Also, note that the burst size of the transaction is not included in the increment, only the burst length of the transaction. This increment operation provides an approximate (not exact) number of bus cycles consumed during the bandwidth.	
		0	Increment by 1
		1	Burst Length Increment for Bandwidth Count
16 (R/W)	BWEN	Bandwidth Mode Enable. Each SWU_CTL[n].BWEN bit controls whether a watchpoint group operates in watchpoint mode or bandwidth mode. In watchpoint mode, the SWU_CTL[n].CNTEN and (optionally) SWU_CTL[n].CNTRPTEN registers control usage of the cycle count for watchpoint group operations. In bandwidth mode, the SWU_CTL[n].BLENINC, SWU_TARG[n], and SWU_HIST[n] registers control usage of watchpoint matches for watchpoint group operations.	
		0	Watchpoint Mode
		1	Bandwidth Mode
14 (R/W)	TRGEN	Trigger Enable. Each SWU_CTL[n].TRGEN bit controls whether a match for a watchpoint group generates a trigger event. This feature is valid in both bandwidth and watchpoint modes.	
		0	Disable
		1	Enable
13 (R/W)	INTEN	Interrupt Enable. Each SWU_CTL[n].INTEN bit controls whether a match for a watchpoint group generates an interrupt. This feature is valid in both bandwidth and watchpoint modes.	
		0	Disable
		1	Enable

Table 46-7: SWU_CTL[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
12 (R/W)	DBGEN	Debug Event Enable. Each SWU_CTL[n].DBGEN bit controls debug event comparison for a watchpoint group, permitting matches based on debug status.	
		0	Disable
		1	Enable
9 (R/W)	CNTRPTEN	Count Repeat Enable. Each SWU_CTL[n].CNTRPTEN bit controls whether the watchpoint group's cycle count is reloaded and repeated after cycle countdown. If the SWU_CTL[n] register's SWU_CTL[n].CNTRPTEN bit is set, the SWU_CUR[n] register's SWU_CUR[n].CURCNT field is reloaded from SWU_CNT[n] register's SWU_CNT[n].COUNT field, and the countdown starts again. If SWU_CTL[n].CNTRPTEN bit is cleared, the expired count remains zero, and no further events are signalled. (See the SWU_CTL[n].CNTEN bit description for information regarding the countdown setup.)	
		0	Disable
		1	Enable
8 (R/W)	CNTEN	Count Enable. Each SWU_CTL[n].CNTEN bit controls whether the cycle count in the watchpoint group's SWU_CNT[n] register is decremented each cycle until it reaches zero. This feature is only valid in watchpoint mode (SWU_CTL[n].BWEN bit == 0).When the count reaches zero, any enabled watchpoint events are triggered. (See the SWU_CTL[n].CNTRPTEN bit description for optional actions at that may occur at the end of the countdown.)	
		0	Disable
		1	Enable
5 (R/W)	SCMPEN	Secure Comparison Enable. Each SWU_CTL[n].SCMPEN bit controls secure transaction comparison operation of an SWU watchpoint group, permitting matches based on transaction security.	
		0	Match on all transaction
		1	Match only secure transactions
4 (R/W)	IDCMPEN	ID Comparison Enable. Each SWU_CTL[n].IDCMPEN bit controls the ID comparison operation of an SWU watchpoint group. The ID match is based on comparison with the value in the SWU_ID[n] register.	

Table 46-7: SWU_CTL[n] Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3:2 (R/W)	ACMPM	Address Comparison Mode. Each set of `SWU_CTL[n].ACMPM` bits control the address comparison operation of an SWU watchpoint group. The address within range for comparison is defined as (`SWU_LA[n]` register <= address < `SWU_UA[n]` register). The address outside range for comparison is defined as (address < `SWU_LA[n]`) or (`SWU_UA[n]` <= address).	
		0	No address comparison
		1	Exact match on LAn
		2	Match on address within range
		3	Match on address outside range
1 (R/W)	DIR	Transaction Direction for Match. Each `SWU_CTL[n].DIR` bit determines whether the SWU check reads or writes for watchpoint matches.	
		0	Match on reads only
		1	Match on writes only
0 (R/W)	EN	Enable Watchpoint. Each `SWU_CTL[n].EN` bit controls the operation of one SWU watchpoint group. Clearing the `SWU_CTL[n].EN` bit halts the execution of watchpoint or bandwidth tracking operations in the watchpoint group without resetting status or configuration registers. Setting the `SWU_CTL[n].EN` bit enables the SWU watchpoint group to begin or resume operation with the current configuration and status.	
		0	Disable
		1	Enable

Current Register n

The SWU current register (SWU_CUR[n]) operation varies depending whether the watchpoint group is in bandwidth mode or watchpoint mode. In both modes, the watchpoint count begins when the SWU loads the register's SWU_CUR[n].CURCNT field from the SWU_CNT[n] register's SWU_CNT[n].COUNT field when the watchpoint count is enabled (SWU_CTL[n] register, SWU_CTL[n].CNTEN bit =1).

In bandwidth mode, the current count field (SWU_CUR[n].CURCNT) contains the cycle count remaining within the current watchpoint period. The SWU decrements this value every cycle until the count reaches zero. At that point, the SWU reloads the SWU_CUR[n].CURCNT field from SWU_CNT[n] register's SWU_CNT[n].COUNT field. In bandwidth mode, the current bandwidth field (SWU_CUR[n].CURBW) contains the count of watchpoint matches (bandwidth) accumulated in the current watchpoint period.

In watchpoint mode, the current count field (SWU_CUR[n].CURCNT) contains the watchpoint match count remaining within the current watchpoint period. The SWU decrements this value with every watchpoint match until the count reaches zero. At that point, the SWU reloads the SWU_CUR[n].CURCNT field from SWU_CNT[n] register's SWU_CNT[n].COUNT field if the SWU_CTL[n] register's SWU_CTL[n].CNTRPTEN bit is set (=1). In watchpoint mode, the current bandwidth field (SWU_CUR[n].CURBW) is undefined.

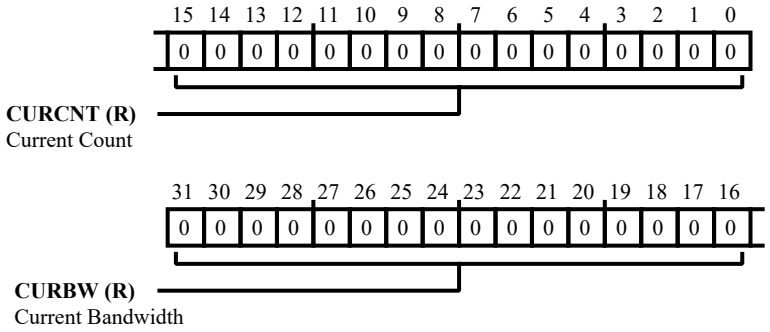

Figure 46-5: SWU_CUR[n] Register Diagram

Table 46-8: SWU_CUR[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/NW)	CURBW	Current Bandwidth.
15:0 (R/NW)	CURCNT	Current Count.

Global Control Register

The SWU global control register (SWU_GCTL) provides SWU reset and enable.

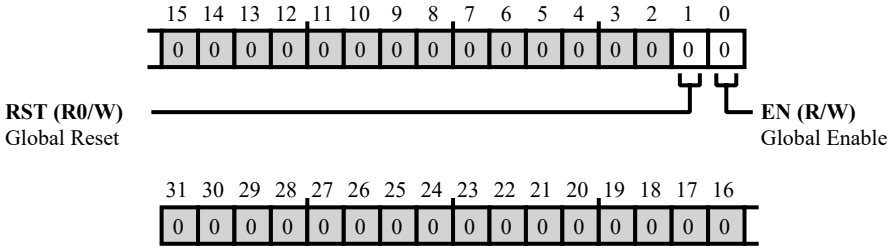

Figure 46-6: SWU_GCTL Register Diagram

Table 46-9: SWU_GCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R0/W)	RST	Global Reset. The SWU_GCTL.RST) is write-1-action/read zero and controls the SWU operational state. Setting SWU_GCTL.RST resets all SWU registers to their default values and halts all SWU operations.	
		0	No Action
		1	Reset
0 (R/W)	EN	Global Enable. The SWU_GCTL.EN controls the SWU operational state. Clearing SWU_GCTL.EN halts the execution of all watchpoint and bandwidth tracking operations without resetting status registers or associated signals. Setting SWU_GCTL.EN enables the SWU to begin/resume operation with the current configuration and status.	
		0	Disable
		1	Enable

Global Status Register

The SWU global status register (SWU_GSTAT) contains status bits for all four watchpoint groups.

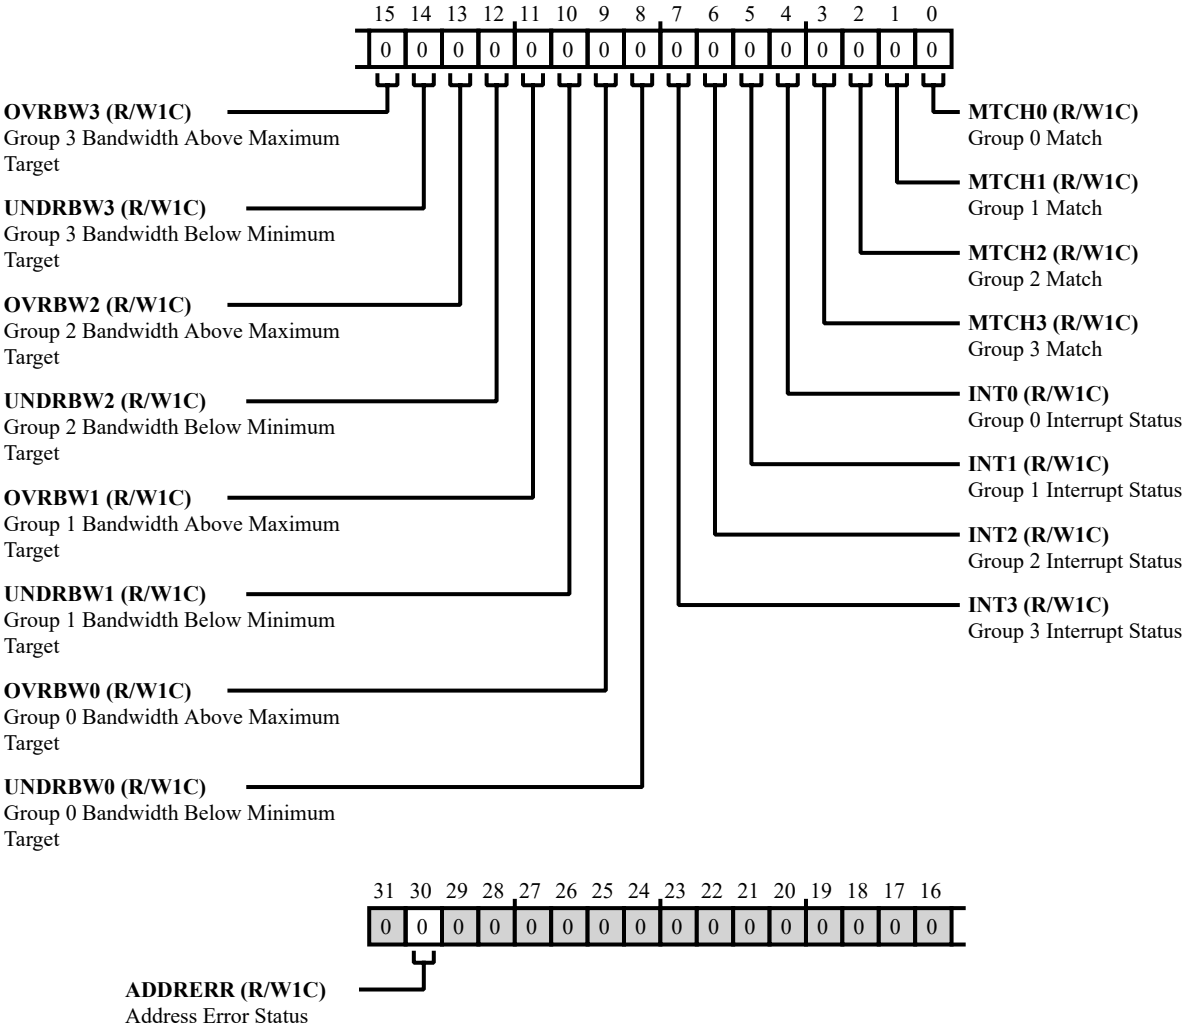

Figure 46-7: SWU_GSTAT Register Diagram

Table 46-10: SWU_GSTAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
30 (R/W1C)	ADDRERR	Address Error Status. The SWU_GSTAT.ADDRERR indicates that the SWU generated an address error. This status bit is sticky; write-1-to-clear it.	
		0	Inactive
		1	Active

Table 46-10: SWU_GSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W1C)	OVRBW3	Group 3 Bandwidth Above Maximum Target. See SWU_GSTAT.OVRBW0 description.	
		0	Group 3 was not above maximum bandwidth
		1	Group 3 was above maximum bandwidth
14 (R/W1C)	UNDRBW3	Group 3 Bandwidth Below Minimum Target. See SWU_GSTAT.UNDRBW0 description.	
		0	Group 3 was not below minimum bandwitdth
		1	Group 3 was below minimum bandwitdth
13 (R/W1C)	OVRBW2	Group 2 Bandwidth Above Maximum Target. See SWU_GSTAT.OVRBW0 description.	
		0	Group 2 was not above maximum bandwidth
		1	Group 2 was above maximum bandwidth
12 (R/W1C)	UNDRBW2	Group 2 Bandwidth Below Minimum Target. See SWU_GSTAT.UNDRBW0 description.	
		0	Group 2 was not below minimum bandwidth
		1	Group 2 was below minimum bandwidth
11 (R/W1C)	OVRBW1	Group 1 Bandwidth Above Maximum Target. See SWU_GSTAT.OVRBW0 description.	
		0	Group 1 was not above maximum bandwidth
		1	Group 1 was above maximum bandwidth
10 (R/W1C)	UNDRBW1	Group 1 Bandwidth Below Minimum Target. See SWU_GSTAT.UNDRBW0 description.	
		0	Group 1 was not below minimum bandwidth
		1	Group 1 was below minimum bandwidth
9 (R/W1C)	OVRBW0	Group 0 Bandwidth Above Maximum Target. The SWU_GSTAT.OVRBW0 - SWU_GSTAT.OVRBW3 -- Group 0 through 3 watch-point bandwidth over maximum target bits. Each maximum bandwidth bit indicate (for each group)s that the measured bandwidth over the period defined by the SWU_CNT[n] register was over the maximum target. This status bit is sticky; write-1-to-clear it.	
		0	Group 0 was not above maximum bandwidth
		1	Group 0 was above maximum bandwidth

Table 46-10: SWU_GSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W1C)	UNDRBW0	Group 0 Bandwidth Below Minimum Target. The SWU_GSTAT.UNDRBW0 - SWU_GSTAT.UNDRBW3 -- Group 0 through 3 watchpoint bandwidth below minimum target bits. Each minimum bandwidth bit indicates (for each group) that the measured bandwidth over the period defined by the SWU_CNT[n] register was below the minimum target. This status bit is sticky; write-1-to-clear it.	
		0	Group 0 was not below minimum bandwidth
		1	Group 0 was below minimum bandwidth
7 (R/W1C)	INT3	Group 3 Interrupt Status. See SWU_GSTAT.INT0 description.	
		0	No Interrupt
		1	Interrupt Occurred
6 (R/W1C)	INT2	Group 2 Interrupt Status. See SWU_GSTAT.INT0 description.	
		0	No Interrupt
		1	Interrupt Occurred
5 (R/W1C)	INT1	Group 1 Interrupt Status. See SWU_GSTAT.INT0 description.	
		0	No Interrupt
		1	Interrupt Occurred
4 (R/W1C)	INT0	Group 0 Interrupt Status. The SWU_GSTAT.INT0 - SWU_GSTAT.INT3 -- Group 0 through 3 interrupt bits. Each interrupt bit indicates (for each group) whether a watchpoint group is contributing to the SWU's interrupt output. This status bit is sticky; write-1-to-clear it.	
		0	No interrupt
		1	Interrupt Occurred
3 (R/W1C)	MTCH3	Group 3 Match. See SWU_GSTAT.MTCH0 description.	
		0	No Match
		1	Group 3 Watchpoint Match

Table 46-10: SWU_GSTAT Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W1C)	MTCH2	Group 2 Match. See SWU_GSTAT.MTCH0 description.	
		0	No match
		1	Group 2 Watchpoint Match
1 (R/W1C)	MTCH1	Group 1 Match. See SWU_GSTAT.MTCH0 description.	
		0	No match
		1	Group 1 Watchpoint Match
0 (R/W1C)	MTCH0	Group 0 Match. The SWU_GSTAT.MTCH0 - SWU_GSTAT.MTCH3 -- Group 0 through 3 match bits. Each match bit indicates (for each group) whether a watchpoint match has occurred in a SWU watchpoint group, as controlled by the group's related watchpoint control register (SWU_CTL[n]). This status bit is sticky; write-1-to-clear it.	
		0	No match
		1	Group 0 Watchpoint Match

Bandwidth History Register n

The SWU bandwidth history registers (SWU_HIST[n]) contain data copied from a watchpoint group's current bandwidth value (SWU_CUR[n] register, SWU_CUR[n].CURBW bits) at the end of the last two watchpoint periods. At the end of each watchpoint period, the SWU copies the previous bandwidth value from the SWU_HIST[n].BWHIST0 field to the SWU_HIST[n].BWHIST1 field and copies the new bandwidth value from the SWU_CUR[n].CURBW field to the SWU_HIST[n].BWHIST0 field.

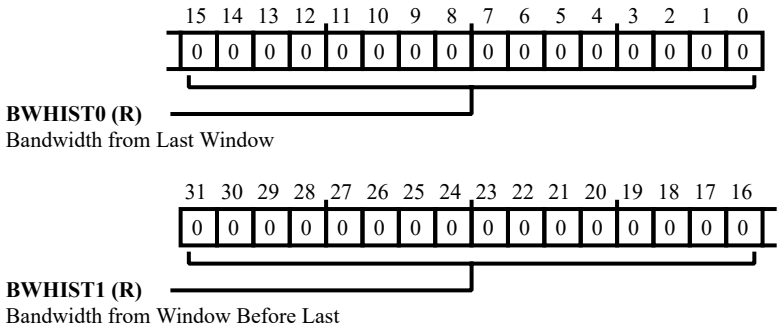

Figure 46-8: SWU_HIST[n] Register Diagram

Table 46-11: SWU_HIST[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/NW)	BWHIST1	Bandwidth from Window Before Last.
15:0 (R/NW)	BWHIST0	Bandwidth from Last Window.

ID Register n

The SWU ID registers (SWU_ID[n]) contain a 16-bit ID field (SWU_ID[n].ID) and a 16-bit ID mask field (SWU_ID[n].IDMASK) that watchpoint groups use for ID comparison. The ID on the bus is AND'ed with the SWU_ID[n].IDMASK field, then the watchpoint group compares the result against the SWU_ID[n].ID field.

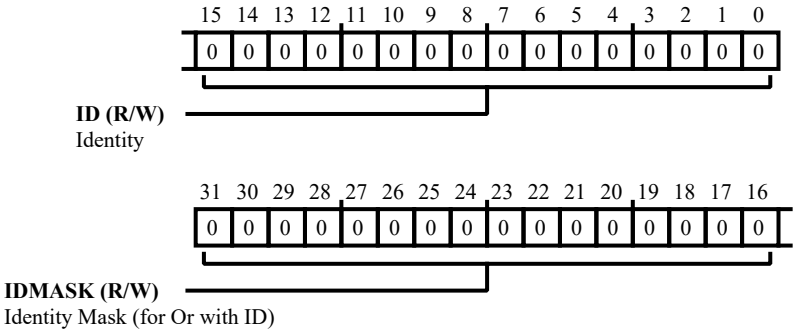

Figure 46-9: SWU_ID[n] Register Diagram

Table 46-12: SWU_ID[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	IDMASK	Identity Mask (for Or with ID).
15:0 (R/W)	ID	Identity.

Lower Address Register n

The SWU lower address registers (SWU_LA[n]) contain each watchpoint group's lower address for address match comparison. In exact match on SWU_LA[n] address mode (SWU_CTL[n].ACMPM bits =01), the watchpoint group uses only this address for match comparison.

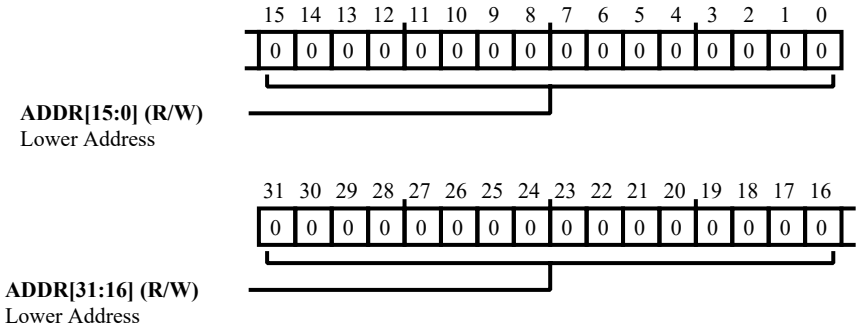

Figure 46-10: SWU_LA[n] Register Diagram

Table 46-13: SWU_LA[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	ADDR	Lower Address.

Target Register n

The SWU target registers (SWU_TARG[n]) contain a minimum value field (SWU_TARG[n].BWMIN) and maximum value field (SWU_TARG[n].BWMAX) of bandwidth targets used by watchpoint groups in bandwidth mode. When the bandwidth period expires, if the current bandwidth value (SWU_CUR[n] register, SWU_CUR[n].CURBW bits) is below the minimum target or above the maximum target, the watchpoint group takes action as enabled by the SWU_CTL[n] register's SWU_CTL[n].MINACT or SWU_CTL[n].MAXACT bits.

In bandwidth mode, note that the watchpoint group increments its count of either data bus transactions or address bus transactions (bursts) as selected by the SWU_CTL[n].BLENINC bit. Keep this mode selection in mind when programming the bandwidth target values.

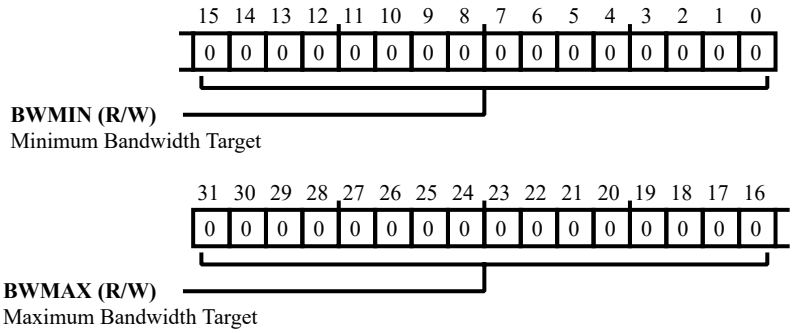

Figure 46-11: SWU_TARG[n] Register Diagram

Table 46-14: SWU_TARG[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/W)	BWMAX	Maximum Bandwidth Target.
15:0 (R/W)	BWMIN	Minimum Bandwidth Target.

Upper Address Register n

The SWU upper address registers (SWU_UA[n]) contain each watchpoint group's upper address for address match comparison. In exact match on SWU_LA[n] address mode (SWU_CTL[n].ACMPM bits =01), the SWU_UA[n] is not used for match comparison.

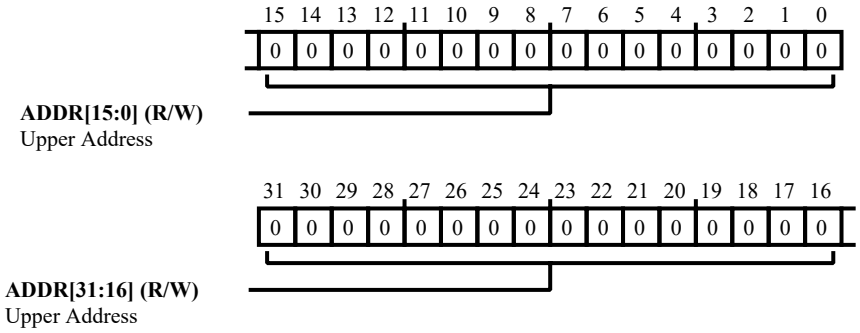

Figure 46-12: SWU_UA[n] Register Diagram

Table 46-15: SWU_UA[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	ADDR	Upper Address.

47 Memory Error Protection Unit (MEPU)

Memory Error Protection Unit (MEPU) handles single-bit and double-bit memory error detection and correction across the memories in the chip and controls routing of their interrupts/triggers.

It consists of following blocks:

- Memory Error Controller (MEC)
- Parity Controller (PCTL)
- ECC Controller (ECTL)

Memory Error Controller (MEC)

The Memory Error Controller (MEC) manages memory parity, ECC errors and warning inputs from various cores and peripherals and sends out interrupt and trigger outputs. It is a generic N x M multiplexer and interrupt controller for error or warning inputs to interrupt and trigger outputs. It has control features such as enable and disable and interrupt masking, and status signaling for input/outputs. For more information on MEC functionality, see the MEC registers description.

MEC Features

The MEC unit has the following features:

- Interrupt controller for memory parity, ECC errors and warnings
- N x M multiplexer for error inputs to interrupt and trigger outputs
- Peripheral bus completer interface for register read and write
- Control and status registers
    - Control for enabling or disabling each input error status and masking its interrupt
    - Control for enabling or disabling each output error interrupt
    - Input error status bits are sticky and write-1-to-clear
    - Output error interrupt status bits are read only

    - Lock feature for control registers write. Status registers capture lock write error.
- Peripheral and component identification registers
- Capability to retain parity, ECC error and warning status even after any reset for fault source debug
- Fully-configurable design

Parity Controller (PCTL)

The Parity Controller (PCTL) handles parity encoding and decoding to and from memory data for single bit memory error detection.

PCTL Features

The PCTL unit has the following features:

- Generic memory parity controller
    - Generation of write parity bits from write data bits
    - Concatenation of parity bits with data bits for memory write data
    - Generation of write enable mask for parity bits to memory
    - Extraction of read data bits from memory read data
    - Detection of read parity error from memory read data
- Even parity logic for parity generation and error detection
- Provision for parity bit interleaving
- Single parity error output per memory instance
- Memory initialization control logic
- Fully-configurable design

MEC Functional Description

The MEC works with the PCTL to detect and correct memory error across the memories in the chip. It also controls the routing of the generated interrupts and triggers.

ADSP-2184x MEC Register List

The Memory Error Controller (MEC) manages memory parity/ inputs from the core and peripherals and sends interrupt/trigger outputs. It is a generic N x M multiplexer and interrupt controller for error to interrupt/trigger outputs. It has control features such as enable/disable and interrupt masking, and status signaling for inputs/outputs. For more information on MEC functionality, see the MEC register descriptions.

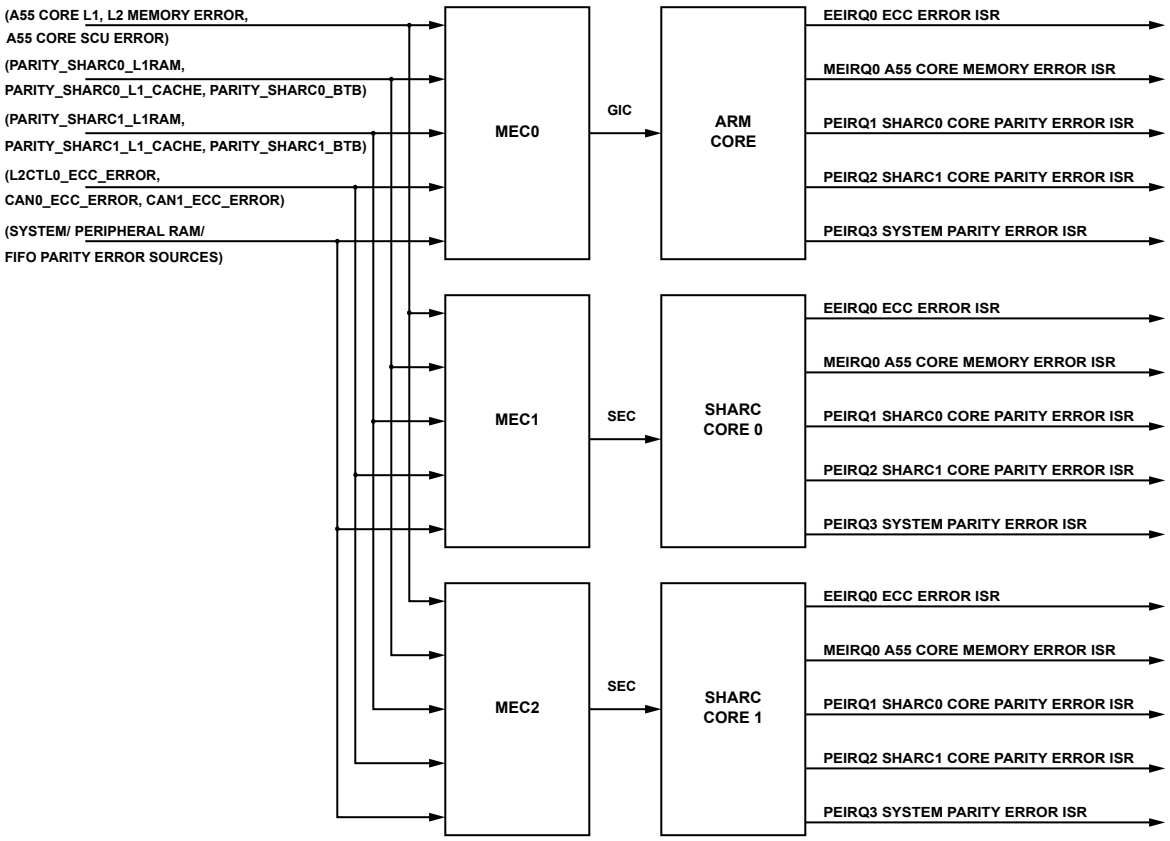

Figure 47-4: MECx Input and Output Block Diagram

MEC Architectural Concepts

The MEC unit communicates with the Cortex-A55 core directly through the subsystem's SYS bus crossbar. It services MMR addresses associated with the MEC function unit and translates the addresses into specific transcendental MEC functions. The results are read from common result registers shared by all the functions in single-precision floating-point format. The block stalls all read accesses until the result is ready.

MEC Configuration

The following tables describe the range of values for configuration and the mapping of parity errors.

Table 47-5: Mapping of Input Parity Errors (PERR)

PERR ID	Name	Description
0	Reserved	Reserved
1	Reserved	Reserved
2	PERR_C1_L1R	Core1 (SHARC0) L1 RAM Parity Error
3	PERR_C1_L1CR	Core1 (SHARC0) L1 Cache RAM Parity Error
4	PERR_C1_BPR	Core1 (SHARC0) Branch Predictor RAM Parity Error

CMERR ID	Name	Description
7	ECCERR_DRAM	Core1 DRAM ECC Error Uncorrectable
6	ECCERR_IRAM	Core1 iRAM ECC Error Uncorrectable
4	ECCERR_DCACHE_DIRTY	Core1 dCache ECC Error Dirty Uncorrectable
3	ECCERR_ICACHE	Core1 iCache ECC Error Uncorrectable
2	ECCERR_DP_CLEAN	Core1 dPref RAM ECC Error Clean Uncorrectable
1	ECCERR_DP_DIRTY	Core1 dPref RAM ECC Error Dirty Uncorrectable
0	ECCERR_IP_CLEAN	Core1 iPref RAM ECC Error Clean Uncorrectable

Table 47-10: Mapping of Input A55 Core n Memory Errors (A55CnERR); n=0, 2

CMERR ID	Name	Description
0	A55 SCU ERR	A55 SCU ERR
1	A55_L1L2_ERR	A55_L1L2_ERR

Table 47-11: Mapping of Output A55 Core n Memory Errors (A55CnEIRQ); n=0, 2

CMERR IRQ ID	Name	Description
0	A55CnEIRQ	A55 Core n Memory Error Interrupt

Error Status and Interrupts

There are two categories of memory errors from the SHARC-FX core:

- Recoverable errors - includes single bit ECC errors and parity and dual bit ECC errors in buffers that can be dropped or refilled from the source.
- Unrecoverable errors - includes the remaining dual bit ECC errors

As the errors occur, this information is relayed over PFaultInfo and sent out to the SEC module via the MPEU module. From the SEC, these signals can be sent out to an external fault pin.

There is an additional signal (PFatalError) that is asserted when the core is stuck in a double/triple exception. The signal directly goes to the SEC module.

The following table lists the recoverable ECC errors in the SHARC-FX core.

Table 47-12: Recoverable Core Memory ECC Errors

SL Number	Fault Category	Type Fault PFaultInfo[50:32]	Description
0		ECC error correctable 32	1-bit ECC error
1		ECC error correctable 34	1-bit ECC error
2		ECC error correctable 36	1-bit ECC error
3		ECC error 37	Clean refill
4		L1S Cache refill 40	Refill from L1V cache
6		ICACHE ECC error correctable 41	1-bit ECC error
7		ECC error refill 42	2-bit ECC error, refill from memory
8	DPREFETCH RAM	DPREF RAM ECC error correctable 44	1-bit ECC error
9	DPREF RAM	ECC error clean drop 45	Clean drop
10	IPREFETCH RAM	IPREF RAM ECC error correctable 48	1-bit ECC error

Table 47-13: Unrecoverable Core Memory ECC Errors

SL Number	Fault Category	Type Fault PFaultInfo[50:32]	Description
1		DRAM ECC error uncorrectable 33	2-bit ECC error
2		IRAM ECC error uncorrectable 35	2-bit ECC error
3		DCACHE ECC error clean uncorrectable 38	2-bit ECC error in unmodified cache line
4		ECC error dirty uncorrectable 39	2-bit ECC error in unmodified cache line
5		ICACHE ECC error uncorrectable 43	2-bit ECC error, cannot be refilled from memory
6	DPREFETCH RAM	DPREF RAM ECC error clean uncorrectable 46	2-bit ECC error in unmodified cache line
7	DPREF RAM	ECC error dirty uncorrectable 47	
8	IPREFETCH RAM	IPREF RAM ECC error uncorrectable 50	

NOTE: In the SH-FX configuration chosen for EHP, the following fault signals are not implemented and tied to 0 in the design and, hence, never occur.

- IPREF RAM ECC error clean drop PFaultInfo[49]
- DCACHE ECC error clean refill PFaultInfo [37]
- DPREF RAM ECC error clean drop PFaultInfo [45]
- DPREF ECC error clean uncorrectable PFaultInfo [46]

Requester Port Bus Interrupts

Bus error responses from the requester ports of the SHARC-FX core are detected and routed to the SEC to raise faults. Although the SHARC-FX core can detect and raise exceptions, when there is a bus error response, there is good chance of data/instruction corruption. Therefore, the core exception handling dependency has been removed. The SEC is directly notified using interrupts.

Instruction Bus Interrupt

Any instruction read error is detected on the instruction requester port; the information is forwarded to the SEC via the core1 instruction read interrupt.

Data Bus Interrupts

Any data read or write error is detected on the data requester port; the information is forwarded to the SEC via the core1 data read interrupt and core1 data write interrupt.

iDMA Bus Interrupts

Any data read or write error that is detected on the iDMA port is forwarded to the SEC via the core1 iDMA read interrupt and core1 iDMA write interrupt.

PCTL Integration

There is one PCTL instance per port per memory instance (for example, one PCTL instance for single port memory and two PCTL instances for dual port memories).

Memory initialization control logic supported by PCTL is used only for instances attached to Arm L1 cache memories.

An additional software trigger requester and initialization trigger completer is provided in TRU for starting memory initialization. A pulse from this trigger completer starts initialization of Arm L1 cache memories. When all the locations of a particular memory instance get initialized, the PCTL generates a memory initialization done signal for the corresponding memory instance. These signals from all PCTL instances corresponding to Arm L1 cache memories are ANDed to generate a single memory initialization done output which is connected as an interrupt to SEC/GIC and a trigger requester to TRU.

ADSP-2184x MEC Register Descriptions

Memory Error Controller (MEC) contains the following registers.

Table 47-14: ADSP-2184x MEC Register List

Name	Description
MEC_A55C0EIRQ_GCTL[n]	A55 Core Memory Errors Interrupt Request Global Control Register
MEC_A55C0EIRQ_GSTAT[n]	A55 Error Interrupt Request Global Status Register
MEC_A55C0ERR_CTL[n]	A55 Error Control Register
MEC_A55C0ERR_IMASK[n]	A55 Error Interrupt Mask Register

Table 47-14: ADSP-2184x MEC Register List (Continued)

Name	Description
MEC_A55C0ERR_STAT[n]	A55 Error Status Register
MEC_A55C2EIRQ_GCTL[n]	A55 Core Memory Errors Interrupt Request Global Control Register
MEC_A55C2EIRQ_GSTAT[n]	A55 Error Interrupt Request Global Status Register
MEC_A55C2ERR_CTL[n]	A55 Error Control Register
MEC_A55C2ERR_IMASK[n]	A55 Error Interrupt Mask Register
MEC_A55C2ERR_STAT[n]	A55 Error Status Register

A55 Core Memory Errors Interrupt Request Global Control Register

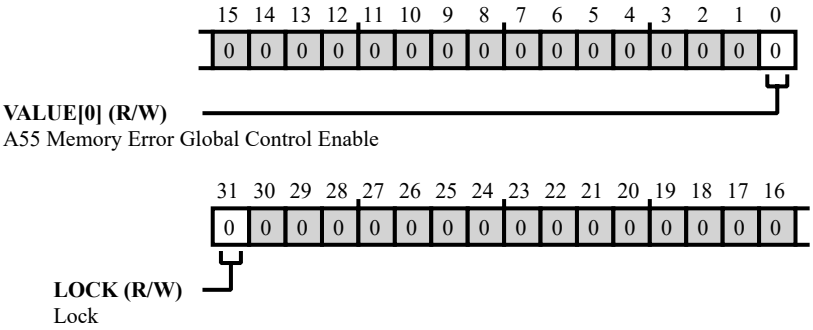

Figure 47-5: MEC_A55C0EIRQ_GCTL[n] Register Diagram

Table 47-15: MEC_A55C0EIRQ_GCTL[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock is enabled (SPU_CTL.GLCK =1) and the `MEC_A55C0EIRQ_GCTL[n].LOCK` bit is enabled, the `MEC_A55C0EIRQ_GCTL[n]` register is read only.	
		0	Unlock
		1	Lock
0 (R/W)	VALUE	A55 Memory Error Global Control Enable. The `MEC_A55C0EIRQ_GCTL[n].VALUE` bit enables the A55 memory error global control.	
		0	Disable
		1	Enable

A55 Error Interrupt Request Global Status Register

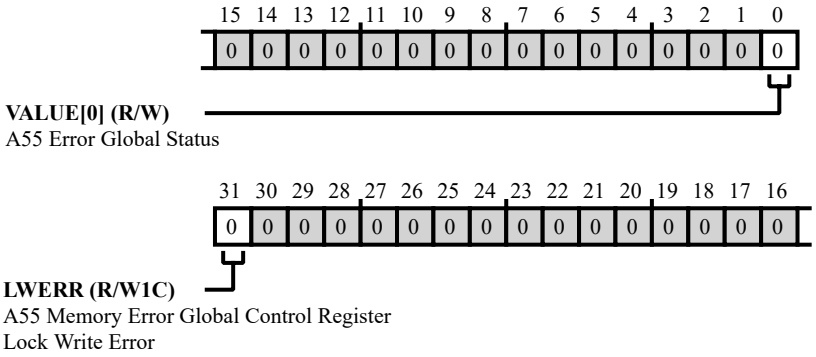

Figure 47-6: MEC_A55C0EIRQ_GSTAT[n] Register Diagram

Table 47-16: MEC_A55C0EIRQ_GSTAT[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W1C)	LWERR	A55 Memory Error Global Control Register Lock Write Error. When set (=1), the `MEC_A55C0EIRQ_GSTAT[n].LWERR` bit indicates that there was an attempted write to an MEC register while the `MEC_EEIRQ_GCTL[n].LOCK` bit was set and while the global lock bit was enabled (SPU_CTL.GLCK =1). This status bit is sticky; write-1-to-clear it.	
		0	No Error
		1	Error Occurred
0 (R/W)	VALUE	A55 Error Global Status. When set (=1), the `MEC_A55C0EIRQ_GSTAT[n].VALUE` bit indicates the assertion of an interrupt/trigger. When cleared (=0), there is no interrupt or trigger.	
		0	No Interrupt/Trigger
		1	Interrupt/Trigger Asserted

A55 Error Control Register

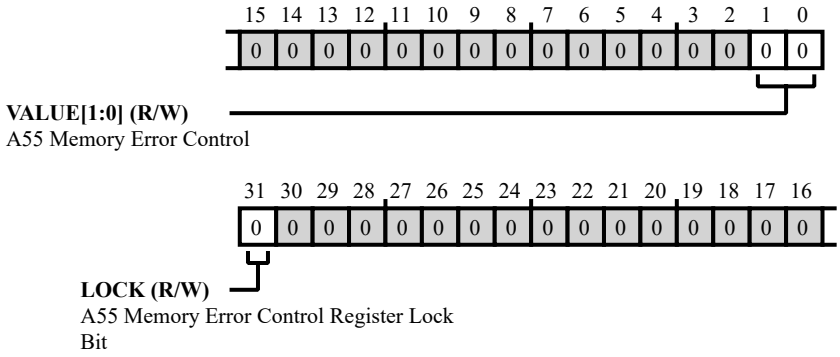

Figure 47-7: MEC_A55C0ERR_CTL[n] Register Diagram

Table 47-17: MEC_A55C0ERR_CTL[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	A55 Memory Error Control Register Lock Bit. If the global lock is enabled (SPU_CTL.GLCK =1) and the `MEC_A55C0ERR_CTL[n].LOCK` bit is enabled, the `MEC_A55C0ERR_CTL[n]` register is read only.	
		0	Unlock
		1	Lock
1:0 (R/W)	VALUE	A55 Memory Error Control. The `MEC_A55C0ERR_CTL[n].VALUE` field enables A55 memory error control. When set (=1), control is enabled. When cleared (=0), control is disabled.	
		1	A55 SCU Err
		2	A55 L1,L2 Err

A55 Error Interrupt Mask Register

		64	iRAM ECC error uncorrectable
		128	dRAM ECC error uncorrectable

ECC Error Control Register

The MEC_ECCERR_CTL[n] register bits control enable/disable for ECC error inputs from various cores/peripherals and decide whether their status will be reflected in ECC error status register bits.

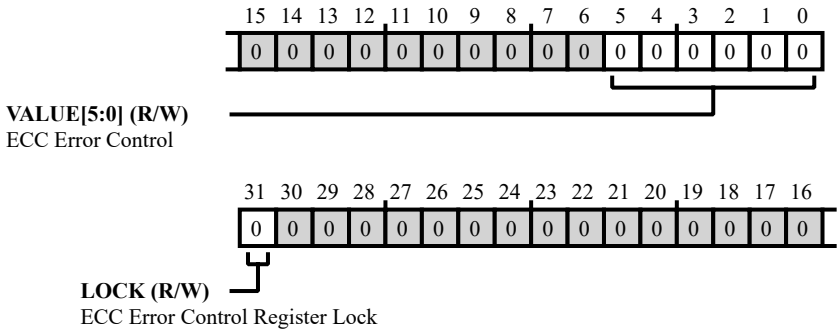

Figure 47-25: MEC_ECCERR_CTL[n] Register Diagram

Table 47-35: MEC_ECCERR_CTL[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	ECC Error Control Register Lock. If the global lock is enabled (SPU_CTL.GLCK =1) and the MEC_ECCERR_CTL[n].LOCK bit is enabled, the MEC_ECCERR_CTL[n] register is read only.	
		0	Unlock
		1	Lock
5:0 (R/W)	VALUE	ECC Error Control. The MEC_ECCERR_CTL[n].VALUE bit indicates whether ECC control is enabled (=1) or disabled (=0).	
		1	L2 CTL ECC Error
		2	CAN0 ECC Error
		4	CAN1 ECC Error
		8	Reserved
		16	L2 CTL 1 ECC Error

ECC Error Interrupt Mask Register

The MEC_ECCERR_IMASK[n] register bits control interrupt masks for ECC error inputs from various cores/peripherals.

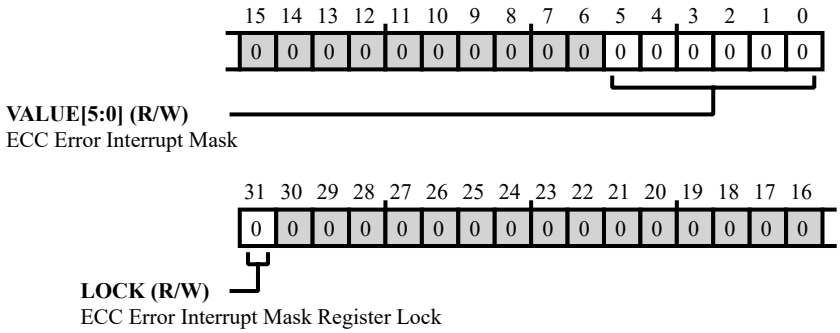

Figure 47-26: MEC_ECCERR_IMASK[n] Register Diagram

Table 47-36: MEC_ECCERR_IMASK[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	ECC Error Interrupt Mask Register Lock. If the global lock is enabled (SPU_CTL.GLCK =1) and the MEC_ECCERR_IMASK[n].LOCK bit is enabled, the MEC_ECCERR_IMASK[n] register is read only.	
		0	Unlock
		1	Lock
5:0 (R/W)	VALUE	ECC Error Interrupt Mask. The MEC_ECCERR_IMASK[n].VALUE bit indicates when the ECC error interrupt is masked (=1) or unmasked (=0).	
		1	L2 CTL ECC Error
		2	CAN0 ECC Error
		4	CAN1 ECC Error
		8	Reserved
		16	L2 CTL 1 ECC Error

ECC Error Status Register

The MEC_ECCERR_STAT[n] register bits reflect status for ECC error inputs from various cores/peripherals. Writing '1' to these bits clear corresponding ECC error status.

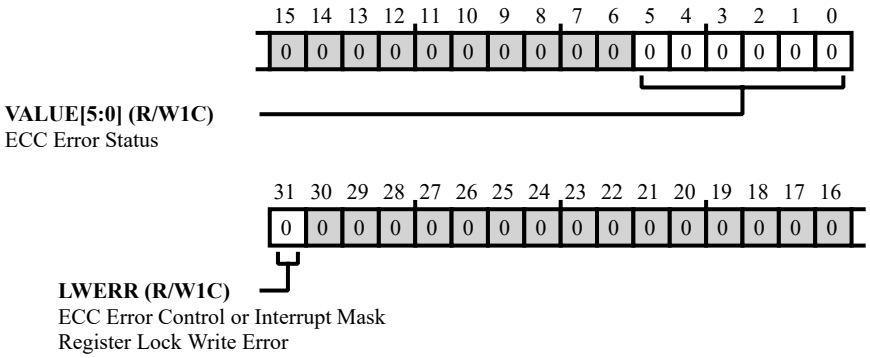

Figure 47-27: MEC_ECCERR_STAT[n] Register Diagram

Table 47-37: MEC_ECCERR_STAT[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W1C)	LWERR	ECC Error Control or Interrupt Mask Register Lock Write Error. The MEC_ECCERR_STAT[n].LWERR bit indicates (when set) there was an attempted write to an MEC register while the bit was set and while the global lock bit was enabled (SPU_CTL.GLCK =1). This status bit is sticky; write 1 to clear it.	
		0	No Error
		1	Error Occurred
5:0 (R/W1C)	VALUE	ECC Error Status. '1' indicates error and '0' indicates no error. Sticky bit, write '1' to clear.	
		1	L2 CTL ECC Error
		2	CAN0 ECC Error
		4	CAN1 ECC Error
		8	Reserved
		16	L2 CTL 1 ECC Error

ECC Error Interrupt Request Global Control Register

The MEC_EEIRQ_GCTL[n] register bits control enable/disable of ECC error interrupt/trigger outputs.

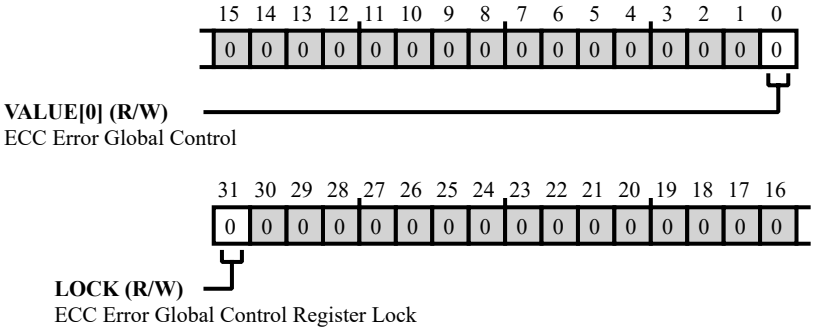

Figure 47-28: MEC_EEIRQ_GCTL[n] Register Diagram

Table 47-38: MEC_EEIRQ_GCTL[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	ECC Error Global Control Register Lock. If the global lock is enabled (SPU_CTL.GLCK =1) and the MEC_EEIRQ_GCTL[n].LOCK bit is enabled, the MEC_EEIRQ_GCTL[n] register is read only.	
		0	Unlock
		1	Lock
0 (R/W)	VALUE	ECC Error Global Control. '1' indicates enable and '0' indicates disable.	

ECC Error Interrupt Request Global Status Register

The `MEC_EEIRQ_GSTAT[n]` register bits reflect the status of the ECC error interrupt/trigger outputs.

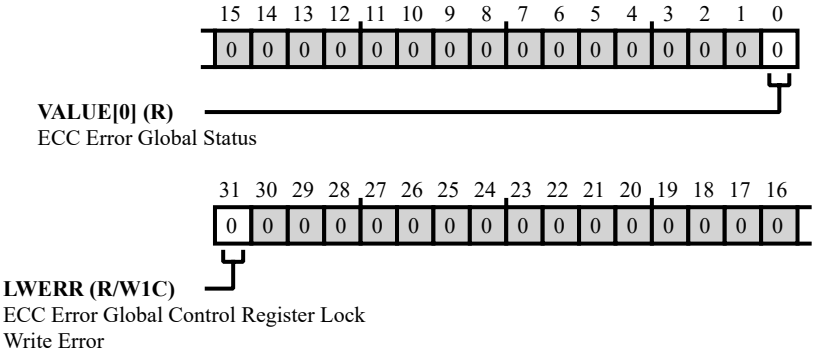

Figure 47-29: MEC_EEIRQ_GSTAT[n] Register Diagram

Table 47-39: MEC_EEIRQ_GSTAT[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W1C)	LWERR	ECC Error Global Control Register Lock Write Error. The `MEC_EEIRQ_GSTAT[n].LWERR` bit indicates (when set) there was an attempted write to an MEC register while the bit was set and while the global lock bit was enabled (SPU_CTL.GLCK =1). This status bit is sticky; write 1 to clear it.	
		0	No Error
		1	Error Occurred
0 (R/NW)	VALUE	ECC Error Global Status. '1' indicates assertion of interrupt/trigger and '0' indicates no interrupt/trigger.	

Parity Error Interrupt Request Global Control Register

The MEC_PEIRQ_GCTL[n] register bits control enable/disable of parity error interrupt/trigger outputs.

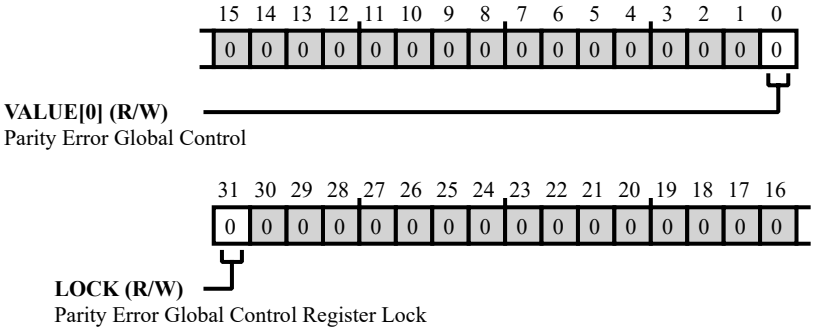

Figure 47-30: MEC_PEIRQ_GCTL[n] Register Diagram

Table 47-40: MEC_PEIRQ_GCTL[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Parity Error Global Control Register Lock. If the global lock is enabled (SPU_CTL.GLCK =1) and the MEC_PEIRQ_GCTL[n].LOCK bit is enabled, the MEC_PEIRQ_GCTL[n] register is read only.	
		0	Unlock
		1	Lock
0 (R/W)	VALUE	Parity Error Global Control. The MEC_PEIRQ_GCTL[n].VALUE bit field indicates whether parity error control is enabled (=1) or disabled (=0).	

Parity Error Interrupt Request Global Status Register

The MEC_PEIRQ_GSTAT[n] register bits reflect status of parity error interrupt/trigger outputs.

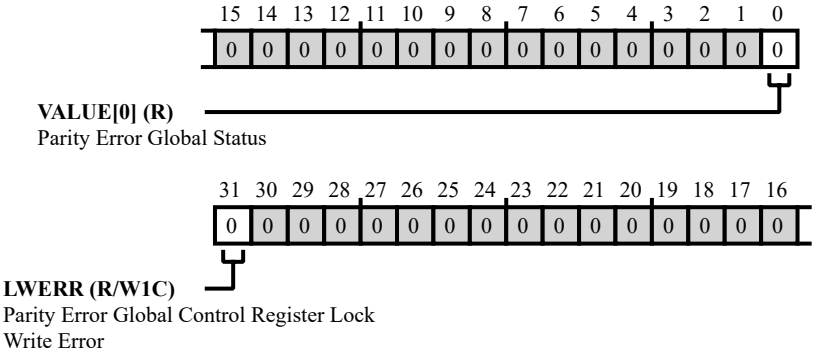

Figure 47-31: MEC_PEIRQ_GSTAT[n] Register Diagram

Table 47-41: MEC_PEIRQ_GSTAT[n] Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W1C)	LWERR	Parity Error Global Control Register Lock Write Error. When set (=1), the MEC_PEIRQ_GSTAT[n].LWERR bit indicates an attempted write to an MEC register while the MEC_PEIRQ_GCTL[n].LOCK bit was set and while the global lock bit was enabled (SPU_CTL.GLCK bit =1). This status bit is sticky; write 1 to clear it.	
		0	No Error
		1	Error Occurred
0 (R/NW)	VALUE	Parity Error Global Status. The MEC_PEIRQ_GSTAT[n].VALUE field indicates the parity error global status. 1 indicates the assertion of the interrupt/trigger; 0 indicates no interrupt/trigger.	

Parity Error Control Register

The MEC_PERR_CTL0 register bits control enable/disable for parity error inputs from various cores/peripherals and decide whether their status will be reflected in parity error status register bits.

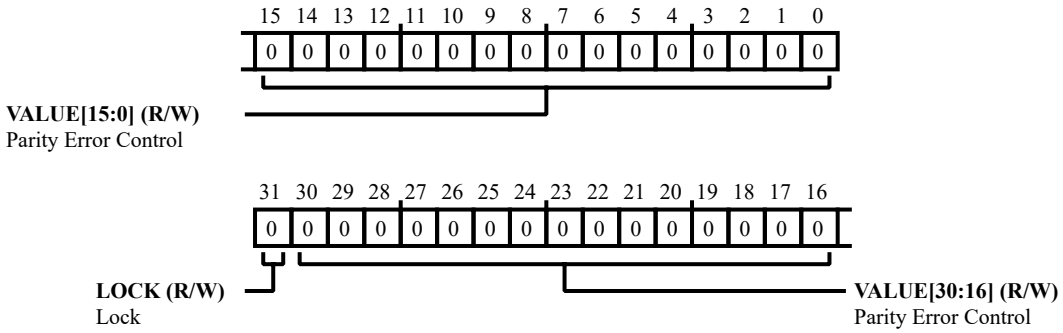

Figure 47-32: MEC_PERR_CTL0 Register Diagram

Table 47-42: MEC_PERR_CTL0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31 (R/W)	LOCK	Lock. If the global lock is enabled (SPU_CTL.GLCK =1) and the MEC_PERR_CTL0.LOCK bit is enabled, the MEC_PERR_CTL0 register is read only.	
		0	Unlock
		1	Lock
30:0 (R/W)	VALUE	Parity Error Control. The MEC_PERR_CTL0.VALUE bit indicates whether parity error control is enabled (=1) or disabled (=0).	
		4	Core 1 L1 RAM Parity Error
		8	Core 1 L1 Cache Parity Error
		16	Core 1 Branch Predictor Parity Error
		256	ASRC0 FIFO Parity Error
		512	ASRC1 FIFO Parity Error
		1024	ASRC2 FIFO Parity Error

Peripheral ID0 Register

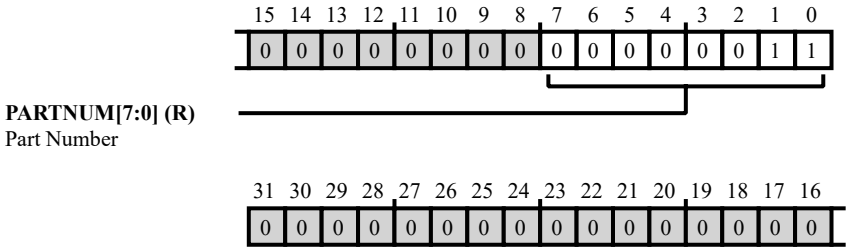

Figure 47-38: MEC_PID0 Register Diagram

Table 47-48: MEC_PID0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:0 (R/NW)	PARTNUM	Part Number. The `MEC_PID0.PARTNUM` field indicates the part number for component identification

Peripheral ID1 Register

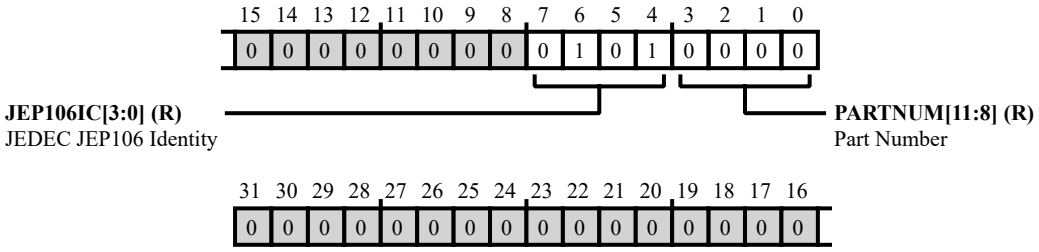

Figure 47-39: MEC_PID1 Register Diagram

Table 47-49: MEC_PID1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:4 (R/NW)	JEP106IC	JEDEC JEP106 Identity. The `MEC_PID1.JEP106IC` field indicates JEDEC JEP106 identity (manufacturer ID) code.
3:0 (R/NW)	PARTNUM	Part Number. The `MEC_PID1.PARTNUM` field indicates the part number for component identification

Peripheral ID2 Register

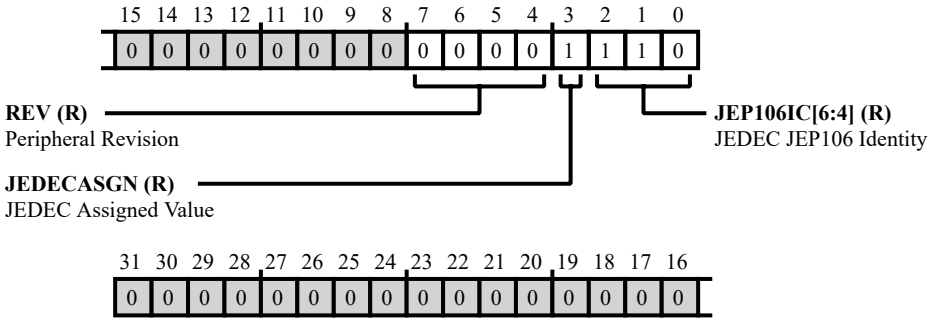

Figure 47-40: MEC_PID2 Register Diagram

Table 47-50: MEC_PID2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:4 (R/NW)	REV	Peripheral Revision.
3 (R/NW)	JEDECASGN	JEDEC Assigned Value.
2:0 (R/NW)	JEP106IC	JEDEC JEP106 Identity. The `MEC_PID2.JEP106IC` field indicates JEDEC JEP106 identity (manufacturer ID) code.

Peripheral ID3 Register

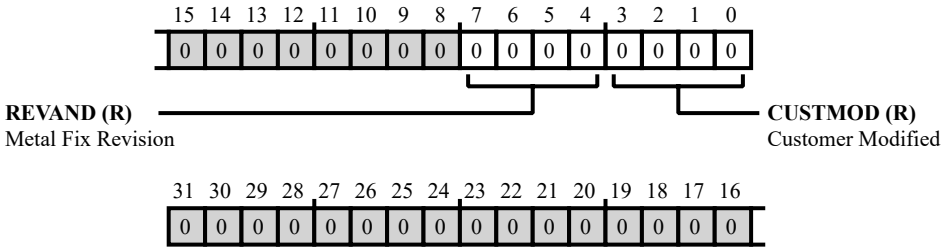

Figure 47-41: MEC_PID3 Register Diagram

Table 47-51: MEC_PID3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:4 (R/NW)	REVAND	Metal Fix Revision.
3:0 (R/NW)	CUSTMOD	Customer Modified.

Peripheral ID4 Register

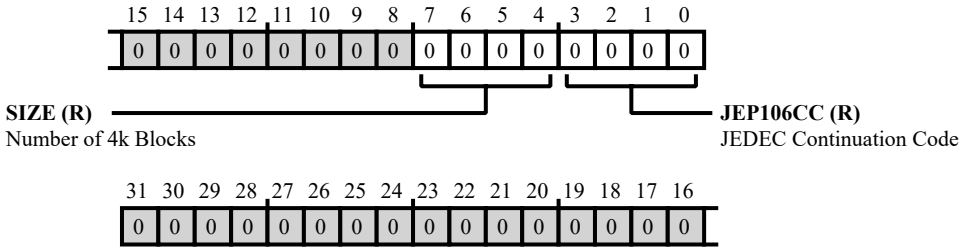

Figure 47-42: MEC_PID4 Register Diagram

Table 47-52: MEC_PID4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
7:4 (R/NW)	SIZE	Number of 4k Blocks. The `MEC_PID4.SIZE` field indicates the size of component 4k chunks minus 1 (for example, 0=4k).
3:0 (R/NW)	JEP106CC	JEDEC Continuation Code. The `MEC_PID4.JEP106CC` field indicates the JEDEC JEP106 continuation code (number of leading 0x7Fs).

48 System Debug and Trace Unit (DBG)

The system debug and trace unit is based on Arm Core Sight technology. CoreSight is a set of architecture specifications defining debug and trace architecture. The processor uses CoreSight infrastructure to provide industry standard debug and trace capabilities.

http://infocenter.arm.com/help/

The applicable documentation for more details about the ArmCoreSight feature includes:

- CoreSight PFT Architecture Specification, ARM IHI 0035B (PFT)
- System Trace Macrocell, Programmers' Model Architecture Specification, ARM IHI 0054A (STM)
- CoreSight Trace Memory Controller, ARM DDI0461B (TMC)
- CoreSight Components Technical Reference Manual, ARM DDI 0314H (TPIU)
- Embedded Cross Trigger Technical Reference Manual, ARM DDI 0291A
- ETM Architecture Specification, ARM IHI0014Q

DBG Features

The debug unit has the following features.

- System JTAG TAP controller for system debug features, boundary scan, and public JTAG features
- A debug interface to core, and other system resources
- Direct and run-time access to the memory system and system MMRs
- Direct control over system reset
- Support for debug immediately after reset (boot debug)
- Group halt (debug event immediately halts all specified endpoints)
- Real-time on-chip visibility is made available to all developers, including software developers

Debug Functional Description

The following sections provide functional descriptions of the DBG unit.

DBG Block Diagram

The DBG block diagram is shown below.

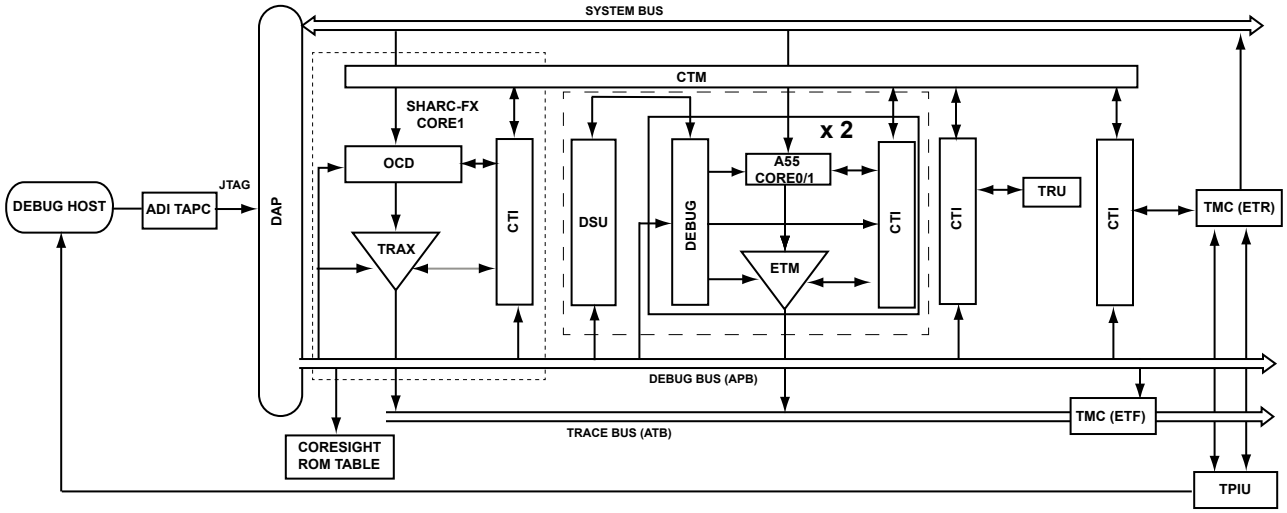

Figure 48-1: Coresight Block Diagram

DBG Definitions

The following terms are useful when working with the debug features of the processor and programming tools.

Test Access Port Controller (TAPC)

Provides IDCODE and SDBGKEY features.

Debug Access Port (DAP)

Core Sight Interface providing a single port for two debug options: JTAG-DP (JTAG Debug Port), SW-DP (Serial Wire Debug Port)

Embedded Trace Macrocell (ETM)

Provides Arm Core Trace.

Program Trace Macrocell (PTM)

Provides DSP (SHARC +) Core Trace.

Standard Trace Macrocell (STM)

Provides capability to trace up to 32 hardware events and supports 32 software stimulus for data transfer between the user and emulator.

Embedded Cross Trigger (ECT)

The ECTs are responsible managing events and triggers as follows.

- CTI (Cross Trigger Interface) is a CoreSight component for enabling cross triggering of events across a system. From the view of the ECT, it is responsible for combining and mapping trigger requests.
- CTM (Cross Trigger Matrix) is a CoreSight component for connecting multiple CTIs. From the view of the ECT, it is responsible for connecting CTIs and distribution of events.

NOTE: An embedded cross trigger is not the same as the requester and completer trigger in the trigger routing unit.

Trace Capture Devices

The trace capture devices capture and format the trace data. There are two trace capture devices in the system:

- ETF - Embedded Trace FIFO - Provides a buffer for burst trace data.
- ETR - Embedded Trace Router - Provides interface for trace data to be stored in system memories.

Trace Port Interface Unit (TPIU)

The TPIU acts as a bridge between the on-chip trace data, with separate IDs, to a data stream. It encapsulates IDs, when required, that the Trace Port Analyzer (TPA) captures.

Serial Wire Output (SWO)

SWO is a trace data drain that acts as a bridge between the on-chip trace data and a data stream that the Trace Port Analyzer (TPA) captures.

Test Access Port Controller (TAPC)

TAPC is an independent component daisy-chained to the DAP in the JTAG scan path. The TAPC component provides the product IDCODE (Chip ID) and a security feature.

The TAPC component provides security features to the chip using a debug key match features. This feature permits only those components which have the SDBGKEY to connect and debug the chip. Initially, a 128-bits user key is programmed in the SDBGKEY registers (`TAPC_SDBGKEY0`, `TAPC_SDBGKEY1`, `TAPC_SDBGKEY2`, `TAPC_SDBGKEY3`) in TAPC by a secure requester. The `TAPC_SDBGKEY_CTL.VALID` bit is set.

Then, a user key is entered through the emulator for a match to the initially programmed-entered user key. On a successful match, the chip connects to the emulator. It can be debugged on a failed user key match. Further attempts at keys matching are disabled. JTAG reset or system reset is required to re-enable the user key match logic.

Embedded Trace Macrocell (ETM)

ETM is the standard trace support provided for the Arm processor. For details of programming and functionality, refer to the Arm documentation.

Debug Access Ports

The DAP provides access to all debug and trace capabilities through a single external interface, a JTAG Debug Port (JTAG-DP). The JTAG-DP is based on the IEEE 1149.1 Test Access Port (TAP) and Boundary Scan Architecture. DAP has some additions to support BSCA and IDCODE features that Core Sight DAP does not support.

Trace Unit

The trace module provides instruction, data tracing, and system activity tracing for the processor. The program trace module on the processor is similar to the embedded trace macrocell module provided by the Arm processor. System trace is provided using the system trace macrocell as part of the CoreSight debug and trace interface. The trace module uses an interface based on the AMBA Trace Bus (ATB) standard to output its trace data. The trace data can be either exported to an off-chip trace port analyzer or captured on an on-chip buffer. The PFT and STM modules capture information on the processor both before and after a specific event. The modules add no burden to the processor performance when it runs at full speed.

- Programmable Flow Trace (CSPFT)
- System Trace Module (STM)

Programmable Flow Trace (CSPFT)

When tracing processor execution, trace information can be generated for every instruction the processor executes. This information would be easy to interpret, but would require a prohibitively high trace bandwidth to get the trace data off the chip. With program flow tracing, only branch points are traced. The debugger uses the source code to infer the rest of the executed code.

Certain instructions in the program and events are identified as waypoints. A waypoint is a point where instruction execution involves a change of program flow. The CSPFT only traces those waypoints. These waypoints are:

- All indirect branches
- All direct branches
- Exceptions or interrupts
- Emulator debug entry and exit

When a waypoint occurs, trace data is generated to describe it. From this data and the source code, a trace decompressor can determine what instructions were executed and recreate the instruction flow. To allow the

decompressor to calculate where it is in the source code, conditional instructions are marked as waypoints, regardless of whether they pass or fail their condition test. Events like interrupts or debug entry and exit can be promoted from non-waypoint instructions to waypoints to trace the interrupted program flow.

Tracing a waypoint implies the execution of all instructions from the target address of the previous waypoint up to the current waypoint. Non-waypoint instructions are not explicitly traced but the debugger must infer them using the source code. The concept of an instruction block is used throughout this manual and refers to the contiguous block of instructions between two waypoints.

The programming model and function is a subset of the PTM (Programmable Trace Module) of Arm.

System Trace Module (STM)

The STM is a trace source that is integrated into a CoreSight system, and is designed primarily for high-bandwidth trace of instrumentation embedded into software. The STM enables tracing of system activity from various sources:

- Instrumented software, using memory-mapped stimulus ports
- Hardware events

The STM supports the following features:

- Multiple software requesters writing software instrumentation independently. Each requester can use multiple stimulus ports.
- Time stamping of the system activity. The time stamp is a global time stamp which can be shared with other trace sources in the system to enable correlation of activity from multiple trace sources.
- Indication that specific events have occurred, such as a particular hardware event or a piece of software instrumentation. These events are known as triggers and can be indicated in the trace stream, or through signals to other system components.

Embedded Cross Trigger (ECT)

ECT provides an interface to the CoreSight debug system enabling the subsystems to interact (cross trigger) with each other. ECT provides a mechanism to forward debug events from one connected subsystem to another connected subsystem. The different subsystems connected to the ECT depend on the processor design. For example, in a multiprocessor system, the interface can be connected to each of the cores and one to the trace subsystem. For a uniprocessor system, the interface can include just the core and trace subsystem connection.

- CTI cross trigger interface. A CoreSight component for enabling cross triggering of events across a system.
- CTM cross trigger matrix. A CoreSight component for connecting multiple cross trigger interfaces.

The main function of the ECT (CTI and CTM) is to pass debug events from one connected subsystem to another connected subsystem.

For example, the ECT can communicate debug state information from the core to trace subsystem for a single processor system or to another core in a multiprocessor-based system. Program execution on both the subsystem can be stopped at the same time.

The ***Trigger Flow*** figure shows a simple debug trigger flow sequence. On each CTI, there are four channel, eight input, and eight output debug triggers. All the eight inputs and outputs can be mapped to a single channel or different channels based on the debug trigger to channel mapping. When a trigger input occurs, it creates a channel event. The channel event causes all the output debug triggers to be triggered. The embedded cross trigger depends on the debug trigger it connects to.

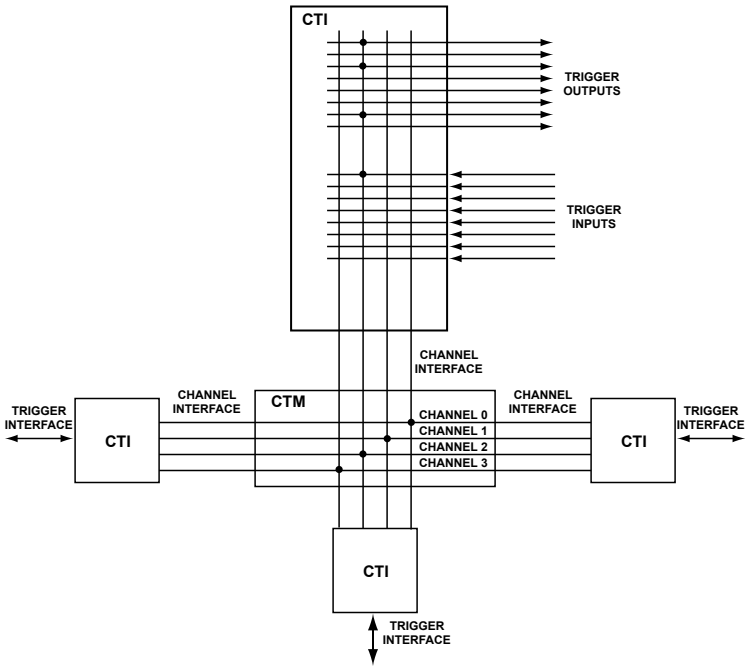

Figure 48-2: Trigger Flow

The ***ECT Integration*** figure shows 3 CTIs in the system that connect to the core, trace, and system module, respectively. The CTIs all interconnect through the CTM. This configuration allows the core to trigger debug events on the trace, on the system and on the core itself.

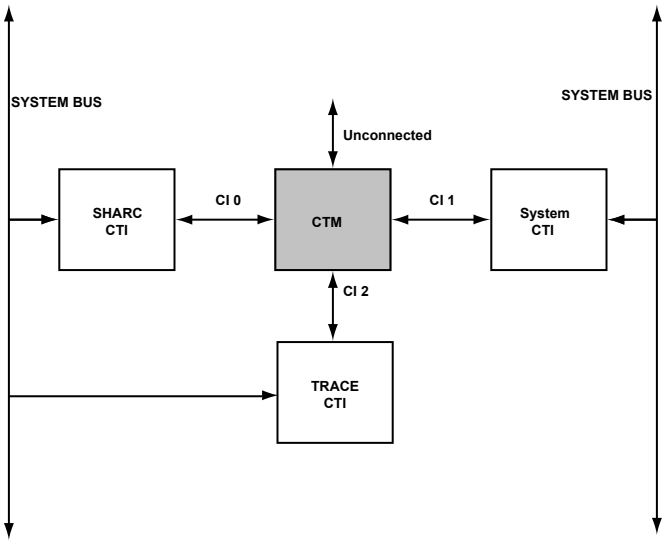

Figure 48-3: ECT Integration

ADSP-2184x A55_CLUSTER Register Descriptions

Your module description, here. (A55_CLUSTER) contains the following registers.

Table 48-1: ADSP-2184x A55_CLUSTER Register List

Name	Description
A55_CLUSTER_ASICCTL	CTI External Multiplexer Control Register
A55_CLUSTER_CTIAPPCLEAR	CTI Application Trigger Clear Register
A55_CLUSTER_CTIAPPPULSE	CTI Application Pulse Register
A55_CLUSTER_CTIAPPSET	CTI Application Trigger Set Register
A55_CLUSTER_CTIAUTHSTATUS	CTI Authentication Status Register
A55_CLUSTER_CTICHINSTATUS	CTI Channel In Status Register
A55_CLUSTER_CTICHOUTSTATUS	CTI Channel Out Status Register
A55_CLUSTER_CTICIDR0	CTI Component Identification 0 Register
A55_CLUSTER_CTICIDR1	CTI Component Identification 1 Register
A55_CLUSTER_CTICIDR2	CTI Component Identification 2 Register
A55_CLUSTER_CTICIDR3	CTI Component Identification 3 Register
A55_CLUSTER_CTICLAIMCLR	CTI Claim Tag Clear Register
A55_CLUSTER_CTICLAIMSET	CTI Claim Tag Set Register
A55_CLUSTER_CTICONTROL	CTI Control Register
A55_CLUSTER_CTIDEVAFF0	CTI Device Affinity 0 Register

CTI External Multiplexer Control Register

Can be used to provide IMPLEMENTATION DEFINED controls for the CTI. For example, the register might be used to control multiplexors for additional IMPLEMENTATION DEFINED triggers. The IMPLEMENTATION DEFINED controls provided by this register might modify the architecturally defined behavior of the CTI. The architecturally-defined triggers must not be multiplexed.

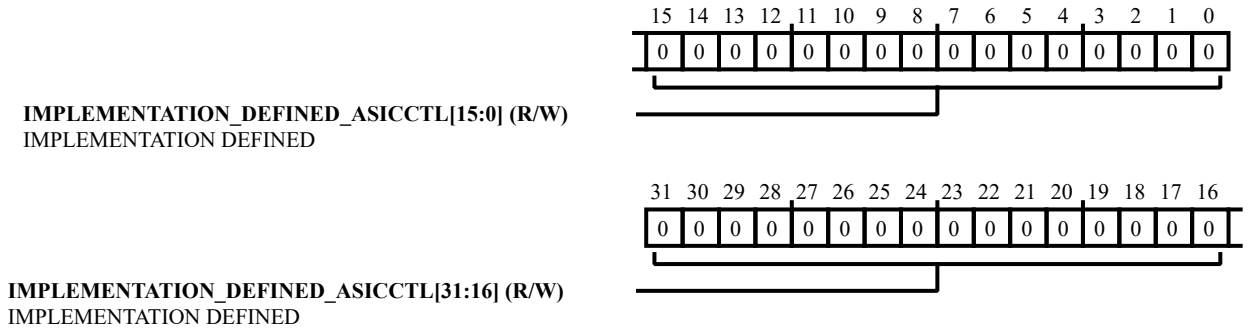

Figure 48-4: A55_CLUSTER_ASICCTL Register Diagram

Table 48-2: A55_CLUSTER_ASICCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	IMPLEMENTATION_DEFINED_ASICCTL	IMPLEMENTATION DEFINED. IMPLEMENTATION DEFINED.

CTI Application Trigger Clear Register

Clears bits of the Application Trigger register.

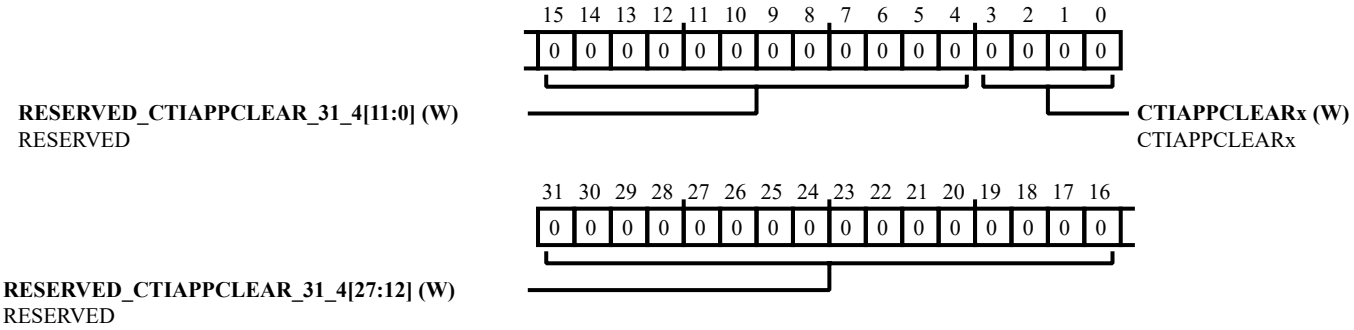

Figure 48-5: A55_CLUSTER_CTIAPPCLEAR Register Diagram

Table 48-3: A55_CLUSTER_CTIAPPCLEAR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (RX/W)	RESERVED_CTIAPP-CLEAR_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (RX/W)	CTIAPPCLEARX	CTIAPPCLEARx. Application trigger <x> disable.	
		0	No effect.
		1	Clear corresponding bit in CTIAPPTRIG to 0 and clear the corresponding channel event.

CTI Application Pulse Register

Causes event pulses to be generated on ECT channels.

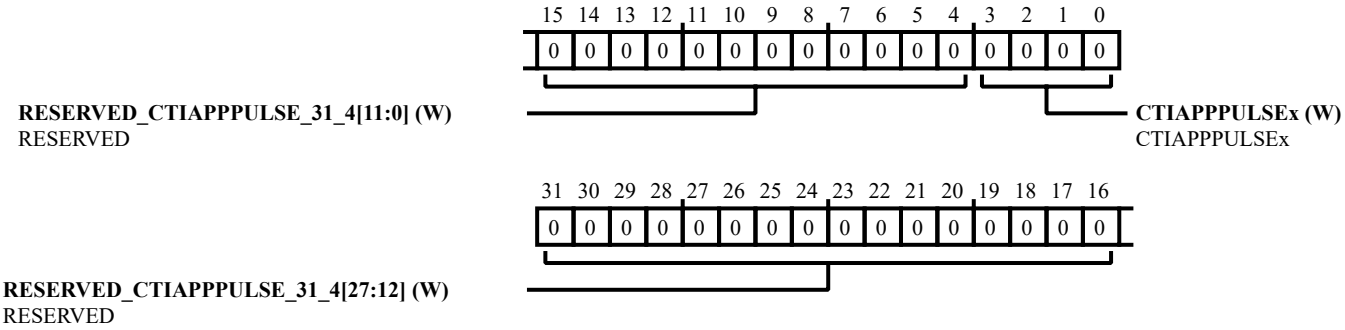

Figure 48-6: A55_CLUSTER_CTIAPPPULSE Register Diagram

Table 48-4: A55_CLUSTER_CTIAPPPULSE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (RX/W)	RESERVED_CTIAPP-PULSE_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (RX/W)	CTIAPPPULSEX	CTIAPPPULSEx. Generate event pulse on ECT channel <x>.	
		0	No effect.
		1	Channel <x> event pulse generated for one clock period.

CTI Application Trigger Set Register

Sets bits of the Application Trigger register.

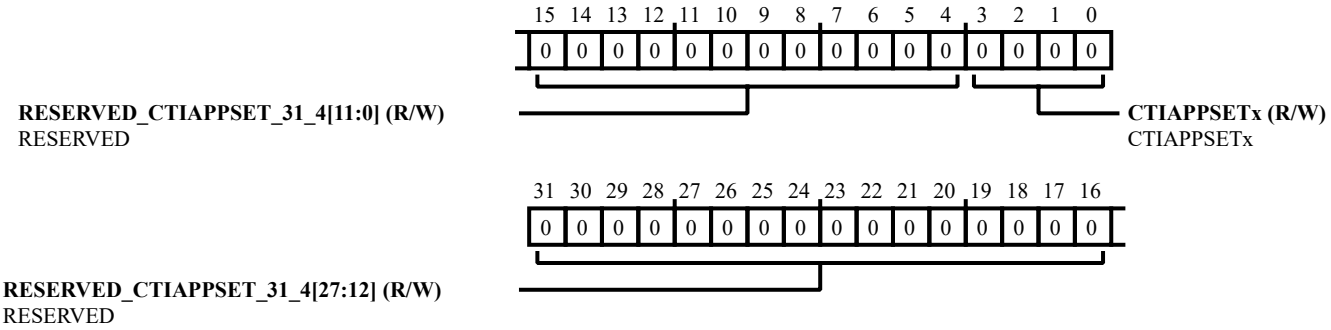

Figure 48-7: A55_CLUSTER_CTIAPPSET Register Diagram

Table 48-5: A55_CLUSTER_CTIAPPSET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/W)	RESERVED_CTIAP-PSET_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/W)	CTIAPPSETX	CTIAPPSETx. Application trigger <x> enable.	
		0	Reading this means the application trigger is inactive. Writing this has no effect.
		1	Reading this means the application trigger is active. Writing this sets the corresponding bit in CTIAPP-TRIG to 1 and generates a channel event.

CTI Authentication Status Register

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for CTI.

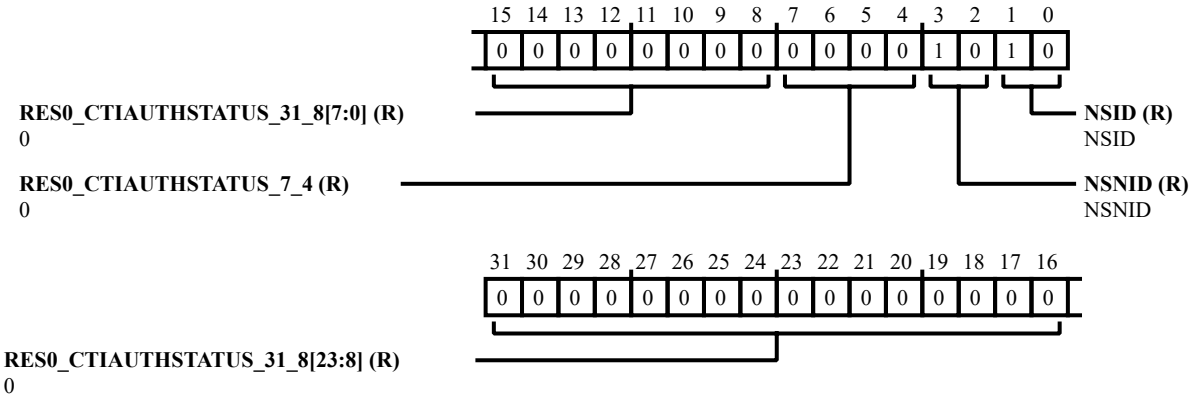

Figure 48-8: A55_CLUSTER_CTIAUTHSTATUS Register Diagram

Table 48-6: A55_CLUSTER_CTIAUTHSTATUS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_CTIAUTHSTATUS_31_8	0. Reserved, RES0.
7:4 (R/NW)	RES0_CTIAUTHSTATUS_7_4	0. Reserved, RAZ.
3:2 (R/NW)	NSNID	NSNID. If EL3 is not implemented and the implemented Security state is Secure state, holds the same value as DBGAUTHSTATUS_EL1.SNID. Otherwise, holds the same value as DBGAUTHSTATUS_EL1.NSNID.
1:0 (R/NW)	NSID	NSID. If EL3 is not implemented and the implemented Security state is Secure state, holds the same value as DBGAUTHSTATUS_EL1.SID. Otherwise, holds the same value as DBGAUTHSTATUS_EL1.NSID.

CTI Channel In Status Register

Provides the raw status of the ECT channel inputs to the CTI.

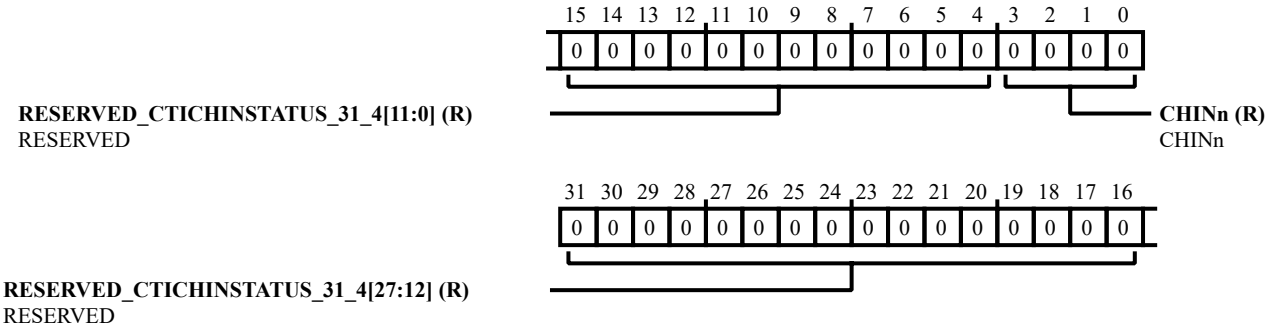

Figure 48-9: A55_CLUSTER_CTICHINSTATUS Register Diagram

Table 48-7: A55_CLUSTER_CTICHINSTATUS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RESERVED_CTICHIN-STATUS_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/NW)	CHINN	CHINn. Provides the raw status of the ECT channel inputs to the CTI.	
		0	Input channel <n> is inactive.
		1	Input channel <n> is active.

CTI Channel Out Status Register

Provides the status of the ECT channel outputs from the CTI.

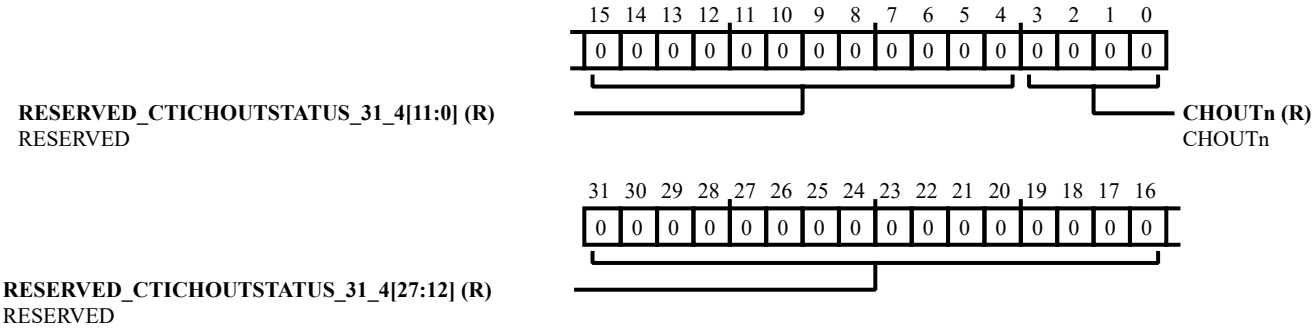

Figure 48-10: A55_CLUSTER_CTICHOUTSTATUS Register Diagram

Table 48-8: A55_CLUSTER_CTICHOUTSTATUS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RESERVED_CTICHOUT-STATUS_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/NW)	CHOUTN	CHOUTn. Provides the status of the ECT channel outputs from the CTI.	
		0	Output channel <n> is inactive.
		1	Output channel <n> is active.

CTI Component Identification 0 Register

Provides information to identify a CTI component.

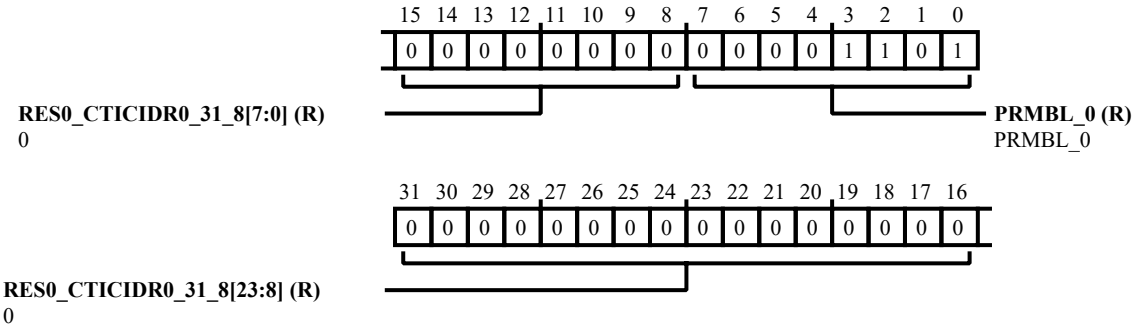

Figure 48-11: A55_CLUSTER_CTICIDR0 Register Diagram

Table 48-9: A55_CLUSTER_CTICIDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_CTICIDR0_31_8	0. Reserved, RES0.
7:0 (R/NW)	PRMBL_0	PRMBL_0. Preamble. Must read as 0x0D.

CTI Component Identification 1 Register

Provides information to identify a CTI component.

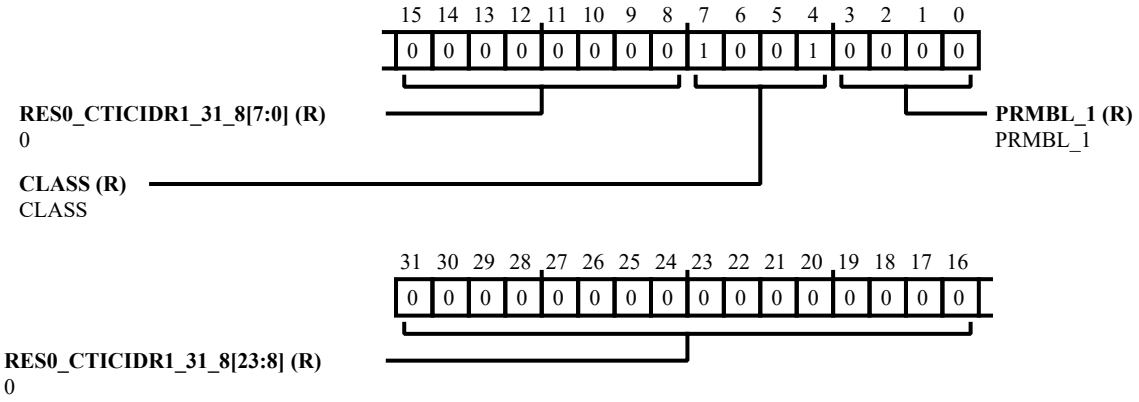

Figure 48-12: A55_CLUSTER_CTICIDR1 Register Diagram

Table 48-10: A55_CLUSTER_CTICIDR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_CTICIDR1_31_8	0. Reserved, RES0.
7:4 (R/NW)	CLASS	CLASS. Component class. Reads as 0x9, debug component.
3:0 (R/NW)	PRMBL_1	PRMBL_1. Preamble. RAZ.

CTI Component Identification 2 Register

Provides information to identify a CTI component.

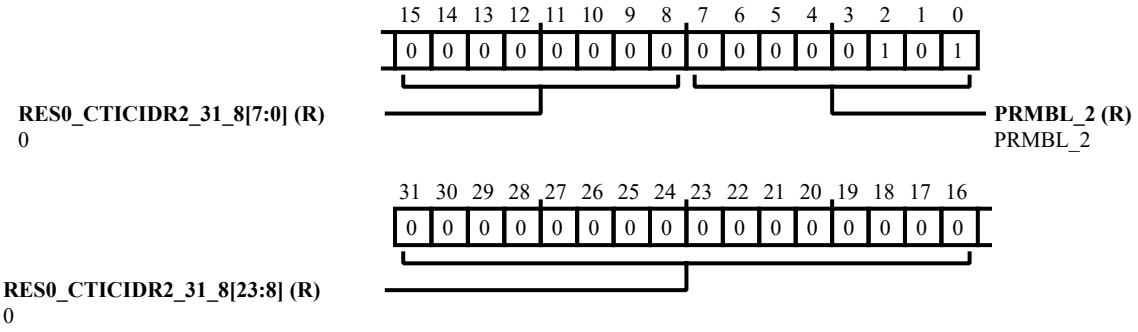

Figure 48-13: A55_CLUSTER_CTICIDR2 Register Diagram

Table 48-11: A55_CLUSTER_CTICIDR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_CTICIDR2_31_8	0. Reserved, RES0.
7:0 (R/NW)	PRMBL_2	PRMBL_2. Preamble. Must read as 0x05.

CTI Component Identification 3 Register

Provides information to identify a CTI component.

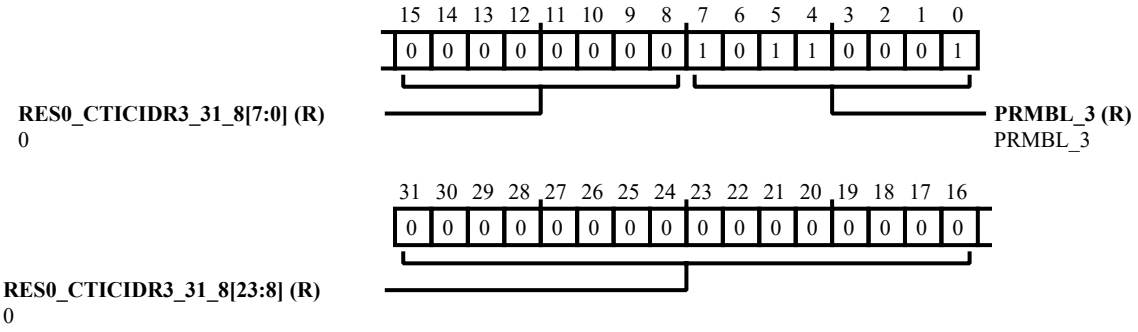

Figure 48-14: A55_CLUSTER_CTICIDR3 Register Diagram

Table 48-12: A55_CLUSTER_CTICIDR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_CTICIDR3_31_8	0. Reserved, RES0.
7:0 (R/NW)	PRMBL_3	PRMBL_3. Preamble. Must read as 0xB1.

CTI Claim Tag Clear Register

Used by software to read the values of the CLAIM bits, and to clear these bits to 0.

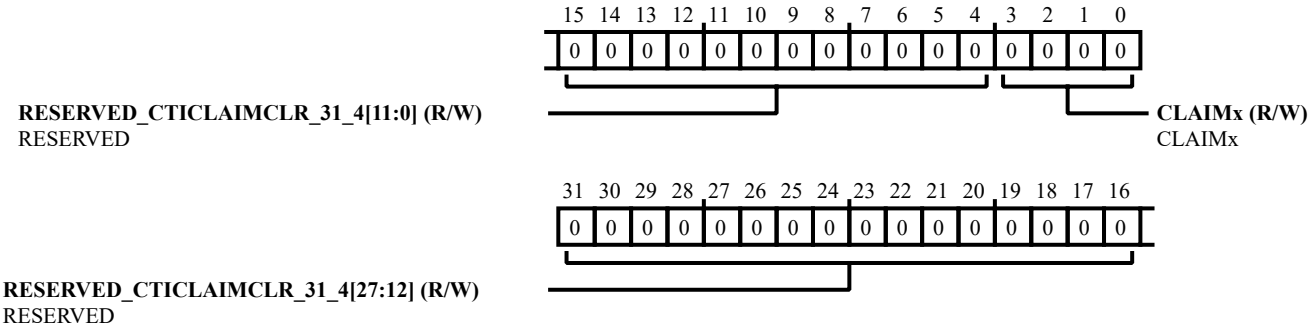

Figure 48-15: A55_CLUSTER_CTICLAIMCLR Register Diagram

Table 48-13: A55_CLUSTER_CTICLAIMCLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/W)	RESERVED_CTI-CLAIMCLR_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/W)	CLAIMX	CLAIMx. Clear CLAIM tag.	
		0	No action.
		1	Indirectly clear CLAIM[x] to 0.

CTI Claim Tag Set Register

Used by software to set CLAIM bits to 1.

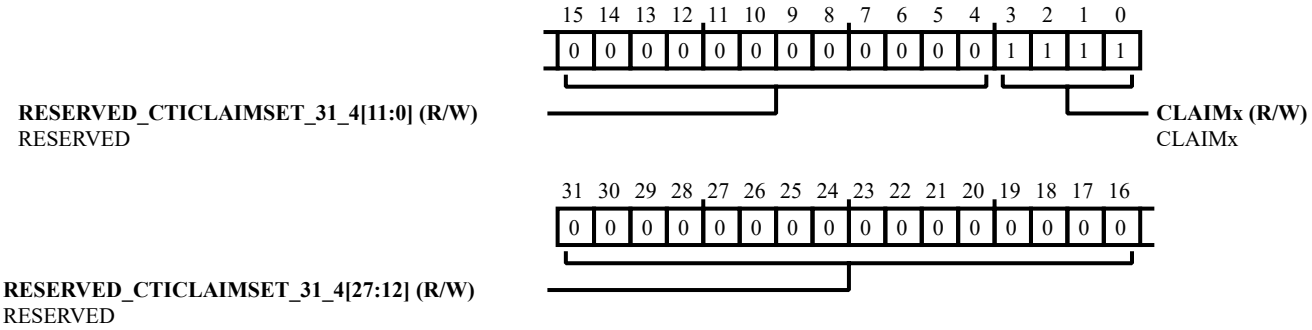

Figure 48-16: A55_CLUSTER_CTICLAIMSET Register Diagram

Table 48-14: A55_CLUSTER_CTICLAIMSET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/W)	RESERVED_CTICLAIM-SET_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/W)	CLAIMX	CLAIMx. CLAIM tag set bit.	
		0	No action.
		1	Indirectly set CLAIM[x] tag to 1.

CTI Control Register

Controls whether the CTI is enabled.

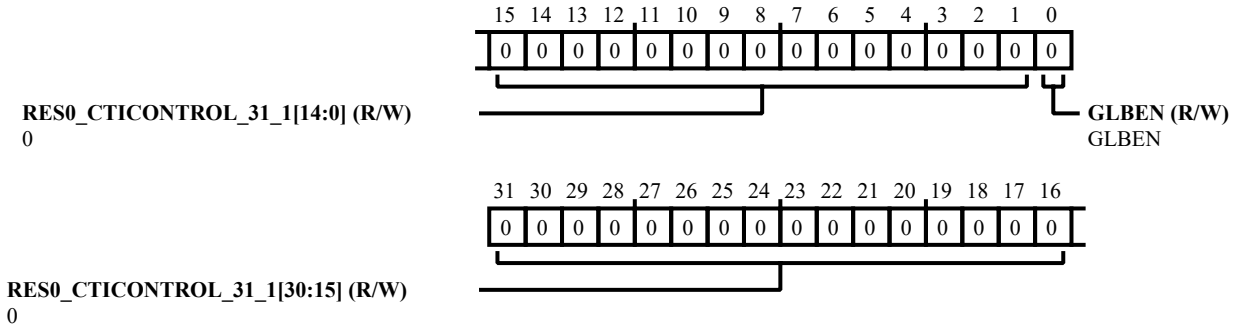

Figure 48-17: A55_CLUSTER_CTICONTROL Register Diagram

Table 48-15: A55_CLUSTER_CTICONTROL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:1 (R/W)	RES0_CTICON-TROL_31_1	0. Reserved, RES0.	
0 (R/W)	GLBEN	GLBEN. Enables or disables the CTI mapping functions. Possible values of this field are: 0 CTI mapping functions disabled. 1 CTI mapping functions enabled. When the mapping functions are disabled, no new events are signaled on either output triggers or output channels. If a previously asserted output trigger has not been acknowledged, it remains asserted after the mapping functions are disabled. All output triggers are disabled by CTI reset. If the ECT supports multicycle channel events any existing output channel events will be terminated.	
		0	CTI mapping functions disabled.
		1	CTI mapping functions enabled.

CTI Device Affinity 0 Register

Copy of the low half of the PE MPIDR_EL1 register that allows a debugger to determine which PE in a multiprocessor system the CTI component relates to.

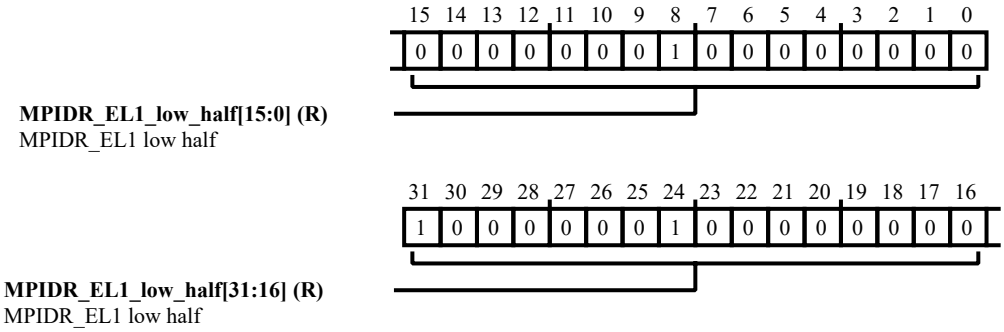

Figure 48-18: A55_CLUSTER_CTIDEVAFF0 Register Diagram

Table 48-16: A55_CLUSTER_CTIDEVAFF0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	MPIDR_EL1_LOW_HALF	MPIDR_EL1 low half. MPIDR_EL1 low half. Read-only copy of the low half of MPIDR_EL1, as seen from the highest implemented Exception level.

CTI Device Affinity 1 Register

Copy of the high half of the PE MPIDR_EL1 register that allows a debugger to determine which PE in a multiprocessor system the CTI component relates to.

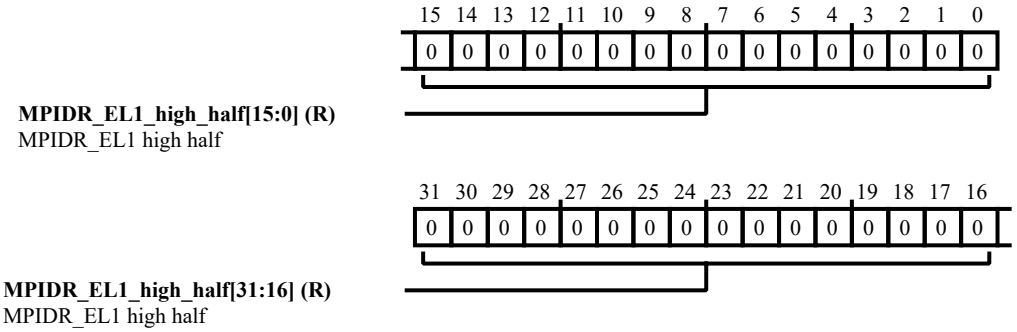

Figure 48-19: A55_CLUSTER_CTIDEVAFF1 Register Diagram

Table 48-17: A55_CLUSTER_CTIDEVAFF1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	MPIDR_EL1_HIGH_HALF	MPIDR_EL1 high half. MPIDR_EL1 high half. Read-only copy of the high half of MPIDR_EL1, as seen from the highest implemented Exception level.

CTI Device Architecture Register

Identifies the programmers' model architecture of the CTI component.

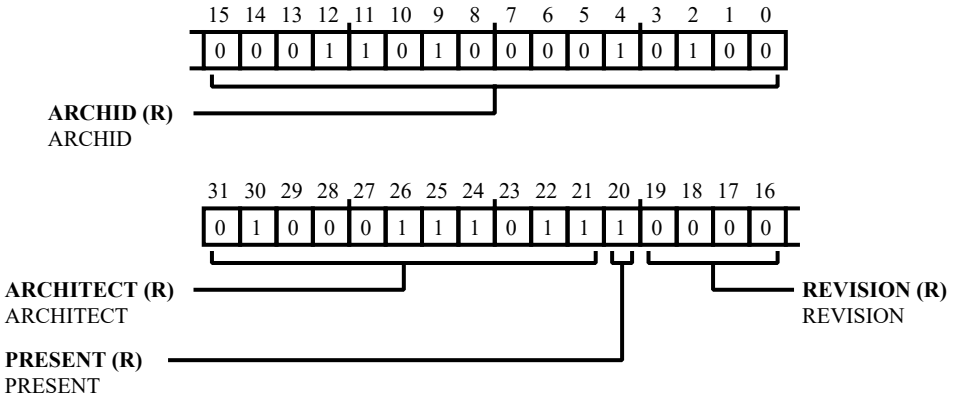

Figure 48-20: A55_CLUSTER_CTIDEVARCH Register Diagram

Table 48-18: A55_CLUSTER_CTIDEVARCH Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:21 (R/NW)	ARCHITECT	ARCHITECT. Defines the architecture of the component. For CTI, this is ARM Limited. Bits [31:28] are the JEP106 continuation code, 0x4. Bits [27:21] are the JEP106 ID code, 0x3B.
20 (R/NW)	PRESENT	PRESENT. When set to 1, indicates that the DEVARCH is present. This field is 1 in ARMv8.
19:16 (R/NW)	REVISION	REVISION. Defines the architecture revision. For architectures defined by ARM this is the minor revision. For CTI, the revision defined by ARMv8 is 0x0. All other values are reserved.
15:0 (R/NW)	ARCHID	ARCHID. Defines this part to be an ARMv8 debug component. For architectures defined by ARM this is further subdivided. For CTI: Bits [15:12] are the architecture version, 0x1. Bits [11:0] are the architecture part number, 0xA14. This corresponds to CTI architecture version CTIv2.

CTI Device ID 0 Register

Describes the CTI component to the debugger.

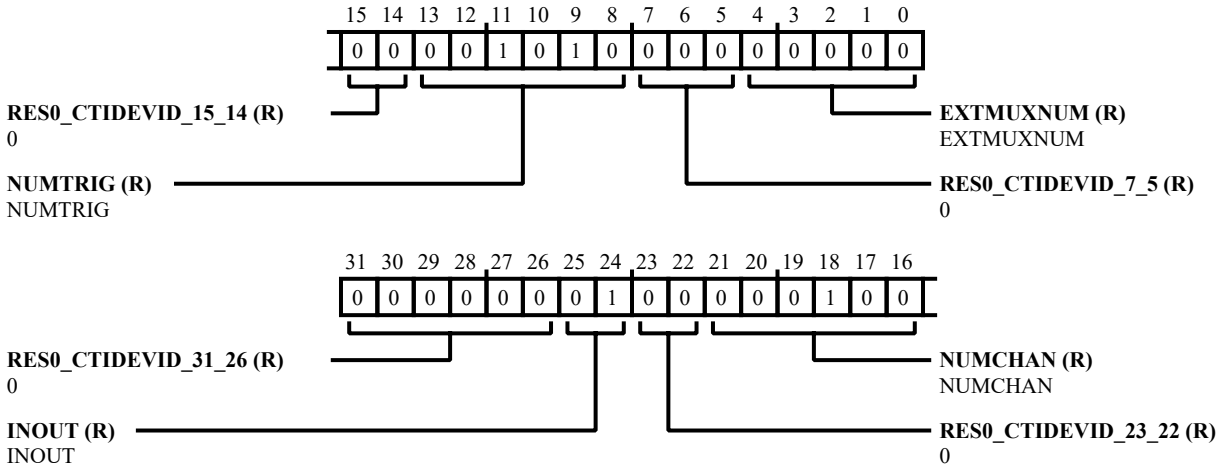

Figure 48-21: A55_CLUSTER_CTIDEVID Register Diagram

Table 48-19: A55_CLUSTER_CTIDEVID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:26 (R/NW)	RES0_CTIDEVID_31_26	0. Reserved, RES0.	
25:24 (R/NW)	INOUT	INOUT. Input/output options. Indicates presence of the input gate. If the CTM is not implemented, this field is RAZ. 00 CTIGATE does not mask propagation of input events from external channels. 01 CTIGATE masks propagation of input events from external channels. All other values are reserved.	
		0	CTIGATE does not mask propagation of input events from external channels.
		1	CTIGATE masks propagation of input events from external channels.
23:22 (R/NW)	RES0_CTIDEVID_23_22	0. Reserved, RES0.	

Table 48-19: A55_CLUSTER_CTIDEVID Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
21:16 (R/NW)	NUMCHAN	NUMCHAN. Number of ECT channels implemented. IMPLEMENTATION DEFINED. For ARMv8, valid values are: 000011 3 channels (0..2) implemented. 000100 4 channels (0..3) implemented. 000101 5 channels (0..4) implemented. 000110 6 channels (0..5) implemented. and so on up to 100000, 32 channels (0..31) implemented. All other values are reserved.	
		3	3 channels (0..2) implemented.
		4	4 channels (0..3) implemented.
		5	5 channels (0..4) implemented.
		6	6 channels (0..5) implemented.
15:14 (R/NW)	RES0_CTIDEVID_15_14	0. Reserved, RES0.	
13:8 (R/NW)	NUMTRIG	NUMTRIG. Number of triggers implemented. IMPLEMENTATION DEFINED. This is one more than the index of the largest trigger, rather than the actual number of triggers. For ARMv8, valid values are: 000011 Up to 3 triggers (0..2) implemented. 001000 Up to 8 triggers (0..7) implemented. 001001 Up to 9 triggers (0..8) implemented. 001010 Up to 10 triggers (0..9) implemented. and so on up to 100000, 32 triggers (0..31) implemented. All other values are reserved. If the contains a Trace extension, this field must be at least 0b001000. There is no guarantee that any of the implemented triggers, including the highest numbered, are connected to any components.	
		3	Up to 3 triggers (0..2) implemented.
		8	Up to 8 triggers (0..7) implemented.
		9	Up to 9 triggers (0..8) implemented.
		10	Up to 10 triggers (0..9) implemented.
7:5 (R/NW)	RES0_CTIDEVID_7_5	0. Reserved, RES0.	
4:0 (R/NW)	EXTMUXNUM	EXTMUXNUM. Number of multiplexors available on triggers. This value is used in conjunction with External Control register, ASICCTL.	

CTI Device ID 1 Register

Reserved for future information about the CTI component to the debugger.

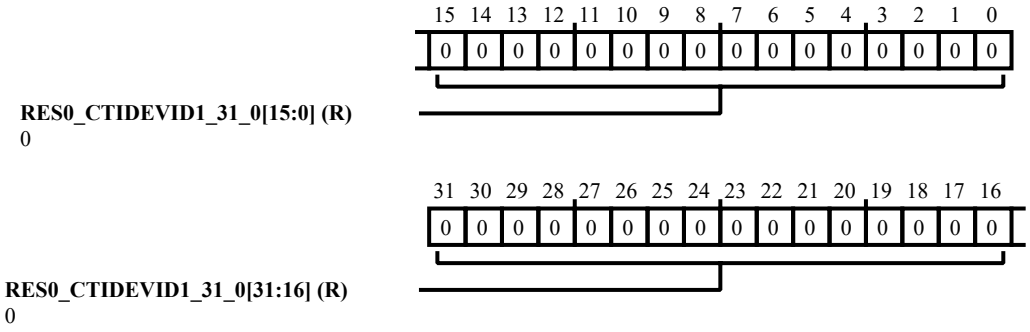

Figure 48-22: A55_CLUSTER_CTIDEVID1 Register Diagram

Table 48-20: A55_CLUSTER_CTIDEVID1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RES0_CTIDEVID1_31_0	0. Reserved, RES0.

CTI Device ID 2 Register

Reserved for future information about the CTI component to the debugger.

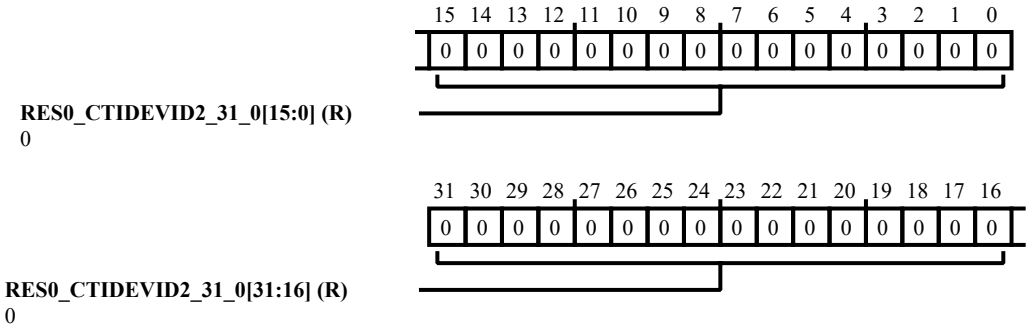

Figure 48-23: A55_CLUSTER_CTIDEVID2 Register Diagram

Table 48-21: A55_CLUSTER_CTIDEVID2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RES0_CTIDEVID2_31_0	0. Reserved, RES0.

CTI Device Type Register

Indicates to a debugger that this component is part of a PEs cross-trigger interface.

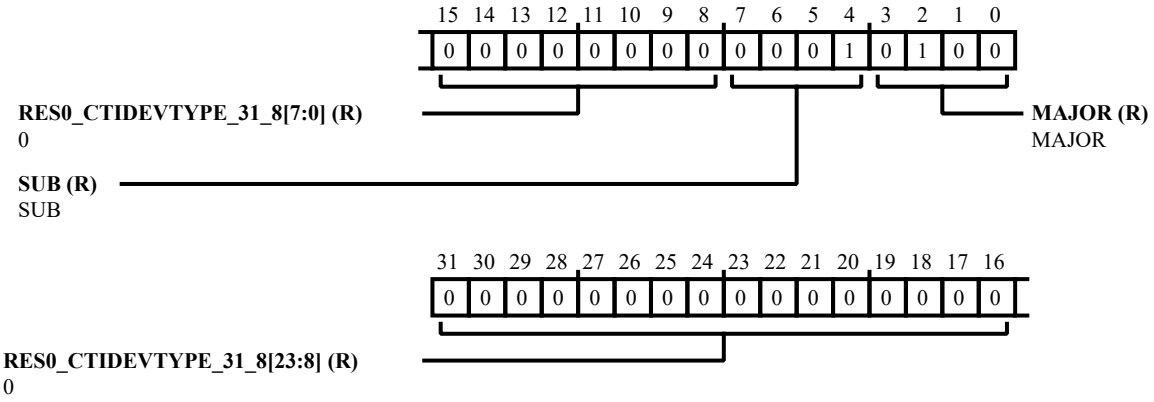

Figure 48-24: A55_CLUSTER_CTIDEVTYPE Register Diagram

Table 48-22: A55_CLUSTER_CTIDEVTYPE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_CTIDEV-TYPE_31_8	0. Reserved, RES0.
7:4 (R/NW)	SUB	SUB. Subtype. Must read as 0x1 to indicate this is a component within a PE.
3:0 (R/NW)	MAJOR	MAJOR. Major type. Must read as 0x4 to indicate this is a cross-trigger component.

CTI Channel Gate Enable Register

Determines whether events on channels propagate through the CTM to other ECT components, or from the CTM into the CTI.

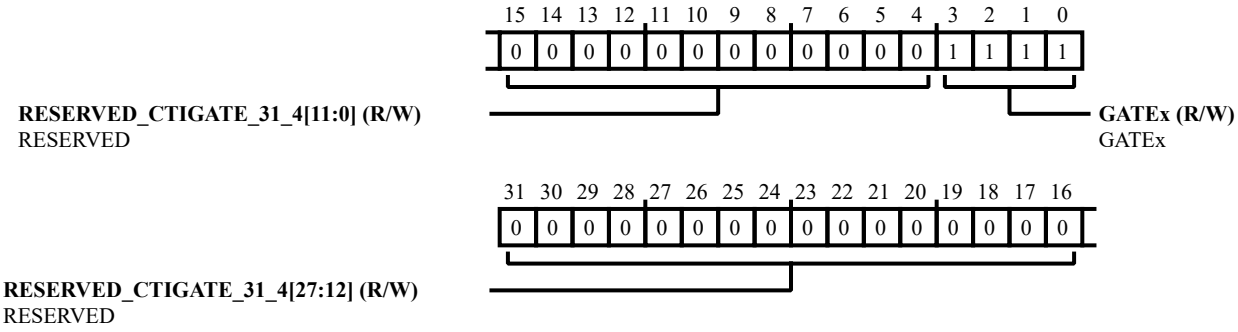

Figure 48-25: A55_CLUSTER_CTIGATE Register Diagram

Table 48-23: A55_CLUSTER_CTIGATE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/W)	RESERVED_CTI-GATE_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/W)	GATEX	GATEx. Determines whether events on channels propagate through the CTM to other ECT components or from the CTM into the CTI.	
		0	Disable output and if CTIDEVID.INOUT == 0b01 input channel <x> propagation.
		1	Enable output and if CTIDEVID.INOUT == 0b01 input channel <x> propagation.

CTI Input Trigger to Output Channel Enable 0 Register

Enables the signaling of an event on output channels when input trigger event 0 is received by the CTI.

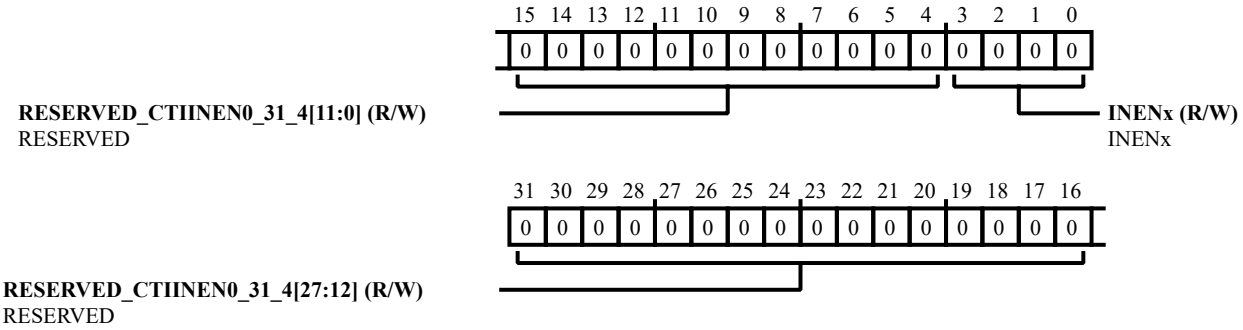

Figure 48-26: A55_CLUSTER_CTIINEN0 Register Diagram

Table 48-24: A55_CLUSTER_CTIINEN0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/W)	RESERVED_CTII-NEN0_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/W)	INENX	INENx. Input trigger 0 to output channel <x> enable.	
		0	Input trigger 0 will not generate an event on output channel <x>.
		1	Input trigger 0 will generate an event on output channel <x>.

CTI Input Trigger to Output Channel Enable 1 Register

Enables the signaling of an event on output channels when input trigger event 1 is received by the CTI.

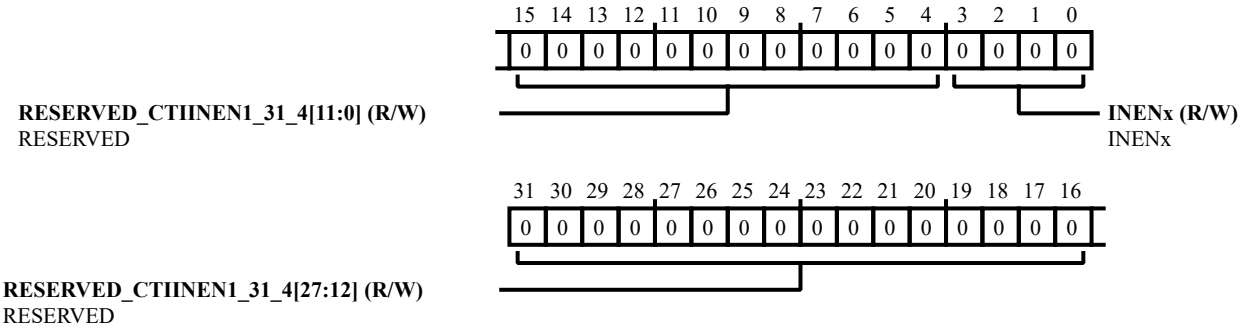

Figure 48-27: A55_CLUSTER_CTIINEN1 Register Diagram

Table 48-25: A55_CLUSTER_CTIINEN1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/W)	RESERVED_CTII-NEN1_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/W)	INENX	INENx. Input trigger 1 to output channel <x> enable.	
		0	Input trigger 1 will not generate an event on output channel <x>.
		1	Input trigger 1 will generate an event on output channel <x>.

CTI Input Trigger to Output Channel Enable 2 Register

Enables the signaling of an event on output channels when input trigger event 2 is received by the CTI.

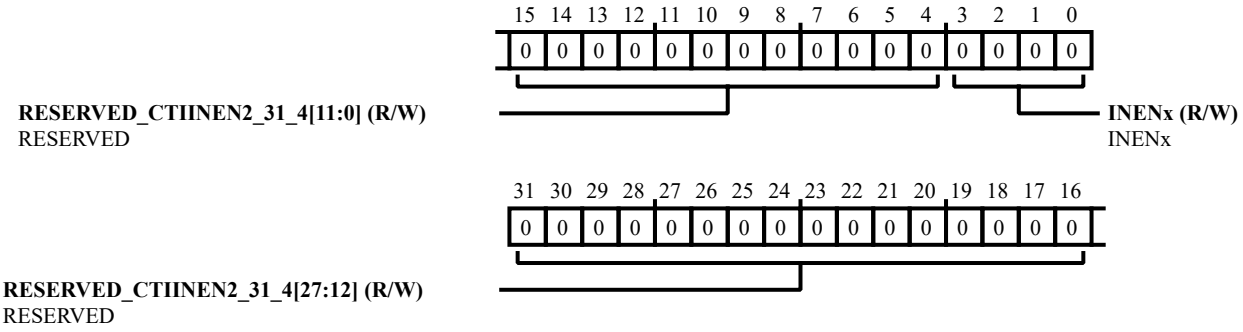

Figure 48-28: A55_CLUSTER_CTIINEN2 Register Diagram

Table 48-26: A55_CLUSTER_CTIINEN2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/W)	RESERVED_CTII-NEN2_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/W)	INENX	INENx. Input trigger 2 to output channel <x> enable.	
		0	Input trigger 2 will not generate an event on output channel <x>.
		1	Input trigger 2 will generate an event on output channel <x>.

CTI Input Trigger to Output Channel Enable 3 Register

Enables the signaling of an event on output channels when input trigger event 3 is received by the CTI.

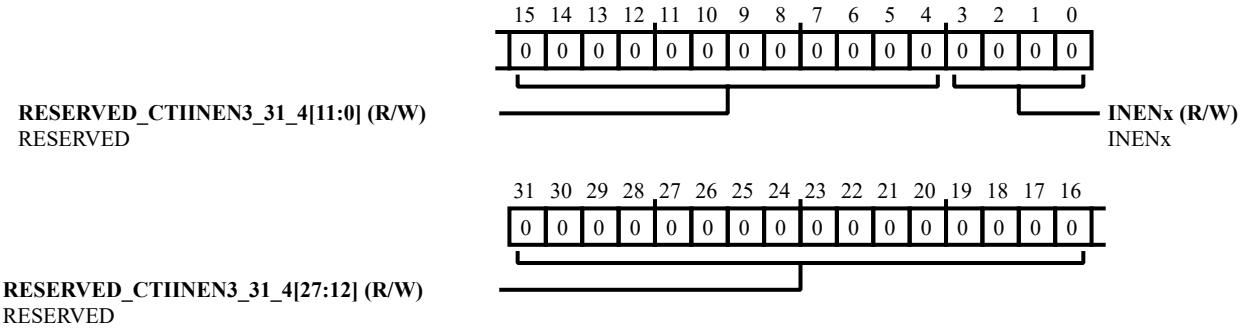

Figure 48-29: A55_CLUSTER_CTIINEN3 Register Diagram

Table 48-27: A55_CLUSTER_CTIINEN3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/W)	RESERVED_CTII-NEN3_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/W)	INENX	INENx. Input trigger 3 to output channel <x> enable.	
		0	Input trigger 3 will not generate an event on output channel <x>.
		1	Input trigger 3 will generate an event on output channel <x>.

CTI Input Trigger to Output Channel Enable 4 Register

Enables the signaling of an event on output channels when input trigger event 4 is received by the CTI.

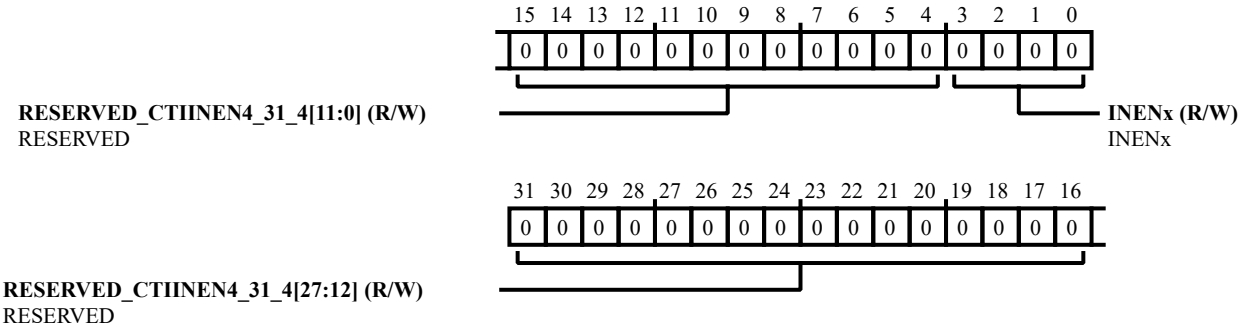

Figure 48-30: A55_CLUSTER_CTIINEN4 Register Diagram

Table 48-28: A55_CLUSTER_CTIINEN4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/W)	RESERVED_CTII-NEN4_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/W)	INENX	INENx. Input trigger 4 to output channel <x> enable.	
		0	Input trigger 4 will not generate an event on output channel <x>.
		1	Input trigger 4 will generate an event on output channel <x>.

CTI Input Trigger to Output Channel Enable 5 Register

Enables the signaling of an event on output channels when input trigger event 5 is received by the CTI.

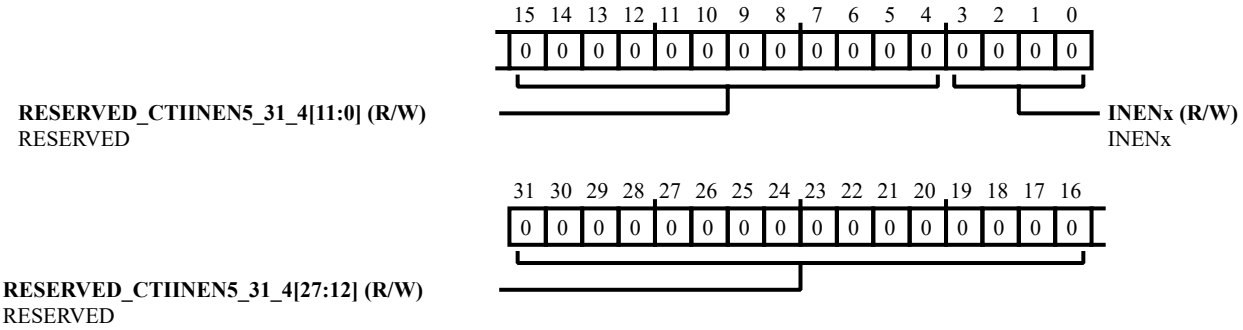

Figure 48-31: A55_CLUSTER_CTIINEN5 Register Diagram

Table 48-29: A55_CLUSTER_CTIINEN5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/W)	RESERVED_CTII-NEN5_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/W)	INENX	INENx. Input trigger 5 to output channel <x> enable.	
		0	Input trigger 5 will not generate an event on output channel <x>.
		1	Input trigger 5 will generate an event on output channel <x>.

CTI Input Trigger to Output Channel Enable 6 Register

Enables the signaling of an event on output channels when input trigger event 6 is received by the CTI.

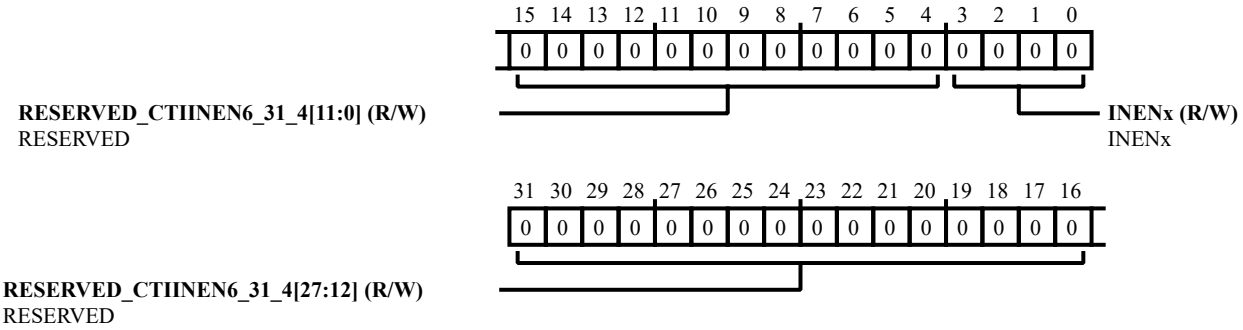

Figure 48-32: A55_CLUSTER_CTIINEN6 Register Diagram

Table 48-30: A55_CLUSTER_CTIINEN6 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/W)	RESERVED_CTII-NEN6_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/W)	INENX	INENx. Input trigger 6 to output channel <x> enable.	
		0	Input trigger 6 will not generate an event on output channel <x>.
		1	Input trigger 6 will generate an event on output channel <x>.

CTI Input Trigger to Output Channel Enable 7 Register

Enables the signaling of an event on output channels when input trigger event 7 is received by the CTI.

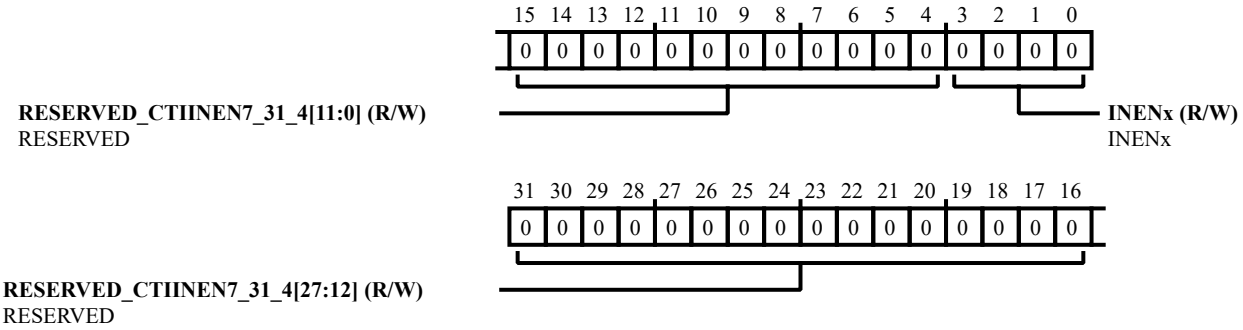

Figure 48-33: A55_CLUSTER_CTIINEN7 Register Diagram

Table 48-31: A55_CLUSTER_CTIINEN7 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/W)	RESERVED_CTII-NEN7_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/W)	INENX	INENx. Input trigger 7 to output channel <x> enable.	
		0	Input trigger 7 will not generate an event on output channel <x>.
		1	Input trigger 7 will generate an event on output channel <x>.

CTI Output Trigger Acknowledge Register

Can be used to deactivate the output triggers.

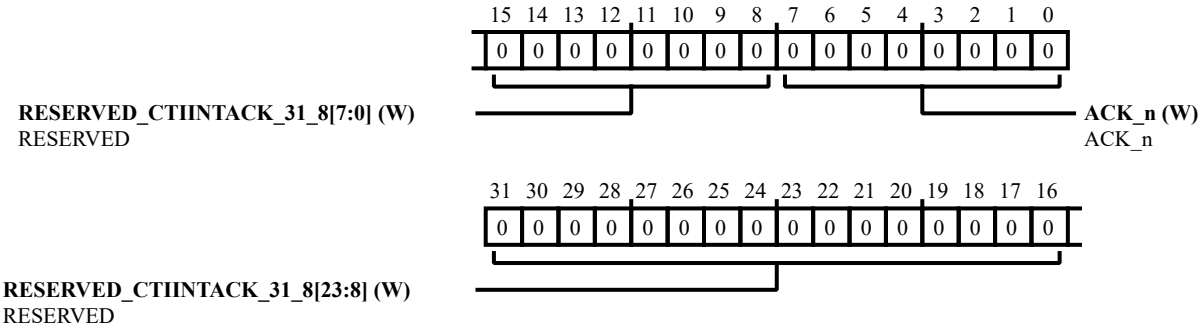

Figure 48-34: A55_CLUSTER_CTIINTACK Register Diagram

Table 48-32: A55_CLUSTER_CTIINTACK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:8 (RX/W)	RESERVED_CTIIN-TACK_31_8	RESERVED. Reserved RES0.	
		0	Reserved.
7:0 (RX/W)	ACK_N	ACK_n. Can be used to create soft acknowledges for output triggers.	
		0	No effect.
		1	Deactivate the trigger.

CTI Integration mode Control Register

Enables the CTI to switch from its default mode into integration mode, where test software can control directly the inputs and outputs of the PE, for integration testing or topology detection.

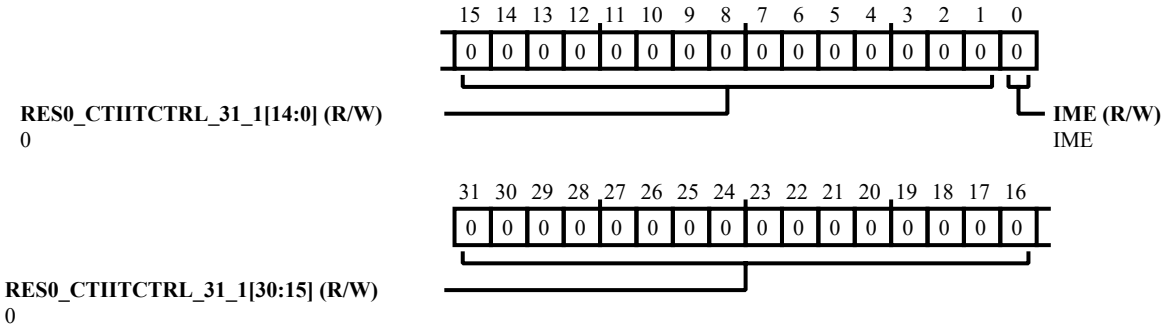

Figure 48-35: A55_CLUSTER_CTIITCTRL Register Diagram

Table 48-33: A55_CLUSTER_CTIITCTRL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:1 (R/W)	RES0_CTIITCTRL_31_1	0. Reserved, RES0.	
0 (R/W)	IME	IME. Integration mode enable. When IME == 1, the device reverts to an integration mode to enable integration testing or topology detection. The integration mode behavior is IMPLEMENTATION DEFINED. 0 Normal operation. 1 Integration mode enabled.	
		0	Normal operation.
		1	Integration mode enabled.

CTI Lock Access Register

Allows or disallows access to the CTI registers through a memory-mapped interface.

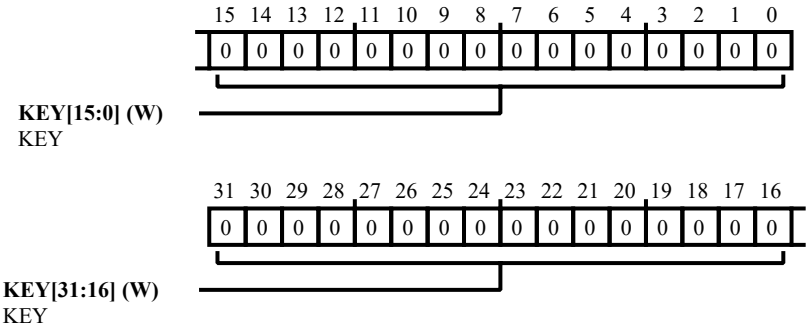

Figure 48-36: A55_CLUSTER_CTILAR Register Diagram

Table 48-34: A55_CLUSTER_CTILAR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (RX/W)	KEY	KEY. Lock Access control. Writing the key value 0xC5ACCE55 to this field unlocks the lock, enabling write accesses to this component's registers through a memory-mapped interface. Writing any other value to this register locks the lock, disabling write accesses to this component's registers through a memory mapped interface.

CTI Lock Status Register

Indicates the current status of the Software Lock for CTI registers.

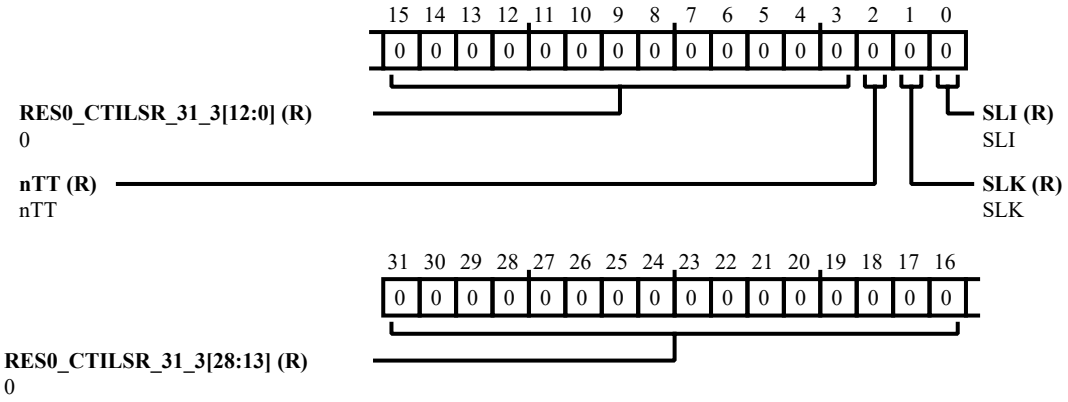

Figure 48-37: A55_CLUSTER_CTILSR Register Diagram

Table 48-35: A55_CLUSTER_CTILSR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:3 (R/NW)	RES0_CTILSR_31_3	0. Reserved, RES0.	
2 (R/NW)	NTT	nTT. Not thirty-two bit access required. RAZ.	
1 (R/NW)	SLK	SLK. Software Lock status for this component. For an access to LSR that is not a memory-mapped access, or when the Software Lock is not implemented, this field is RES0. For memory-mapped accesses when the Software Lock is implemented, possible values of this field are: 0 Lock clear. Writes are permitted to this component's registers. 1 Lock set. Writes to this component's registers are ignored, and reads have no side effects.	
		0	Lock clear. Writes are permitted to this component's registers.
		1	Lock set. Writes to this component's registers are ignored, and reads have no side effects.

Table 48-35: A55_CLUSTER_CTILSR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/NW)	SLI	SLI. Software Lock implemented. For an access to LSR that is not a memory-mapped access, this field is RAZ. For memory-mapped accesses, the value of this field is IMPLEMENTATION DEFINED. Permitted values are: 0 Software Lock not implemented or not memory-mapped access. 1 Software Lock implemented and memory-mapped access.	
		0	Software Lock not implemented or not memory-mapped access.
		1	Software Lock implemented and memory-mapped access.

CTI Input Channel to Output Trigger Enable 0 Register

Defines which input channels generate output trigger 0.

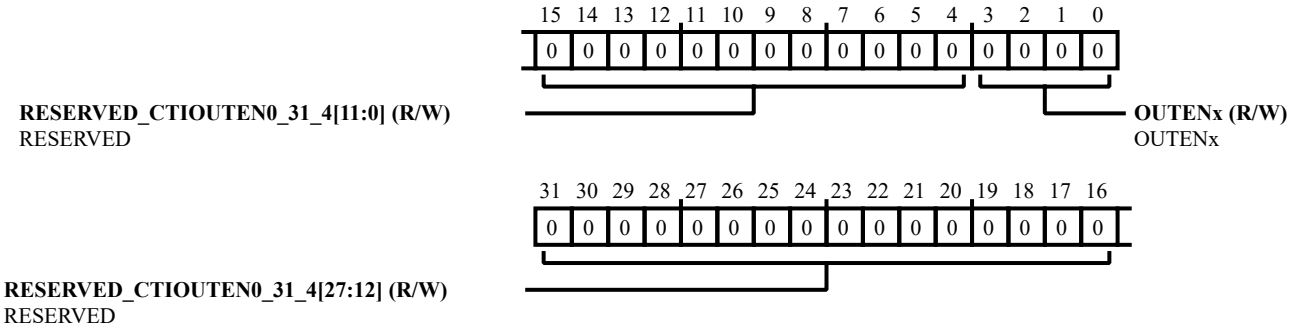

Figure 48-38: A55_CLUSTER_CTIOUTEN0 Register Diagram

Table 48-36: A55_CLUSTER_CTIOUTEN0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/W)	RESERVED_CTIOUT-EN0_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/W)	OUTENX	OUTENx. Input channel <x> to output trigger 0 enable.	
		0	An event on input channel <x> will not cause output trigger 0 to be asserted.
		1	An event on input channel <x> will cause output trigger 0 to be asserted.

CTI Input Channel to Output Trigger Enable 1 Register

Defines which input channels generate output trigger 1.

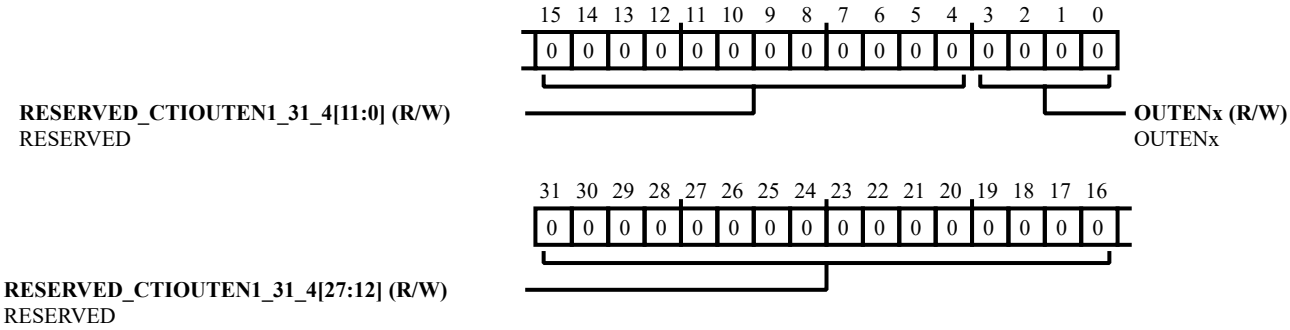

Figure 48-39: A55_CLUSTER_CTIOUTEN1 Register Diagram

Table 48-37: A55_CLUSTER_CTIOUTEN1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/W)	RESERVED_CTIOUT-EN1_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/W)	OUTENX	OUTENx. Input channel <x> to output trigger 1 enable.	
		0	An event on input channel <x> will not cause output trigger 1 to be asserted.
		1	An event on input channel <x> will cause output trigger 1 to be asserted.

CTI Input Channel to Output Trigger Enable 2 Register

Defines which input channels generate output trigger 2.

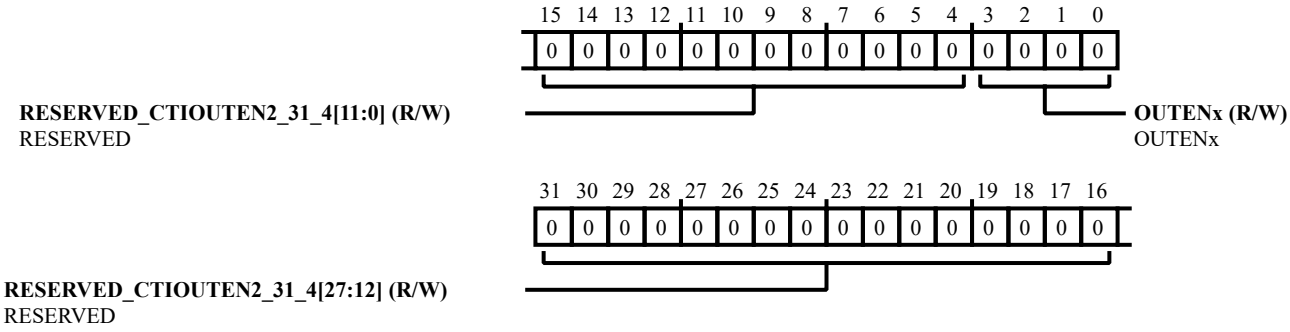

Figure 48-40: A55_CLUSTER_CTIOUTEN2 Register Diagram

Table 48-38: A55_CLUSTER_CTIOUTEN2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/W)	RESERVED_CTIOUT-EN2_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/W)	OUTENX	OUTENx. Input channel <x> to output trigger 2 enable.	
		0	An event on input channel <x> will not cause output trigger 2 to be asserted.
		1	An event on input channel <x> will cause output trigger 2 to be asserted.

CTI Input Channel to Output Trigger Enable 3 Register

Defines which input channels generate output trigger 3.

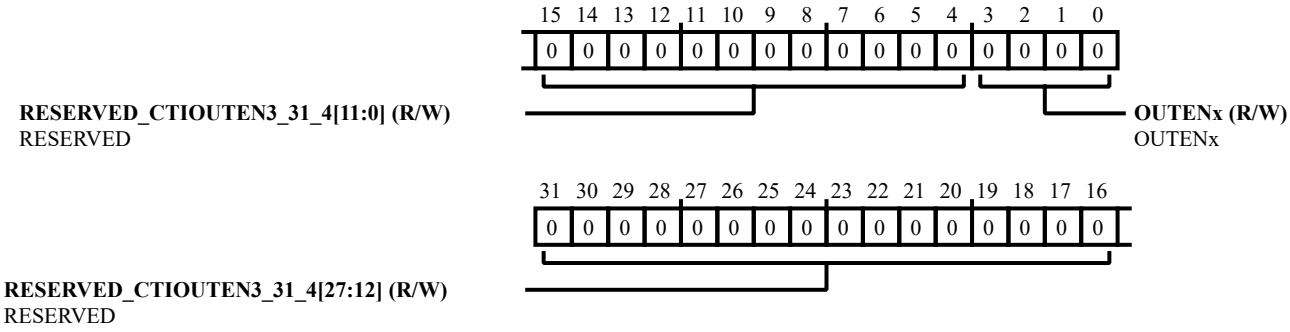

Figure 48-41: A55_CLUSTER_CTIOUTEN3 Register Diagram

Table 48-39: A55_CLUSTER_CTIOUTEN3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/W)	RESERVED_CTIOUT-EN3_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/W)	OUTENX	OUTENx. Input channel <x> to output trigger 3 enable.	
		0	An event on input channel <x> will not cause output trigger 3 to be asserted.
		1	An event on input channel <x> will cause output trigger 3 to be asserted.

CTI Input Channel to Output Trigger Enable 4 Register

Defines which input channels generate output trigger 4.

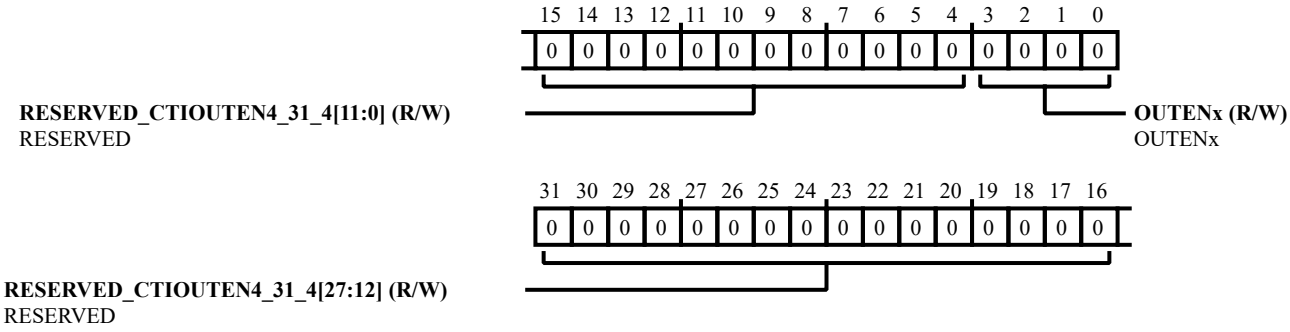

Figure 48-42: A55_CLUSTER_CTIOUTEN4 Register Diagram

Table 48-40: A55_CLUSTER_CTIOUTEN4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/W)	RESERVED_CTIOUT-EN4_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/W)	OUTENX	OUTENx. Input channel <x> to output trigger 4 enable.	
		0	An event on input channel <x> will not cause output trigger 4 to be asserted.
		1	An event on input channel <x> will cause output trigger 4 to be asserted.

CTI Input Channel to Output Trigger Enable 5 Register

Defines which input channels generate output trigger 5.

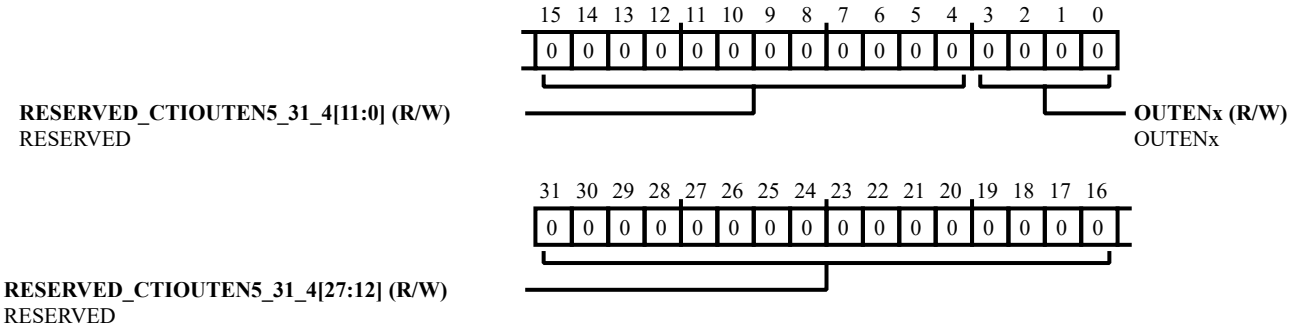

Figure 48-43: A55_CLUSTER_CTIOUTEN5 Register Diagram

Table 48-41: A55_CLUSTER_CTIOUTEN5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/W)	RESERVED_CTIOUT-EN5_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/W)	OUTENX	OUTENx. Input channel <x> to output trigger 5 enable.	
		0	An event on input channel <x> will not cause output trigger 5 to be asserted.
		1	An event on input channel <x> will cause output trigger 5 to be asserted.

CTI Input Channel to Output Trigger Enable 6 Register

Defines which input channels generate output trigger 6.

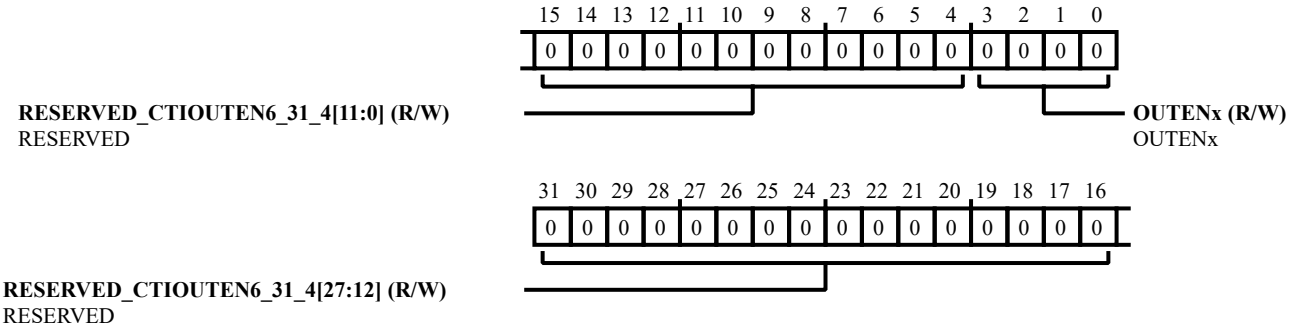

Figure 48-44: A55_CLUSTER_CTIOUTEN6 Register Diagram

Table 48-42: A55_CLUSTER_CTIOUTEN6 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/W)	RESERVED_CTIOUT-EN6_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/W)	OUTENX	OUTENx. Input channel <x> to output trigger 6 enable.	
		0	An event on input channel <x> will not cause output trigger 6 to be asserted.
		1	An event on input channel <x> will cause output trigger 6 to be asserted.

CTI Input Channel to Output Trigger Enable 7 Register

Defines which input channels generate output trigger 7.

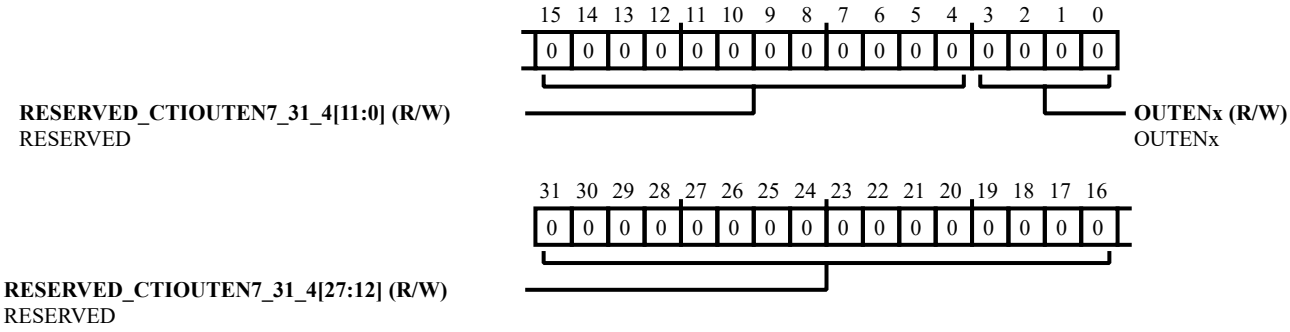

Figure 48-45: A55_CLUSTER_CTIOUTEN7 Register Diagram

Table 48-43: A55_CLUSTER_CTIOUTEN7 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/W)	RESERVED_CTIOUT-EN7_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/W)	OUTENX	OUTENx. Input channel <x> to output trigger 7 enable.	
		0	An event on input channel <x> will not cause output trigger 7 to be asserted.
		1	An event on input channel <x> will cause output trigger 7 to be asserted.

CTI Peripheral Identification 0 Register

Provides information to identify a CTI component.

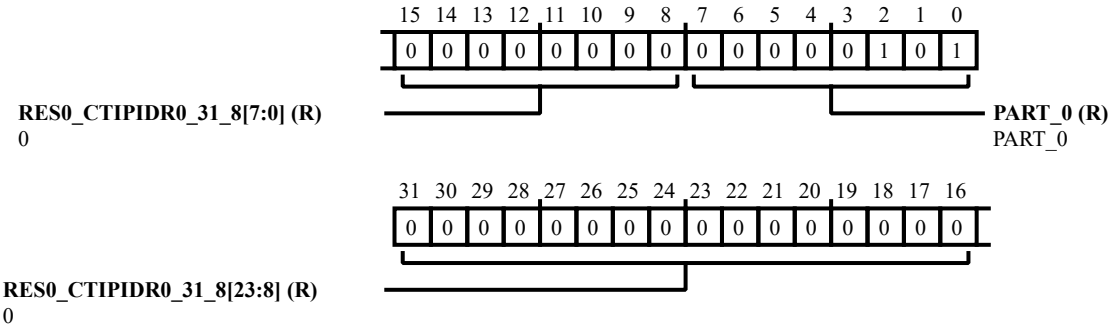

Figure 48-46: A55_CLUSTER_CTIPIDR0 Register Diagram

Table 48-44: A55_CLUSTER_CTIPIDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_CTIPIDR0_31_8	0. Reserved, RES0.
7:0 (R/NW)	PART_0	PART_0. Part number, least significant byte.

CTI Peripheral Identification 1 Register

Provides information to identify a CTI component.

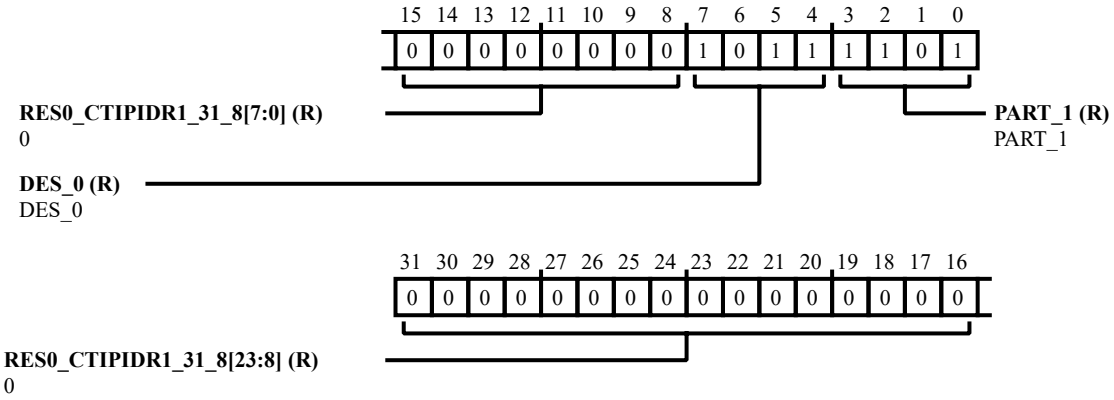

Figure 48-47: A55_CLUSTER_CTIPIDR1 Register Diagram

Table 48-45: A55_CLUSTER_CTIPIDR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_CTIPIDR1_31_8	0. Reserved, RES0.
7:4 (R/NW)	DES_0	DES_0. Designer, least significant nibble of JEP106 ID code. For ARM Limited, this field is 0b1011.
3:0 (R/NW)	PART_1	PART_1. Part number, most significant nibble.

CTI Peripheral Identification 2 Register

Provides information to identify a CTI component.

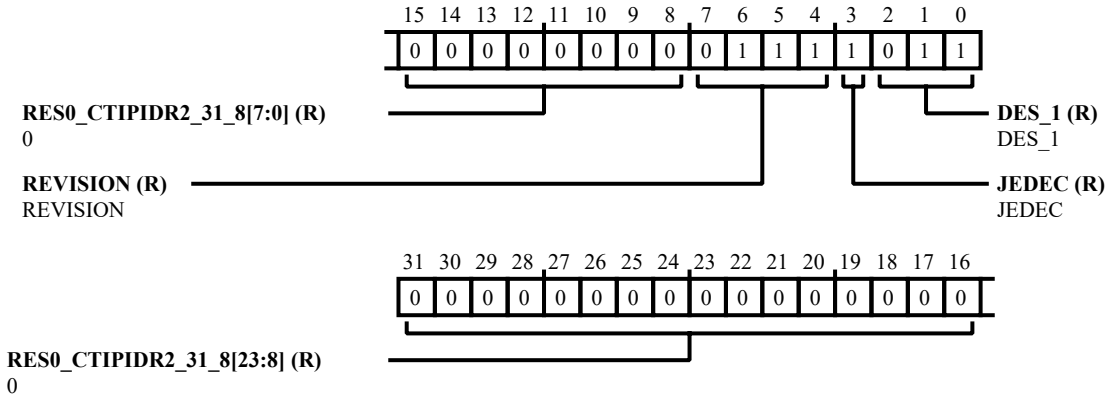

Figure 48-48: A55_CLUSTER_CTIPIDR2 Register Diagram

Table 48-46: A55_CLUSTER_CTIPIDR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_CTIPIDR2_31_8	0. Reserved, RES0.
7:4 (R/NW)	REVISION	REVISION. Part major revision. Parts can also use this field to extend Part number to 16-bits.
3 (R/NW)	JEDEC	JEDEC. RAO. Indicates a JEP106 identity code is used.
2:0 (R/NW)	DES_1	DES_1. Designer, most significant bits of JEP106 ID code. For ARM Limited, this field is 0b011.

CTI Peripheral Identification 3 Register

Provides information to identify a CTI component.

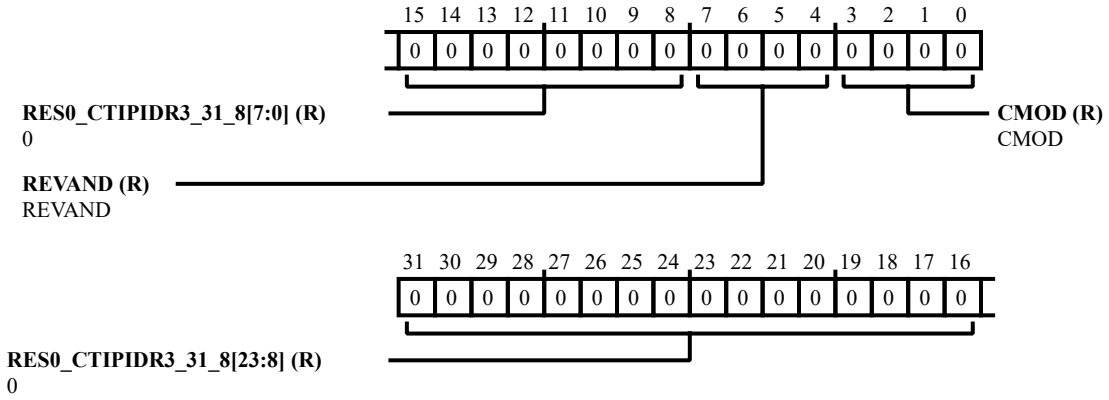

Figure 48-49: A55_CLUSTER_CTIPIDR3 Register Diagram

Table 48-47: A55_CLUSTER_CTIPIDR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_CTIPIDR3_31_8	0. Reserved, RES0.
7:4 (R/NW)	REVAND	REVAND. Part minor revision. Parts using CTIPIDR2.REVISION as an extension to the Part number must use this field as a major revision number.
3:0 (R/NW)	CMOD	CMOD. Customer modified. Indicates someone other than the Designer has modified the component.

CTI Peripheral Identification 4 Register

Provides information to identify a CTI component.

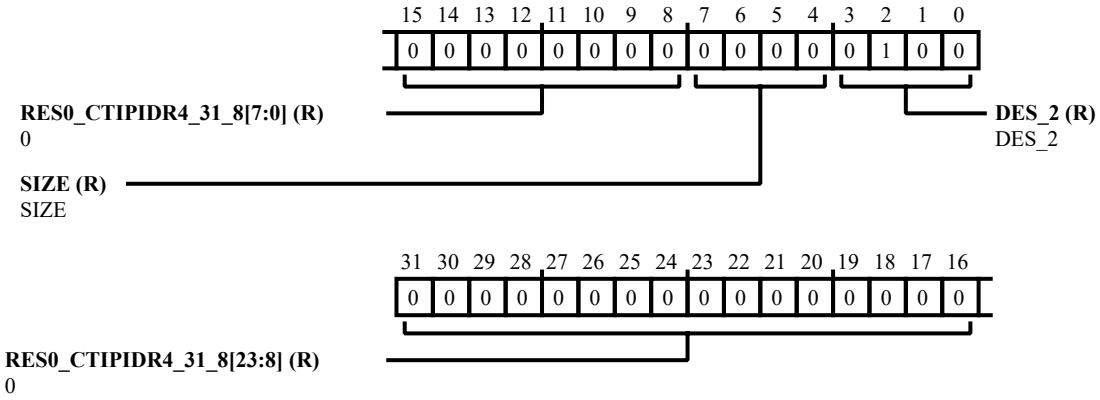

Figure 48-50: A55_CLUSTER_CTIPIDR4 Register Diagram

Table 48-48: A55_CLUSTER_CTIPIDR4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_CTIPIDR4_31_8	0. Reserved, RES0.
7:4 (R/NW)	SIZE	SIZE. Size of the component. RAZ. Log2 of the number of 4KB pages from the start of the component to the end of the component ID registers.
3:0 (R/NW)	DES_2	DES_2. Designer, JEP106 continuation code, least significant nibble. For ARM Limited, this field is 0b0100.

CTI Peripheral Identification 5 Register

Provides information to identify a CTI component.

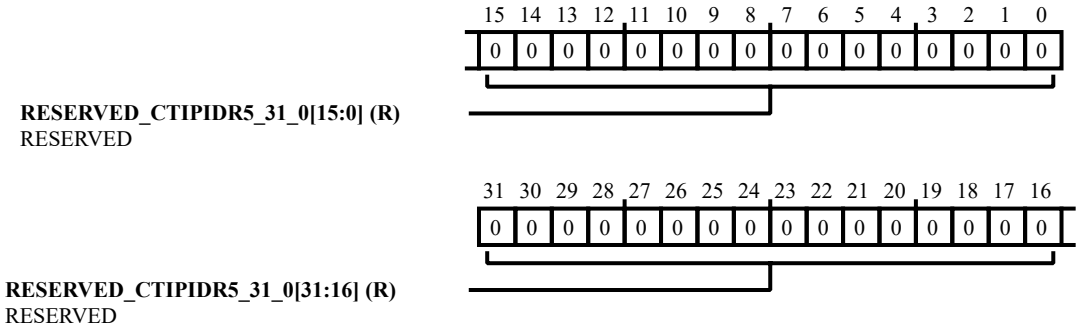

Figure 48-51: A55_CLUSTER_CTIPIDR5 Register Diagram

Table 48-49: A55_CLUSTER_CTIPIDR5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RESERVED_CTI-PIDR5_31_0	RESERVED. Reserved RES0.

CTI Peripheral Identification 6 Register

Provides information to identify a CTI component.

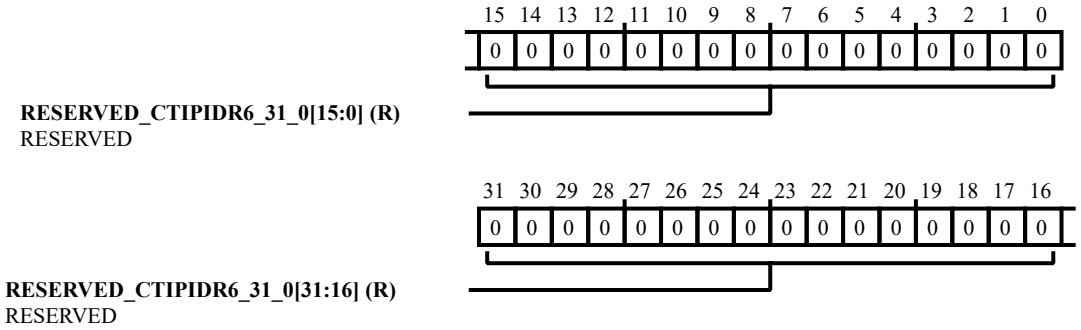

Figure 48-52: A55_CLUSTER_CTIPIDR6 Register Diagram

Table 48-50: A55_CLUSTER_CTIPIDR6 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RESERVED_CTI-PIDR6_31_0	RESERVED. Reserved RES0.

CTI Peripheral Identification 7 Register

Provides information to identify a CTI component.

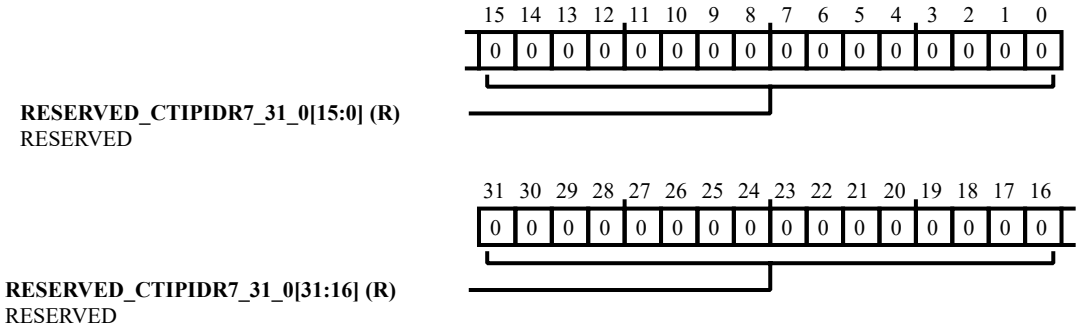

Figure 48-53: A55_CLUSTER_CTIPIDR7 Register Diagram

Table 48-51: A55_CLUSTER_CTIPIDR7 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RESERVED_CTI-PIDR7_31_0	RESERVED. Reserved RES0.

CTI Trigger In Status Register

Provides the status of the trigger inputs.

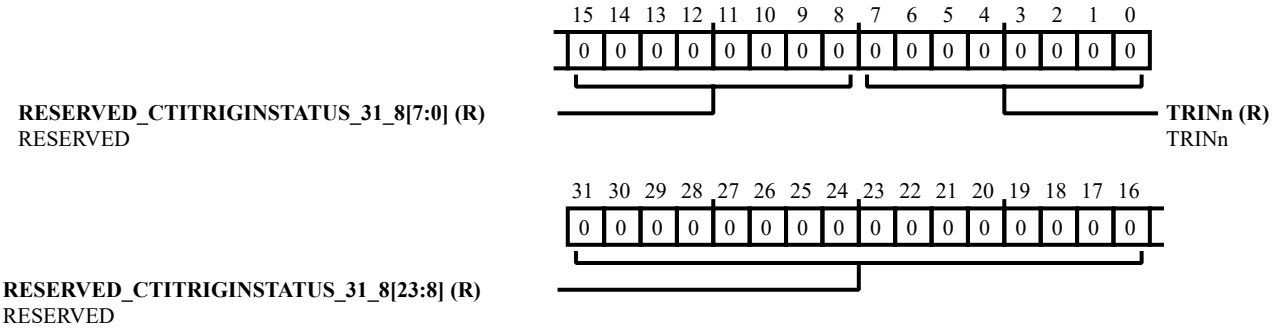

Figure 48-54: A55_CLUSTER_CTITRIGINSTATUS Register Diagram

Table 48-52: A55_CLUSTER_CTITRIGINSTATUS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:8 (R/NW)	RESERVED_CTITRIGIN-STATUS_31_8	RESERVED. Reserved RES0.	
		0	Reserved.
7:0 (R/NW)	TRINN	TRINn. Provides the status of the trigger inputs.	
		0	Input trigger n is inactive.
		1	Input trigger n is active.

CTI Trigger Out Status Register

Provides the raw status of the trigger outputs, after processing by any IMPLEMENTATION DEFINED trigger interface logic. For output triggers that are self-acknowledging, this is only meaningful if the CTI implements multicycle channel events.

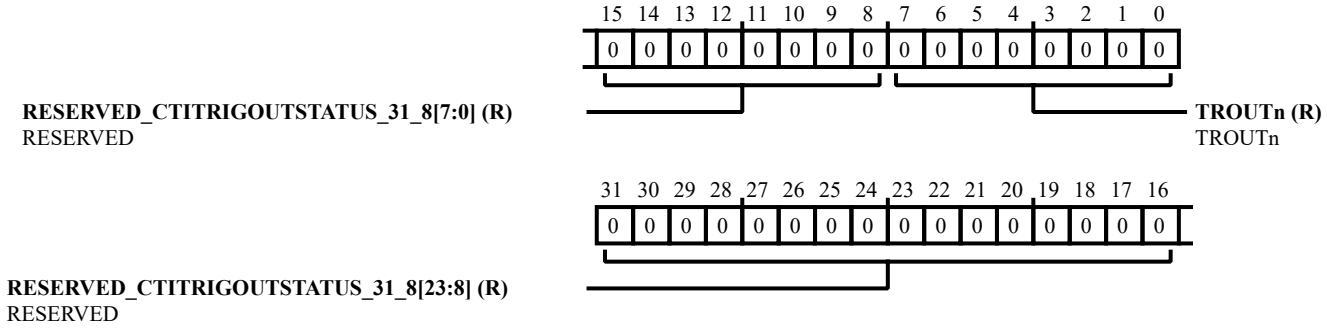

Figure 48-55: A55_CLUSTER_CTITRIGOUTSTATUS Register Diagram

Table 48-53: A55_CLUSTER_CTITRIGOUTSTATUS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:8 (R/NW)	RESERVED_CTITRI-GOUTSTATUS_31_8	RESERVED. Reserved RES0.	
		0	Reserved.
7:0 (R/NW)	TROUTN	TROUTn. Provides the status of the trigger outputs.	
		0	Output trigger n is inactive.
		1	Output trigger n is active.

Debug Authentication Status Register

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for debug.

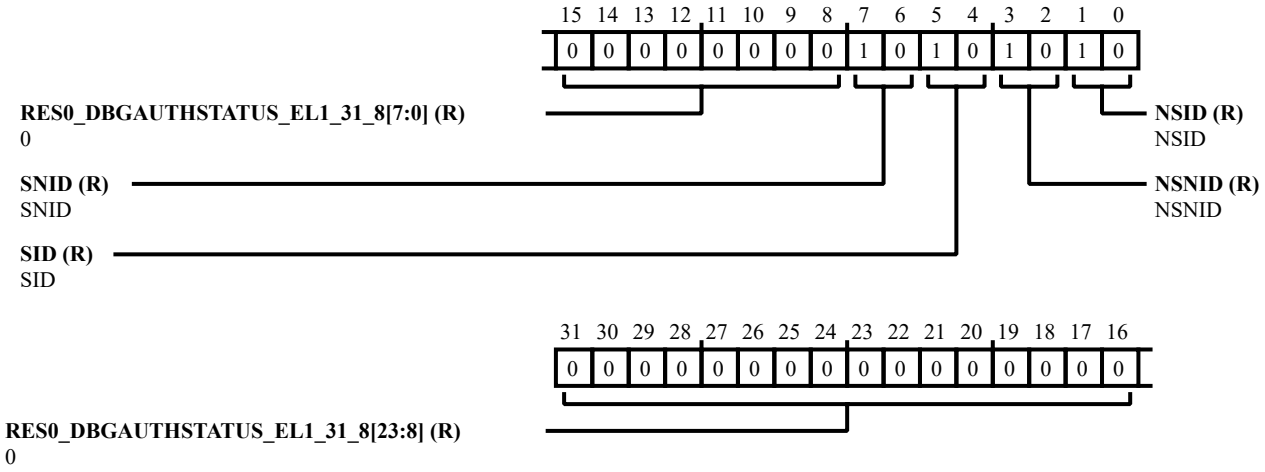

Figure 48-56: A55_CLUSTER_DBGAUTHSTATUS_EL1 Register Diagram

Table 48-54: A55_CLUSTER_DBGAUTHSTATUS_EL1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:8 (R/NW)	RES0_DBGAUTHSTATUS_EL1_31_8	0. Reserved, RES0.	
7:6 (R/NW)	SNID	SNID. Secure non-invasive debug. Possible values of this field are: 00 Not implemented. EL3 is not implemented and the implemented Security state is Non-secure state. 10 Implemented and disabled. ExternalSecureNoninvasiveDebugEnabled() == FALSE. 11 Implemented and enabled. ExternalSecureNoninvasiveDebugEnabled() == TRUE. Other values are reserved.	
		0	Not implemented. EL3 is not implemented and the implemented Security state is Non-secure state.
		2	Implemented and disabled. ExternalSecureNoninvasive-DebugEnabled() == FALSE.
		3	Implemented and enabled. ExternalSecureNoninvasive-DebugEnabled() == TRUE.

Table 48-54: A55_CLUSTER_DBGAUTHSTATUS_EL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5:4 (R/NW)	SID	SID. Secure invasive debug. Possible values of this field are: 00 Not implemented. EL3 is not implemented and the implemented Security state is Non-secure state. 10 Implemented and disabled. ExternalSecureInvasiveDebugEnabled() == FALSE. 11 Implemented and enabled. ExternalSecureInvasiveDebugEnabled() == TRUE. Other values are reserved.	
		0	Not implemented. EL3 is not implemented and the implemented Security state is Non-secure state.
		2	Implemented and disabled. ExternalSecureInvasiveDebugEnabled() == FALSE.
		3	Implemented and enabled. ExternalSecureInvasiveDebugEnabled() == TRUE.
3:2 (R/NW)	NSNID	NSNID. Non-secure non-invasive debug. Possible values of this field are: 00 Not implemented. EL3 is not implemented and the implemented Security state is Secure state. 10 Implemented and disabled. ExternalNoninvasiveDebugEnabled() == FALSE. 11 Implemented and enabled. ExternalNoninvasiveDebugEnabled() == TRUE. Other values are reserved.	
		0	Not implemented. EL3 is not implemented and the implemented Security state is Secure state.
		2	Implemented and disabled. ExternalNoninvasiveDebugEnabled() == FALSE.
		3	Implemented and enabled. ExternalNoninvasiveDebugEnabled() == TRUE.
1:0 (R/NW)	NSID	NSID. Non-secure invasive debug. Possible values of this field are: 00 Not implemented. EL3 is not implemented and the implemented Security state is Secure state. 10 Implemented and disabled. ExternalInvasiveDebugEnabled() == FALSE. 11 Implemented and enabled. ExternalInvasiveDebugEnabled() == TRUE. Other values are reserved.	
		0	Not implemented. EL3 is not implemented and the implemented Security state is Secure state.
		2	Implemented and disabled. ExternalInvasiveDebugEnabled() == FALSE.
		3	Implemented and enabled. ExternalInvasiveDebugEnabled() == TRUE.

External Debug Component Identification 0 Register

Provides information to identify an external debug component.

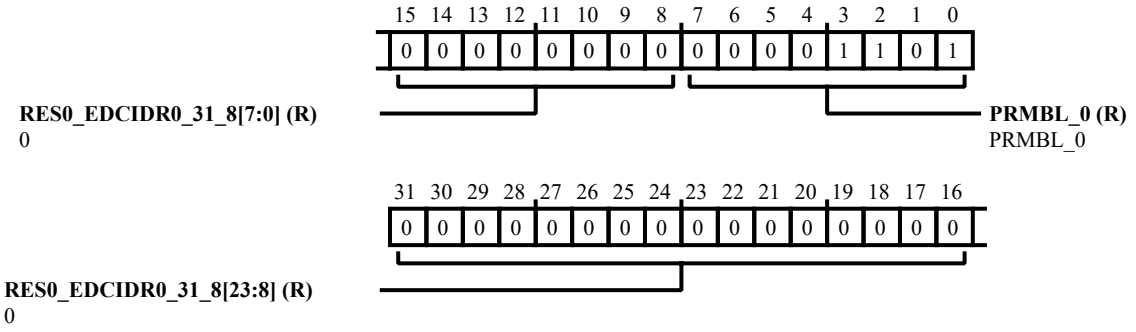

Figure 48-57: A55_CLUSTER_EDCIDR0 Register Diagram

Table 48-55: A55_CLUSTER_EDCIDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_EDCIDR0_31_8	0. Reserved, RES0.
7:0 (R/NW)	PRMBL_0	PRMBL_0. Preamble. Must read as 0x0D.

External Debug Component Identification 1 Register

Provides information to identify an external debug component.

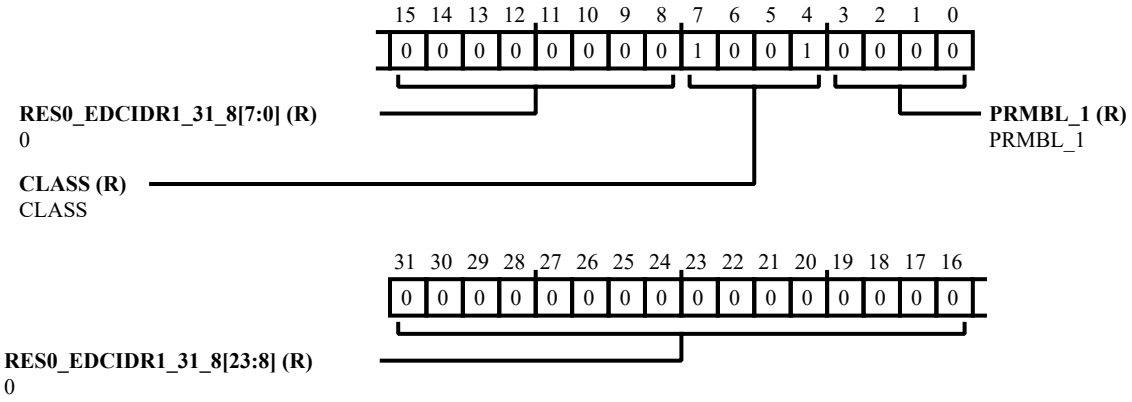

Figure 48-58: A55_CLUSTER_EDCIDR1 Register Diagram

Table 48-56: A55_CLUSTER_EDCIDR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_EDCIDR1_31_8	0. Reserved, RES0.
7:4 (R/NW)	CLASS	CLASS. Component class. Reads as 0x9, debug component.
3:0 (R/NW)	PRMBL_1	PRMBL_1. Preamble. RAZ.

External Debug Component Identification 2 Register

Provides information to identify an external debug component.

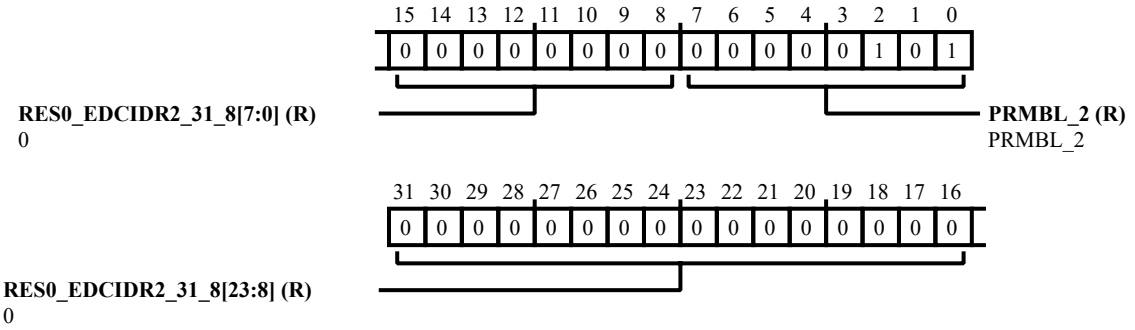

Figure 48-59: A55_CLUSTER_EDCIDR2 Register Diagram

Table 48-57: A55_CLUSTER_EDCIDR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_EDCIDR2_31_8	0. Reserved, RES0.
7:0 (R/NW)	PRMBL_2	PRMBL_2. Preamble. Must read as 0x05.

External Debug Component Identification 3 Register

Provides information to identify an external debug component.

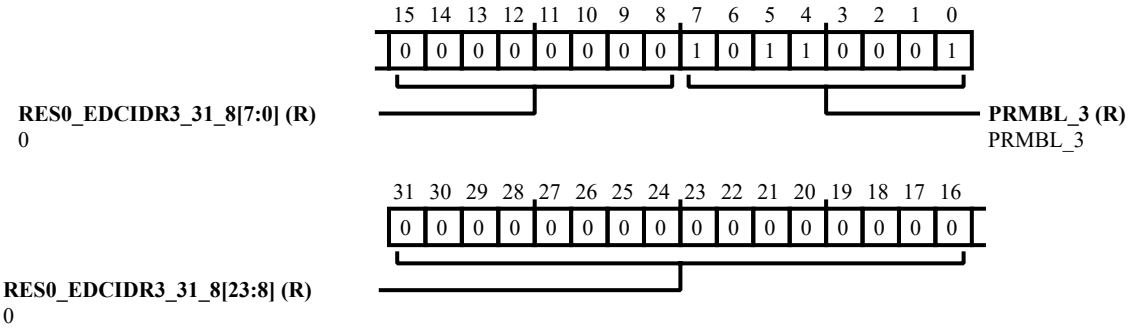

Figure 48-60: A55_CLUSTER_EDCIDR3 Register Diagram

Table 48-58: A55_CLUSTER_EDCIDR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_EDCIDR3_31_8	0. Reserved, RES0.
7:0 (R/NW)	PRMBL_3	PRMBL_3. Preamble. Must read as 0xB1.

External Debug Device Affinity 0 Register

Copy of the low half of the PE MPIDR_EL1 register that allows a debugger to determine which PE in a multiprocessor system the external debug component relates to.

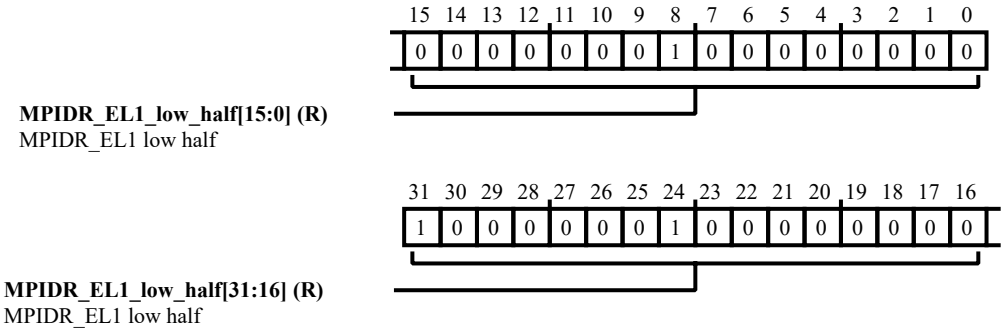

Figure 48-61: A55_CLUSTER_EDDEVAFF0 Register Diagram

Table 48-59: A55_CLUSTER_EDDEVAFF0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	MPIDR_EL1_LOW_HALF	MPIDR_EL1 low half. MPIDR_EL1 low half. Read-only copy of the low half of MPIDR_EL1, as seen from the highest implemented Exception level.

External Debug Device Affinity 1 Register

Copy of the high half of the PE MPIDR_EL1 register that allows a debugger to determine which PE in a multiprocessor system the external debug component relates to.

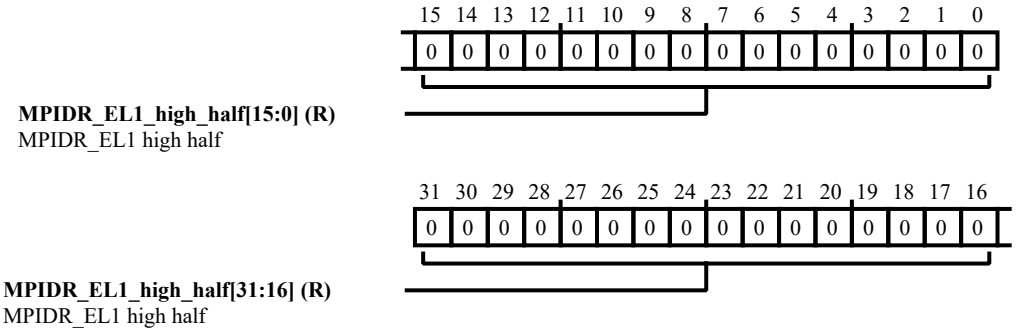

Figure 48-62: A55_CLUSTER_EDDEVAFF1 Register Diagram

Table 48-60: A55_CLUSTER_EDDEVAFF1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	MPIDR_EL1_HIGH_HALF	MPIDR_EL1 high half. MPIDR_EL1 high half. Read-only copy of the high half of MPIDR_EL1, as seen from the highest implemented Exception level.

External Debug Device Architecture Register

Identifies the programmers' model architecture of the external debug component.

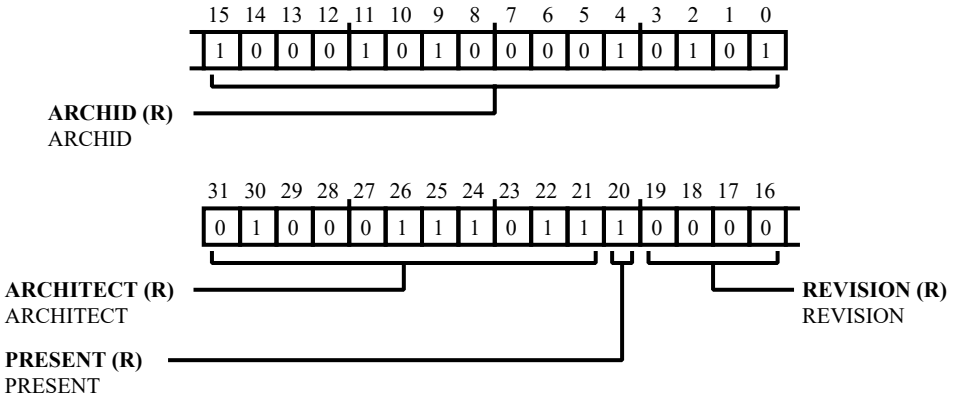

Figure 48-63: A55_CLUSTER_EDDEVARCH Register Diagram

Table 48-61: A55_CLUSTER_EDDEVARCH Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:21 (R/NW)	ARCHITECT	ARCHITECT. Defines the architecture of the component. For debug, this is ARM Limited. Bits [31:28] are the JEP106 continuation code, 0x4. Bits [27:21] are the JEP106 ID code, 0x3B.
20 (R/NW)	PRESENT	PRESENT. When set to 1, indicates that the DEVARCH is present. This field is 1 in ARMv8.
19:16 (R/NW)	REVISION	REVISION. Defines the architecture revision. For architectures defined by ARM this is the minor revision. For debug, the revision defined by ARMv8 is 0x0. All other values are reserved.
15:0 (R/NW)	ARCHID	ARCHID. Defines this part to be an ARMv8 debug component. For architectures defined by ARM this is further subdivided. For debug: Bits [15:12] are the architecture version:In ARMv8-A, this is 0x6.In ARMv8.1, this is 0x7.In ARMv8.2, this is0x8. Bits [11:0] are the architecture part number, 0xA15. This corresponds to the ARMv8 debug architecture version.

External Debug Device ID 0 Register

Provides extra information for external debuggers about features of the debug implementation.

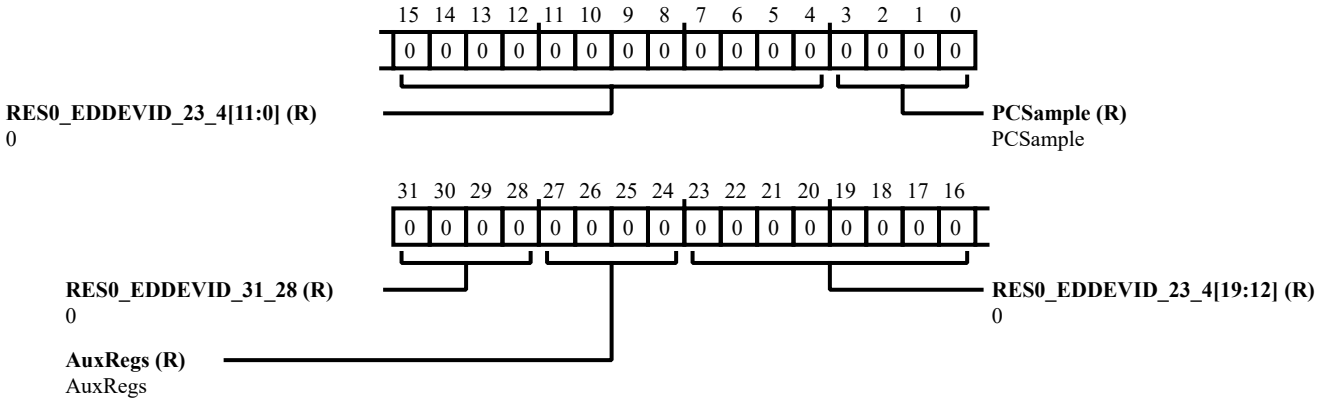

Figure 48-64: A55_CLUSTER_EDDEVID Register Diagram

Table 48-62: A55_CLUSTER_EDDEVID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:28 (R/NW)	RES0_EDDEVID_31_28	0. Reserved, RES0.	
27:24 (R/NW)	AUXREGS	AuxRegs. Indicates support for Auxiliary registers. Permitted values for this field are: 0000 None supported. 0001 Support for External Debug Auxiliary Control Register, EDACR. All other values are reserved.	
		0	None supported.
		1	Support for External Debug Auxiliary Control Register, EDACR.
23:4 (R/NW)	RES0_EDDEVID_23_4	0. Reserved, RES0.	

Table 48-62: A55_CLUSTER_EDDEVID Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3:0 (R/NW)	PCSAMPLE	PCSample. Indicates the level of PC Sample-based profiling support using external debug registers 40 through 43. Permitted values of this field in ARMv8 are: 0000 Architecture-defined form of PC Sample-based profiling not implemented. 0010 EDPCSR and EDCIDSR are implemented (only permitted if EL3 and EL2 are not implemented). 0011 EDPCSR, EDCIDSR, and EDVIDSR are implemented. All other values are reserved. In ARMv8.2 implementations, this field reads as 0b0000.	
		0	Architecture-defined form of PC Sample-based profiling not implemented.
		2	EDPCSR and EDCIDSR are implemented (only permitted if EL3 and EL2 are not implemented).
		3	EDPCSR, EDCIDSR, and EDVIDSR are implemented.

External Debug Device ID 1 Register

Provides extra information for external debuggers about features of the debug implementation.

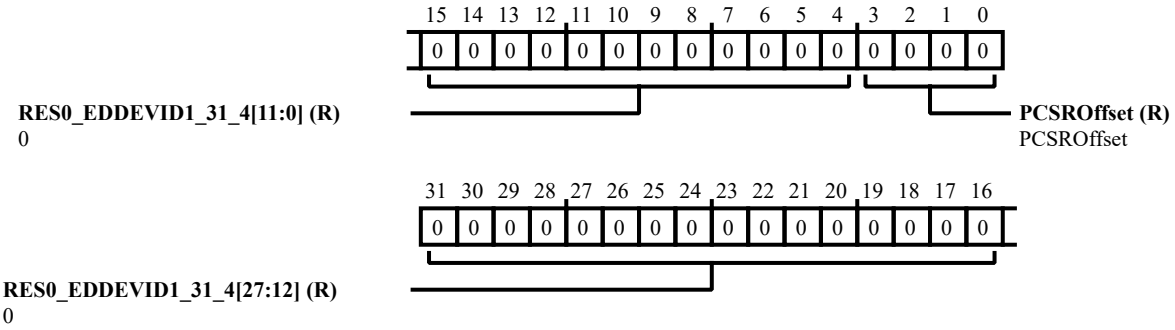

Figure 48-65: A55_CLUSTER_EDDEVID1 Register Diagram

Table 48-63: A55_CLUSTER_EDDEVID1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_EDDEVID1_31_4	0. Reserved, RES0.	
3:0 (R/NW)	PCSROFFSET	PCSROffset. This field indicates the offset applied to PC samples returned by reads of EDPCSR. Permitted values of this field in ARMv8 are: 0000 EDPCSR not implemented. 0010 EDPCSR implemented, and samples have no offset applied and do not sample the instruction set state in AArch32 state. In ARMv8.2 implementations, this field reads as 0b0000.	
		0	EDPCSR not implemented.
		2	EDPCSR implemented, and samples have no offset applied and do not sample the instruction set state in AArch32 state.

External Debug Device ID 2 Register

Reserved for future descriptions of features of the debug implementation.

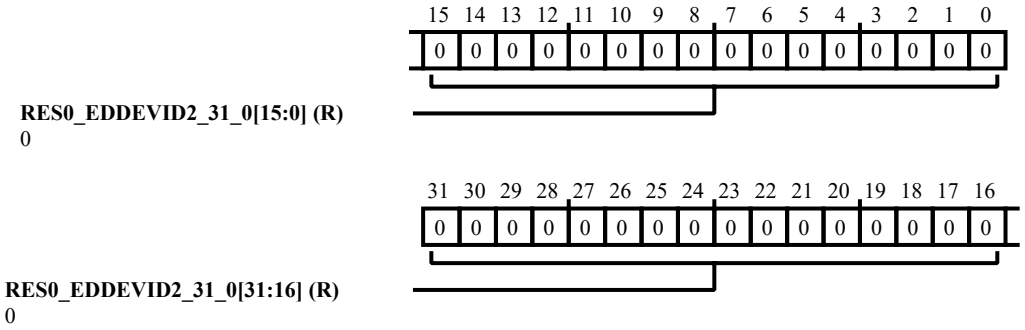

Figure 48-66: A55_CLUSTER_EDDEVID2 Register Diagram

Table 48-64: A55_CLUSTER_EDDEVID2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RES0_EDDEVID2_31_0	0. Reserved, RES0.

External Debug Device Type Register

Indicates to a debugger that this component is part of a PEs debug logic.

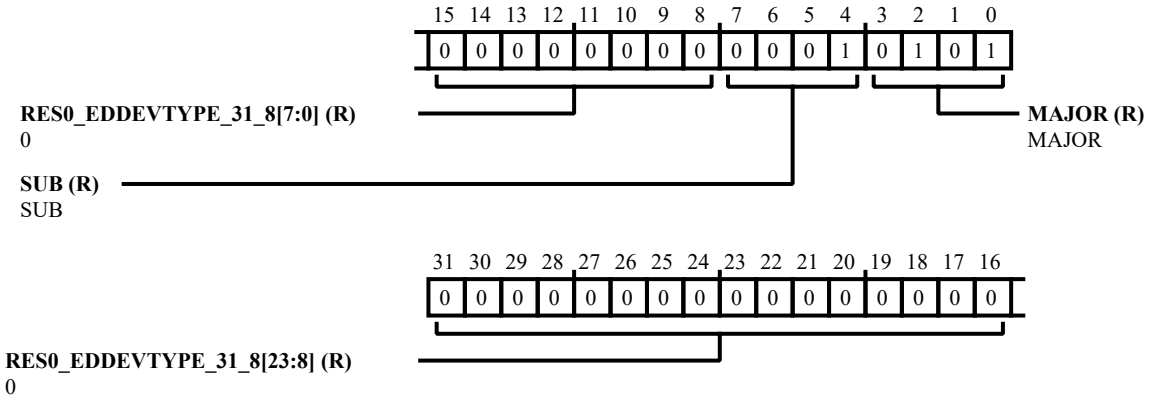

Figure 48-67: A55_CLUSTER_EDDEVTYPE Register Diagram

Table 48-65: A55_CLUSTER_EDDEVTYPE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_EDDEVTYPE_31_8	0. Reserved, RES0.
7:4 (R/NW)	SUB	SUB. Subtype. Must read as 0x1 to indicate this is a component within a PE.
3:0 (R/NW)	MAJOR	MAJOR. Major type. Must read as 0x5 to indicate this is a debug logic component.

External Debug Feature Register

Provides top level information about the debug system. Debuggers must use EDDEVARCH to determine the Debug architecture version. For general information about the interpretation of the ID registers see .

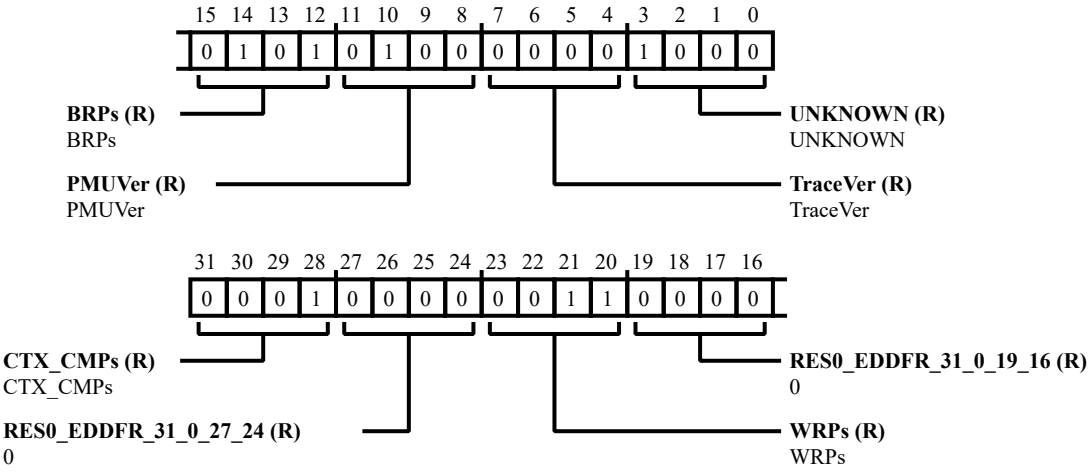

Figure 48-68: A55_CLUSTER_EDDFR_31_0 Register Diagram

Table 48-66: A55_CLUSTER_EDDFR_31_0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:28 (R/NW)	CTX_CMPS	CTX_CMPs. Number of breakpoints that are context-aware, minus 1. These are the highest numbered breakpoints. In an ARMv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64DFR0_EL1.CTX_CMPs.
27:24 (R/NW)	RES0_EDDFR_31_0_27_24	0. Reserved, RES0.
23:20 (R/NW)	WRPS	WRPs. Number of watchpoints, minus 1. The value of 0b0000 is reserved. In an ARMv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64DFR0_EL1.WRPs.
19:16 (R/NW)	RES0_EDDFR_31_0_19_16	0. Reserved, RES0.
15:12 (R/NW)	BRPS	BRPs. Number of breakpoints, minus 1. The value of 0b0000 is reserved. In an ARMv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64DFR0_EL1.BRPs.

Table 48-66: A55_CLUSTER_EDDFR_31_0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11:8 (R/NW)	PMUVER	PMUVer. Performance Monitors Extension version. Indicates whether System register interface to Performance Monitors extension is implemented. Defined values are: 0000 Performance Monitors Extension System registers not implemented. 0001 Performance Monitors Extension System registers implemented, PMUv3. 0100 Performance Monitors Extension System registers implemented, PMUv3, with a 16-bit evtCount field, and if EL2 is implemented, the addition of the MDCR_EL2.HPMD bit. 1111 IMPLEMENTATION DEFINED form of performance monitors supported, PMUv3 not supported. All other values are reserved. In ARMv8-A the permitted values are 0b0000, 0b0001 and 0b1111. In ARMv8.1 the permitted values are 0b0000, 0b0100 and 0b1111. In an ARMv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64DFR0_EL1.PMUVer.	
		0	Performance Monitors Extension System registers not implemented.
		1	Performance Monitors Extension System registers implemented, PMUv3.
		4	Performance Monitors Extension System registers implemented, PMUv3, with a 16-bit evtCount field, and if EL2 is implemented, the addition of the MDCR_EL2.HPMD bit.
		15	IMPLEMENTATION DEFINED form of performance monitors supported, PMUv3 not supported.
7:4 (R/NW)	TRACEVER	TraceVer. Trace support. Indicates whether System register interface to a trace macrocell is implemented. Defined values are: 0000 Trace macrocell System registers not implemented. 0001 Trace macrocell System registers implemented. All other values are reserved. A value of 0b0000 only indicates that no System register interface to a trace macrocell is implemented. A trace macrocell might nevertheless be implemented without a System register interface. In an ARMv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64DFR0_EL1.TraceVer.	
		0	Trace macrocell System registers not implemented.
		1	Trace macrocell System registers implemented.
3:0 (R/NW)	UNKNOWN	UNKNOWN. Reserved, UNKNOWN.	

External Debug Feature Register

Provides top level information about the debug system. Debuggers must use EDDEVARCH to determine the Debug architecture version. For general information about the interpretation of the ID registers see .

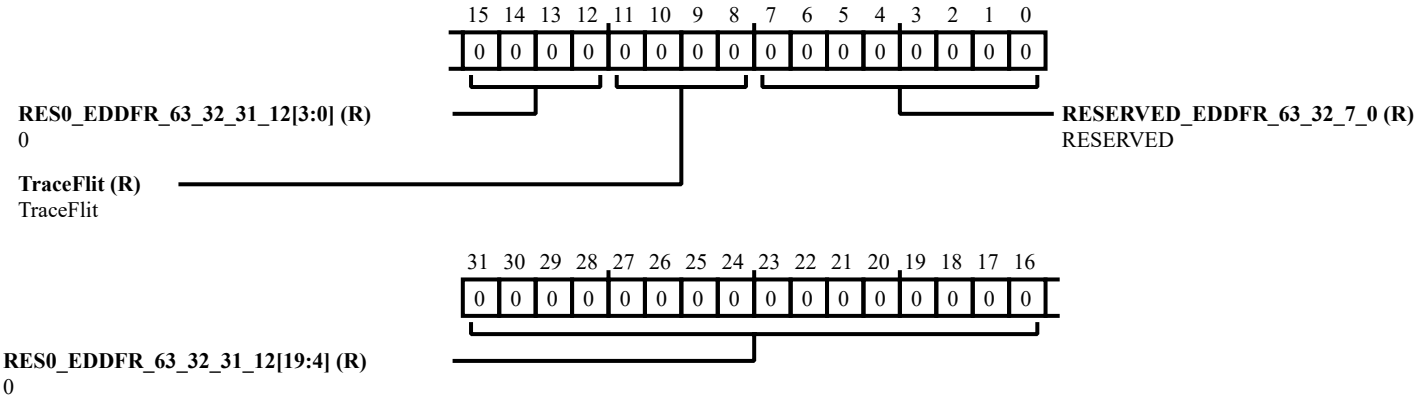

Figure 48-69: A55_CLUSTER_EDDFR_63_32 Register Diagram

Table 48-67: A55_CLUSTER_EDDFR_63_32 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:12 (R/NW)	RES0_EDDFR_63_32_31_12	0. Reserved, RES0.
11:8 (R/NW)	TRACEFLIT	TraceFlit. ARMv8.4 Self-hosted Trace Extension implemented.
7:0 (R/NW)	RESERVED_EDDFR_63_32_7_0	RESERVED. Reserved. This field reads as an UNKNOWN value.

External Debug Execution Control Register

Controls Halting debug events.

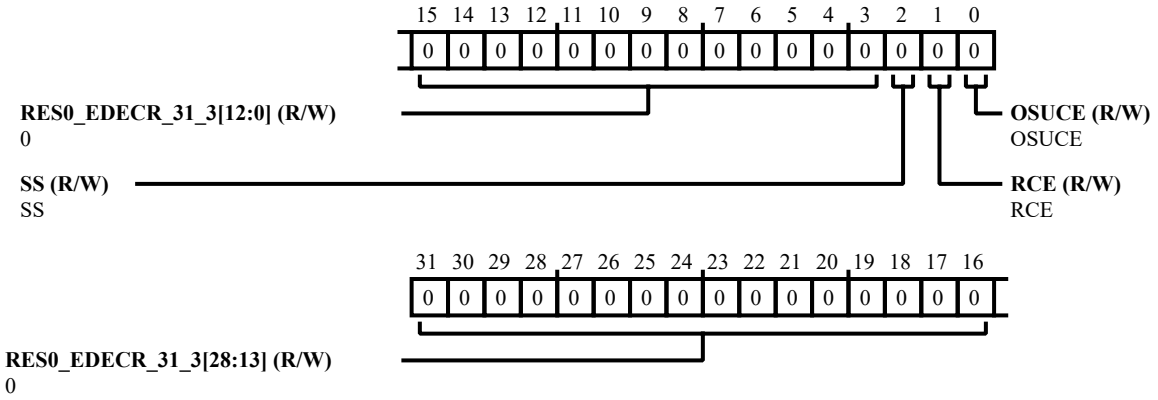

Figure 48-70: A55_CLUSTER_EDECR Register Diagram

Table 48-68: A55_CLUSTER_EDECR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:3 (R/W)	RES0_EDECR_31_3	0. Reserved, RES0.	
2 (R/W)	SS	SS. Halting step enable. Possible values of this field are: 0 Halting step debug event disabled. 1 Halting step debug event enabled. If the value of EDECR.SS is changed when the PE is in Non-debug state, behavior is CONSTRAINED UNPREDICTABLE as described in .	
		0	Halting step debug event disabled.
		1	Halting step debug event enabled.
1 (R/W)	RCE	RCE. Reset Catch enable. Possible values of this field are: 0 Reset Catch debug event disabled. 1 Reset Catch debug event enabled.	
		0	Reset Catch debug event disabled.
		1	Reset Catch debug event enabled.
0 (R/W)	OSUCE	OSUCE. OS Unlock Catch enabled. Possible values of this field are: 0 OS Unlock Catch debug event disabled. 1 OS Unlock Catch debug event enabled.	
		0	OS Unlock Catch debug event disabled.
		1	OS Unlock Catch debug event enabled.

External Debug Lock Access Register

Allows or disallows access to the external debug registers through a memory-mapped interface.

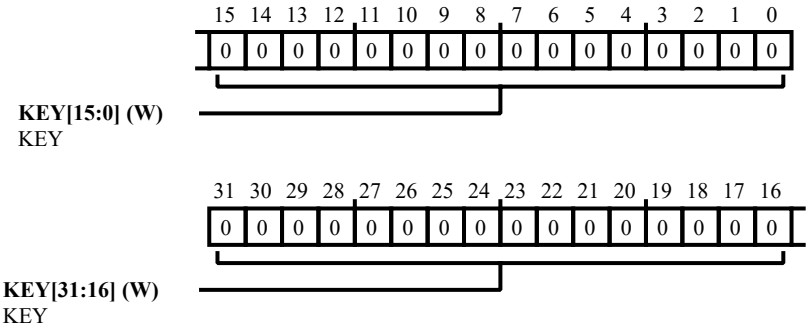

Figure 48-71: A55_CLUSTER_EDLAR Register Diagram

Table 48-69: A55_CLUSTER_EDLAR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (RX/W)	KEY	KEY. Lock Access control. Writing the key value 0xC5ACCE55 to this field unlocks the lock, enabling write accesses to this component's registers through a memory-mapped interface. Writing any other value to this register locks the lock, disabling write accesses to this component's registers through a memory mapped interface.

External Debug Lock Status Register

Indicates the current status of the software lock for external debug registers.

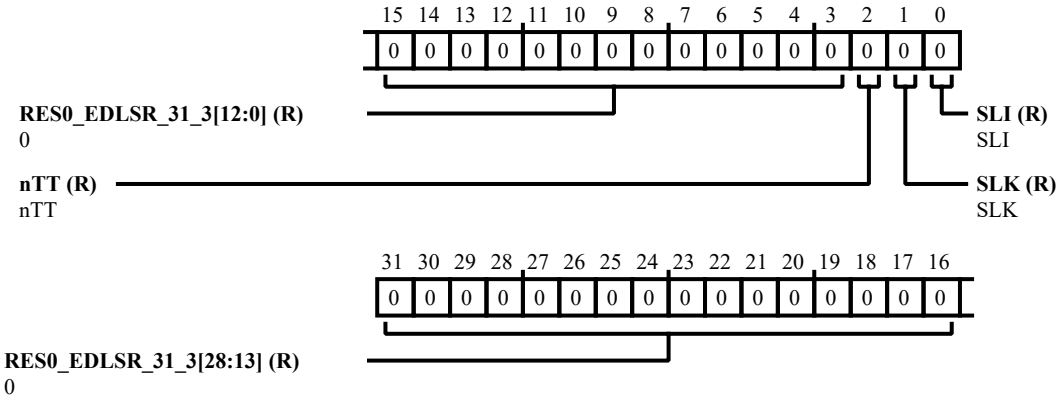

Figure 48-72: A55_CLUSTER_EDLSR Register Diagram

Table 48-70: A55_CLUSTER_EDLSR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:3 (R/NW)	RES0_EDLSR_31_3	0. Reserved, RES0.	
2 (R/NW)	NTT	nTT. Not thirty-two bit access required. RAZ.	
1 (R/NW)	SLK	SLK. Software Lock status for this component. For an access to LSR that is not a memory-mapped access, or when the Software Lock is not implemented, this field is RES0. For memory-mapped accesses when the Software Lock is implemented, possible values of this field are: 0 Lock clear. Writes are permitted to this component's registers. 1 Lock set. Writes to this component's registers are ignored, and reads have no side effects.	
		0	Lock clear. Writes are permitted to this component's registers.
		1	Lock set. Writes to this component's registers are ignored, and reads have no side effects.

Table 48-70: A55_CLUSTER_EDLSR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/NW)	SLI	SLI. Software Lock implemented. For an access to LSR that is not a memory-mapped access, this field is RAZ. For memory-mapped accesses, the value of this field is IMPLEMENTATION DEFINED. Permitted values are: 0 Software Lock not implemented or not memory-mapped access. 1 Software Lock implemented and memory-mapped access.	
		0	Software Lock not implemented or not memory-mapped access.
		1	Software Lock implemented and memory-mapped access.

External Debug Processor Feature Register

Provides information about implemented PE features. For general information about the interpretation of the ID registers see .

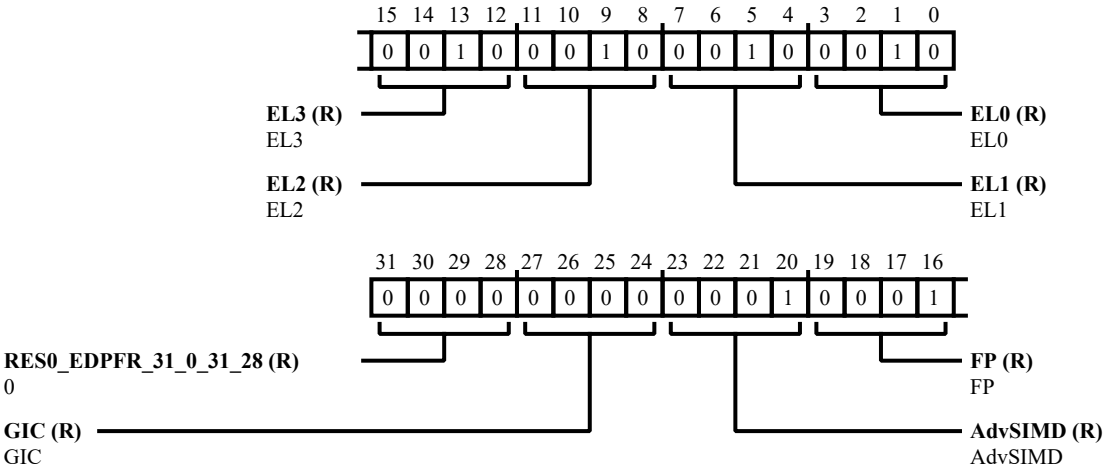

Figure 48-73: A55_CLUSTER_EDPFR_31_0 Register Diagram

Table 48-71: A55_CLUSTER_EDPFR_31_0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:28 (R/NW)	RES0_EDPFR_31_0_31_28	0. Reserved, RES0.	
27:24 (R/NW)	GIC	GIC. System register GIC interface support. Defined values are: 0000 No System register interface to the GIC is supported. 0001 System register interface to versions 3.0 and 4.0 of the GIC CPU interface is supported. All other values are reserved. In an ARMv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64PFR0_EL1.GIC.	
		0	No System register interface to the GIC is supported.
		1	System register interface to versions 3.0 and 4.0 of the GIC CPU interface is supported.
23:20 (R/NW)	ADVSIMD	AdvSIMD. Advanced SIMD. Defined values are: 0000 Advanced SIMD is implemented. 1111 Advanced SIMD is not implemented. All other values are reserved. In an ARMv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64PFR0_EL1.AdvSIMD.	
		0	Advanced SIMD is implemented.
		15	Advanced SIMD is not implemented.

Table 48-71: A55_CLUSTER_EDPFR_31_0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
19:16 (R/NW)	FP	FP. Floating-point. Defined values are: 0000 Floating-point is implemented. 1111 Floating-point is not implemented. All other values are reserved. In an ARMv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64PFR0_EL1.FP.	
		0	Floating-point is implemented.
		15	Floating-point is not implemented.
15:12 (R/NW)	EL3	EL3. AArch64 EL3 Exception level handling. Defined values are: 0000 EL3 is not implemented or cannot be executed in AArch64 state. 0001 EL3 can be executed in AArch64 state only. 0010 EL3 can be executed in either AArch64 or AArch32 state. When the value of EDAA32PFR.EL3 is non-zero, this field must be 0000. All other values are reserved. In an ARMv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64PFR0_EL1.EL3.	
		0	EL3 is not implemented or cannot be executed in AArch64 state.
		1	EL3 can be executed in AArch64 state only.
		2	EL3 can be executed in either AArch64 or AArch32 state.
11:8 (R/NW)	EL2	EL2. AArch64 EL2 Exception level handling. Defined values are: 0000 EL2 is not implemented or cannot be executed in AArch64 state. 0001 EL2 can be executed in AArch64 state only. 0010 EL2 can be executed in either AArch64 or AArch32 state. When the value of EDAA32PFR.EL2 is non-zero, this field must be 0000. All other values are reserved. In an ARMv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64PFR0_EL1.EL2.	
		0	EL2 is not implemented or cannot be executed in AArch64 state.
		1	EL2 can be executed in AArch64 state only.
		2	EL2 can be executed in either AArch64 or AArch32 state.

Table 48-71: A55_CLUSTER_EDPFR_31_0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7:4 (R/NW)	EL1	EL1. AArch64 EL1 Exception level handling. Defined values are: 0000 EL1 can be executed in AArch32 state only. 0001 EL1 can be executed in AArch64 state only. 0010 EL1 can be executed in either AArch64 or AArch32 state. All other values are reserved. In an ARMv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64PFR0_EL1.EL1.	
		0	EL1 can be executed in AArch32 state only.
		1	EL1 can be executed in AArch64 state only.
		2	EL1 can be executed in either AArch64 or AArch32 state.
3:0 (R/NW)	EL0	EL0. AArch64 EL0 Exception level handling. Defined values are: 0000 EL0 can be executed in AArch32 state only. 0001 EL0 can be executed in AArch64 state only. 0010 EL0 can be executed in either AArch64 or AArch32 state. All other values are reserved. In an ARMv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64PFR0_EL1.EL0.	
		0	EL0 can be executed in AArch32 state only.
		1	EL0 can be executed in AArch64 state only.
		2	EL0 can be executed in either AArch64 or AArch32 state.

External Debug Processor Feature Register

Provides information about implemented PE features. For general information about the interpretation of the ID registers see .

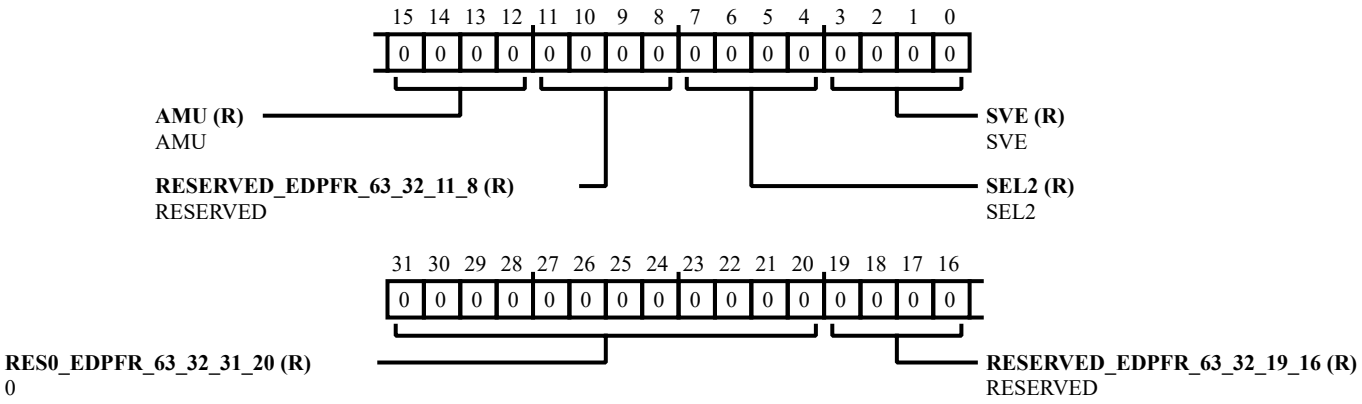

Figure 48-74: A55_CLUSTER_EDPFR_63_32 Register Diagram

Table 48-72: A55_CLUSTER_EDPFR_63_32 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:20 (R/NW)	RES0_EDPFR_63_32_31_20	0. Reserved, RES0.
19:16 (R/NW)	RESERVED_EDPFR_63_32_19_16	RESERVED. Reserved. This field reads as an UNKNOWN value.
15:12 (R/NW)	AMU	AMU. AMU.
11:8 (R/NW)	RESERVED_EDPFR_63_32_11_8	RESERVED. Reserved. This field reads as an UNKNOWN value.
7:4 (R/NW)	SEL2	SEL2. Secure EL2 implemented.
3:0 (R/NW)	SVE	SVE. SVE.

External Debug Peripheral Identification 0 Register

Provides information to identify an external debug component.

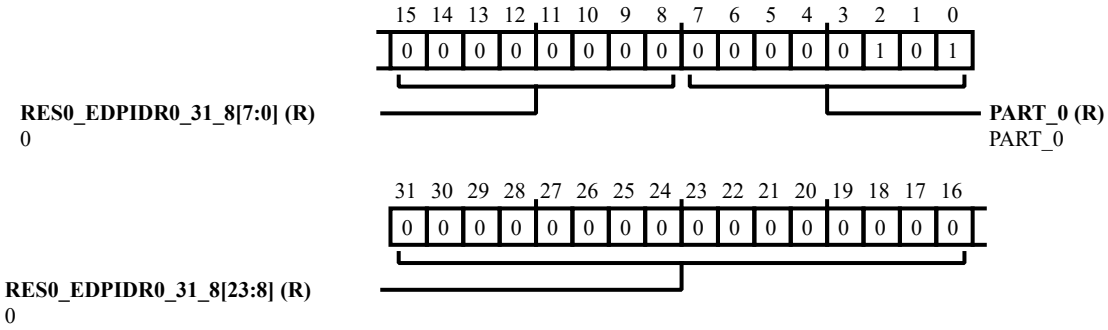

Figure 48-75: A55_CLUSTER_EDPIDR0 Register Diagram

Table 48-73: A55_CLUSTER_EDPIDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_EDPIDR0_31_8	0. Reserved, RES0.
7:0 (R/NW)	PART_0	PART_0. Part number, least significant byte.

External Debug Peripheral Identification 1 Register

Provides information to identify an external debug component.

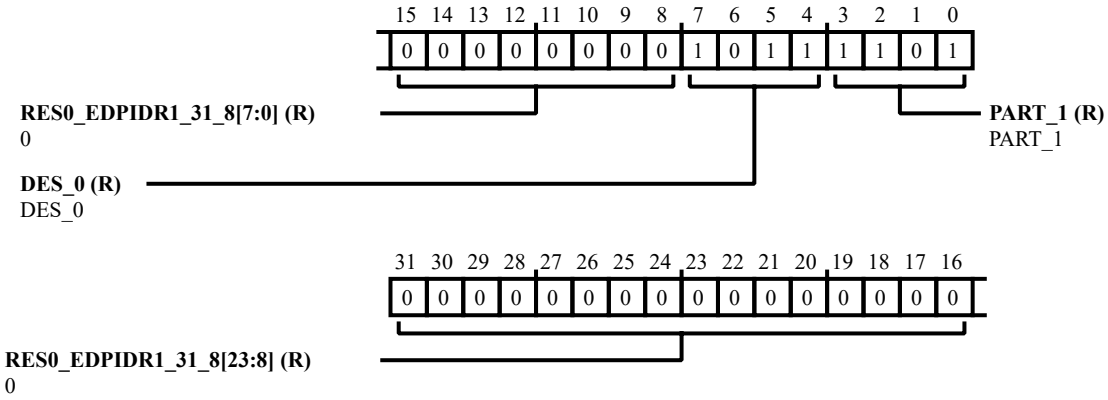

Figure 48-76: A55_CLUSTER_EDPIDR1 Register Diagram

Table 48-74: A55_CLUSTER_EDPIDR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_EDPIDR1_31_8	0. Reserved, RES0.
7:4 (R/NW)	DES_0	DES_0. Designer, least significant nibble of JEP106 ID code. For ARM Limited, this field is 0b1011.
3:0 (R/NW)	PART_1	PART_1. Part number, most significant nibble.

External Debug Peripheral Identification 2 Register

Provides information to identify an external debug component.

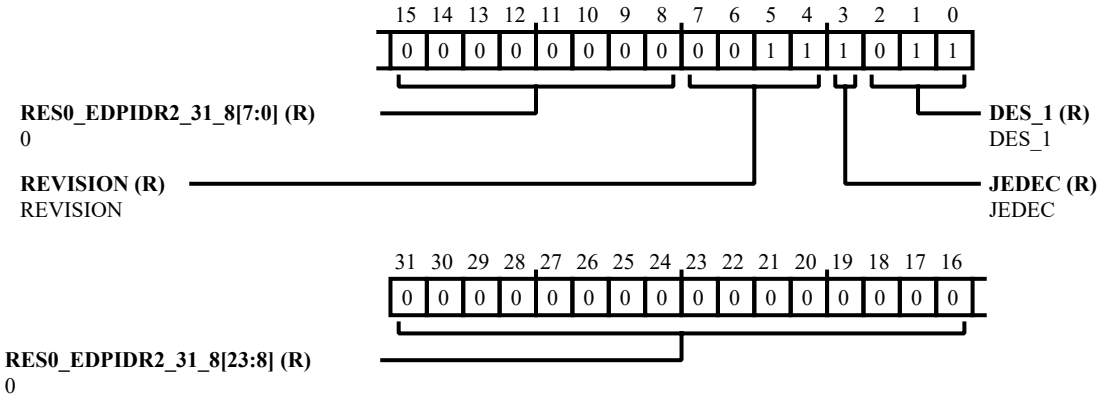

Figure 48-77: A55_CLUSTER_EDPIDR2 Register Diagram

Table 48-75: A55_CLUSTER_EDPIDR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_EDPIDR2_31_8	0. Reserved, RES0.
7:4 (R/NW)	REVISION	REVISION. Part major revision. Parts can also use this field to extend Part number to 16-bits.
3 (R/NW)	JEDEC	JEDEC. RAO. Indicates a JEP106 identity code is used.
2:0 (R/NW)	DES_1	DES_1. Designer, most significant bits of JEP106 ID code. For ARM Limited, this field is 0b011.

External Debug Peripheral Identification 3 Register

Provides information to identify an external debug component.

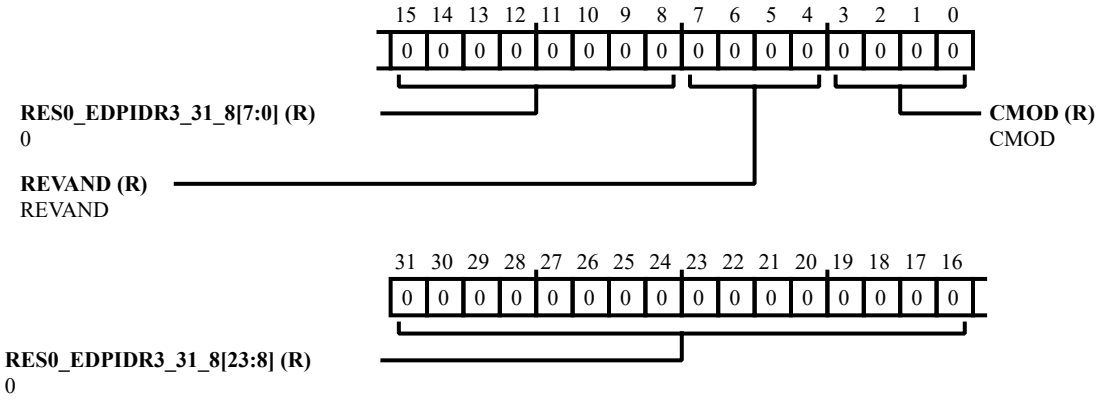

Figure 48-78: A55_CLUSTER_EDPIDR3 Register Diagram

Table 48-76: A55_CLUSTER_EDPIDR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_EDPIDR3_31_8	0. Reserved, RES0.
7:4 (R/NW)	REVAND	REVAND. Part minor revision. Parts using EDPIDR2.REVISION as an extension to the Part number must use this field as a major revision number.
3:0 (R/NW)	CMOD	CMOD. Customer modified. Indicates someone other than the Designer has modified the component.

External Debug Peripheral Identification 4 Register

Provides information to identify an external debug component.

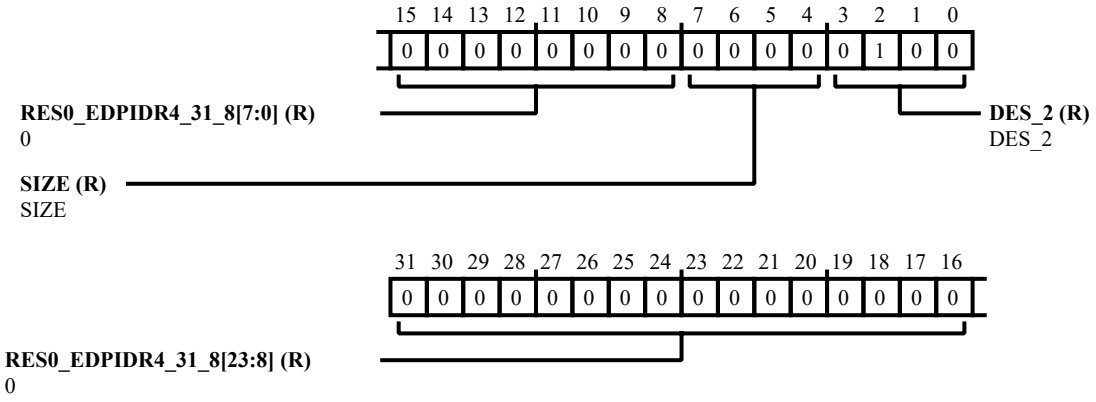

Figure 48-79: A55_CLUSTER_EDPIDR4 Register Diagram

Table 48-77: A55_CLUSTER_EDPIDR4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_EDPIDR4_31_8	0. Reserved, RES0.
7:4 (R/NW)	SIZE	SIZE. Size of the component. RAZ. Log2 of the number of 4KB pages from the start of the component to the end of the component ID registers.
3:0 (R/NW)	DES_2	DES_2. Designer, JEP106 continuation code, least significant nibble. For ARM Limited, this field is 0b0100.

External Debug Peripheral Identification 5 Register

Provides information to identify an external debug component.

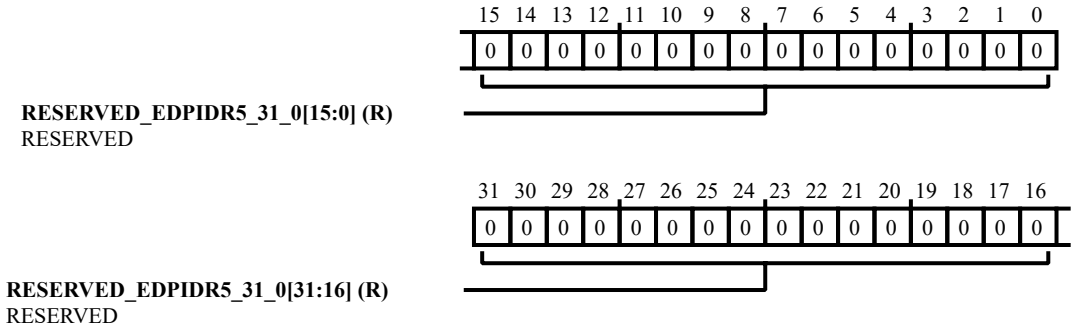

Figure 48-80: A55_CLUSTER_EDPIDR5 Register Diagram

Table 48-78: A55_CLUSTER_EDPIDR5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RESERVED_ED-PIDR5_31_0	RESERVED. Reserved RES0.

External Debug Peripheral Identification 6 Register

Provides information to identify an external debug component.

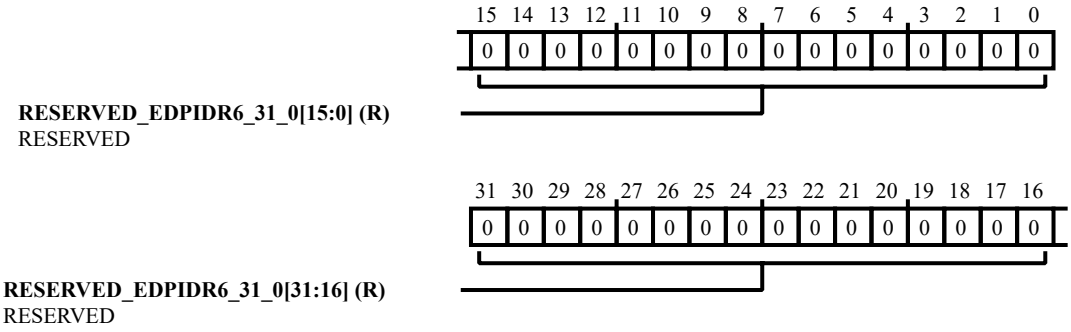

Figure 48-81: A55_CLUSTER_EDPIDR6 Register Diagram

Table 48-79: A55_CLUSTER_EDPIDR6 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RESERVED_ED-PIDR6_31_0	RESERVED. Reserved RES0.

External Debug Peripheral Identification 7 Register

Provides information to identify an external debug component.

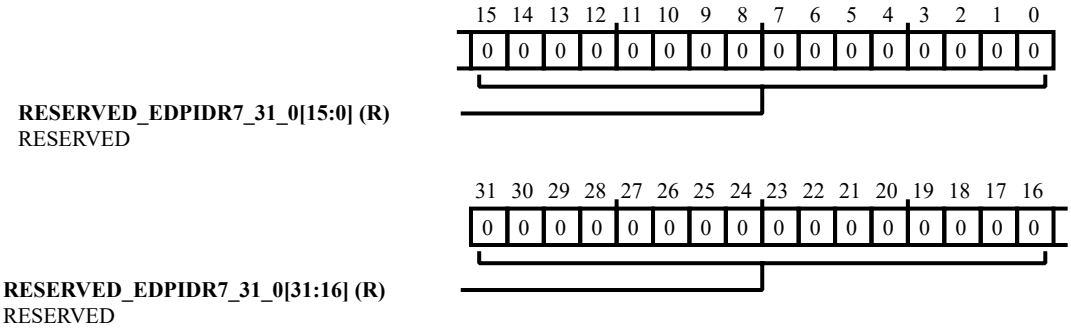

Figure 48-82: A55_CLUSTER_EDPIDR7 Register Diagram

Table 48-80: A55_CLUSTER_EDPIDR7 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RESERVED_ED-PIDR7_31_0	RESERVED. Reserved RES0.

Main ID Register

Provides identification information for the PE, including an implementer code for the device and a device ID number.

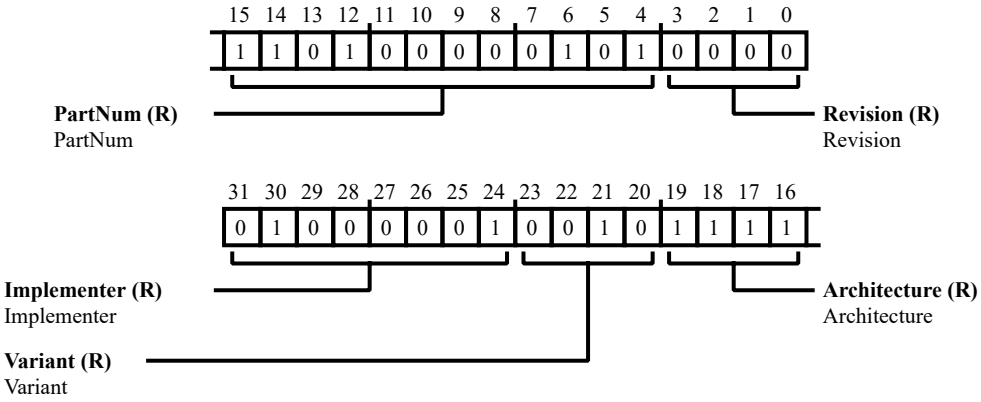

Figure 48-83: A55_CLUSTER_MIDR_EL1 Register Diagram

Table 48-81: A55_CLUSTER_MIDR_EL1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:24 (R/NW)	IMPLEMENTER	Implementer. The Implementer code. This field must hold an implementer code that has been assigned by ARM.	
23:20 (R/NW)	VARIANT	Variant. An IMPLEMENTATION DEFINED variant number. Typically this field is used to distinguish between different product variants or major revisions of a product.	
19:16 (R/NW)	ARCHITECTURE	Architecture. The Architecture used.	
		1	ARMv4.
		2	ARMv4T.
		3	ARMv5 (obsolete).
		4	ARMv5T.
		5	ARMv5TE.
		6	ARMv5TEJ.
		7	ARMv6.
		15	Defined by CPUID scheme.

Table 48-81: A55_CLUSTER_MIDR_EL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15:4 (R/NW)	PARTNUM	PartNum. An IMPLEMENTATION DEFINED primary part number for the device. On processors implemented by ARM if the top four bits of the primary part number are 0x0 or 0x7 the variant and architecture are encoded differently.
3:0 (R/NW)	REVISION	Revision. An IMPLEMENTATION DEFINED revision number for the device.

Trace Authentication Status Register

Returns the level of tracing that the trace unit can support.

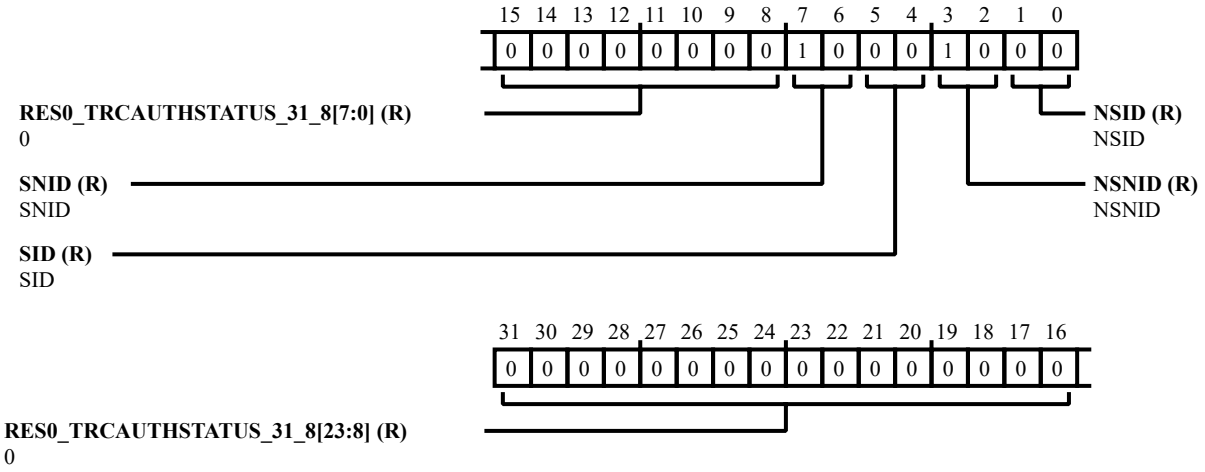

Figure 48-84: A55_CLUSTER_TRCAUTHSTATUS Register Diagram

Table 48-82: A55_CLUSTER_TRCAUTHSTATUS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:8 (R/NW)	RES0_TRCAUTHSTA-TUS_31_8	0. Reserved, RES0.	
7:6 (R/NW)	SNID	SNID. Indicates whether the system enables the trace unit to support Secure non-invasive debug: 00 The trace unit does not implement support for Secure non-invasive debug. 01 Reserved. 10 Secure non-invasive debug is disabled. 11 Secure non-invasive debug is enabled.	
		0	The trace unit does not implement support for Secure non-invasive debug.
		1	Reserved.
		2	Secure non-invasive debug is disabled.
		3	Secure non-invasive debug is enabled.
5:4 (R/NW)	SID	SID. Indicates whether the trace unit supports Secure invasive debug: 00 The trace unit does not support Secure invasive debug. All other values are reserved.	
		0	The trace unit does not support Secure invasive debug.

Table 48-82: A55_CLUSTER_TRCAUTHSTATUS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3:2 (R/NW)	NSNID	NSNID. Indicates whether the system enables the trace unit to support Non-secure non-invasive debug: 00 The trace unit does not implement support for Non-secure non-invasive debug. 01 Reserved. 10 Non-secure non-invasive debug is disabled. 11 Non-secure non-invasive debug is enabled.	
		0	The trace unit does not implement support for Non-secure non-invasive debug.
		1	Reserved.
		2	Non-secure non-invasive debug is disabled.
		3	Non-secure non-invasive debug is enabled.
1:0 (R/NW)	NSID	NSID. Indicates whether the trace unit supports Non-secure invasive debug: 00 The trace unit does not support Non-secure invasive debug. All other values are reserved.	
		0	The trace unit does not support Non-secure invasive debug.

Trace Component ID 0 Register

Return byte 0 of the CoreSight preamble information.

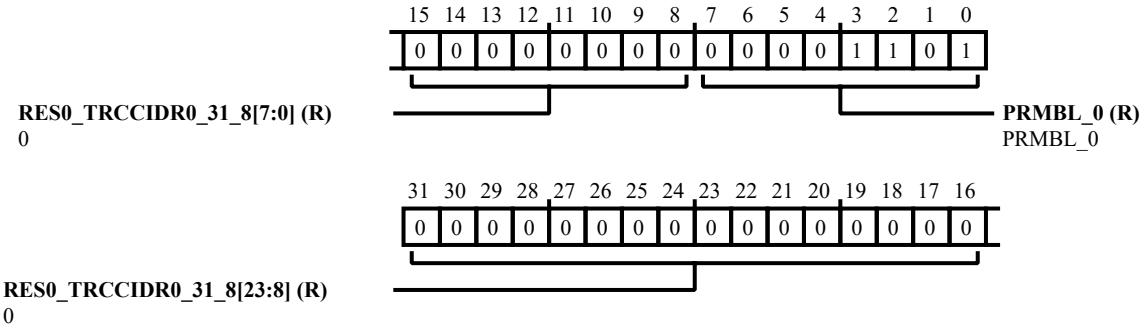

Figure 48-85: A55_CLUSTER_TRCCIDR0 Register Diagram

Table 48-83: A55_CLUSTER_TRCCIDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_TRCCIDR0_31_8	0. Reserved, RES0.
7:0 (R/NW)	PRMBL_0	PRMBL_0. Preamble. Must read as 0x0D.

Trace Component ID 1 Register

Return byte 1 of the CoreSight preamble information.

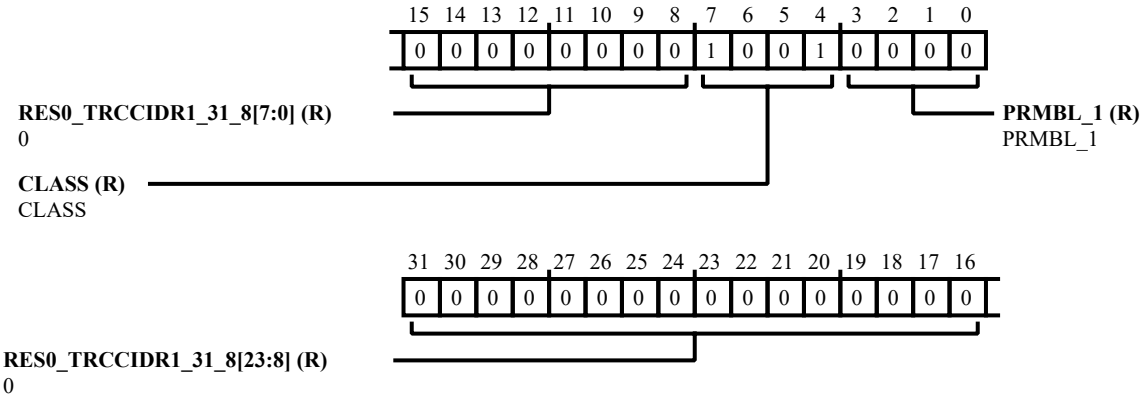

Figure 48-86: A55_CLUSTER_TRCCIDR1 Register Diagram

Table 48-84: A55_CLUSTER_TRCCIDR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_TRCCIDR1_31_8	0. Reserved, RES0.
7:4 (R/NW)	CLASS	CLASS. Component class. Reads as 0x9, to indicate that the ETM is a debug component, with CoreSight architecture compliant management registers.
3:0 (R/NW)	PRMBL_1	PRMBL_1. Preamble. Must read as 0x0.

Trace Component ID 2 Register

Return byte 2 of the CoreSight preamble information.

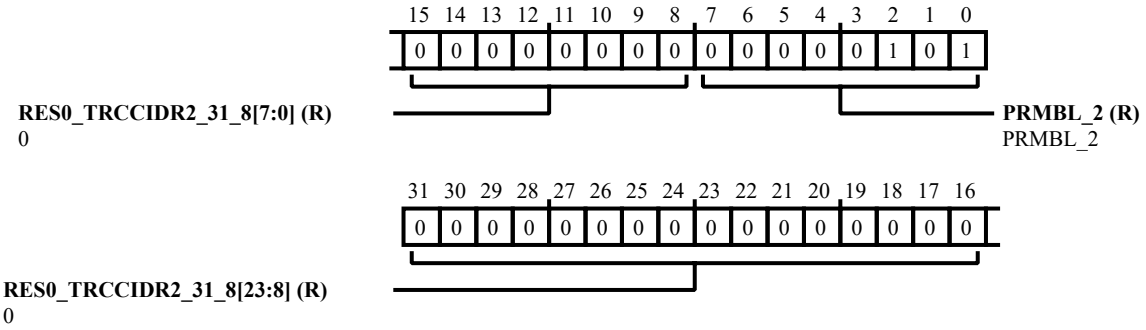

Figure 48-87: A55_CLUSTER_TRCCIDR2 Register Diagram

Table 48-85: A55_CLUSTER_TRCCIDR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_TRCCIDR2_31_8	0. Reserved, RES0.
7:0 (R/NW)	PRMBL_2	PRMBL_2. Preamble. Must read as 0x05.

Trace Component ID 3 Register

Return byte 3 of the CoreSight preamble information.

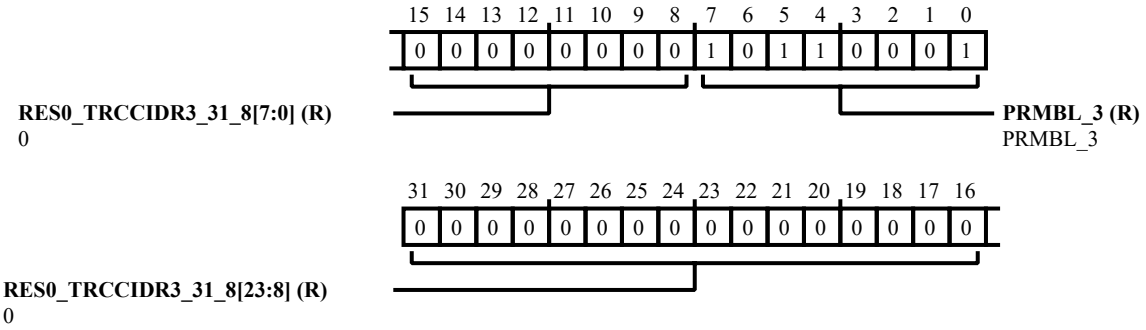

Figure 48-88: A55_CLUSTER_TRCCIDR3 Register Diagram

Table 48-86: A55_CLUSTER_TRCCIDR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_TRCCIDR3_31_8	0. Reserved, RES0.
7:0 (R/NW)	PRMBL_3	PRMBL_3. Preamble. Must read as 0xB1.

Trace Device Affinity 0 Register

Returns the value of the lower 32 bits of MPIDR_EL1 as seen from the highest implemented exception level, unaffected by VMPIDR_EL2. If the trace unit is shared between multiple processors, the value in this register indicates the MPIDR value of the processor that TRCPROCSELR selects.

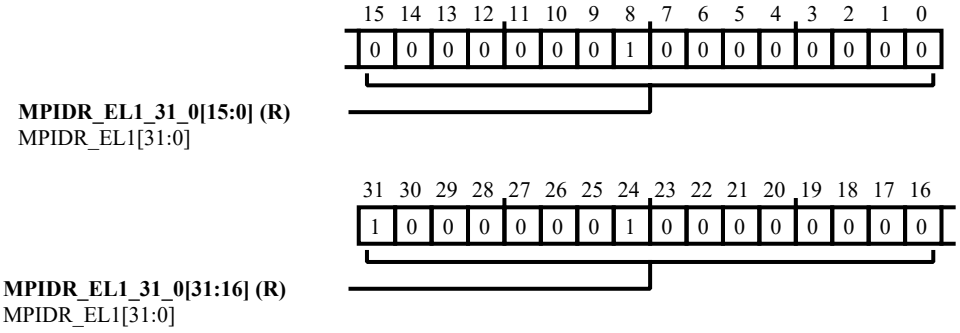

Figure 48-89: A55_CLUSTER_TRCDEVAFF0 Register Diagram

Table 48-87: A55_CLUSTER_TRCDEVAFF0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	MPIDR_EL1_31_0	MPIDR_EL1[31:0]. Read-only copy of the low half of MPIDR_EL1, as seen from the highest implemented exception level.

Trace Device Affinity 1 Register

Returns the value of the upper 32 bits of MPIDR_EL1 as seen from the highest implemented exception level, unaffected by VMPIDR_EL2. If the trace unit is shared between multiple processors, the value in this register indicates the MPIDR value of the processor that TRCPROCSELR selects.

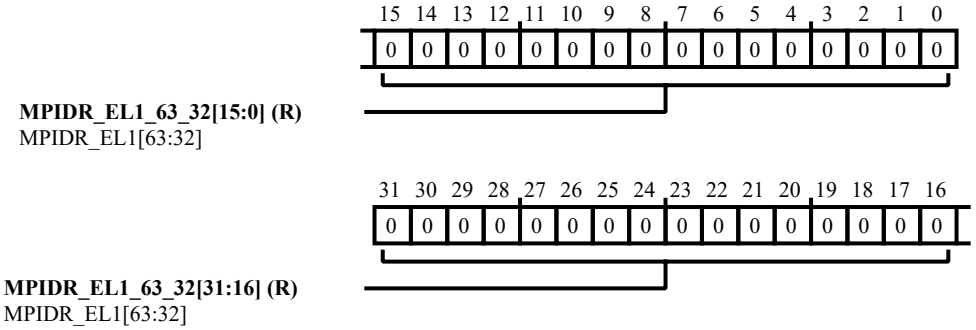

Figure 48-90: A55_CLUSTER_TRCDEVAFF1 Register Diagram

Table 48-88: A55_CLUSTER_TRCDEVAFF1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	MPIDR_EL1_63_32	MPIDR_EL1[63:32]. Read-only copy of the high half of MPIDR_EL1, as seen from the highest implemented exception level.

Trace Device Architecture Register

Identifies the trace unit as an ETMv4 component. This enables debuggers to make some use of a component that conforms to the architecture definition but whose part number is not necessarily recognized.

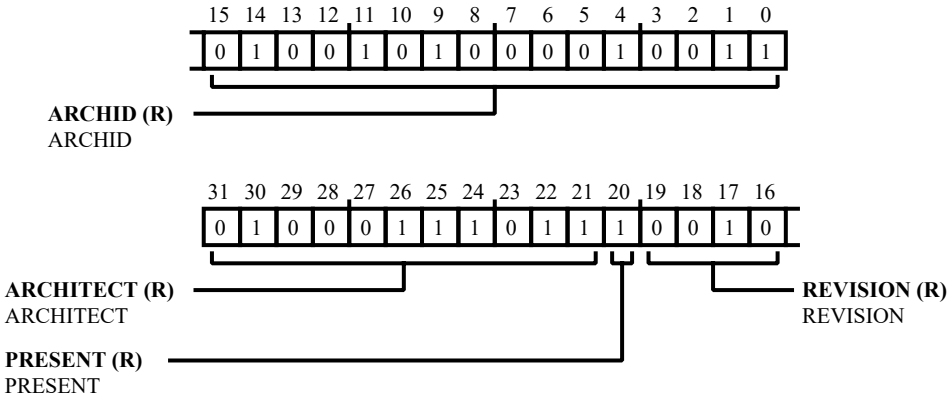

Figure 48-91: A55_CLUSTER_TRCDEVARCH Register Diagram

Table 48-89: A55_CLUSTER_TRCDEVARCH Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:21 (R/NW)	ARCHITECT	ARCHITECT. Defines the architecture of the component. For trace, this is ARM Limited.Bits [31:28] are the JEP 106 continuation code, 0x4.Bits [27:21] are the JEP 106 ID code, 0x3B.
20 (R/NW)	PRESENT	PRESENT. When set to 1, indicates that the DEVARCH is present.This field is RAO.
19:16 (R/NW)	REVISION	REVISION. Defines the architecture revision. For architectures defined by ARM this is the minor revision.For trace, the revision defined by ETMv4 is 0x0.All other values are reserved.
15:0 (R/NW)	ARCHID	ARCHID. Defines this part to be a v8-A debug component. For architectures defined by ARM this is further subdivided.For trace, bits [15:12] are the architecture version, 0x4; bits [11:0] are the architecture part number, 0xA13.This corresponds to trace architecture version ETMv4.

Trace Device ID Register

Returns an IMPLEMENTATION DEFINED CoreSight component capabilities field.

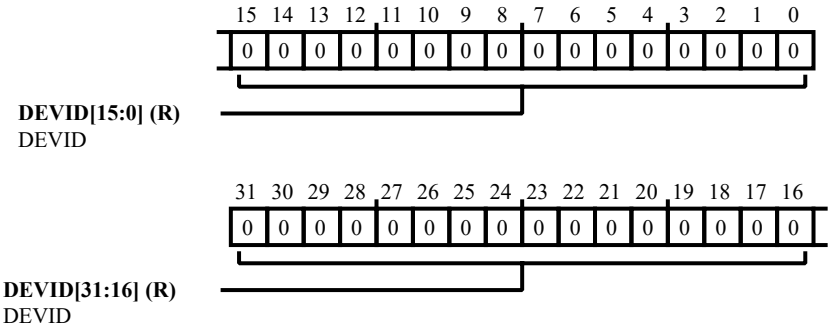

Figure 48-92: A55_CLUSTER_TRCDEVID Register Diagram

Table 48-90: A55_CLUSTER_TRCDEVID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	DEVID	DEVID. Indicates the capabilities of the trace unit. The implemented width of this field and its bit assignments are IMPLEMENTATION DEFINED. Unimplemented bits are RAZ/WI.If a component is configurable then ARM recommends that this field can also indicate which configuration options are implemented that differ from the standard configuration.

Trace Device Type Register

Indicates what type of CoreSight device the trace unit is.

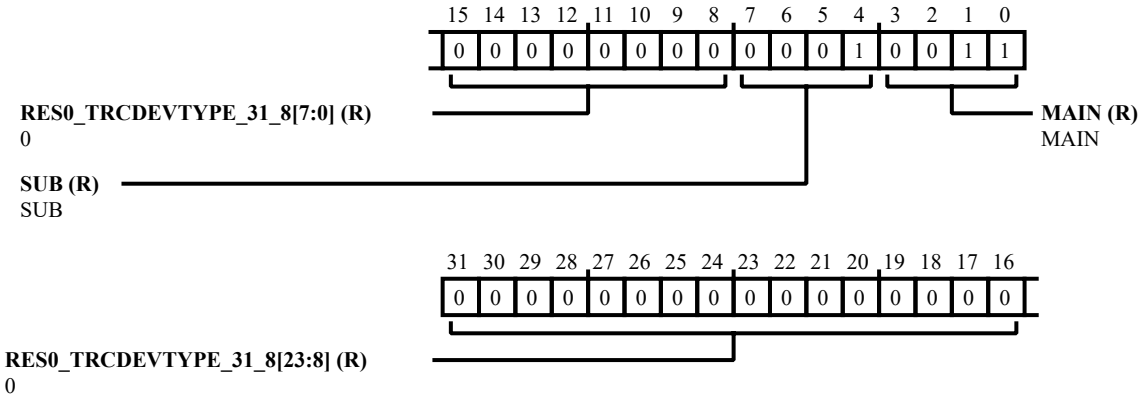

Figure 48-93: A55_CLUSTER_TRCDEVTYPE Register Diagram

Table 48-91: A55_CLUSTER_TRCDEVTYPE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_TRCDEV-TYPE_31_8	0. Reserved, RES0.
7:4 (R/NW)	SUB	SUB. Returns 0x1, to indicate that the ETM generates processor trace.All other values are reserved.
3:0 (R/NW)	MAIN	MAIN. Returns 0x3, to indicate that the ETM is a trace source.All other values are reserved.

Trace Software Lock Access Register

Controls whether the Software Lock is locked. When the Software Lock is locked, the trace unit ignores write accesses from the memory-mapped interface to all ETM registers other than the TRCLAR, and does not change the TRCPDSR.STICKYPD bit if a read access occurs to the TRCPDSR on the memory-mapped interface.

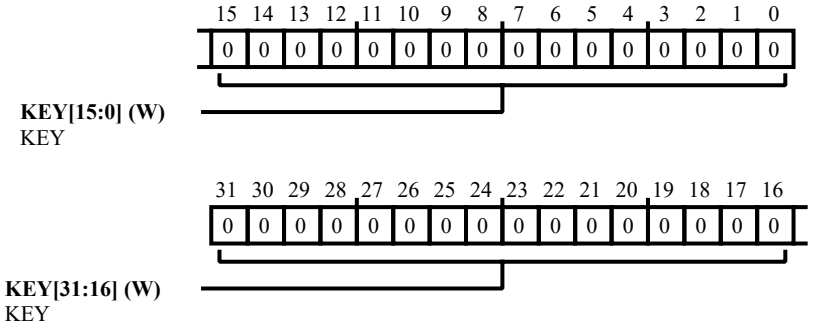

Figure 48-94: A55_CLUSTER_TRCLAR Register Diagram

Table 48-92: A55_CLUSTER_TRCLAR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (RX/W)	KEY	KEY. Writing the key value 0xC5ACCE55 to this field clears the lock, enabling write accesses to this component's registers through a memory-mapped interface.Writing any other value to this register sets the lock, disabling write accesses to this component's registers through a memory mapped interface.Software can use the Software Lock to prevent accidental modification of the trace unit registers by software being debugged. For example, software that accidentally initializes an incorrect region of memory might disable the trace unit and make it impossible to trace the software.

Trace Software Lock Status Register

Trace Software Lock Status Register.

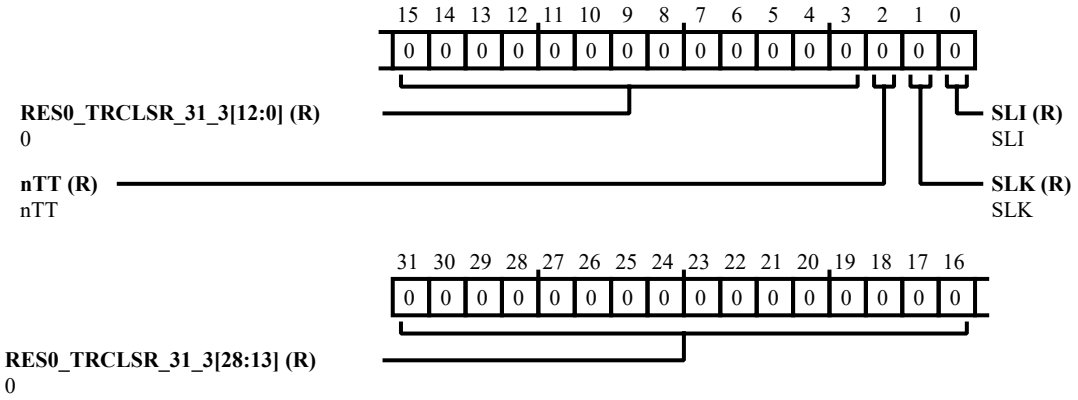

Figure 48-95: A55_CLUSTER_TRCLSR Register Diagram

Table 48-93: A55_CLUSTER_TRCLSR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:3 (R/NW)	RES0_TRCLSR_31_3	0. Reserved, RES0.	
2 (R/NW)	NTT	nTT. Not thirty-two bit access required. RAZ.	
1 (R/NW)	SLK	SLK. Software lock status for this component. Possible values of this field are: 0 Lock clear. Writes are permitted to this component's registers. 1 Lock set. Writes to this component's registers are ignored, and reads have no side effects.	
		0	Lock clear. Writes are permitted to this component's registers.
		1	Lock set. Writes to this component's registers are ignored, and reads have no side effects.
0 (R/NW)	SLI	SLI. Software lock implemented. RAO.	

Trace PowerDown Control Register

Requests the system to provide power to the trace unit.

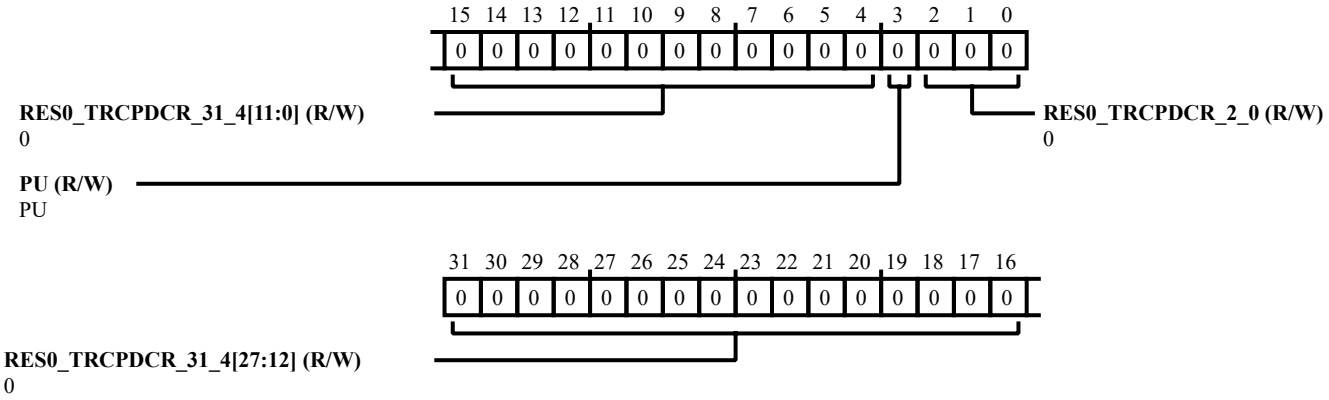

Figure 48-96: A55_CLUSTER_TRCPDCR Register Diagram

Table 48-94: A55_CLUSTER_TRCPDCR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/W)	RES0_TRCPDCR_31_4	0. Reserved, RES0.	
3 (R/W)	PU	PU. Powerup request bit: 0 The system can remove power from the trace unit. The TRCPDSR indicates if the trace unit is powered down. 1 The system must provide power to the trace unit. Typically, a trace unit drives a signal representing the value of this bit to a power controller to request that the trace unit core power domain is powered up. However, if the trace unit and the processor are in the same power domain then the implementation might combine the PU status with a signal from the processor.	
		0	The system can remove power from the trace unit. The TRCPDSR indicates if the trace unit is powered down.
		1	The system must provide power to the trace unit.
2:0 (R/W)	RES0_TRCPDCR_2_0	0. Reserved, RES0.	

Trace Peripheral ID 0 Register

Returns information that helps identify the peripheral. If software reads the TRCPIDR[7:0] register group then it can determine the 64-bit CoreSight Peripheral ID for the ETM.

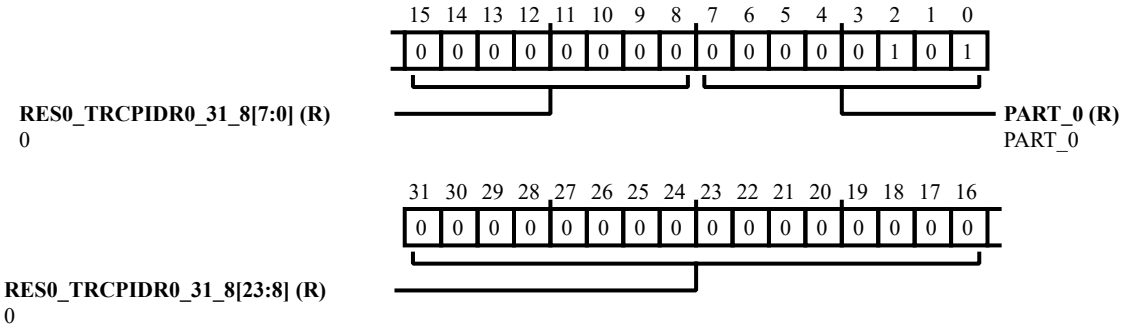

Figure 48-97: A55_CLUSTER_TRCPIDR0 Register Diagram

Table 48-95: A55_CLUSTER_TRCPIDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_TRCPIDR0_31_8	0. Reserved, RES0.
7:0 (R/NW)	PART_0	PART_0. Part number, bits[7:0].

Trace Peripheral ID 1 Register

Returns information that helps identify the peripheral. If software reads the TRCPIDR[7:0] register group then it can determine the 64-bit CoreSight Peripheral ID for the ETM.

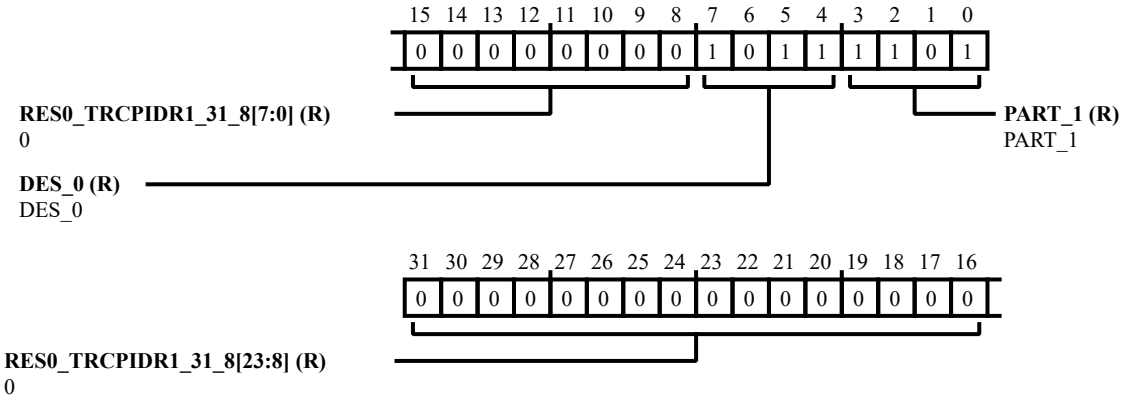

Figure 48-98: A55_CLUSTER_TRCPIDR1 Register Diagram

Table 48-96: A55_CLUSTER_TRCPIDR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_TRCPIDR1_31_8	0. Reserved, RES0.
7:4 (R/NW)	DES_0	DES_0. Designer, bits[3:0] of JEP106 ID code. For ARM Limited, this field is 0b1011.
3:0 (R/NW)	PART_1	PART_1. Part number, bits[11:8].

Trace Peripheral ID 2 Register

Returns information that helps identify the peripheral. If software reads the TRCPIDR[7:0] register group then it can determine the 64-bit CoreSight Peripheral ID for the ETM.

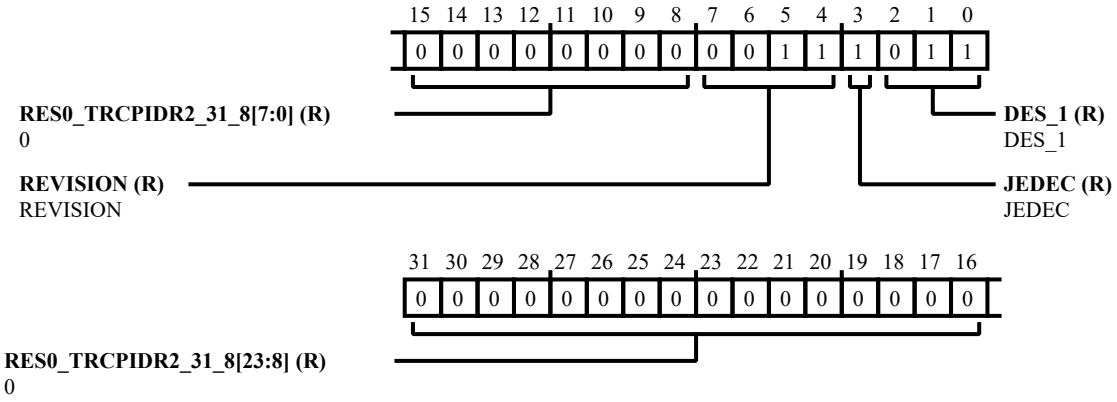

Figure 48-99: A55_CLUSTER_TRCPIDR2 Register Diagram

Table 48-97: A55_CLUSTER_TRCPIDR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_TRCPIDR2_31_8	0. Reserved, RES0.
7:4 (R/NW)	REVISION	REVISION. The IMPLEMENTATION DEFINED revision number for the ETM implementation. See also TRCIDR1.REVISION.
3 (R/NW)	JEDEC	JEDEC. RAO. Indicates a JEP106 identity code is used.
2:0 (R/NW)	DES_1	DES_1. Designer, most significant bits of JEP106 ID code. For ARM Limited, this field is 0b011.

Trace Peripheral ID 3 Register

Returns information that helps identify the peripheral. If software reads the TRCPIDR[7:0] register group then it can determine the 64-bit CoreSight Peripheral ID for the ETM.

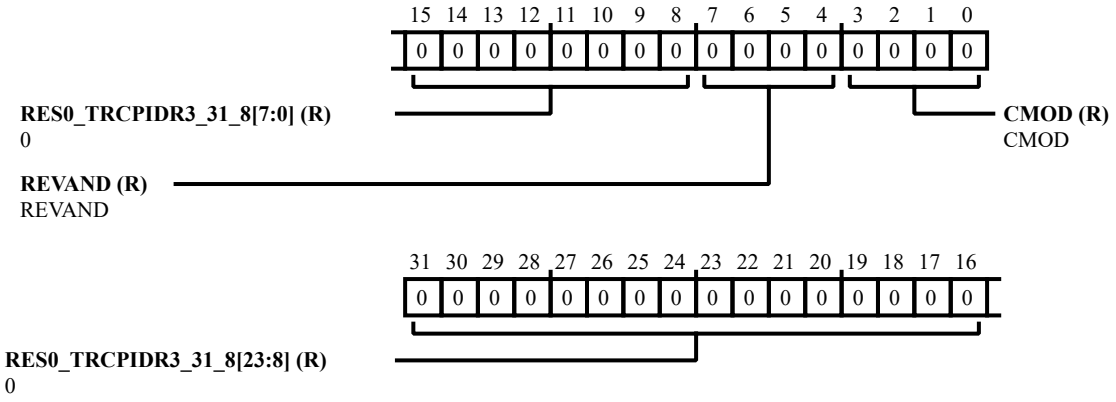

Figure 48-100: A55_CLUSTER_TRCPIDR3 Register Diagram

Table 48-98: A55_CLUSTER_TRCPIDR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_TRCPIDR3_31_8	0. Reserved, RES0.
7:4 (R/NW)	REVAND	REVAND. The IMPLEMENTATION DEFINED manufacturing revision number for the implementation. After silicon is available, if metal fixes are necessary, the manufacturer can alter the top metal layer so that this field can indicate any post-fab silicon changes.
3:0 (R/NW)	CMOD	CMOD. Customer modified. Indicates someone other than the Designer has modified the component.

Trace Peripheral ID 4 Register

Returns information that helps identify the peripheral. If software reads the TRCPIDR[7:0] register group then it can determine the 64-bit CoreSight Peripheral ID for the ETM.

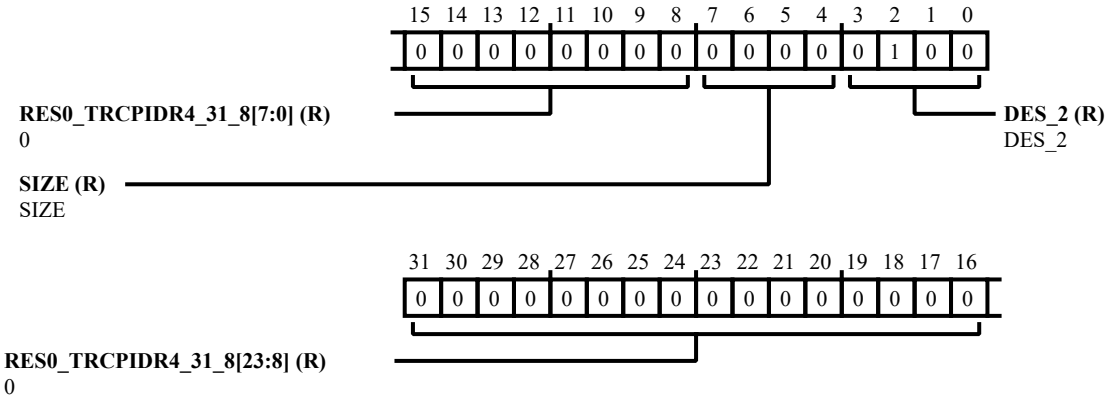

Figure 48-101: A55_CLUSTER_TRCPIDR4 Register Diagram

Table 48-99: A55_CLUSTER_TRCPIDR4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_TRCPIDR4_31_8	0. Reserved, RES0.
7:4 (R/NW)	SIZE	SIZE. Size of the component. RES0. This indicates that the ETM memory map occupies 4KB.
3:0 (R/NW)	DES_2	DES_2. Designer, JEP106 continuation code. For ARM Limited, this field is 0b0100.

Performance Monitors Authentication Status Register

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for Performance Monitors.

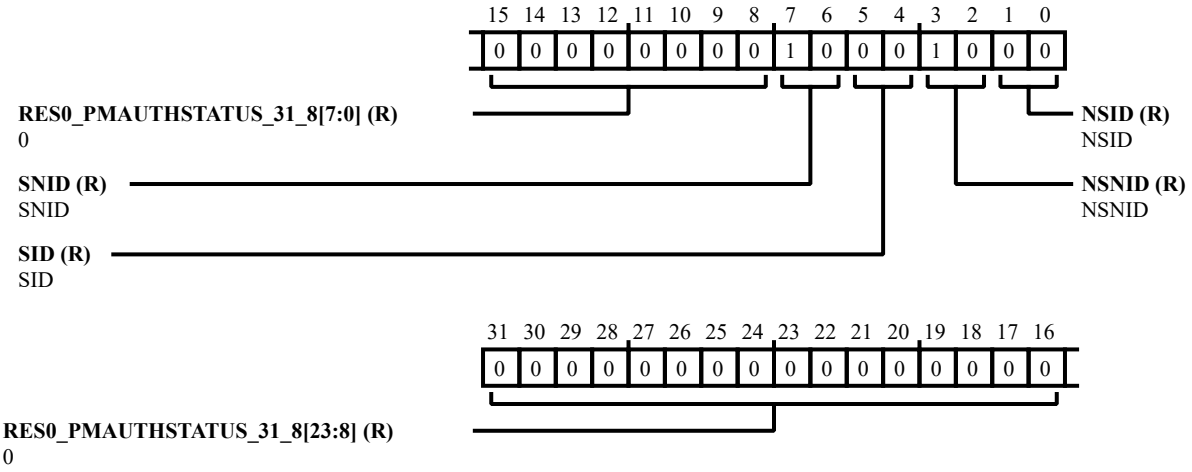

Figure 48-102: A55_CLUSTER_PMAUTHSTATUS Register Diagram

Table 48-100: A55_CLUSTER_PMAUTHSTATUS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:8 (R/NW)	RES0_PMAUTHSTATUS_31_8	0. Reserved, RES0.	
7:6 (R/NW)	SNID	SNID. Holds the same value as DBGAUTHSTATUS_EL1.SNID.	
5:4 (R/NW)	SID	SID. Secure invasive debug. Possible values of this field are: 00 Not implemented. All other values are reserved.	
		0	Not implemented.
3:2 (R/NW)	NSNID	NSNID. Holds the same value as DBGAUTHSTATUS_EL1.NSNID.	
1:0 (R/NW)	NSID	NSID. Non-secure invasive debug. Possible values of this field are: 00 Not implemented. All other values are reserved.	
		0	Not implemented.

Performance Monitors Component Identification 0 Register

Provides information to identify a Performance Monitor component.

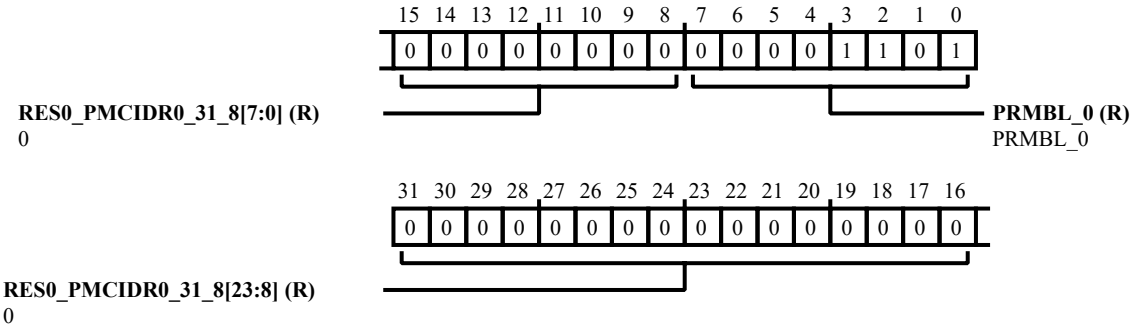

Figure 48-103: A55_CLUSTER_PMCIDR0 Register Diagram

Table 48-101: A55_CLUSTER_PMCIDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_PMCIDR0_31_8	0. Reserved, RES0.
7:0 (R/NW)	PRMBL_0	PRMBL_0. Preamble. Must read as 0x0D.

Performance Monitors Component Identification 1 Register

Provides information to identify a Performance Monitor component.

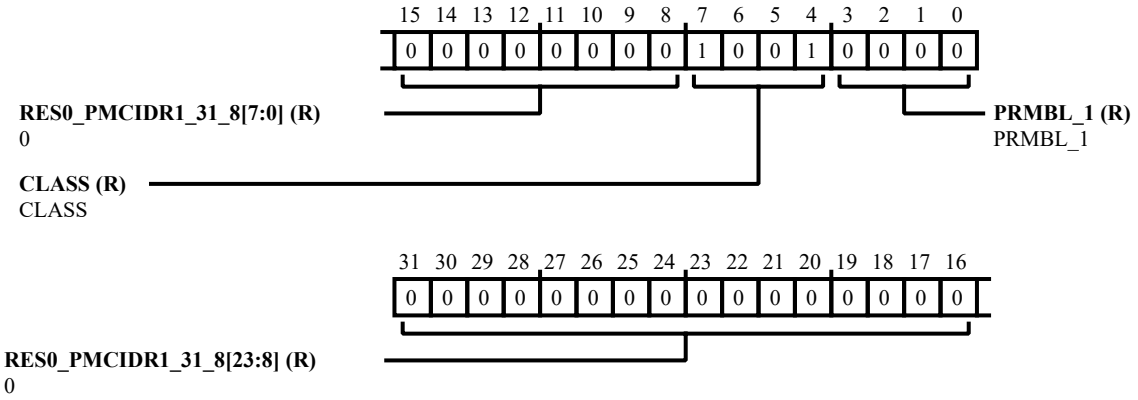

Figure 48-104: A55_CLUSTER_PMCIDR1 Register Diagram

Table 48-102: A55_CLUSTER_PMCIDR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_PMCIDR1_31_8	0. Reserved, RES0.
7:4 (R/NW)	CLASS	CLASS. Component class. Reads as 0x9, debug component.
3:0 (R/NW)	PRMBL_1	PRMBL_1. Preamble. RAZ.

Performance Monitors Component Identification 2 Register

Provides information to identify a Performance Monitor component.

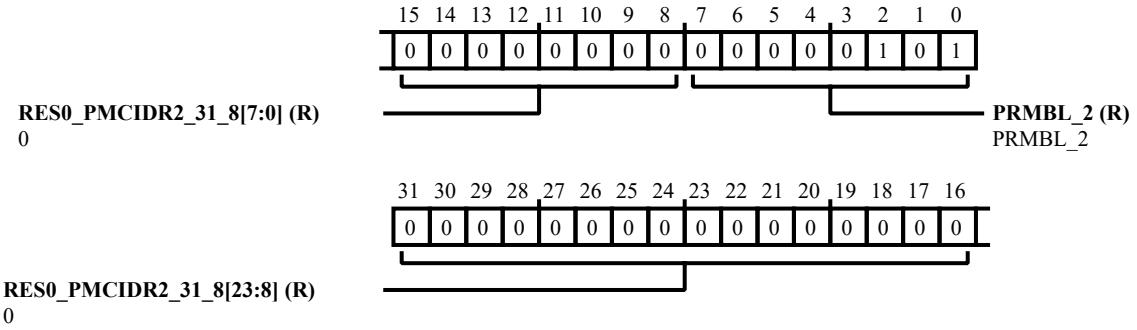

Figure 48-105: A55_CLUSTER_PMCIDR2 Register Diagram

Table 48-103: A55_CLUSTER_PMCIDR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_PMCIDR2_31_8	0. Reserved, RES0.
7:0 (R/NW)	PRMBL_2	PRMBL_2. Preamble. Must read as 0x05.

Performance Monitors Component Identification 3 Register

Provides information to identify a Performance Monitor component.

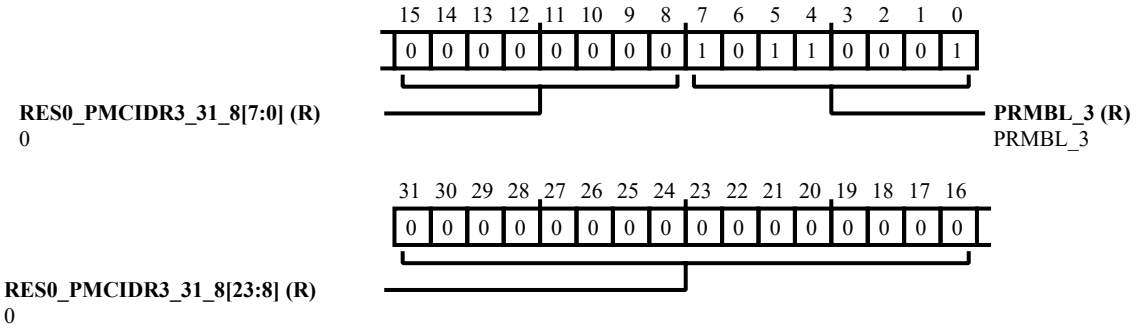

Figure 48-106: A55_CLUSTER_PMCIDR3 Register Diagram

Table 48-104: A55_CLUSTER_PMCIDR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_PMCIDR3_31_8	0. Reserved, RES0.
7:0 (R/NW)	PRMBL_3	PRMBL_3. Preamble. Must read as 0xB1.

Performance Monitors Device Affinity 0 Register

Copy of the low half of the PE MPIDR_EL1 register that allows a debugger to determine which PE in a multiprocessor system the Performance Monitor component relates to.

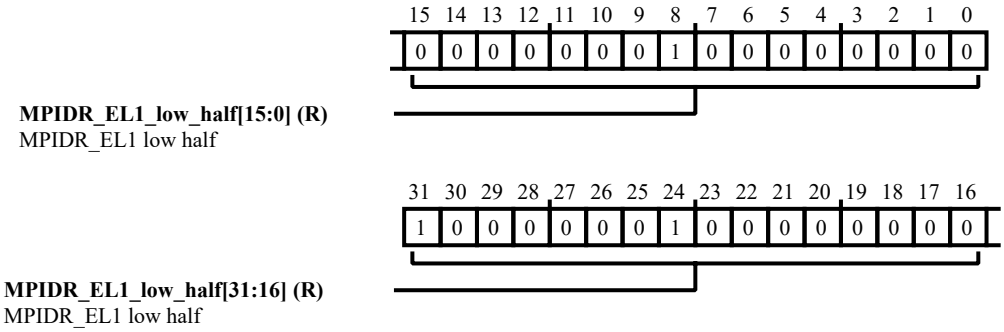

Figure 48-107: A55_CLUSTER_PMDEVAFF0 Register Diagram

Table 48-105: A55_CLUSTER_PMDEVAFF0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	MPIDR_EL1_LOW_HALF	MPIDR_EL1 low half. MPIDR_EL1 low half. Read-only copy of the low half of MPIDR_EL1, as seen from the highest implemented Exception level.

Performance Monitors Device Affinity 1 Register

Copy of the high half of the PE MPIDR_EL1 register that allows a debugger to determine which PE in a multiprocessor system the Performance Monitor component relates to.

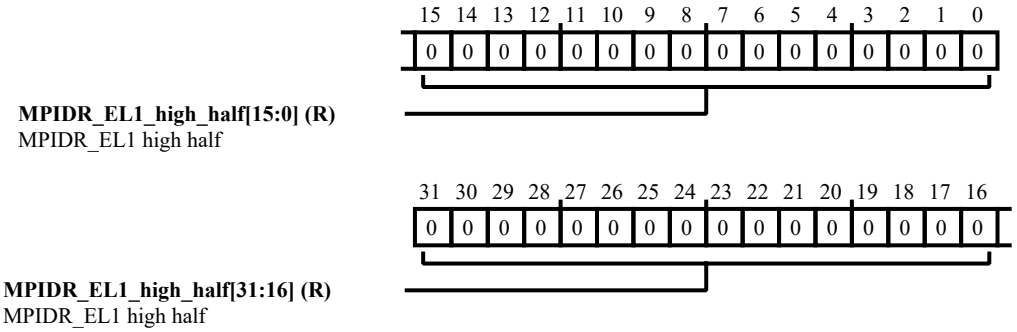

Figure 48-108: A55_CLUSTER_PMDEVAFF1 Register Diagram

Table 48-106: A55_CLUSTER_PMDEVAFF1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	MPIDR_EL1_HIGH_HALF	MPIDR_EL1 high half. MPIDR_EL1 high half. Read-only copy of the high half of MPIDR_EL1, as seen from the highest implemented Exception level.

Performance Monitors Device Architecture Register

Identifies the programmers' model architecture of the Performance Monitor component.

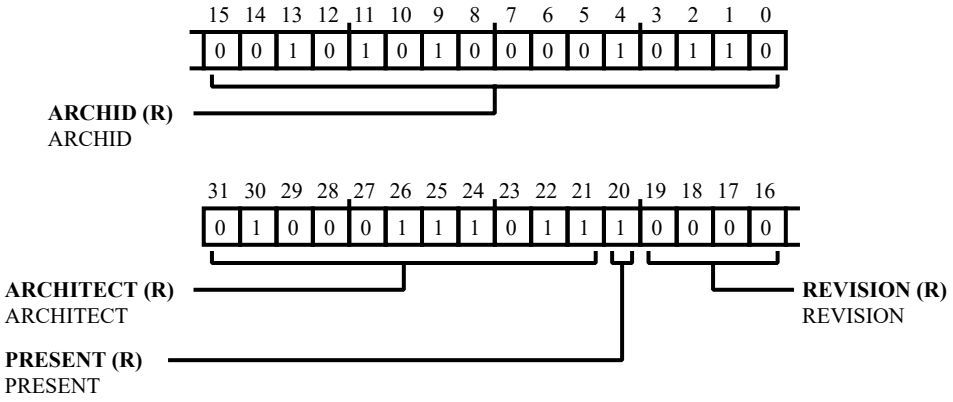

Figure 48-109: A55_CLUSTER_PMDEVARCH Register Diagram

Table 48-107: A55_CLUSTER_PMDEVARCH Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:21 (R/NW)	ARCHITECT	ARCHITECT. Defines the architecture of the component. For Performance Monitors, this is ARM Limited. Bits [31:28] are the JEP106 continuation code, 0x4. Bits [27:21] are the JEP106 ID code, 0x3B.
20 (R/NW)	PRESENT	PRESENT. When set to 1, indicates that the DEVARCH is present. This field is 1 in ARMv8.
19:16 (R/NW)	REVISION	REVISION. Defines the architecture revision. For architectures defined by ARM this is the minor revision. For Performance Monitors, the revision defined by ARMv8 is 0x0. All other values are reserved.
15:0 (R/NW)	ARCHID	ARCHID. Defines this part to be an ARMv8 debug component. For architectures defined by ARM this is further subdivided. For Performance Monitors: Bits [15:12] are the architecture version, 0x2. Bits [11:0] are the architecture part number, 0xA16. This corresponds to Performance Monitors architecture version PMUv3. The PMUv3 memory-mapped programmers' model can be used by devices other than ARMv8 processors. Software must determine whether the PMU is attached to an ARMv8 processor by using the PMDEVAFF0 and PMDEVAFF1 registers to discover the affinity of the PMU to any ARMv8 processors.

Performance Monitors Device Type Register

Indicates to a debugger that this component is part of a PEs performance monitor interface.

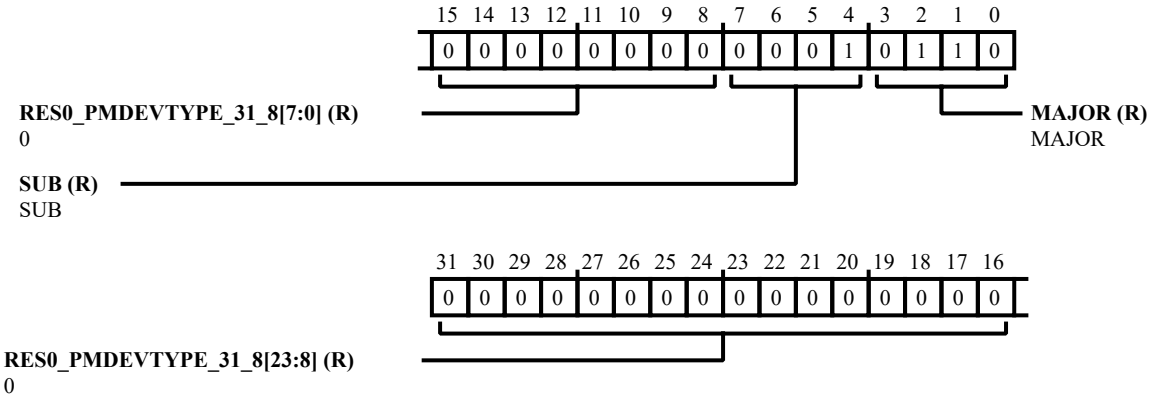

Figure 48-110: A55_CLUSTER_PMDEVTYPE Register Diagram

Table 48-108: A55_CLUSTER_PMDEVTYPE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_PMDEVTYPE_31_8	0. Reserved, RES0.
7:4 (R/NW)	SUB	SUB. Subtype. Must read as 0x1 to indicate this is a component within a PE.
3:0 (R/NW)	MAJOR	MAJOR. Major type. Must read as 0x6 to indicate this is a performance monitor component.

Performance Monitors Lock Access Register

Allows or disallows access to the Performance Monitors registers through a memory-mapped interface.

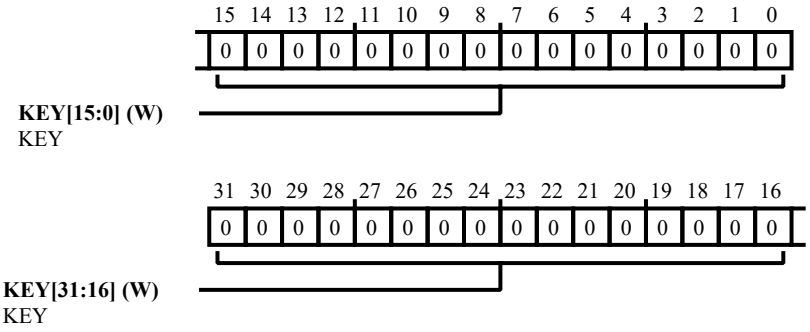

Figure 48-111: A55_CLUSTER_PMLAR Register Diagram

Table 48-109: A55_CLUSTER_PMLAR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (RX/W)	KEY	KEY. Lock Access control. Writing the key value 0xC5ACCE55 to this field unlocks the lock, enabling write accesses to this component's registers through a memory-mapped interface. Writing any other value to this register locks the lock, disabling write accesses to this component's registers through a memory mapped interface.

Performance Monitors Lock Status Register

Indicates the current status of the software lock for Performance Monitors registers.

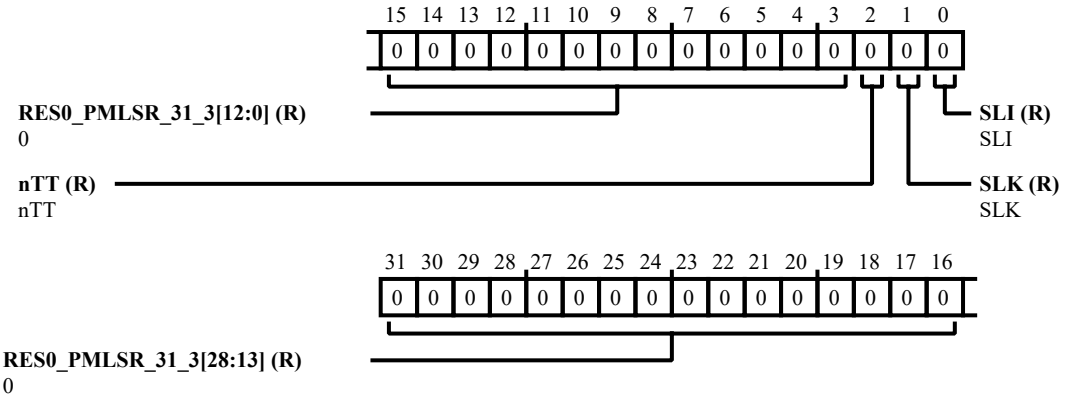

Figure 48-112: A55_CLUSTER_PMLSR Register Diagram

Table 48-110: A55_CLUSTER_PMLSR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:3 (R/NW)	RES0_PMLSR_31_3	0. Reserved, RES0.	
2 (R/NW)	NTT	nTT. Not thirty-two bit access required. RAZ.	
1 (R/NW)	SLK	SLK. Software Lock status for this component. For an access to LSR that is not a memory-mapped access, or when the Software Lock is not implemented, this field is RES0. For memory-mapped accesses when the software lock is implemented, possible values of this field are: 0 Lock clear. Writes are permitted to this component's registers. 1 Lock set. Writes to this component's registers are ignored, and reads have no side effects.	
		0	Lock clear. Writes are permitted to this component's registers.
		1	Lock set. Writes to this component's registers are ignored, and reads have no side effects.

Table 48-110: A55_CLUSTER_PMLSR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/NW)	SLI	SLI. Software Lock implemented. For an access to LSR that is not a memory-mapped access, this field is RAZ. For memory-mapped accesses, the value of this field is IMPLEMENTATION DEFINED. Permitted values are: 0 Software Lock not implemented or not memory-mapped access. 1 Software Lock implemented and memory-mapped access.	
		0	Software Lock not implemented or not memory-mapped access.
		1	Software Lock implemented and memory-mapped access.

Performance Monitors Peripheral Identification 0 Register

Provides information to identify a Performance Monitor component.

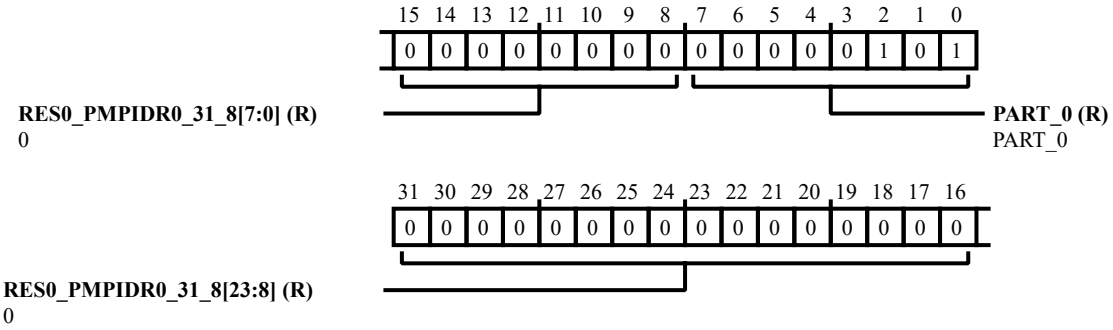

Figure 48-113: A55_CLUSTER_PMPIDR0 Register Diagram

Table 48-111: A55_CLUSTER_PMPIDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_PMPIDR0_31_8	0. Reserved, RES0.
7:0 (R/NW)	PART_0	PART_0. Part number, least significant byte.

Performance Monitors Peripheral Identification 1 Register

Provides information to identify a Performance Monitor component.

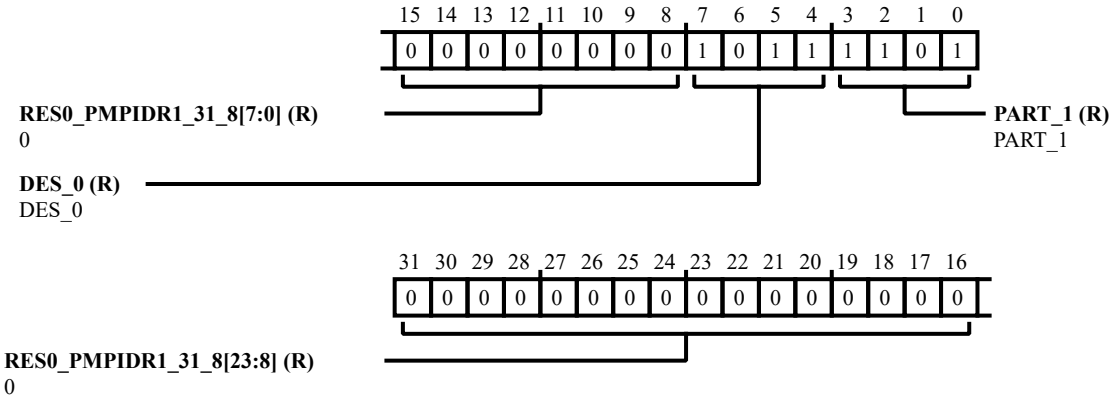

Figure 48-114: A55_CLUSTER_PMPIDR1 Register Diagram

Table 48-112: A55_CLUSTER_PMPIDR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_PMPIDR1_31_8	0. Reserved, RES0.
7:4 (R/NW)	DES_0	DES_0. Designer, least significant nibble of JEP106 ID code. For ARM Limited, this field is 0b1011.
3:0 (R/NW)	PART_1	PART_1. Part number, most significant nibble.

Performance Monitors Peripheral Identification 2 Register

Provides information to identify a Performance Monitor component.

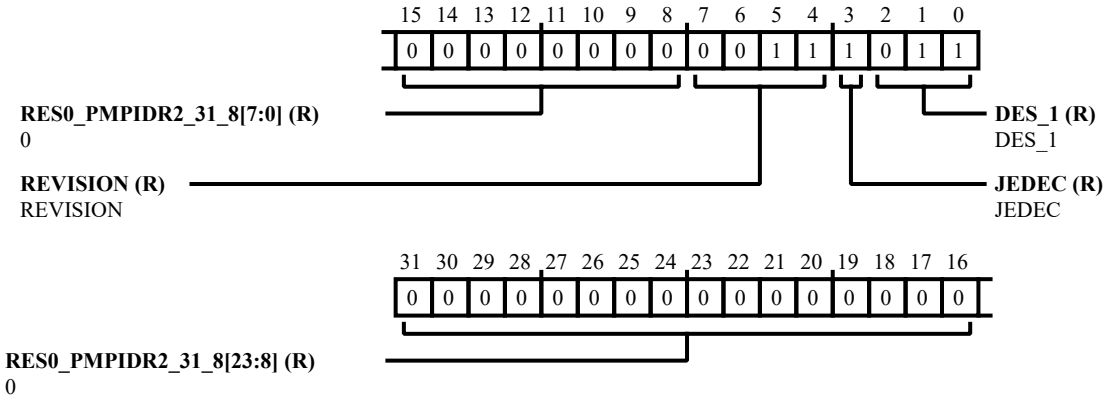

Figure 48-115: A55_CLUSTER_PMPIDR2 Register Diagram

Table 48-113: A55_CLUSTER_PMPIDR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_PMPIDR2_31_8	0. Reserved, RES0.
7:4 (R/NW)	REVISION	REVISION. Part major revision. Parts can also use this field to extend Part number to 16-bits.
3 (R/NW)	JEDEC	JEDEC. RAO. Indicates a JEP106 identity code is used.
2:0 (R/NW)	DES_1	DES_1. Designer, most significant bits of JEP106 ID code. For ARM Limited, this field is 0b011.

Performance Monitors Peripheral Identification 3 Register

Provides information to identify a Performance Monitor component.

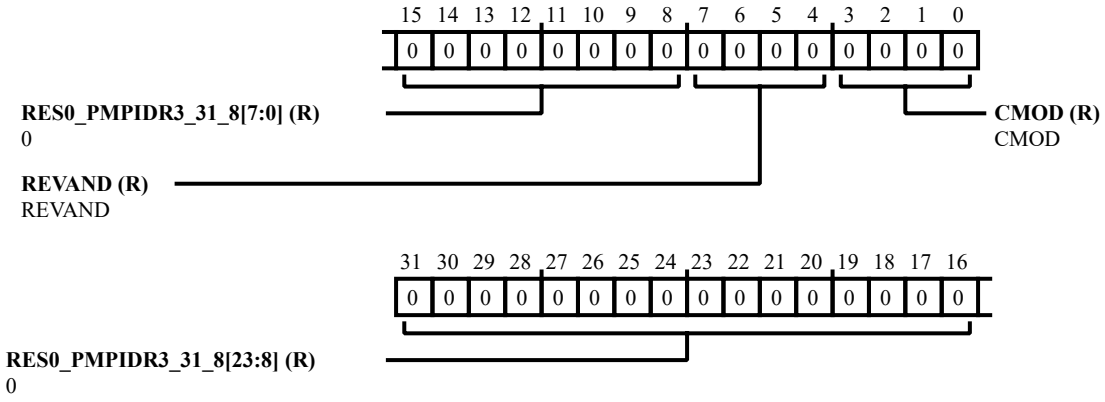

Figure 48-116: A55_CLUSTER_PMPIDR3 Register Diagram

Table 48-114: A55_CLUSTER_PMPIDR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_PMPIDR3_31_8	0. Reserved, RES0.
7:4 (R/NW)	REVAND	REVAND. Part minor revision. Parts using PMPIDR2.REVISION as an extension to the Part number must use this field as a major revision number.
3:0 (R/NW)	CMOD	CMOD. Customer modified. Indicates someone other than the Designer has modified the component.

Performance Monitors Peripheral Identification 4 Register

Provides information to identify a Performance Monitor component.

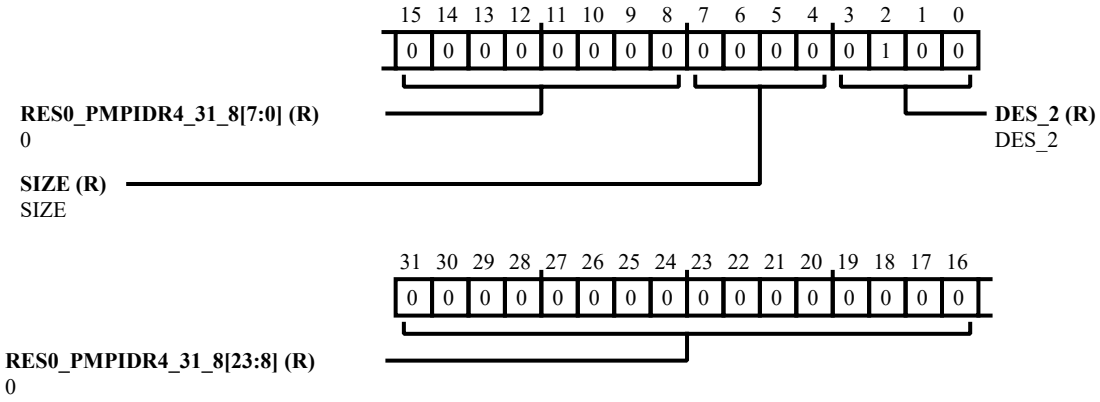

Figure 48-117: A55_CLUSTER_PMPIDR4 Register Diagram

Table 48-115: A55_CLUSTER_PMPIDR4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_PMPIDR4_31_8	0. Reserved, RES0.
7:4 (R/NW)	SIZE	SIZE. Size of the component. RAZ. Log2 of the number of 4KB pages from the start of the component to the end of the component ID registers.
3:0 (R/NW)	DES_2	DES_2. Designer, JEP106 continuation code, least significant nibble. For ARM Limited, this field is 0b0100.

Performance Monitors Peripheral Identification 5 Register

Provides information to identify a Performance Monitor component.

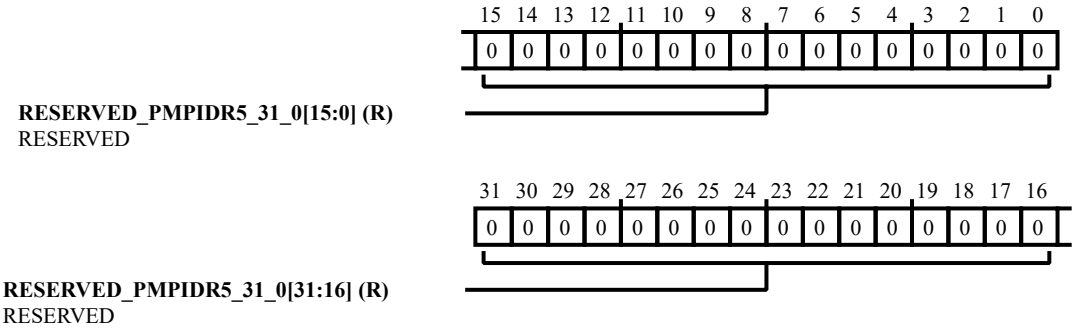

Figure 48-118: A55_CLUSTER_PMPIDR5 Register Diagram

Table 48-116: A55_CLUSTER_PMPIDR5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RESERVED_PMPIDR5_31_0	RESERVED. Reserved RES0.

Performance Monitors Peripheral Identification 6 Register

Provides information to identify a Performance Monitor component.

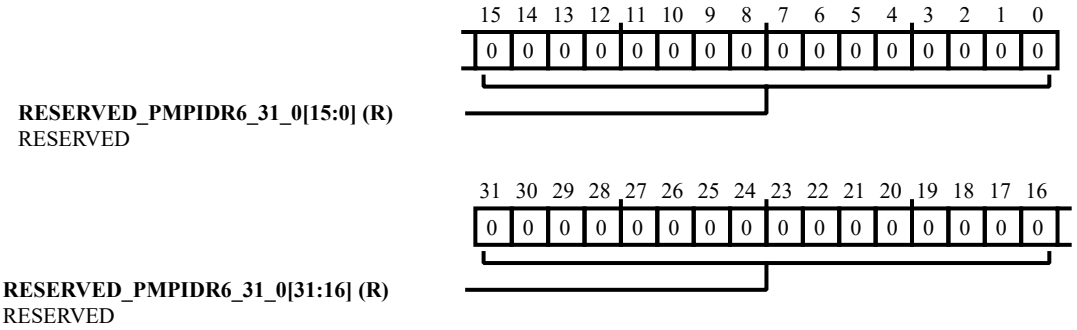

Figure 48-119: A55_CLUSTER_PMPIDR6 Register Diagram

Table 48-117: A55_CLUSTER_PMPIDR6 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RESERVED_PMPIDR6_31_0	RESERVED. Reserved RES0.

Performance Monitors Peripheral Identification 7 Register

Provides information to identify a Performance Monitor component.

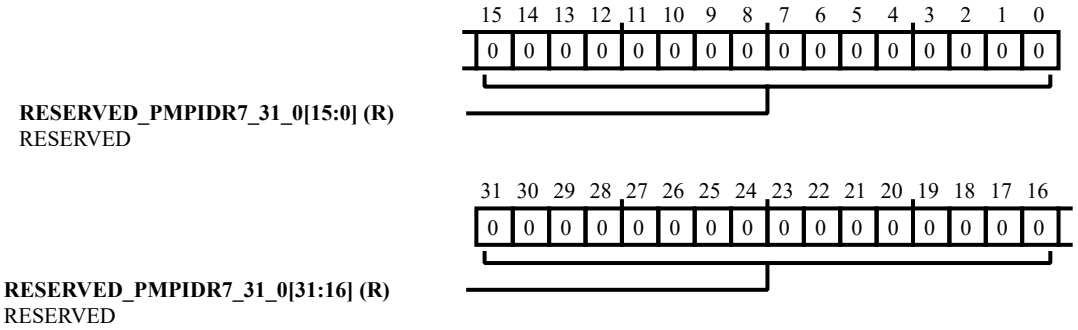

Figure 48-120: A55_CLUSTER_PMPIDR7 Register Diagram

Table 48-118: A55_CLUSTER_PMPIDR7 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RESERVED_PMPIDR7_31_0	RESERVED. Reserved RES0.

CTI External Multiplexer Control Register

Can be used to provide IMPLEMENTATION DEFINED controls for the CTI. For example, the register might be used to control multiplexors for additional IMPLEMENTATION DEFINED triggers. The IMPLEMENTATION DEFINED controls provided by this register might modify the architecturally defined behavior of the CTI. The architecturally-defined triggers must not be multiplexed.

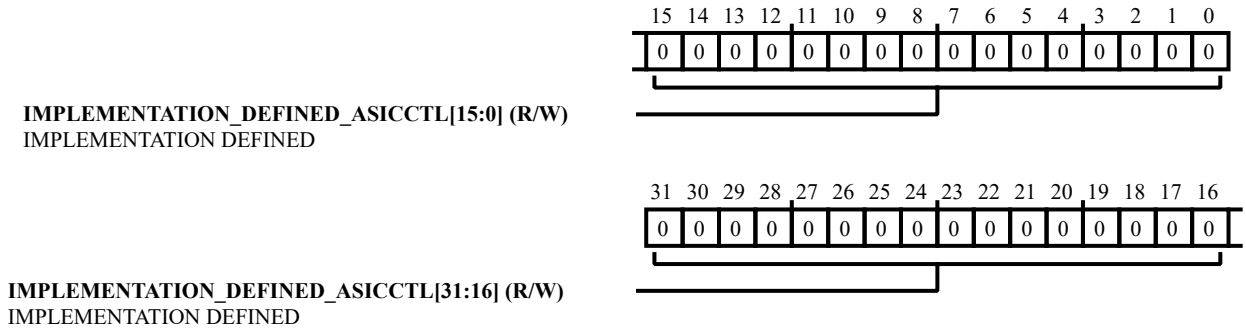

Figure 48-121: A55_CLUSTER_ASICCTL Register Diagram

Table 48-119: A55_CLUSTER_ASICCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	IMPLEMENTATION_DEFINED_ASICCTL	IMPLEMENTATION DEFINED. IMPLEMENTATION DEFINED.

CTI Application Trigger Clear Register

Clears bits of the Application Trigger register.

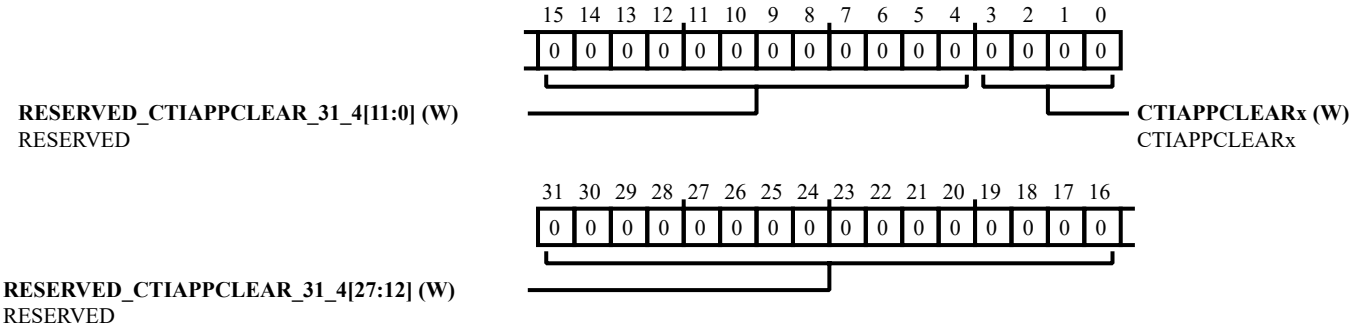

Figure 48-122: A55_CLUSTER_CTIAPPCLEAR Register Diagram

Table 48-120: A55_CLUSTER_CTIAPPCLEAR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (RX/W)	RESERVED_CTIAPP-CLEAR_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (RX/W)	CTIAPPCLEARX	CTIAPPCLEARx. Application trigger <x> disable.	
		0	No effect.
		1	Clear corresponding bit in CTIAPPTRIG to 0 and clear the corresponding channel event.

CTI Application Pulse Register

Causes event pulses to be generated on ECT channels.

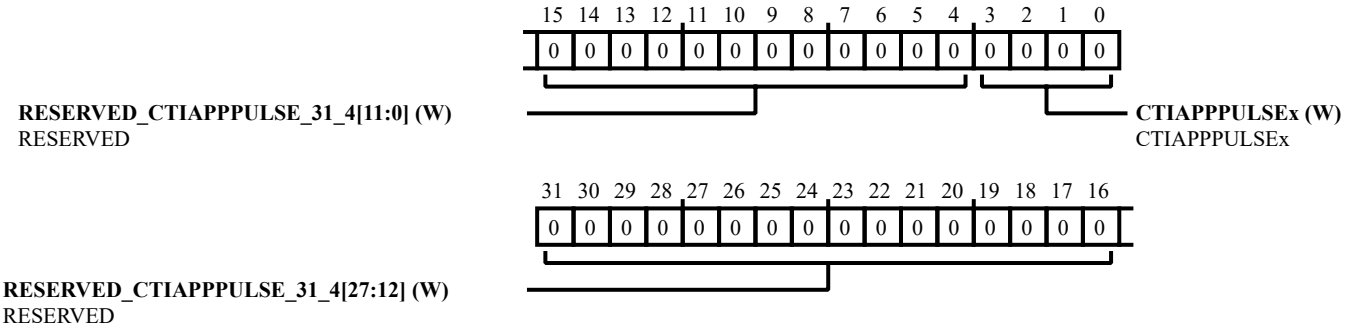

Figure 48-123: A55_CLUSTER_CTIAPPPULSE Register Diagram

Table 48-121: A55_CLUSTER_CTIAPPPULSE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (RX/W)	RESERVED_CTIAPP-PULSE_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (RX/W)	CTIAPPPULSEX	CTIAPPPULSEx. Generate event pulse on ECT channel <x>.	
		0	No effect.
		1	Channel <x> event pulse generated for one clock period.

CTI Application Trigger Set Register

Sets bits of the Application Trigger register.

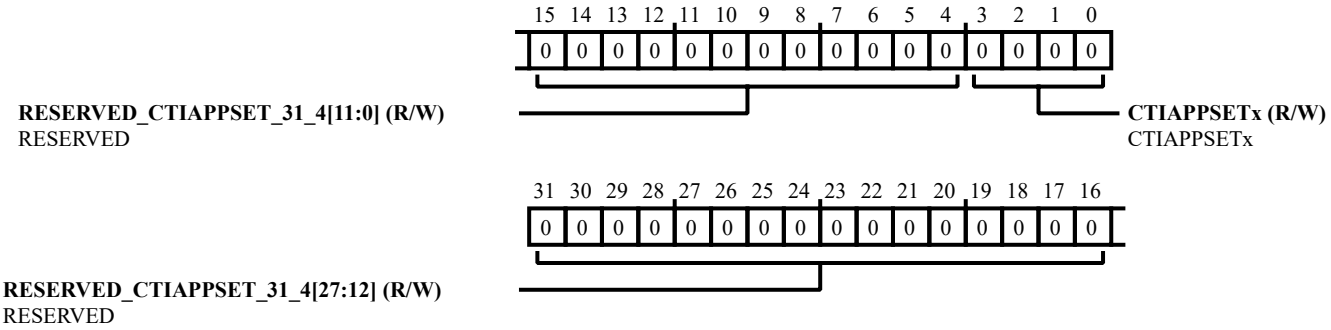

Figure 48-124: A55_CLUSTER_CTIAPPSET Register Diagram

Table 48-122: A55_CLUSTER_CTIAPPSET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/W)	RESERVED_CTIAP-PSET_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/W)	CTIAPPSETX	CTIAPPSETx. Application trigger <x> enable.	
		0	Reading this means the application trigger is inactive. Writing this has no effect.
		1	Reading this means the application trigger is active. Writing this sets the corresponding bit in CTIAPP-TRIG to 1 and generates a channel event.

CTI Authentication Status Register

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for CTI.

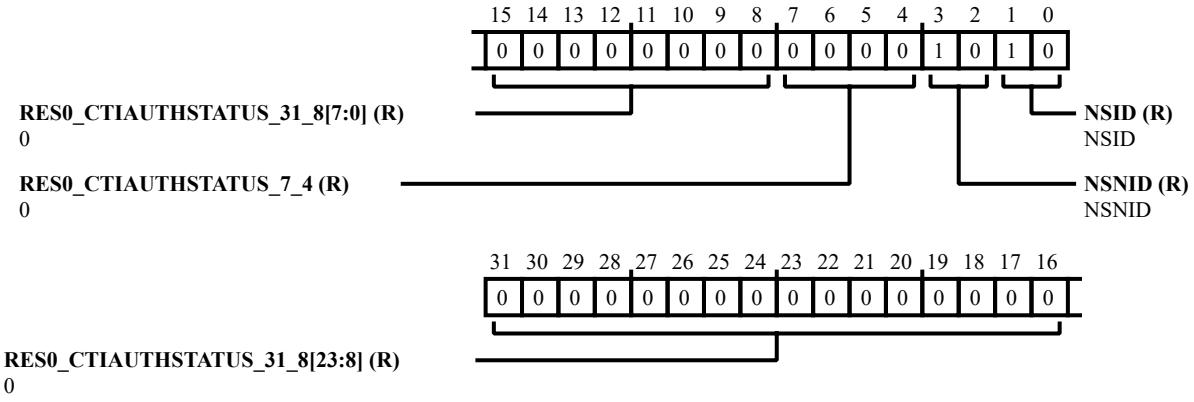

Figure 48-125: A55_CLUSTER_CTIAUTHSTATUS Register Diagram

Table 48-123: A55_CLUSTER_CTIAUTHSTATUS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_CTIAUTHSTATUS_31_8	0. Reserved, RES0.
7:4 (R/NW)	RES0_CTIAUTHSTATUS_7_4	0. Reserved, RAZ.
3:2 (R/NW)	NSNID	NSNID. If EL3 is not implemented and the implemented Security state is Secure state, holds the same value as DBGAUTHSTATUS_EL1.SNID. Otherwise, holds the same value as DBGAUTHSTATUS_EL1.NSNID.
1:0 (R/NW)	NSID	NSID. If EL3 is not implemented and the implemented Security state is Secure state, holds the same value as DBGAUTHSTATUS_EL1.SID. Otherwise, holds the same value as DBGAUTHSTATUS_EL1.NSID.

CTI Channel In Status Register

Provides the raw status of the ECT channel inputs to the CTI.

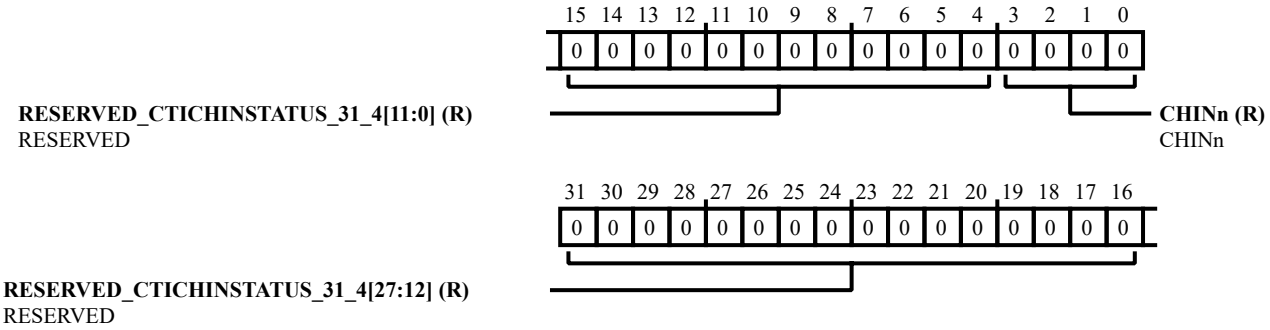

Figure 48-126: A55_CLUSTER_CTICHINSTATUS Register Diagram

Table 48-124: A55_CLUSTER_CTICHINSTATUS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RESERVED_CTICHIN-STATUS_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/NW)	CHINN	CHINn. Provides the raw status of the ECT channel inputs to the CTI.	
		0	Input channel <n> is inactive.
		1	Input channel <n> is active.

CTI Channel Out Status Register

Provides the status of the ECT channel outputs from the CTI.

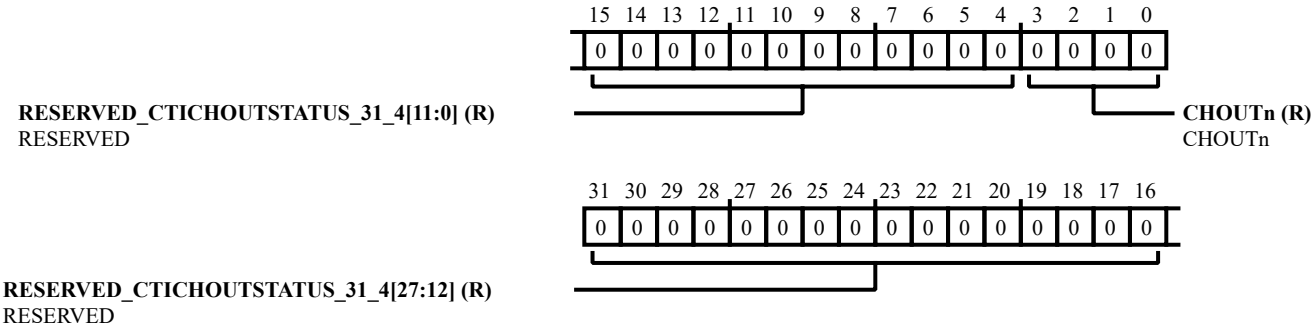

Figure 48-127: A55_CLUSTER_CTICHOUTSTATUS Register Diagram

Table 48-125: A55_CLUSTER_CTICHOUTSTATUS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RESERVED_CTICHOUT-STATUS_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/NW)	CHOUTN	CHOUTn. Provides the status of the ECT channel outputs from the CTI.	
		0	Output channel <n> is inactive.
		1	Output channel <n> is active.

CTI Component Identification 0 Register

Provides information to identify a CTI component.

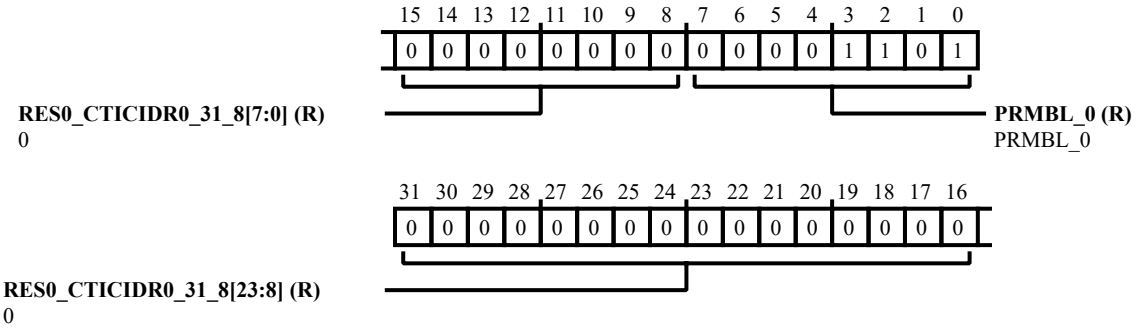

Figure 48-128: A55_CLUSTER_CTICIDR0 Register Diagram

Table 48-126: A55_CLUSTER_CTICIDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_CTICIDR0_31_8	0. Reserved, RES0.
7:0 (R/NW)	PRMBL_0	PRMBL_0. Preamble. Must read as 0x0D.

CTI Component Identification 1 Register

Provides information to identify a CTI component.

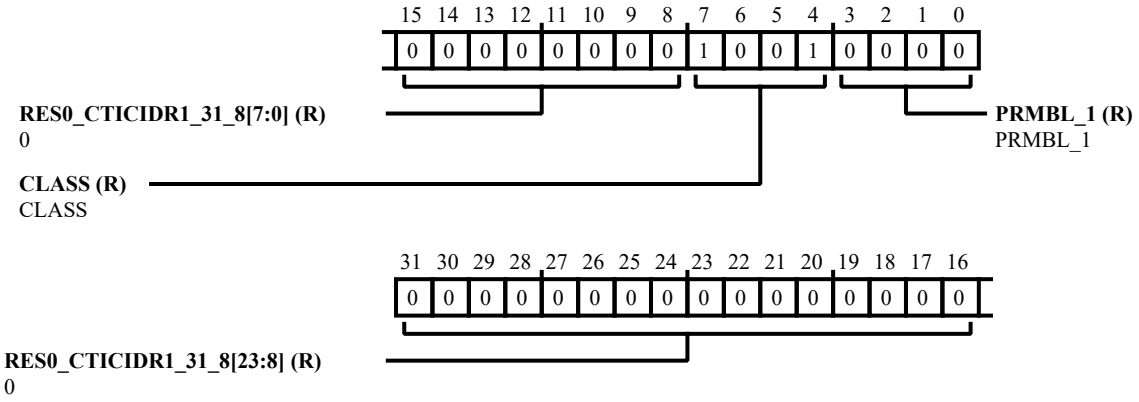

Figure 48-129: A55_CLUSTER_CTICIDR1 Register Diagram

Table 48-127: A55_CLUSTER_CTICIDR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_CTICIDR1_31_8	0. Reserved, RES0.
7:4 (R/NW)	CLASS	CLASS. Component class. Reads as 0x9, debug component.
3:0 (R/NW)	PRMBL_1	PRMBL_1. Preamble. RAZ.

CTI Component Identification 2 Register

Provides information to identify a CTI component.

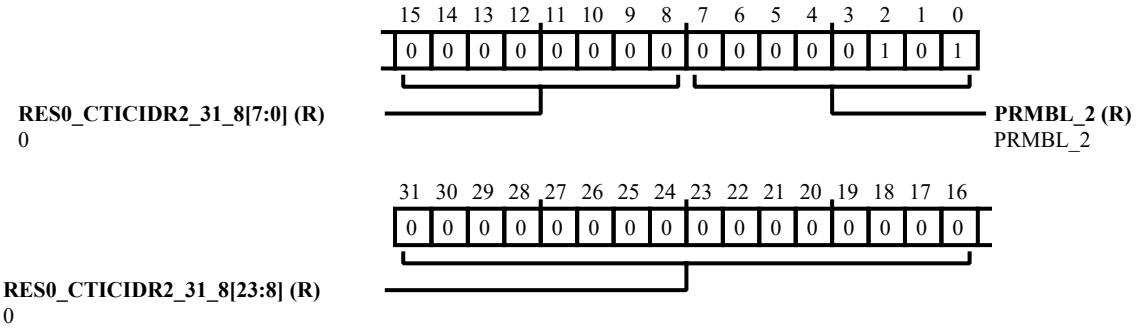

Figure 48-130: A55_CLUSTER_CTICIDR2 Register Diagram

Table 48-128: A55_CLUSTER_CTICIDR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_CTICIDR2_31_8	0. Reserved, RES0.
7:0 (R/NW)	PRMBL_2	PRMBL_2. Preamble. Must read as 0x05.

CTI Component Identification 3 Register

Provides information to identify a CTI component.

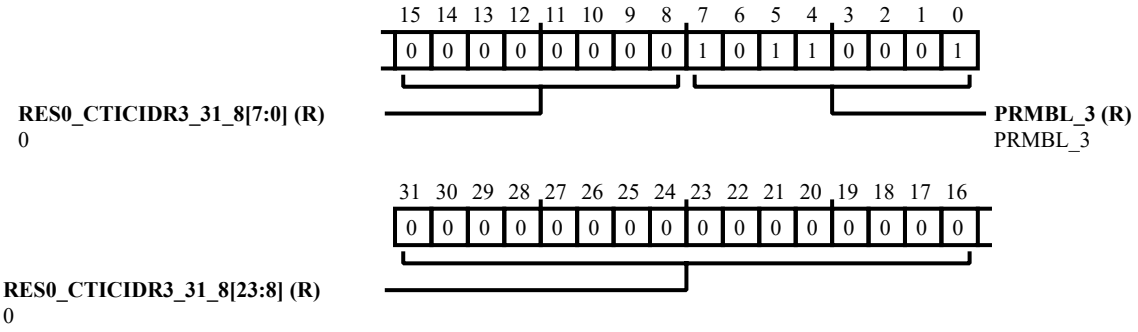

Figure 48-131: A55_CLUSTER_CTICIDR3 Register Diagram

Table 48-129: A55_CLUSTER_CTICIDR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_CTICIDR3_31_8	0. Reserved, RES0.
7:0 (R/NW)	PRMBL_3	PRMBL_3. Preamble. Must read as 0xB1.

CTI Claim Tag Clear Register

Used by software to read the values of the CLAIM bits, and to clear these bits to 0.

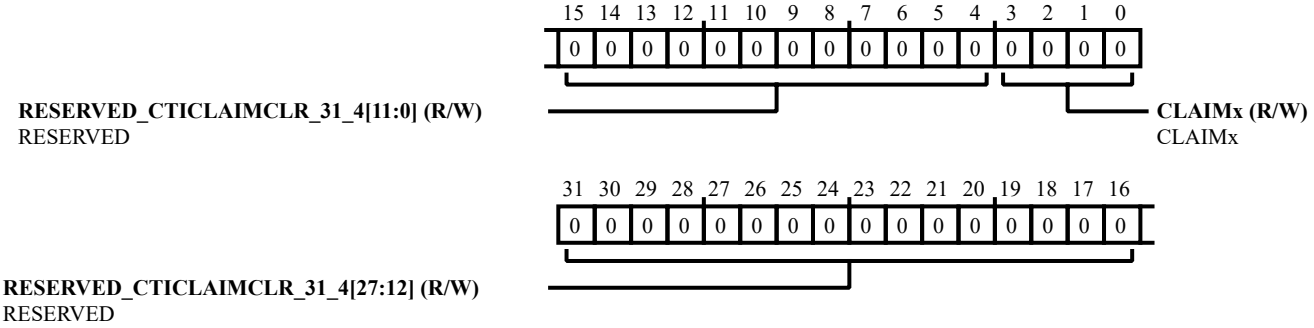

Figure 48-132: A55_CLUSTER_CTICLAIMCLR Register Diagram

Table 48-130: A55_CLUSTER_CTICLAIMCLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/W)	RESERVED_CTI-CLAIMCLR_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/W)	CLAIMX	CLAIMx. Clear CLAIM tag.	
		0	No action.
		1	Indirectly clear CLAIM[x] to 0.

CTI Claim Tag Set Register

Used by software to set CLAIM bits to 1.

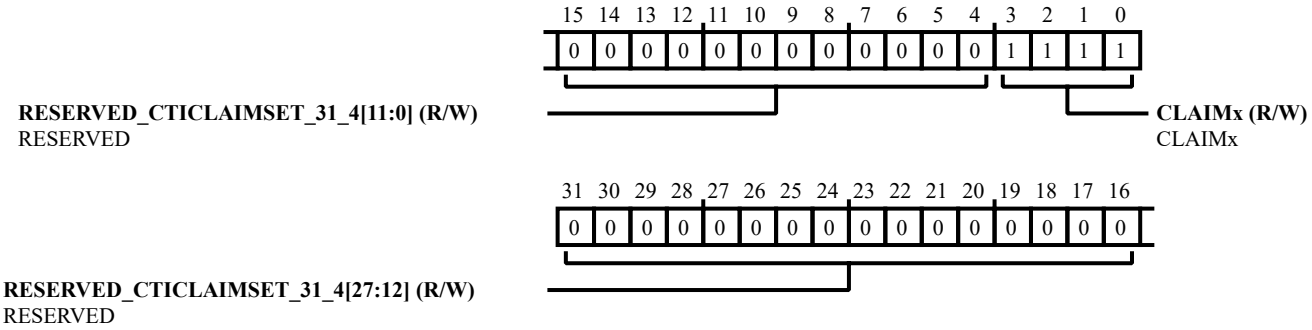

Figure 48-133: A55_CLUSTER_CTICLAIMSET Register Diagram

Table 48-131: A55_CLUSTER_CTICLAIMSET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/W)	RESERVED_CTICLAIM-SET_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/W)	CLAIMX	CLAIMx. CLAIM tag set bit.	
		0	No action.
		1	Indirectly set CLAIM[x] tag to 1.

CTI Control Register

Controls whether the CTI is enabled.

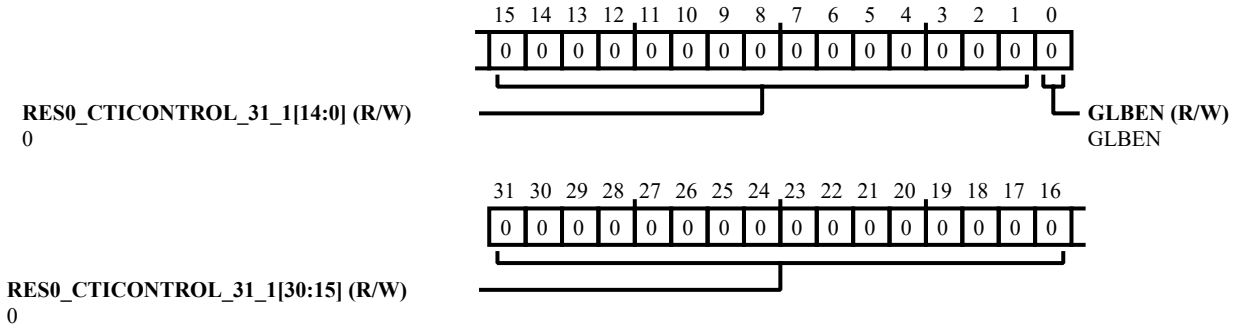

Figure 48-134: A55_CLUSTER_CTICONTROL Register Diagram

Table 48-132: A55_CLUSTER_CTICONTROL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:1 (R/W)	RES0_CTICON-TROL_31_1	0. Reserved, RES0.	
0 (R/W)	GLBEN	GLBEN. Enables or disables the CTI mapping functions. Possible values of this field are: 0 CTI mapping functions disabled. 1 CTI mapping functions enabled. When the mapping functions are disabled, no new events are signaled on either output triggers or output channels. If a previously asserted output trigger has not been acknowledged, it remains asserted after the mapping functions are disabled. All output triggers are disabled by CTI reset. If the ECT supports multicycle channel events any existing output channel events will be terminated.	
		0	CTI mapping functions disabled.
		1	CTI mapping functions enabled.

CTI Device Affinity 0 Register

Copy of the low half of the PE MPIDR_EL1 register that allows a debugger to determine which PE in a multiprocessor system the CTI component relates to.

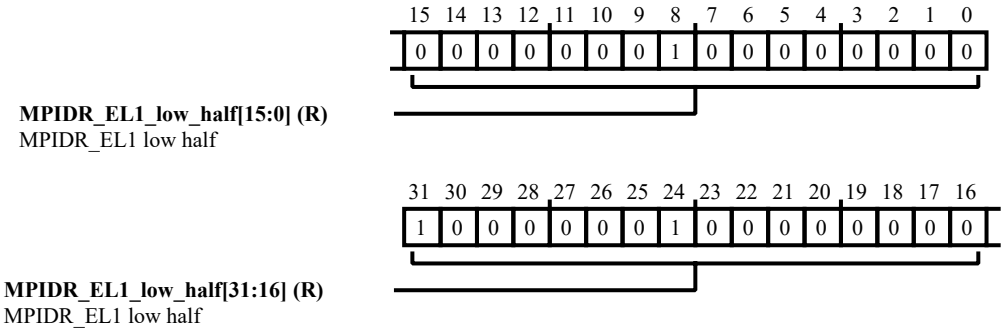

Figure 48-135: A55_CLUSTER_CTIDEVAFF0 Register Diagram

Table 48-133: A55_CLUSTER_CTIDEVAFF0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	MPIDR_EL1_LOW_HALF	MPIDR_EL1 low half. MPIDR_EL1 low half. Read-only copy of the low half of MPIDR_EL1, as seen from the highest implemented Exception level.

CTI Device Affinity 1 Register

Copy of the high half of the PE MPIDR_EL1 register that allows a debugger to determine which PE in a multiprocessor system the CTI component relates to.

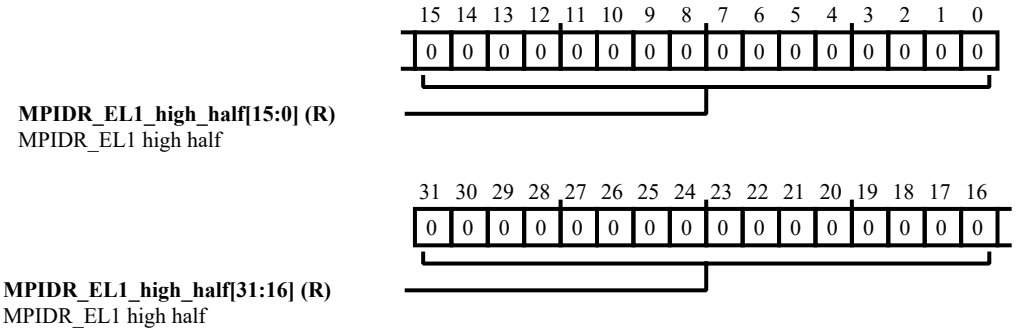

Figure 48-136: A55_CLUSTER_CTIDEVAFF1 Register Diagram

Table 48-134: A55_CLUSTER_CTIDEVAFF1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	MPIDR_EL1_HIGH_HALF	MPIDR_EL1 high half. MPIDR_EL1 high half. Read-only copy of the high half of MPIDR_EL1, as seen from the highest implemented Exception level.

CTI Device Architecture Register

Identifies the programmers' model architecture of the CTI component.

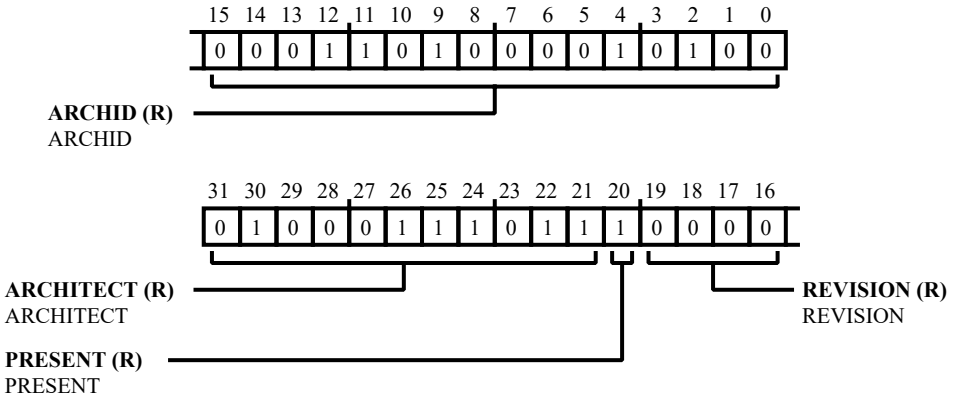

Figure 48-137: A55_CLUSTER_CTIDEVARCH Register Diagram

Table 48-135: A55_CLUSTER_CTIDEVARCH Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:21 (R/NW)	ARCHITECT	ARCHITECT. Defines the architecture of the component. For CTI, this is ARM Limited. Bits [31:28] are the JEP106 continuation code, 0x4. Bits [27:21] are the JEP106 ID code, 0x3B.
20 (R/NW)	PRESENT	PRESENT. When set to 1, indicates that the DEVARCH is present. This field is 1 in ARMv8.
19:16 (R/NW)	REVISION	REVISION. Defines the architecture revision. For architectures defined by ARM this is the minor revision. For CTI, the revision defined by ARMv8 is 0x0. All other values are reserved.
15:0 (R/NW)	ARCHID	ARCHID. Defines this part to be an ARMv8 debug component. For architectures defined by ARM this is further subdivided. For CTI: Bits [15:12] are the architecture version, 0x1. Bits [11:0] are the architecture part number, 0xA14. This corresponds to CTI architecture version CTIv2.

CTI Device ID 0 Register

Describes the CTI component to the debugger.

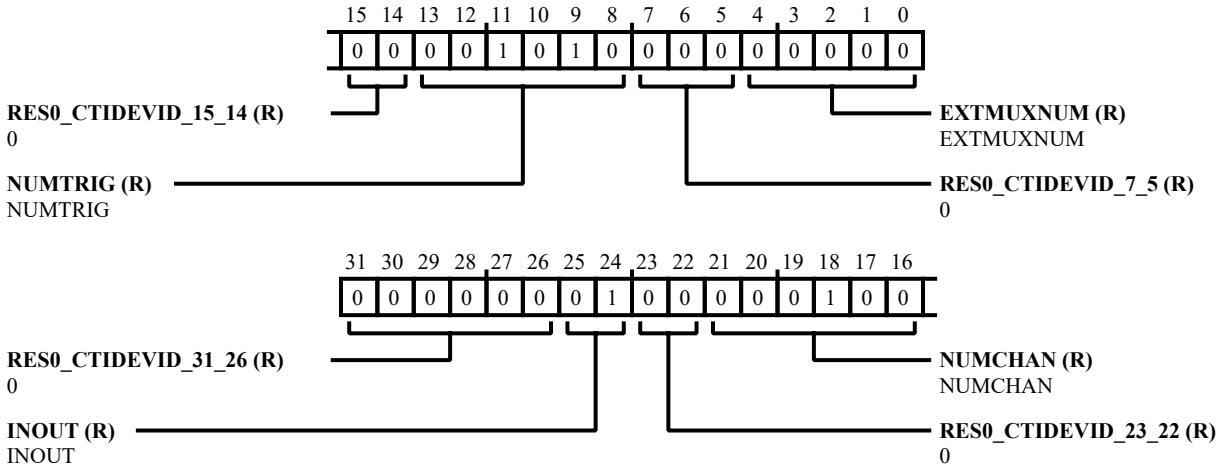

Figure 48-138: A55_CLUSTER_CTIDEVID Register Diagram

Table 48-136: A55_CLUSTER_CTIDEVID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:26 (R/NW)	RES0_CTIDEVID_31_26	0. Reserved, RES0.	
25:24 (R/NW)	INOUT	INOUT. Input/output options. Indicates presence of the input gate. If the CTM is not implemented, this field is RAZ. 00 CTIGATE does not mask propagation of input events from external channels. 01 CTIGATE masks propagation of input events from external channels. All other values are reserved.	
		0	CTIGATE does not mask propagation of input events from external channels.
		1	CTIGATE masks propagation of input events from external channels.
23:22 (R/NW)	RES0_CTIDEVID_23_22	0. Reserved, RES0.	

Table 48-136: A55_CLUSTER_CTIDEVID Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
21:16 (R/NW)	NUMCHAN	NUMCHAN. Number of ECT channels implemented. IMPLEMENTATION DEFINED. For ARMv8, valid values are: 000011 3 channels (0..2) implemented. 000100 4 channels (0..3) implemented. 000101 5 channels (0..4) implemented. 000110 6 channels (0..5) implemented. and so on up to 100000, 32 channels (0..31) implemented. All other values are reserved.	
		3	3 channels (0..2) implemented.
		4	4 channels (0..3) implemented.
		5	5 channels (0..4) implemented.
		6	6 channels (0..5) implemented.
15:14 (R/NW)	RES0_CTIDEVID_15_14	0. Reserved, RES0.	
13:8 (R/NW)	NUMTRIG	NUMTRIG. Number of triggers implemented. IMPLEMENTATION DEFINED. This is one more than the index of the largest trigger, rather than the actual number of triggers. For ARMv8, valid values are: 000011 Up to 3 triggers (0..2) implemented. 001000 Up to 8 triggers (0..7) implemented. 001001 Up to 9 triggers (0..8) implemented. 001010 Up to 10 triggers (0..9) implemented. and so on up to 100000, 32 triggers (0..31) implemented. All other values are reserved. If the contains a Trace extension, this field must be at least 0b001000. There is no guarantee that any of the implemented triggers, including the highest numbered, are connected to any components.	
		3	Up to 3 triggers (0..2) implemented.
		8	Up to 8 triggers (0..7) implemented.
		9	Up to 9 triggers (0..8) implemented.
		10	Up to 10 triggers (0..9) implemented.
7:5 (R/NW)	RES0_CTIDEVID_7_5	0. Reserved, RES0.	
4:0 (R/NW)	EXTMUXNUM	EXTMUXNUM. Number of multiplexors available on triggers. This value is used in conjunction with External Control register, ASICCTL.	

CTI Device ID 1 Register

Reserved for future information about the CTI component to the debugger.

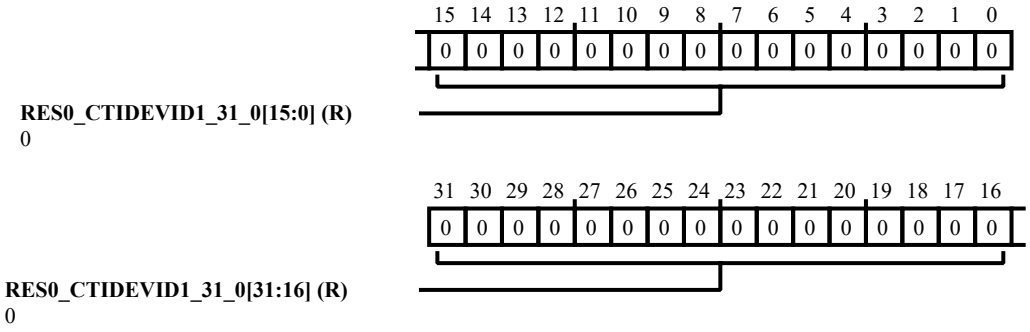

Figure 48-139: A55_CLUSTER_CTIDEVID1 Register Diagram

Table 48-137: A55_CLUSTER_CTIDEVID1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RES0_CTIDEVID1_31_0	0. Reserved, RES0.

CTI Device ID 2 Register

Reserved for future information about the CTI component to the debugger.

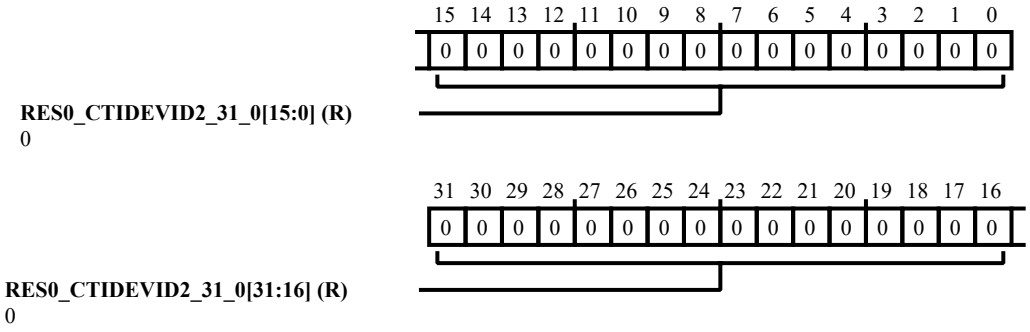

Figure 48-140: A55_CLUSTER_CTIDEVID2 Register Diagram

Table 48-138: A55_CLUSTER_CTIDEVID2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RES0_CTIDEVID2_31_0	0. Reserved, RES0.

CTI Device Type Register

Indicates to a debugger that this component is part of a PEs cross-trigger interface.

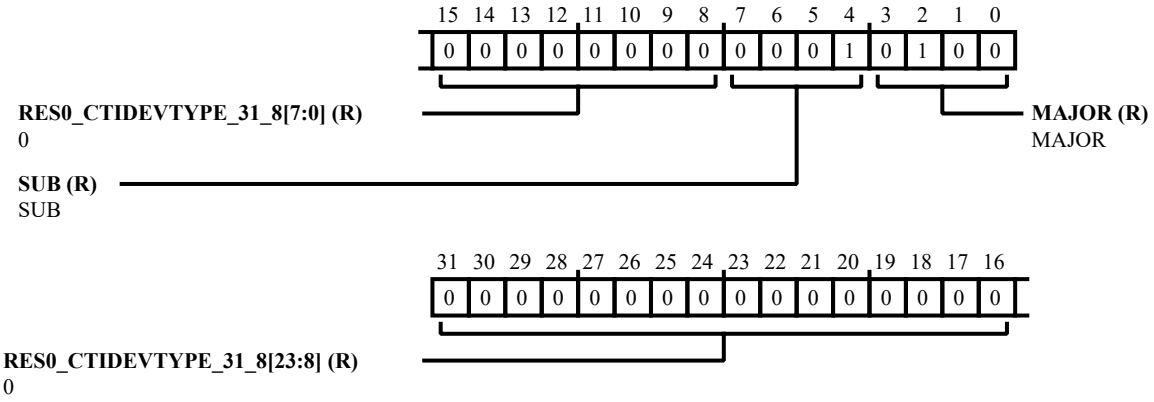

Figure 48-141: A55_CLUSTER_CTIDEVTYPE Register Diagram

Table 48-139: A55_CLUSTER_CTIDEVTYPE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_CTIDEV-TYPE_31_8	0. Reserved, RES0.
7:4 (R/NW)	SUB	SUB. Subtype. Must read as 0x1 to indicate this is a component within a PE.
3:0 (R/NW)	MAJOR	MAJOR. Major type. Must read as 0x4 to indicate this is a cross-trigger component.

CTI Channel Gate Enable Register

Determines whether events on channels propagate through the CTM to other ECT components, or from the CTM into the CTI.

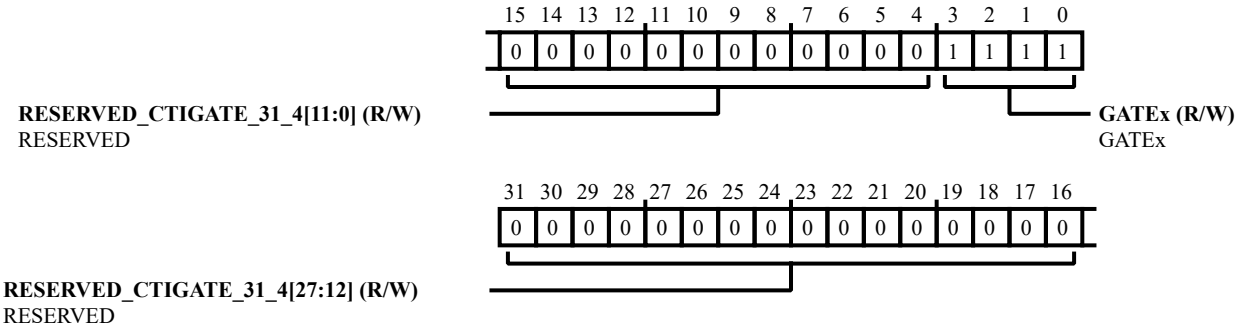

Figure 48-142: A55_CLUSTER_CTIGATE Register Diagram

Table 48-140: A55_CLUSTER_CTIGATE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/W)	RESERVED_CTI-GATE_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/W)	GATEX	GATEx. Determines whether events on channels propagate through the CTM to other ECT components or from the CTM into the CTI.	
		0	Disable output and if CTIDEVID.INOUT == 0b01 input channel <x> propagation.
		1	Enable output and if CTIDEVID.INOUT == 0b01 input channel <x> propagation.

CTI Input Trigger to Output Channel Enable 0 Register

Enables the signaling of an event on output channels when input trigger event n is received by the CTI.

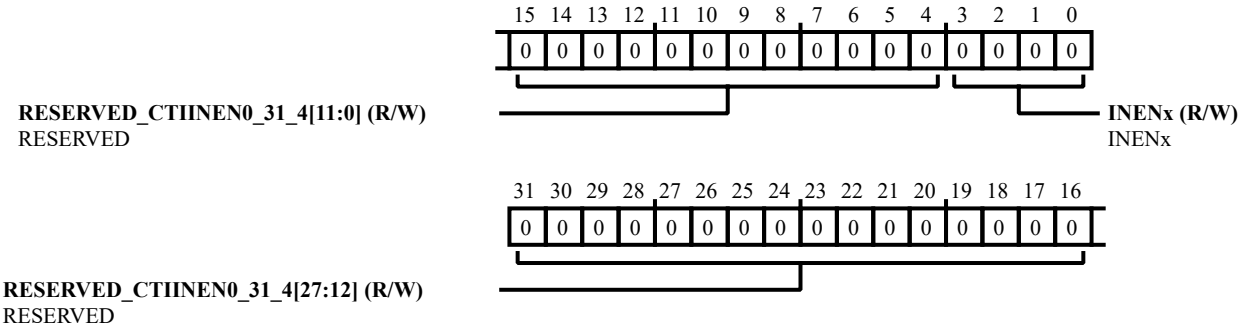

Figure 48-143: A55_CLUSTER_CTIINEN0 Register Diagram

Table 48-141: A55_CLUSTER_CTIINEN0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/W)	RESERVED_CTII-NEN0_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/W)	INENX	INENx. Input trigger 0 to output channel <x> enable.	
		0	Input trigger 0 will not generate an event on output channel <x>.
		1	Input trigger 0 will generate an event on output channel <x>.

CTI Input Trigger to Output Channel Enable 1 Register

Enables the signaling of an event on output channels when input trigger event n is received by the CTI.

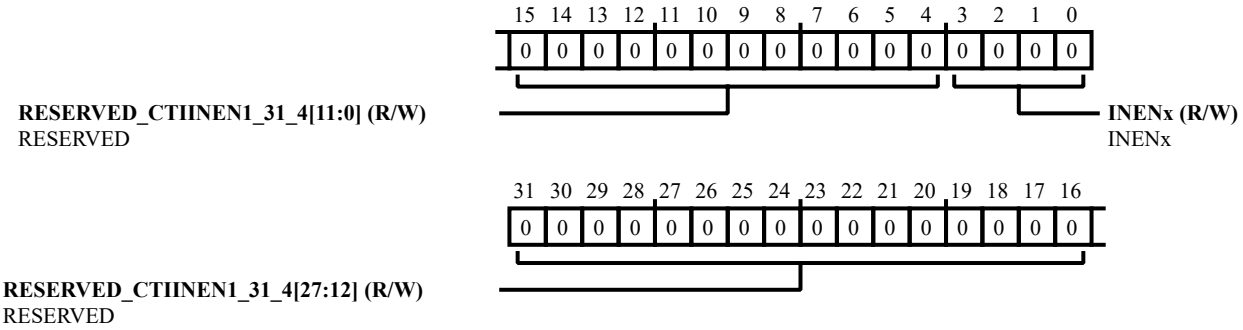

Figure 48-144: A55_CLUSTER_CTIINEN1 Register Diagram

Table 48-142: A55_CLUSTER_CTIINEN1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/W)	RESERVED_CTII-NEN1_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/W)	INENX	INENx. Input trigger 1 to output channel <x> enable.	
		0	Input trigger 1 will not generate an event on output channel <x>.
		1	Input trigger 1 will generate an event on output channel <x>.

CTI Input Trigger to Output Channel Enable 2 Register

Enables the signaling of an event on output channels when input trigger event n is received by the CTI.

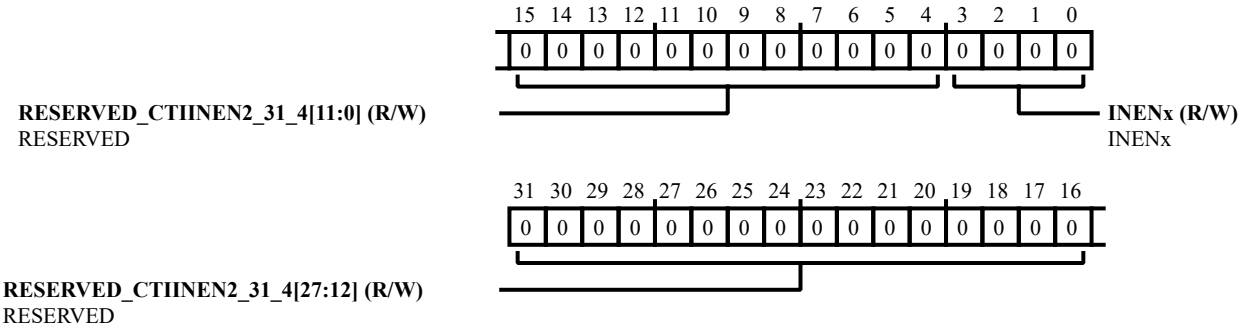

Figure 48-145: A55_CLUSTER_CTIINEN2 Register Diagram

Table 48-143: A55_CLUSTER_CTIINEN2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/W)	RESERVED_CTII-NEN2_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/W)	INENX	INENx. Input trigger 2 to output channel <x> enable.	
		0	Input trigger 2 will not generate an event on output channel <x>.
		1	Input trigger 2 will generate an event on output channel <x>.

CTI Input Trigger to Output Channel Enable 3 Register

Enables the signaling of an event on output channels when input trigger event n is received by the CTI.

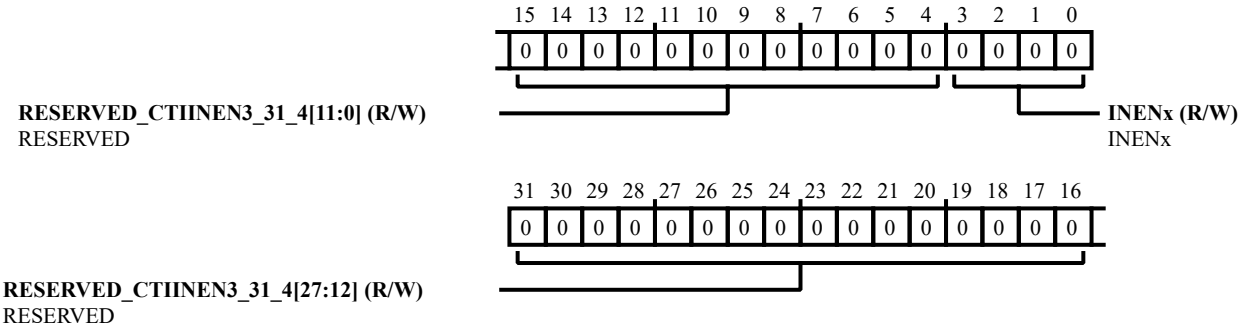

Figure 48-146: A55_CLUSTER_CTIINEN3 Register Diagram

Table 48-144: A55_CLUSTER_CTIINEN3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/W)	RESERVED_CTII-NEN3_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/W)	INENX	INENx. Input trigger 3 to output channel <x> enable.	
		0	Input trigger 3 will not generate an event on output channel <x>.
		1	Input trigger 3 will generate an event on output channel <x>.

CTI Input Trigger to Output Channel Enable 4 Register

Enables the signaling of an event on output channels when input trigger event n is received by the CTI.

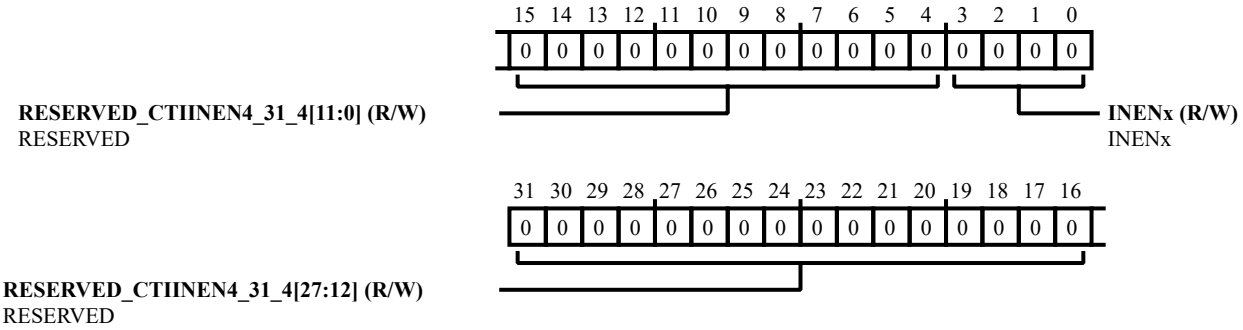

Figure 48-147: A55_CLUSTER_CTIINEN4 Register Diagram

Table 48-145: A55_CLUSTER_CTIINEN4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/W)	RESERVED_CTII-NEN4_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/W)	INENX	INENx. Input trigger 4 to output channel <x> enable.	
		0	Input trigger 4 will not generate an event on output channel <x>.
		1	Input trigger 4 will generate an event on output channel <x>.

CTI Input Trigger to Output Channel Enable 5 Register

Enables the signaling of an event on output channels when input trigger event n is received by the CTI.

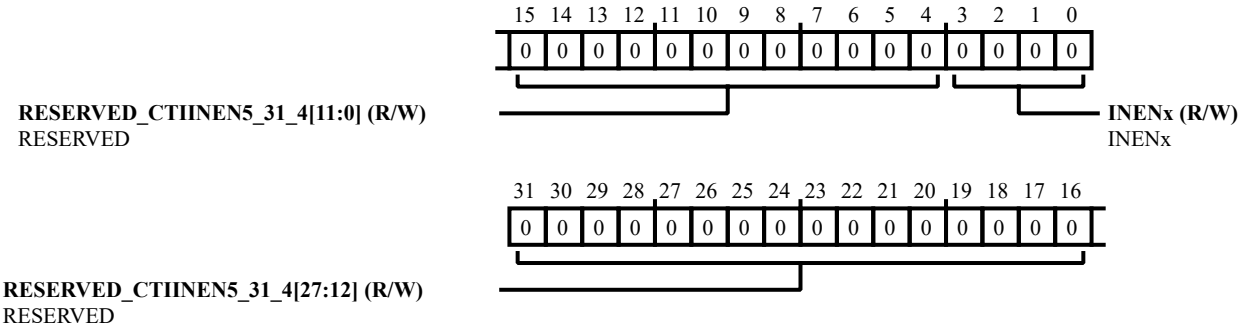

Figure 48-148: A55_CLUSTER_CTIINEN5 Register Diagram

Table 48-146: A55_CLUSTER_CTIINEN5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/W)	RESERVED_CTII-NEN5_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/W)	INENX	INENx. Input trigger 5 to output channel <x> enable.	
		0	Input trigger 5 will not generate an event on output channel <x>.
		1	Input trigger 5 will generate an event on output channel <x>.

CTI Input Trigger to Output Channel Enable 6 Register

Enables the signaling of an event on output channels when input trigger event n is received by the CTI.

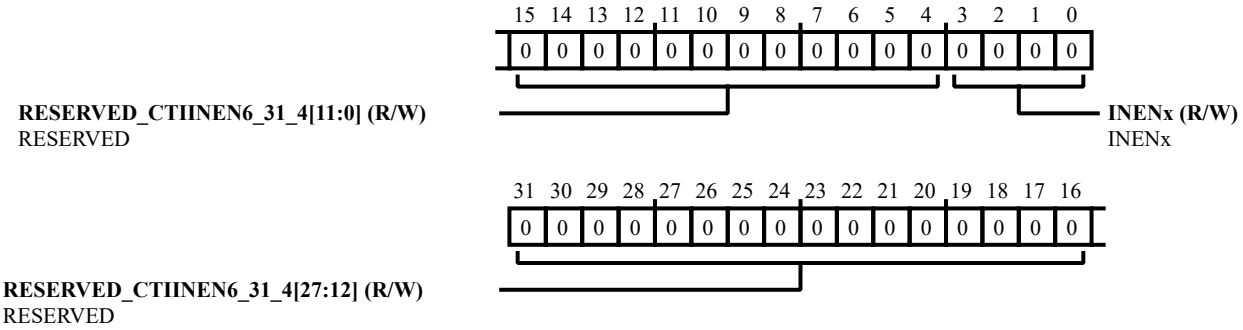

Figure 48-149: A55_CLUSTER_CTIINEN6 Register Diagram

Table 48-147: A55_CLUSTER_CTIINEN6 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/W)	RESERVED_CTII-NEN6_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/W)	INENX	INENx. Input trigger 6 to output channel <x> enable.	
		0	Input trigger 6 will not generate an event on output channel <x>.
		1	Input trigger 6 will generate an event on output channel <x>.

CTI Input Trigger to Output Channel Enable 7 Register

Enables the signaling of an event on output channels when input trigger event n is received by the CTI.

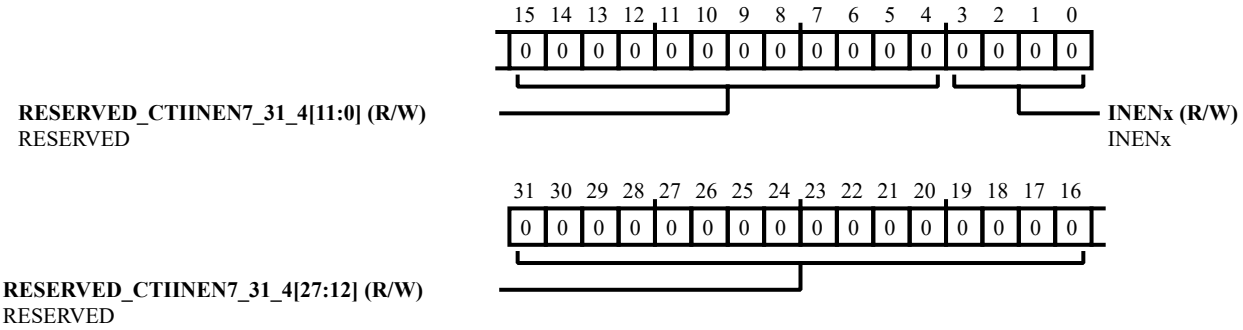

Figure 48-150: A55_CLUSTER_CTIINEN7 Register Diagram

Table 48-148: A55_CLUSTER_CTIINEN7 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/W)	RESERVED_CTII-NEN7_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/W)	INENX	INENx. Input trigger 7 to output channel <x> enable.	
		0	Input trigger 7 will not generate an event on output channel <x>.
		1	Input trigger 7 will generate an event on output channel <x>.

CTI Output Trigger Acknowledge Register

Can be used to deactivate the output triggers.

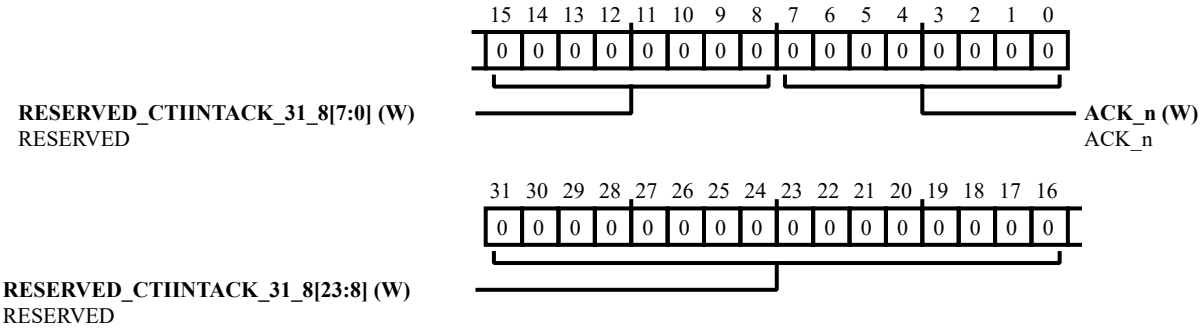

Figure 48-151: A55_CLUSTER_CTIINTACK Register Diagram

Table 48-149: A55_CLUSTER_CTIINTACK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:8 (RX/W)	RESERVED_CTIIN-TACK_31_8	RESERVED. Reserved RES0.	
		0	Reserved.
7:0 (RX/W)	ACK_N	ACK_n. Can be used to create soft acknowledges for output triggers.	
		0	No effect.
		1	Deactivate the trigger.

CTI Integration mode Control Register

Enables the CTI to switch from its default mode into integration mode, where test software can control directly the inputs and outputs of the PE, for integration testing or topology detection.

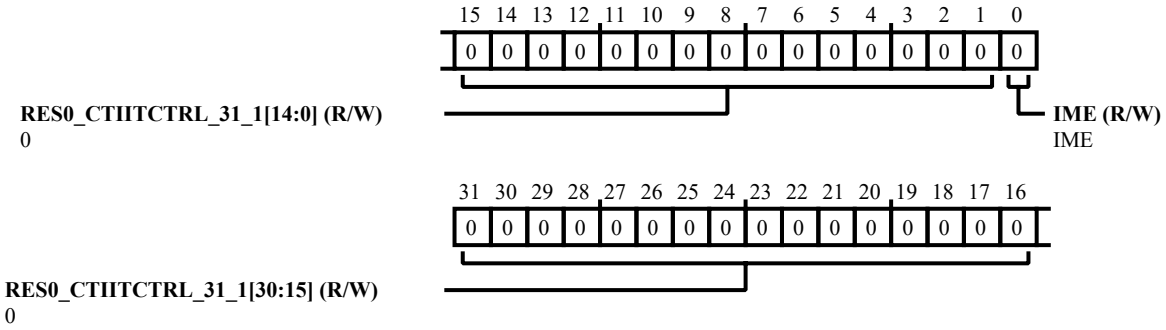

Figure 48-152: A55_CLUSTER_CTIITCTRL Register Diagram

Table 48-150: A55_CLUSTER_CTIITCTRL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:1 (R/W)	RES0_CTIITCTRL_31_1	0. Reserved, RES0.	
0 (R/W)	IME	IME. Integration mode enable. When IME == 1, the device reverts to an integration mode to enable integration testing or topology detection. The integration mode behavior is IMPLEMENTATION DEFINED. 0 Normal operation. 1 Integration mode enabled.	
		0	Normal operation.
		1	Integration mode enabled.

CTI Lock Access Register

Allows or disallows access to the CTI registers through a memory-mapped interface.

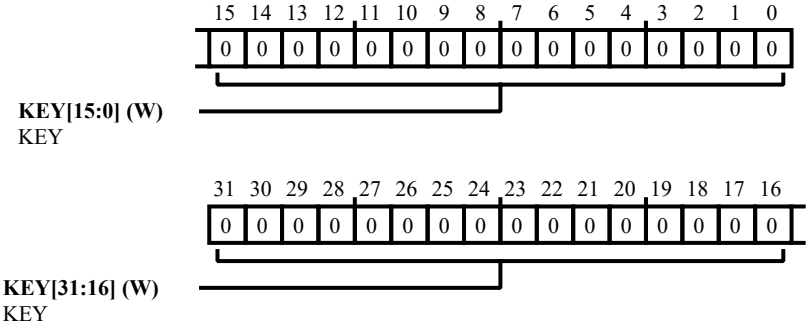

Figure 48-153: A55_CLUSTER_CTILAR Register Diagram

Table 48-151: A55_CLUSTER_CTILAR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (RX/W)	KEY	KEY. Lock Access control. Writing the key value 0xC5ACCE55 to this field unlocks the lock, enabling write accesses to this component's registers through a memory-mapped interface. Writing any other value to this register locks the lock, disabling write accesses to this component's registers through a memory mapped interface.

CTI Lock Status Register

Indicates the current status of the Software Lock for CTI registers.

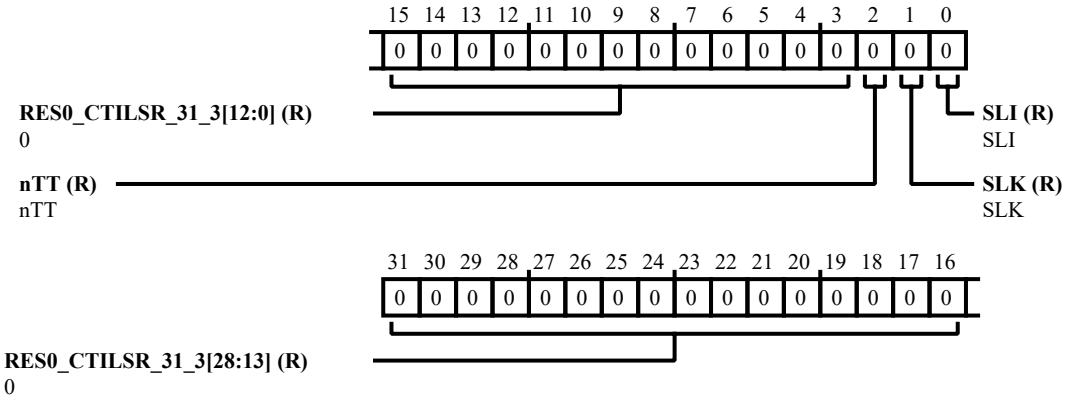

Figure 48-154: A55_CLUSTER_CTILSR Register Diagram

Table 48-152: A55_CLUSTER_CTILSR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:3 (R/NW)	RES0_CTILSR_31_3	0. Reserved, RES0.	
2 (R/NW)	NTT	nTT. Not thirty-two bit access required. RAZ.	
1 (R/NW)	SLK	SLK. Software Lock status for this component. For an access to LSR that is not a memory-mapped access, or when the Software Lock is not implemented, this field is RES0. For memory-mapped accesses when the Software Lock is implemented, possible values of this field are: 0 Lock clear. Writes are permitted to this component's registers. 1 Lock set. Writes to this component's registers are ignored, and reads have no side effects.	
		0	Lock clear. Writes are permitted to this component's registers.
		1	Lock set. Writes to this component's registers are ignored, and reads have no side effects.

Table 48-152: A55_CLUSTER_CTILSR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/NW)	SLI	SLI. Software Lock implemented. For an access to LSR that is not a memory-mapped access, this field is RAZ. For memory-mapped accesses, the value of this field is IMPLEMENTATION DEFINED. Permitted values are: 0 Software Lock not implemented or not memory-mapped access. 1 Software Lock implemented and memory-mapped access.	
		0	Software Lock not implemented or not memory-mapped access.
		1	Software Lock implemented and memory-mapped access.

CTI Input Channel to Output Trigger Enable 0 Register

Defines which input channels generate output trigger n.

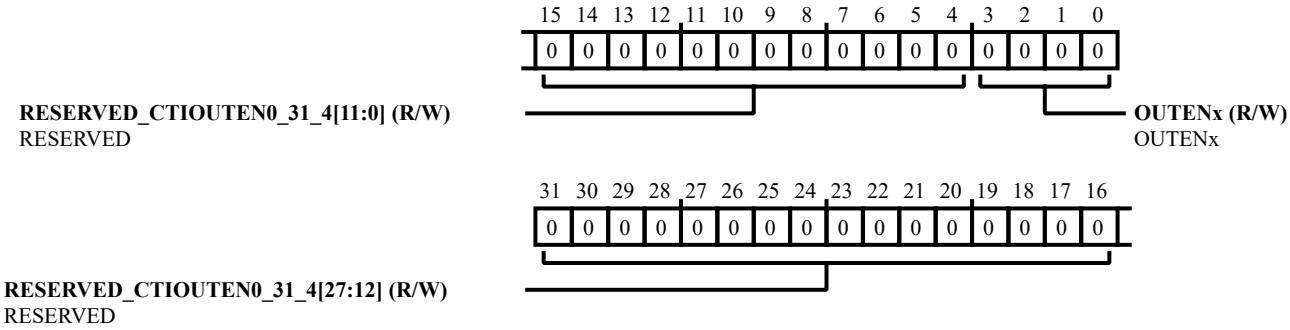

Figure 48-155: A55_CLUSTER_CTIOUTEN0 Register Diagram

Table 48-153: A55_CLUSTER_CTIOUTEN0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/W)	RESERVED_CTIOUT-EN0_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/W)	OUTENX	OUTENx. Input channel <x> to output trigger 0 enable.	
		0	An event on input channel <x> will not cause output trigger 0 to be asserted.
		1	An event on input channel <x> will cause output trigger 0 to be asserted.

CTI Input Channel to Output Trigger Enable 1 Register

Defines which input channels generate output trigger n.

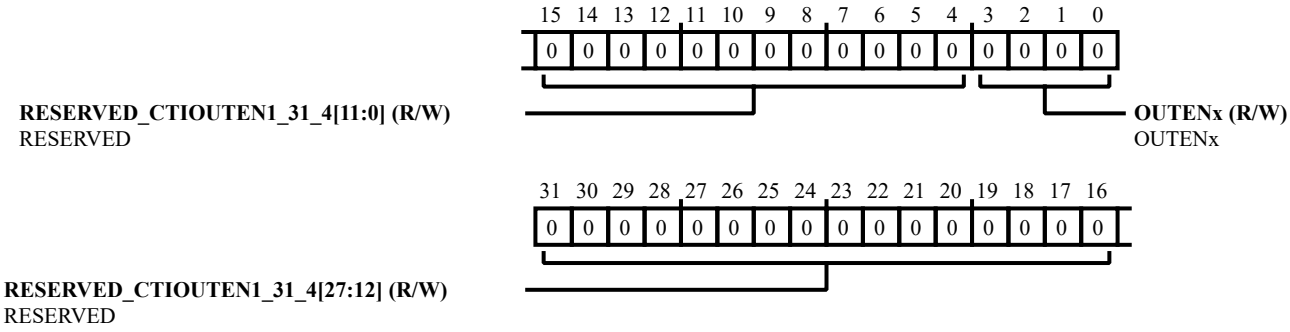

Figure 48-156: A55_CLUSTER_CTIOUTEN1 Register Diagram

Table 48-154: A55_CLUSTER_CTIOUTEN1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/W)	RESERVED_CTIOUT-EN1_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/W)	OUTENX	OUTENx. Input channel <x> to output trigger 1 enable.	
		0	An event on input channel <x> will not cause output trigger 1 to be asserted.
		1	An event on input channel <x> will cause output trigger 1 to be asserted.

CTI Input Channel to Output Trigger Enable 2 Register

Defines which input channels generate output trigger n.

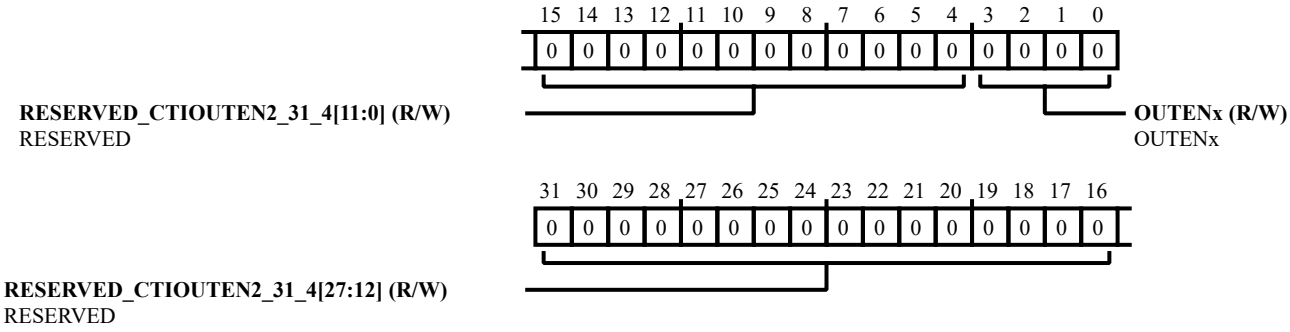

Figure 48-157: A55_CLUSTER_CTIOUTEN2 Register Diagram

Table 48-155: A55_CLUSTER_CTIOUTEN2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/W)	RESERVED_CTIOUT-EN2_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/W)	OUTENX	OUTENx. Input channel <x> to output trigger 2 enable.	
		0	An event on input channel <x> will not cause output trigger 2 to be asserted.
		1	An event on input channel <x> will cause output trigger 2 to be asserted.

CTI Input Channel to Output Trigger Enable 3 Register

Defines which input channels generate output trigger n.

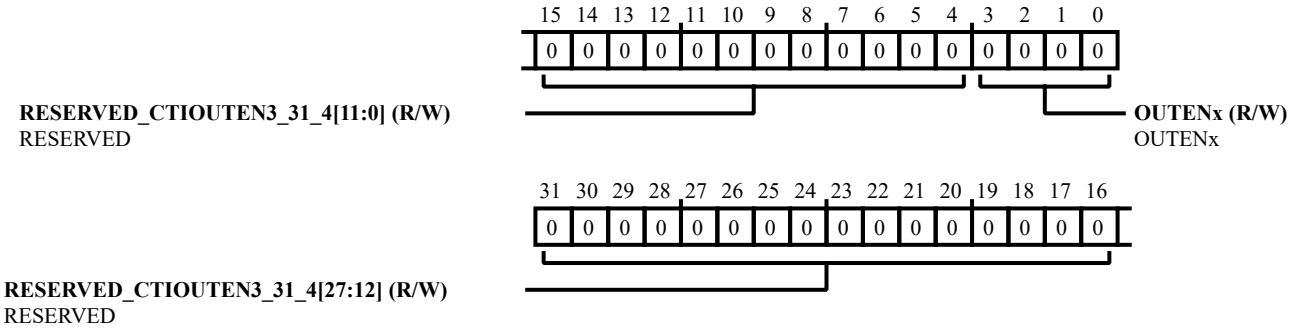

Figure 48-158: A55_CLUSTER_CTIOUTEN3 Register Diagram

Table 48-156: A55_CLUSTER_CTIOUTEN3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/W)	RESERVED_CTIOUT-EN3_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/W)	OUTENX	OUTENx. Input channel <x> to output trigger 3 enable.	
		0	An event on input channel <x> will not cause output trigger 3 to be asserted.
		1	An event on input channel <x> will cause output trigger 3 to be asserted.

CTI Input Channel to Output Trigger Enable 4 Register

Defines which input channels generate output trigger n.

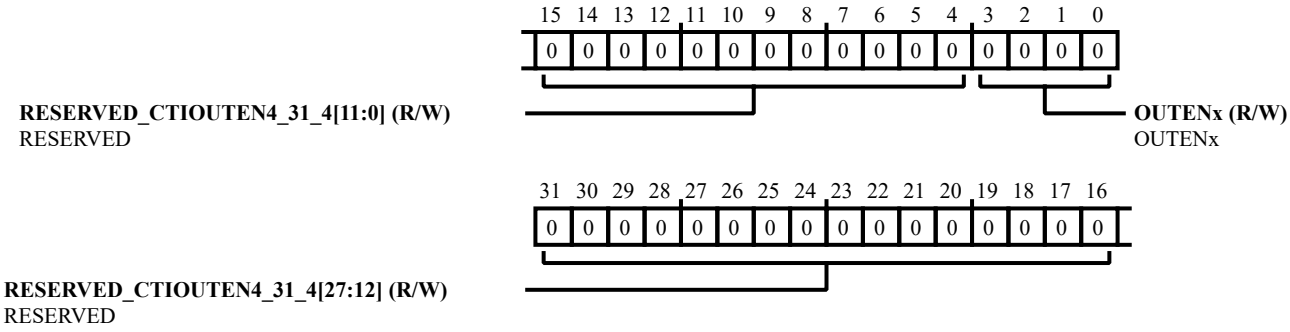

Figure 48-159: A55_CLUSTER_CTIOUTEN4 Register Diagram

Table 48-157: A55_CLUSTER_CTIOUTEN4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/W)	RESERVED_CTIOUT-EN4_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/W)	OUTENX	OUTENx. Input channel <x> to output trigger 4 enable.	
		0	An event on input channel <x> will not cause output trigger 4 to be asserted.
		1	An event on input channel <x> will cause output trigger 4 to be asserted.

CTI Input Channel to Output Trigger Enable 5 Register

Defines which input channels generate output trigger n.

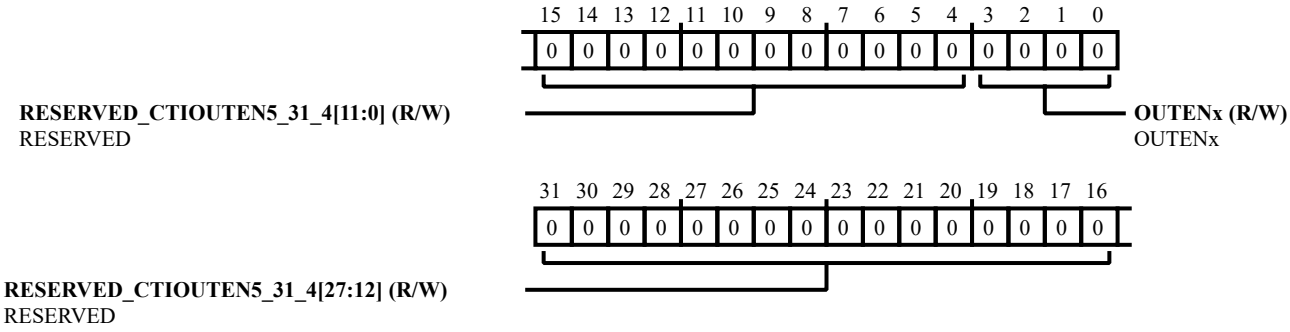

Figure 48-160: A55_CLUSTER_CTIOUTEN5 Register Diagram

Table 48-158: A55_CLUSTER_CTIOUTEN5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/W)	RESERVED_CTIOUT-EN5_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/W)	OUTENX	OUTENx. Input channel <x> to output trigger 5 enable.	
		0	An event on input channel <x> will not cause output trigger 5 to be asserted.
		1	An event on input channel <x> will cause output trigger 5 to be asserted.

CTI Input Channel to Output Trigger Enable 6 Register

Defines which input channels generate output trigger n.

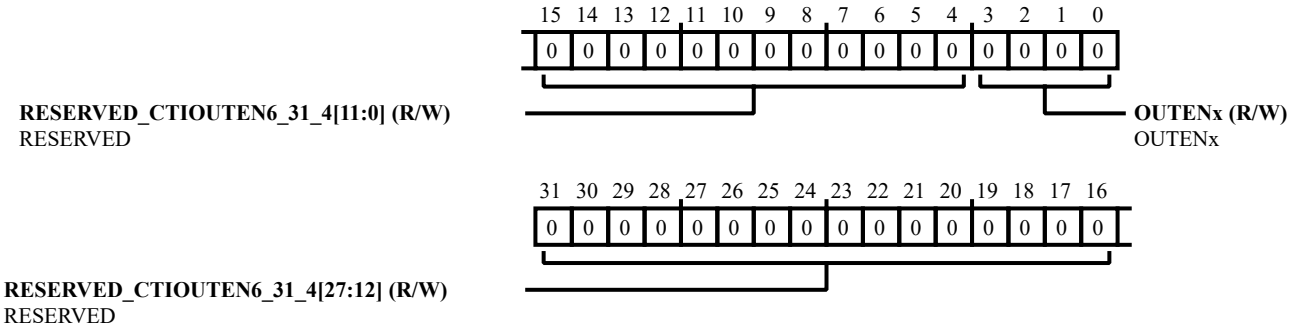

Figure 48-161: A55_CLUSTER_CTIOUTEN6 Register Diagram

Table 48-159: A55_CLUSTER_CTIOUTEN6 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/W)	RESERVED_CTIOUT-EN6_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/W)	OUTENX	OUTENx. Input channel <x> to output trigger 6 enable.	
		0	An event on input channel <x> will not cause output trigger 6 to be asserted.
		1	An event on input channel <x> will cause output trigger 6 to be asserted.

CTI Input Channel to Output Trigger Enable 7 Register

Defines which input channels generate output trigger n.

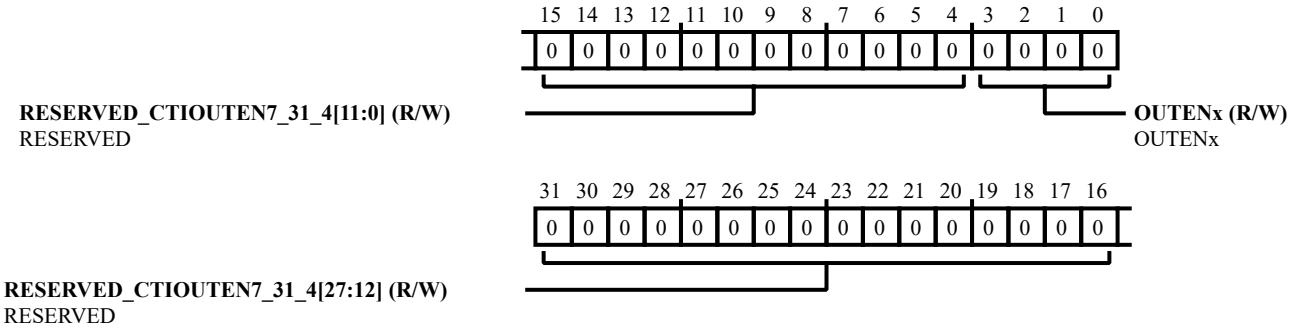

Figure 48-162: A55_CLUSTER_CTIOUTEN7 Register Diagram

Table 48-160: A55_CLUSTER_CTIOUTEN7 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/W)	RESERVED_CTIOUT-EN7_31_4	RESERVED. Reserved RES0.	
		0	Reserved.
3:0 (R/W)	OUTENX	OUTENx. Input channel <x> to output trigger 7 enable.	
		0	An event on input channel <x> will not cause output trigger 7 to be asserted.
		1	An event on input channel <x> will cause output trigger 7 to be asserted.

CTI Peripheral Identification 0 Register

Provides information to identify a CTI component.

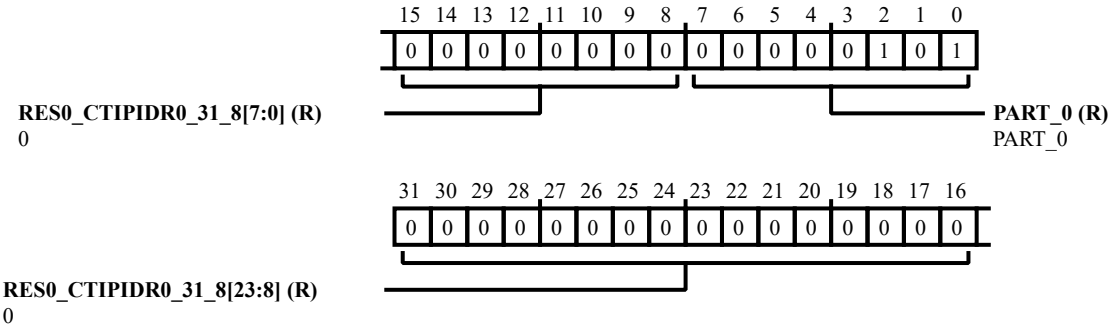

Figure 48-163: A55_CLUSTER_CTIPIDR0 Register Diagram

Table 48-161: A55_CLUSTER_CTIPIDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_CTIPIDR0_31_8	0. Reserved, RES0.
7:0 (R/NW)	PART_0	PART_0. Part number, least significant byte.

CTI Peripheral Identification 1 Register

Provides information to identify a CTI component.

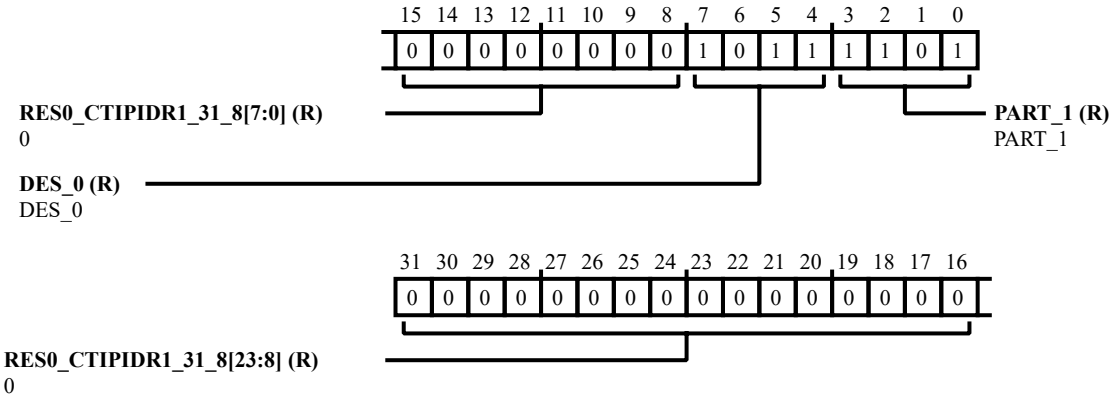

Figure 48-164: A55_CLUSTER_CTIPIDR1 Register Diagram

Table 48-162: A55_CLUSTER_CTIPIDR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_CTIPIDR1_31_8	0. Reserved, RES0.
7:4 (R/NW)	DES_0	DES_0. Designer, least significant nibble of JEP106 ID code. For ARM Limited, this field is 0b1011.
3:0 (R/NW)	PART_1	PART_1. Part number, most significant nibble.

CTI Peripheral Identification 2 Register

Provides information to identify a CTI component.

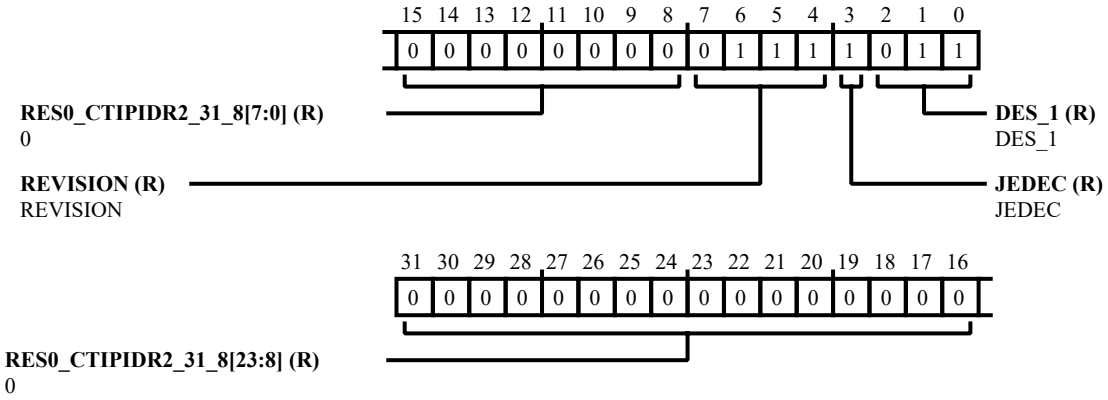

Figure 48-165: A55_CLUSTER_CTIPIDR2 Register Diagram

Table 48-163: A55_CLUSTER_CTIPIDR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_CTIPIDR2_31_8	0. Reserved, RES0.
7:4 (R/NW)	REVISION	REVISION. Part major revision. Parts can also use this field to extend Part number to 16-bits.
3 (R/NW)	JEDEC	JEDEC. RAO. Indicates a JEP106 identity code is used.
2:0 (R/NW)	DES_1	DES_1. Designer, most significant bits of JEP106 ID code. For ARM Limited, this field is 0b011.

CTI Peripheral Identification 3 Register

Provides information to identify a CTI component.

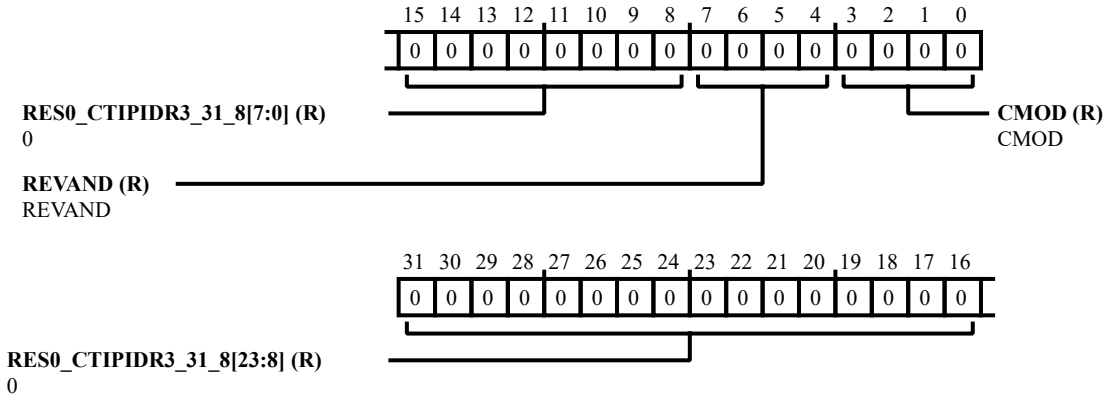

Figure 48-166: A55_CLUSTER_CTIPIDR3 Register Diagram

Table 48-164: A55_CLUSTER_CTIPIDR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_CTIPIDR3_31_8	0. Reserved, RES0.
7:4 (R/NW)	REVAND	REVAND. Part minor revision. Parts using CTIPIDR2.REVISION as an extension to the Part number must use this field as a major revision number.
3:0 (R/NW)	CMOD	CMOD. Customer modified. Indicates someone other than the Designer has modified the component.

CTI Peripheral Identification 4 Register

Provides information to identify a CTI component.

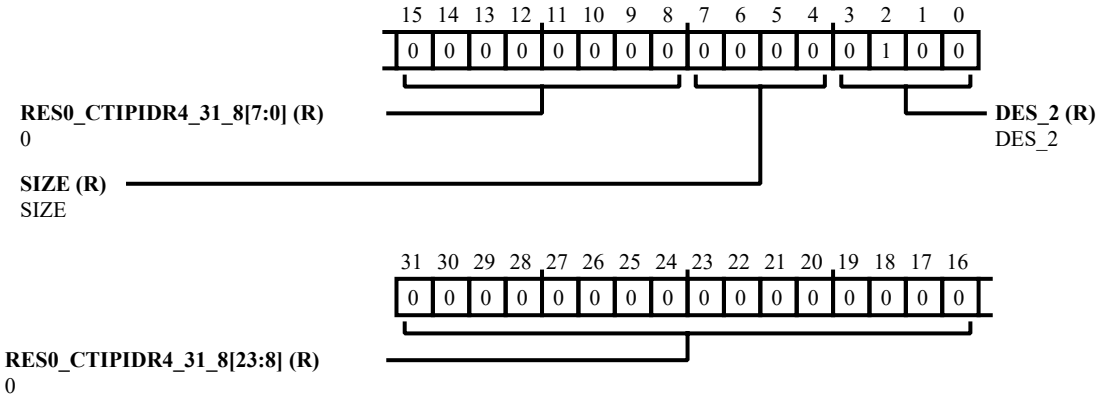

Figure 48-167: A55_CLUSTER_CTIPIDR4 Register Diagram

Table 48-165: A55_CLUSTER_CTIPIDR4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_CTIPIDR4_31_8	0. Reserved, RES0.
7:4 (R/NW)	SIZE	SIZE. Size of the component. RAZ. Log2 of the number of 4KB pages from the start of the component to the end of the component ID registers.
3:0 (R/NW)	DES_2	DES_2. Designer, JEP106 continuation code, least significant nibble. For ARM Limited, this field is 0b0100.

CTI Peripheral Identification 5 Register

Provides information to identify a CTI component.

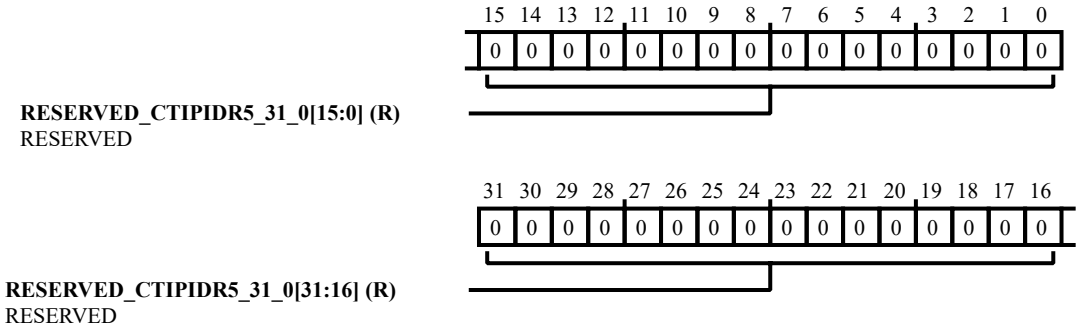

Figure 48-168: A55_CLUSTER_CTIPIDR5 Register Diagram

Table 48-166: A55_CLUSTER_CTIPIDR5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RESERVED_CTI-PIDR5_31_0	RESERVED. Reserved RES0.

CTI Peripheral Identification 6 Register

Provides information to identify a CTI component.

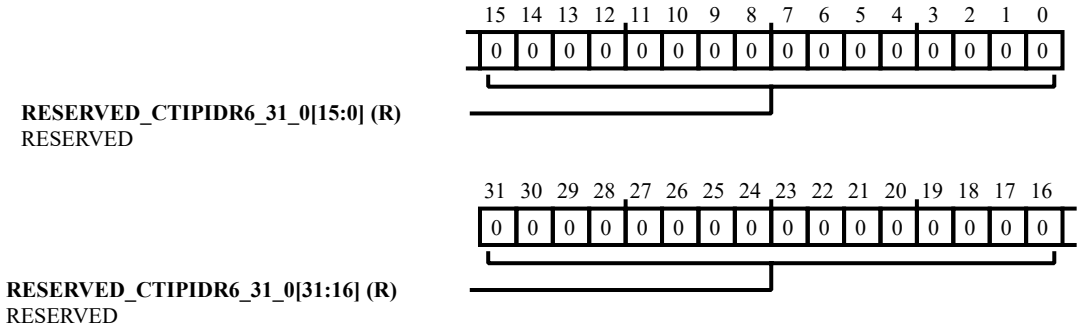

Figure 48-169: A55_CLUSTER_CTIPIDR6 Register Diagram

Table 48-167: A55_CLUSTER_CTIPIDR6 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RESERVED_CTI-PIDR6_31_0	RESERVED. Reserved RES0.

CTI Peripheral Identification 7 Register

Provides information to identify a CTI component.

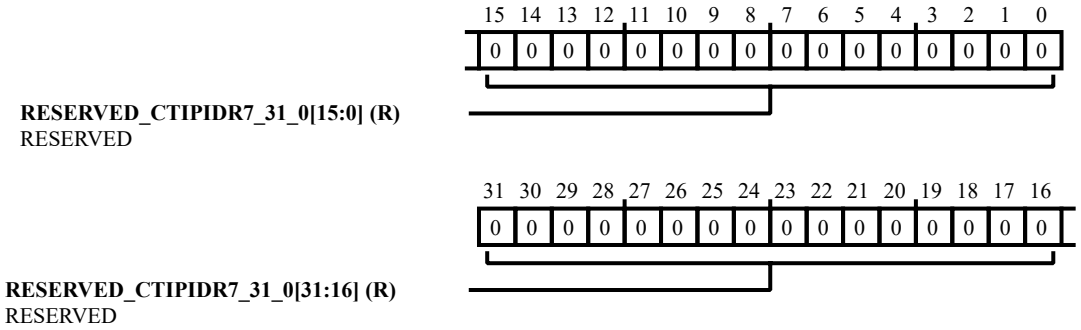

Figure 48-170: A55_CLUSTER_CTIPIDR7 Register Diagram

Table 48-168: A55_CLUSTER_CTIPIDR7 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RESERVED_CTI-PIDR7_31_0	RESERVED. Reserved RES0.

CTI Trigger In Status Register

Provides the status of the trigger inputs.

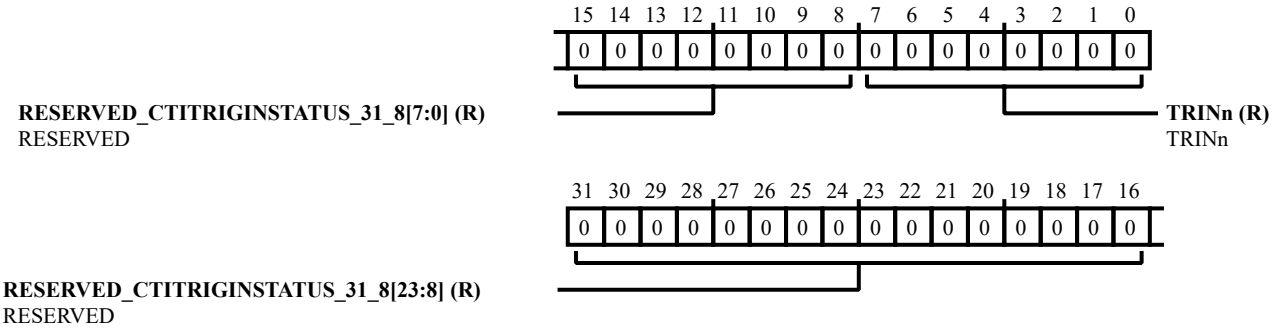

Figure 48-171: A55_CLUSTER_CTITRIGINSTATUS Register Diagram

Table 48-169: A55_CLUSTER_CTITRIGINSTATUS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:8 (R/NW)	RESERVED_CTITRIGIN-STATUS_31_8	RESERVED. Reserved RES0.	
		0	Reserved.
7:0 (R/NW)	TRINN	TRINn. Provides the status of the trigger inputs.	
		0	Input trigger n is inactive.
		1	Input trigger n is active.

CTI Trigger Out Status Register

Provides the raw status of the trigger outputs, after processing by any IMPLEMENTATION DEFINED trigger interface logic. For output triggers that are self-acknowledging, this is only meaningful if the CTI implements multicycle channel events.

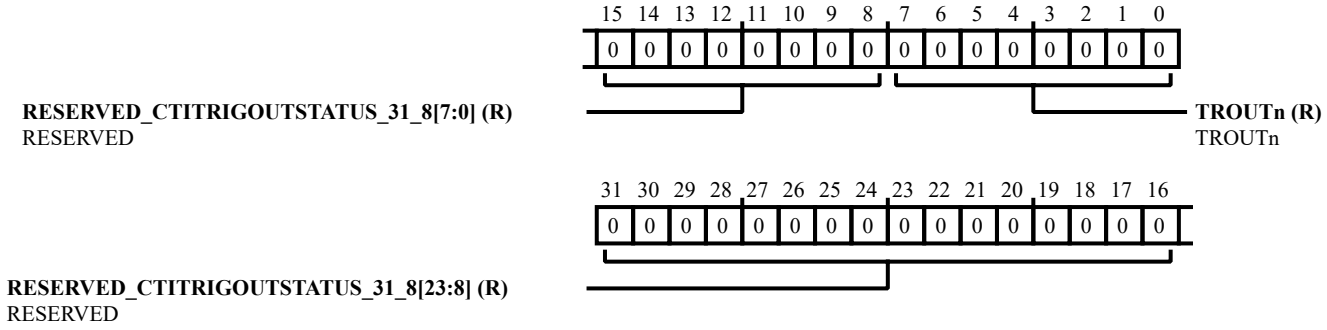

Figure 48-172: A55_CLUSTER_CTITRIGOUTSTATUS Register Diagram

Table 48-170: A55_CLUSTER_CTITRIGOUTSTATUS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:8 (R/NW)	RESERVED_CTITRI-GOUTSTATUS_31_8	RESERVED. Reserved RES0.	
		0	Reserved.
7:0 (R/NW)	TROUTN	TROUTn. Provides the status of the trigger outputs.	
		0	Output trigger n is inactive.
		1	Output trigger n is active.

Debug Authentication Status Register

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for debug.

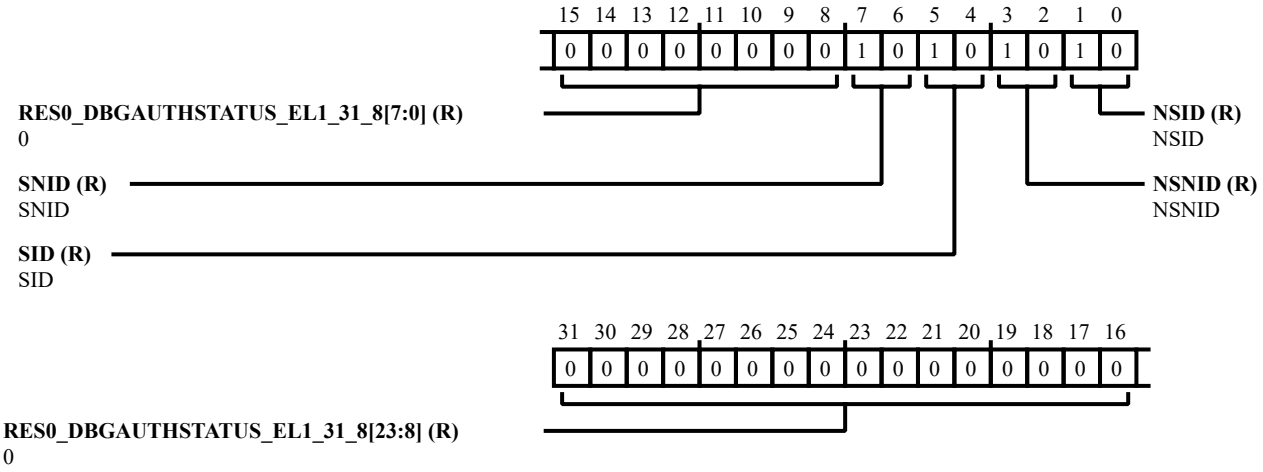

Figure 48-173: A55_CLUSTER_DBGAUTHSTATUS_EL1 Register Diagram

Table 48-171: A55_CLUSTER_DBGAUTHSTATUS_EL1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:8 (R/NW)	RES0_DBGAUTHSTATUS_EL1_31_8	0. Reserved, RES0.	
7:6 (R/NW)	SNID	SNID. Secure non-invasive debug. Possible values of this field are: 00 Not implemented. EL3 is not implemented and the implemented Security state is Non-secure state. 10 Implemented and disabled. ExternalSecureNoninvasiveDebugEnabled() == FALSE. 11 Implemented and enabled. ExternalSecureNoninvasiveDebugEnabled() == TRUE. Other values are reserved.	
		0	Not implemented. EL3 is not implemented and the implemented Security state is Non-secure state.
		2	Implemented and disabled. ExternalSecureNoninvasiveDebugEnabled() == FALSE.
		3	Implemented and enabled. ExternalSecureNoninvasiveDebugEnabled() == TRUE.

Table 48-171: A55_CLUSTER_DBGAUTHSTATUS_EL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
5:4 (R/NW)	SID	SID. Secure invasive debug. Possible values of this field are: 00 Not implemented. EL3 is not implemented and the implemented Security state is Non-secure state. 10 Implemented and disabled. ExternalSecureInvasiveDebugEnabled() == FALSE. 11 Implemented and enabled. ExternalSecureInvasiveDebugEnabled() == TRUE. Other values are reserved.	
		0	Not implemented. EL3 is not implemented and the implemented Security state is Non-secure state.
		2	Implemented and disabled. ExternalSecureInvasiveDebugEnabled() == FALSE.
		3	Implemented and enabled. ExternalSecureInvasiveDebugEnabled() == TRUE.
3:2 (R/NW)	NSNID	NSNID. Non-secure non-invasive debug. Possible values of this field are: 00 Not implemented. EL3 is not implemented and the implemented Security state is Secure state. 10 Implemented and disabled. ExternalNoninvasiveDebugEnabled() == FALSE. 11 Implemented and enabled. ExternalNoninvasiveDebugEnabled() == TRUE. Other values are reserved.	
		0	Not implemented. EL3 is not implemented and the implemented Security state is Secure state.
		2	Implemented and disabled. ExternalNoninvasiveDebugEnabled() == FALSE.
		3	Implemented and enabled. ExternalNoninvasiveDebugEnabled() == TRUE.
1:0 (R/NW)	NSID	NSID. Non-secure invasive debug. Possible values of this field are: 00 Not implemented. EL3 is not implemented and the implemented Security state is Secure state. 10 Implemented and disabled. ExternalInvasiveDebugEnabled() == FALSE. 11 Implemented and enabled. ExternalInvasiveDebugEnabled() == TRUE. Other values are reserved.	
		0	Not implemented. EL3 is not implemented and the implemented Security state is Secure state.
		2	Implemented and disabled. ExternalInvasiveDebugEnabled() == FALSE.
		3	Implemented and enabled. ExternalInvasiveDebugEnabled() == TRUE.

External Debug Component Identification 0 Register

Provides information to identify an external debug component.

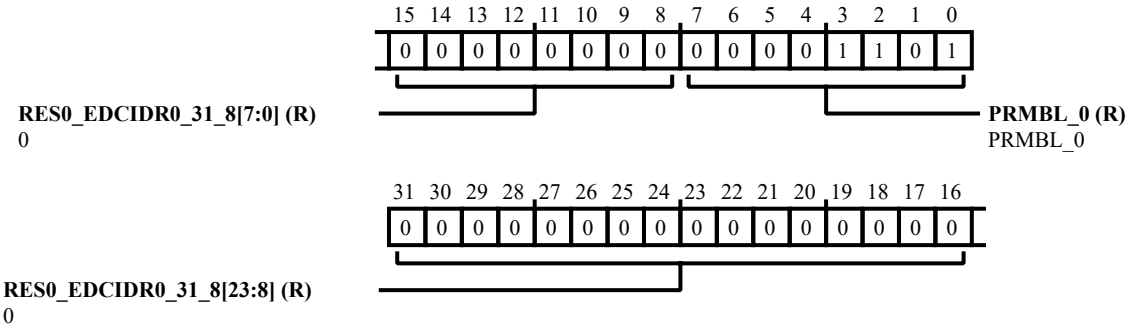

Figure 48-174: A55_CLUSTER_EDCIDR0 Register Diagram

Table 48-172: A55_CLUSTER_EDCIDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_EDCIDR0_31_8	0. Reserved, RES0.
7:0 (R/NW)	PRMBL_0	PRMBL_0. Preamble. Must read as 0x0D.

External Debug Component Identification 1 Register

Provides information to identify an external debug component.

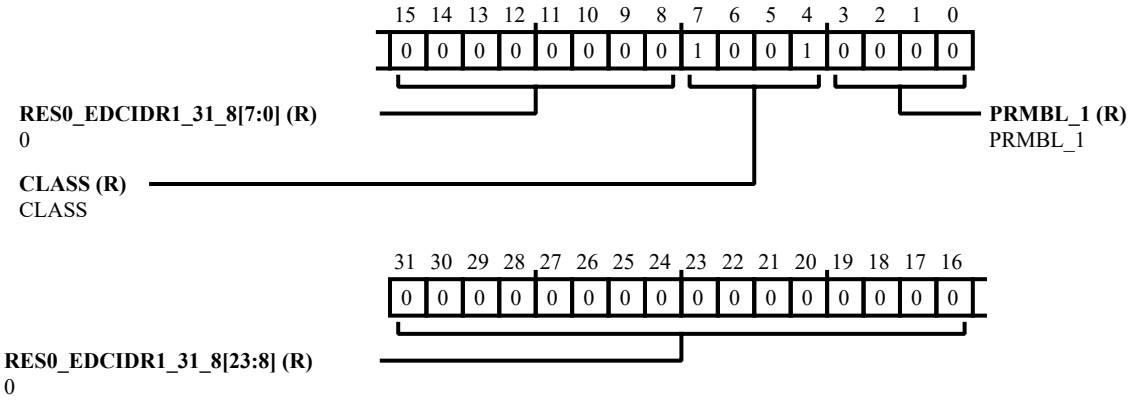

Figure 48-175: A55_CLUSTER_EDCIDR1 Register Diagram

Table 48-173: A55_CLUSTER_EDCIDR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_EDCIDR1_31_8	0. Reserved, RES0.
7:4 (R/NW)	CLASS	CLASS. Component class. Reads as 0x9, debug component.
3:0 (R/NW)	PRMBL_1	PRMBL_1. Preamble. RAZ.

External Debug Component Identification 2 Register

Provides information to identify an external debug component.

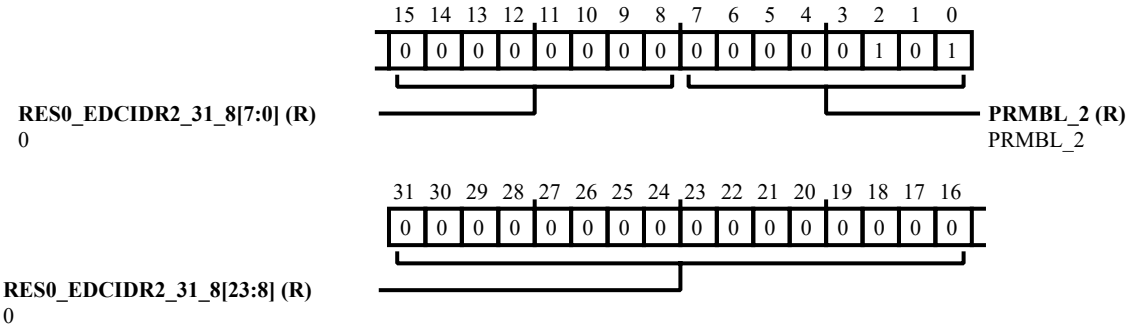

Figure 48-176: A55_CLUSTER_EDCIDR2 Register Diagram

Table 48-174: A55_CLUSTER_EDCIDR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_EDCIDR2_31_8	0. Reserved, RES0.
7:0 (R/NW)	PRMBL_2	PRMBL_2. Preamble. Must read as 0x05.

External Debug Component Identification 3 Register

Provides information to identify an external debug component.

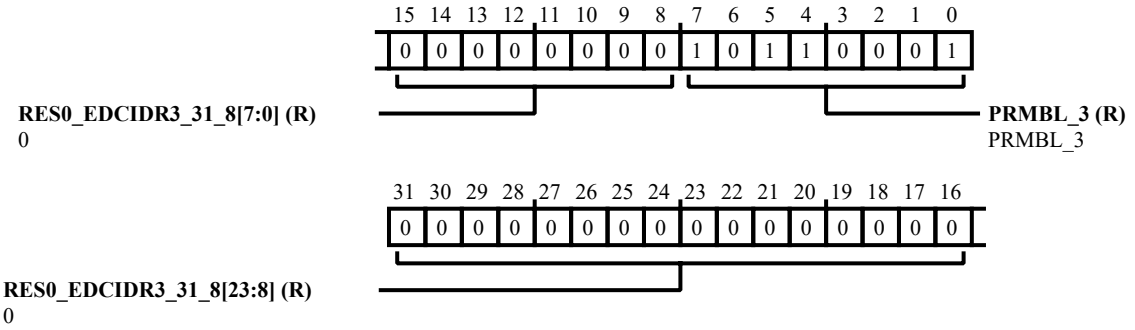

Figure 48-177: A55_CLUSTER_EDCIDR3 Register Diagram

Table 48-175: A55_CLUSTER_EDCIDR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_EDCIDR3_31_8	0. Reserved, RES0.
7:0 (R/NW)	PRMBL_3	PRMBL_3. Preamble. Must read as 0xB1.

External Debug Device Affinity 0 Register

Copy of the low half of the PE MPIDR_EL1 register that allows a debugger to determine which PE in a multiprocessor system the external debug component relates to.

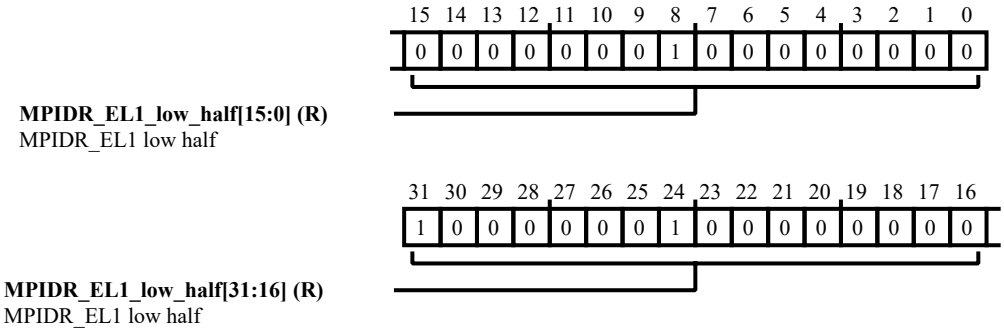

Figure 48-178: A55_CLUSTER_EDDEVAFF0 Register Diagram

Table 48-176: A55_CLUSTER_EDDEVAFF0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	MPIDR_EL1_LOW_HALF	MPIDR_EL1 low half. MPIDR_EL1 low half. Read-only copy of the low half of MPIDR_EL1, as seen from the highest implemented Exception level.

External Debug Device Affinity 1 Register

Copy of the high half of the PE MPIDR_EL1 register that allows a debugger to determine which PE in a multiprocessor system the external debug component relates to.

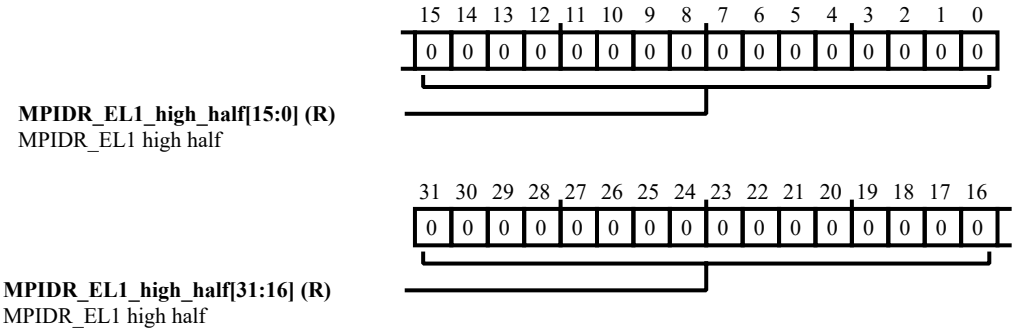

Figure 48-179: A55_CLUSTER_EDDEVAFF1 Register Diagram

Table 48-177: A55_CLUSTER_EDDEVAFF1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	MPIDR_EL1_HIGH_HALF	MPIDR_EL1 high half. MPIDR_EL1 high half. Read-only copy of the high half of MPIDR_EL1, as seen from the highest implemented Exception level.

External Debug Device Architecture Register

Identifies the programmers' model architecture of the external debug component.

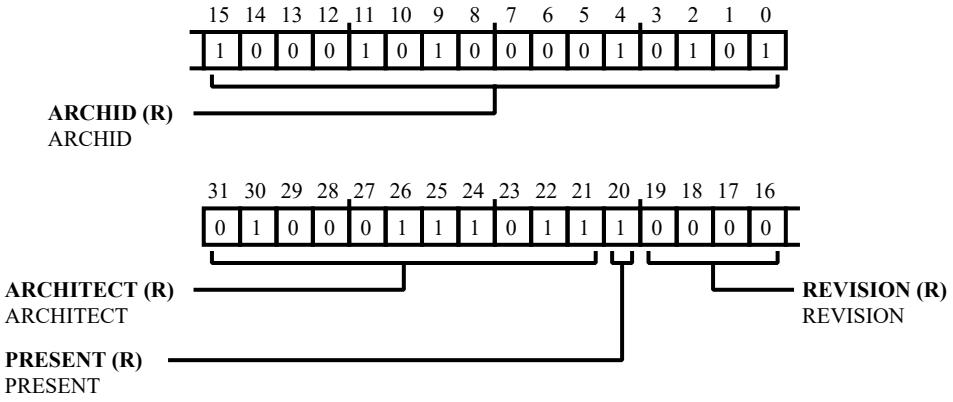

Figure 48-180: A55_CLUSTER_EDDEVARCH Register Diagram

Table 48-178: A55_CLUSTER_EDDEVARCH Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:21 (R/NW)	ARCHITECT	ARCHITECT. Defines the architecture of the component. For debug, this is ARM Limited. Bits [31:28] are the JEP106 continuation code, 0x4. Bits [27:21] are the JEP106 ID code, 0x3B.
20 (R/NW)	PRESENT	PRESENT. When set to 1, indicates that the DEVARCH is present. This field is 1 in ARMv8.
19:16 (R/NW)	REVISION	REVISION. Defines the architecture revision. For architectures defined by ARM this is the minor revision. For debug, the revision defined by ARMv8 is 0x0. All other values are reserved.
15:0 (R/NW)	ARCHID	ARCHID. Defines this part to be an ARMv8 debug component. For architectures defined by ARM this is further subdivided. For debug: Bits [15:12] are the architecture version:In ARMv8-A, this is 0x6.In ARMv8.1, this is 0x7.In ARMv8.2, this is0x8. Bits [11:0] are the architecture part number, 0xA15. This corresponds to the ARMv8 debug architecture version.

External Debug Device ID 0 Register

Provides extra information for external debuggers about features of the debug implementation.

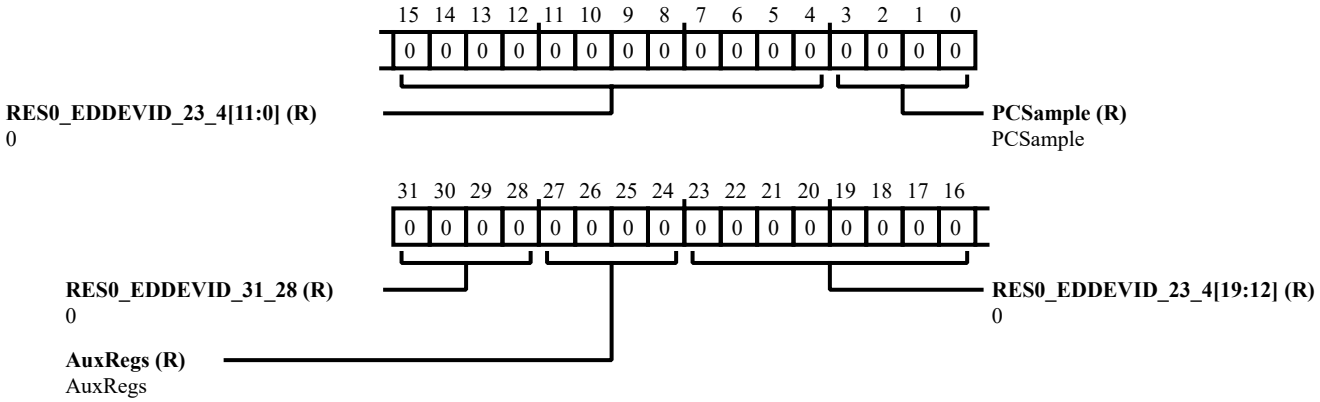

Figure 48-181: A55_CLUSTER_EDDEVID Register Diagram

Table 48-179: A55_CLUSTER_EDDEVID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:28 (R/NW)	RES0_EDDEVID_31_28	0. Reserved, RES0.	
27:24 (R/NW)	AUXREGS	AuxRegs. Indicates support for Auxiliary registers. Permitted values for this field are: 0000 None supported. 0001 Support for External Debug Auxiliary Control Register, EDACR. All other values are reserved.	
		0	None supported.
		1	Support for External Debug Auxiliary Control Register, EDACR.
23:4 (R/NW)	RES0_EDDEVID_23_4	0. Reserved, RES0.	

Table 48-179: A55_CLUSTER_EDDEVID Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3:0 (R/NW)	PCSAMPLE	PCSample. Indicates the level of PC Sample-based profiling support using external debug registers 40 through 43. Permitted values of this field in ARMv8 are: 0000 Architecture-defined form of PC Sample-based profiling not implemented. 0010 EDPCSR and EDCIDSR are implemented (only permitted if EL3 and EL2 are not implemented). 0011 EDPCSR, EDCIDSR, and EDVIDSR are implemented. All other values are reserved. In ARMv8.2 implementations, this field reads as 0b0000.	
		0	Architecture-defined form of PC Sample-based profiling not implemented.
		2	EDPCSR and EDCIDSR are implemented (only permitted if EL3 and EL2 are not implemented).
		3	EDPCSR, EDCIDSR, and EDVIDSR are implemented.

External Debug Device ID 1 Register

Provides extra information for external debuggers about features of the debug implementation.

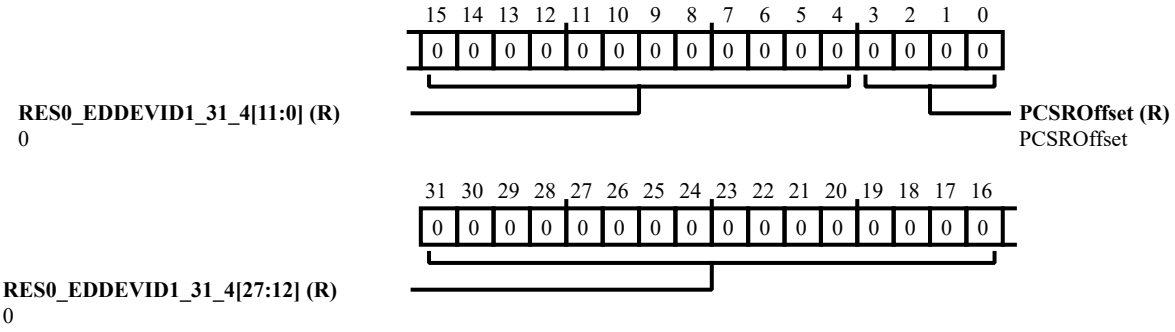

Figure 48-182: A55_CLUSTER_EDDEVID1 Register Diagram

Table 48-180: A55_CLUSTER_EDDEVID1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_EDDEVID1_31_4	0. Reserved, RES0.	
3:0 (R/NW)	PCSROFFSET	PCSROffset. This field indicates the offset applied to PC samples returned by reads of EDPCSR. Permitted values of this field in ARMv8 are: 0000 EDPCSR not implemented. 0010 EDPCSR implemented, and samples have no offset applied and do not sample the instruction set state in AArch32 state. In ARMv8.2 implementations, this field reads as 0b0000.	
		0	EDPCSR not implemented.
		2	EDPCSR implemented, and samples have no offset applied and do not sample the instruction set state in AArch32 state.

External Debug Device ID 2 Register

Reserved for future descriptions of features of the debug implementation.

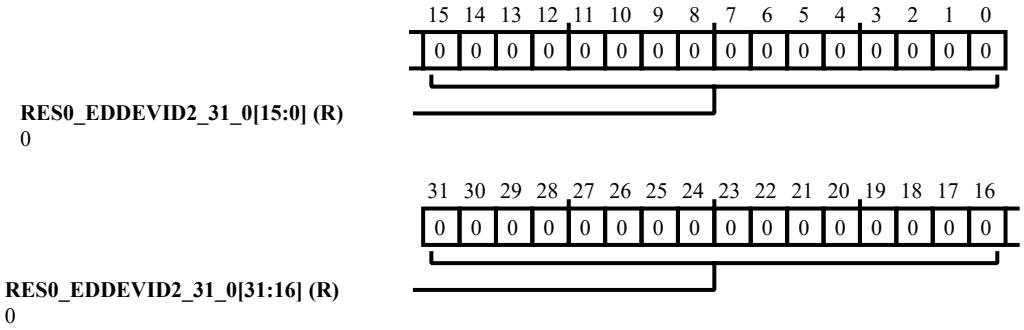

Figure 48-183: A55_CLUSTER_EDDEVID2 Register Diagram

Table 48-181: A55_CLUSTER_EDDEVID2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RES0_EDDEVID2_31_0	0. Reserved, RES0.

External Debug Device Type Register

Indicates to a debugger that this component is part of a PEs debug logic.

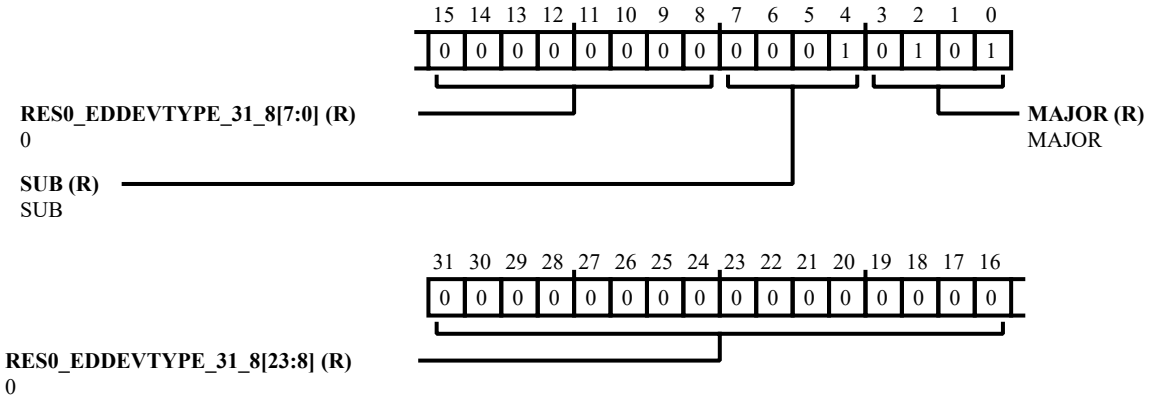

Figure 48-184: A55_CLUSTER_EDDEVTYPE Register Diagram

Table 48-182: A55_CLUSTER_EDDEVTYPE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_EDDEVTYPE_31_8	0. Reserved, RES0.
7:4 (R/NW)	SUB	SUB. Subtype. Must read as 0x1 to indicate this is a component within a PE.
3:0 (R/NW)	MAJOR	MAJOR. Major type. Must read as 0x5 to indicate this is a debug logic component.

External Debug Feature Register

Provides top level information about the debug system. Debuggers must use EDDEVARCH to determine the Debug architecture version. For general information about the interpretation of the ID registers see .

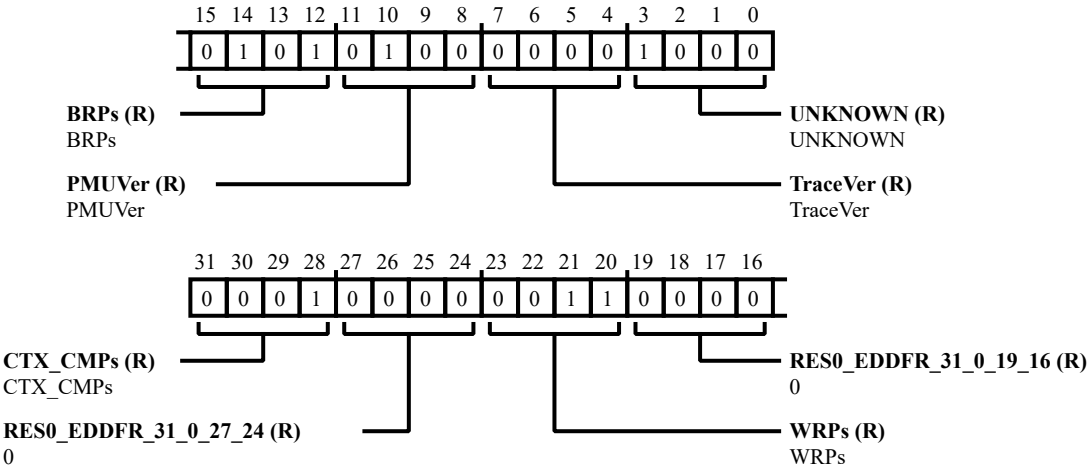

Figure 48-185: A55_CLUSTER_EDDFR_31_0 Register Diagram

Table 48-183: A55_CLUSTER_EDDFR_31_0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:28 (R/NW)	CTX_CMPS	CTX_CMPs. Number of breakpoints that are context-aware, minus 1. These are the highest numbered breakpoints. In an ARMv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64DFR0_EL1.CTX_CMPs.
27:24 (R/NW)	RES0_EDDFR_31_0_27_24	0. Reserved, RES0.
23:20 (R/NW)	WRPS	WRPs. Number of watchpoints, minus 1. The value of 0b0000 is reserved. In an ARMv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64DFR0_EL1.WRPs.
19:16 (R/NW)	RES0_EDDFR_31_0_19_16	0. Reserved, RES0.
15:12 (R/NW)	BRPS	BRPs. Number of breakpoints, minus 1. The value of 0b0000 is reserved. In an ARMv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64DFR0_EL1.BRPs.

Table 48-183: A55_CLUSTER_EDDFR_31_0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11:8 (R/NW)	PMUVER	PMUVer. Performance Monitors Extension version. Indicates whether System register interface to Performance Monitors extension is implemented. Defined values are: 0000 Performance Monitors Extension System registers not implemented. 0001 Performance Monitors Extension System registers implemented, PMUv3. 0100 Performance Monitors Extension System registers implemented, PMUv3, with a 16-bit evtCount field, and if EL2 is implemented, the addition of the MDCR_EL2.HPMD bit. 1111 IMPLEMENTATION DEFINED form of performance monitors supported, PMUv3 not supported. All other values are reserved. In ARMv8-A the permitted values are 0b0000, 0b0001 and 0b1111. In ARMv8.1 the permitted values are 0b0000, 0b0100 and 0b1111. In an ARMv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64DFR0_EL1.PMUVer.	
		0	Performance Monitors Extension System registers not implemented.
		1	Performance Monitors Extension System registers implemented, PMUv3.
		4	Performance Monitors Extension System registers implemented, PMUv3, with a 16-bit evtCount field, and if EL2 is implemented, the addition of the MDCR_EL2.HPMD bit.
		15	IMPLEMENTATION DEFINED form of performance monitors supported, PMUv3 not supported.
7:4 (R/NW)	TRACEVER	TraceVer. Trace support. Indicates whether System register interface to a trace macrocell is implemented. Defined values are: 0000 Trace macrocell System registers not implemented. 0001 Trace macrocell System registers implemented. All other values are reserved. A value of 0b0000 only indicates that no System register interface to a trace macrocell is implemented. A trace macrocell might nevertheless be implemented without a System register interface. In an ARMv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64DFR0_EL1.TraceVer.	
		0	Trace macrocell System registers not implemented.
		1	Trace macrocell System registers implemented.
3:0 (R/NW)	UNKNOWN	UNKNOWN. Reserved, UNKNOWN.	

External Debug Feature Register

Provides top level information about the debug system. Debuggers must use EDDEVARCH to determine the Debug architecture version. For general information about the interpretation of the ID registers see .

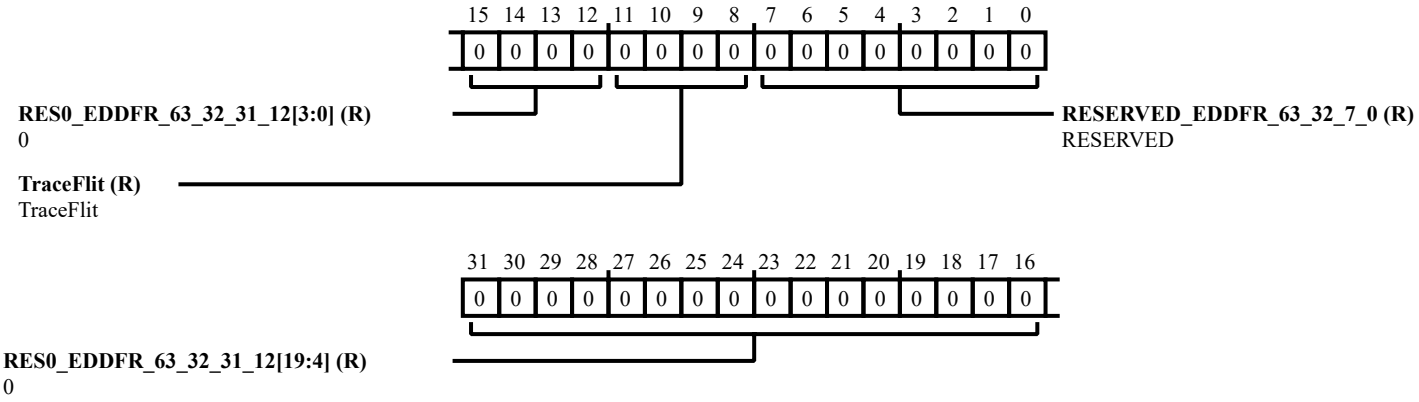

Figure 48-186: A55_CLUSTER_EDDFR_63_32 Register Diagram

Table 48-184: A55_CLUSTER_EDDFR_63_32 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:12 (R/NW)	RES0_EDDFR_63_32_31_12	0. Reserved, RES0.
11:8 (R/NW)	TRACEFLIT	TraceFlit. ARMv8.4 Self-hosted Trace Extension implemented.
7:0 (R/NW)	RESERVED_EDDFR_63_32_7_0	RESERVED. Reserved. This field reads as an UNKNOWN value.

External Debug Execution Control Register

Controls Halting debug events.

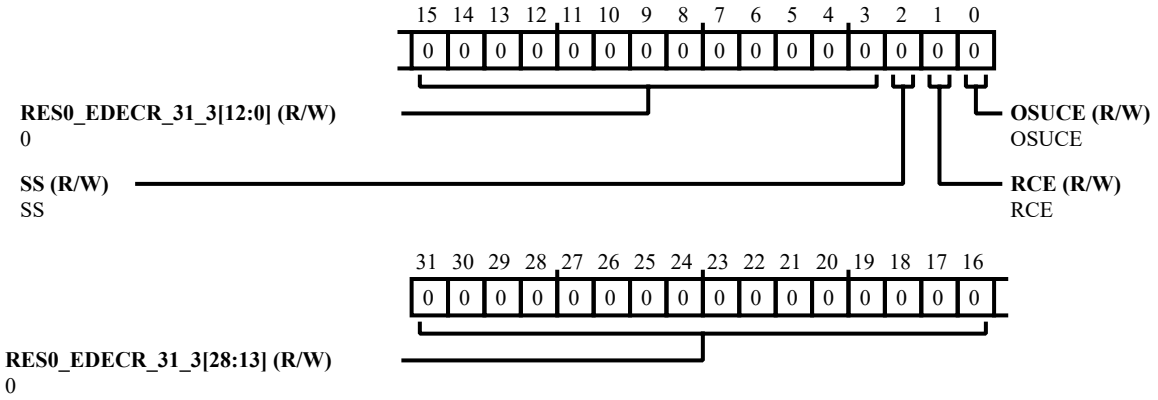

Figure 48-187: A55_CLUSTER_EDECR Register Diagram

Table 48-185: A55_CLUSTER_EDECR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:3 (R/W)	RES0_EDECR_31_3	0. Reserved, RES0.	
2 (R/W)	SS	SS. Halting step enable. Possible values of this field are: 0 Halting step debug event disabled. 1 Halting step debug event enabled. If the value of EDECR.SS is changed when the PE is in Non-debug state, behavior is CONSTRAINED UNPREDICTABLE as described in .	
		0	Halting step debug event disabled.
		1	Halting step debug event enabled.
1 (R/W)	RCE	RCE. Reset Catch enable. Possible values of this field are: 0 Reset Catch debug event disabled. 1 Reset Catch debug event enabled.	
		0	Reset Catch debug event disabled.
		1	Reset Catch debug event enabled.
0 (R/W)	OSUCE	OSUCE. OS Unlock Catch enabled. Possible values of this field are: 0 OS Unlock Catch debug event disabled. 1 OS Unlock Catch debug event enabled.	
		0	OS Unlock Catch debug event disabled.
		1	OS Unlock Catch debug event enabled.

External Debug Lock Access Register

Allows or disallows access to the external debug registers through a memory-mapped interface.

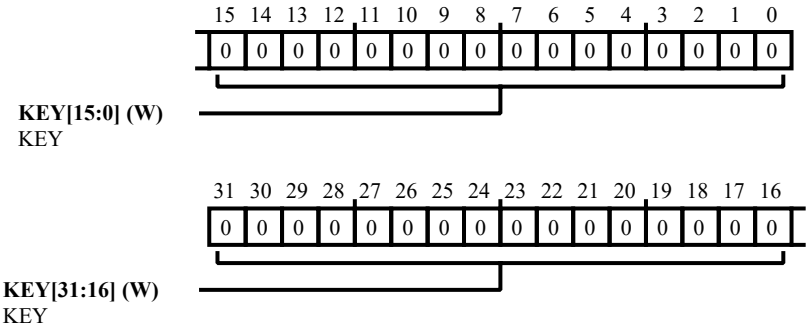

Figure 48-188: A55_CLUSTER_EDLAR Register Diagram

Table 48-186: A55_CLUSTER_EDLAR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (RX/W)	KEY	KEY. Lock Access control. Writing the key value 0xC5ACCE55 to this field unlocks the lock, enabling write accesses to this component's registers through a memory-mapped interface. Writing any other value to this register locks the lock, disabling write accesses to this component's registers through a memory mapped interface.

External Debug Lock Status Register

Indicates the current status of the software lock for external debug registers.

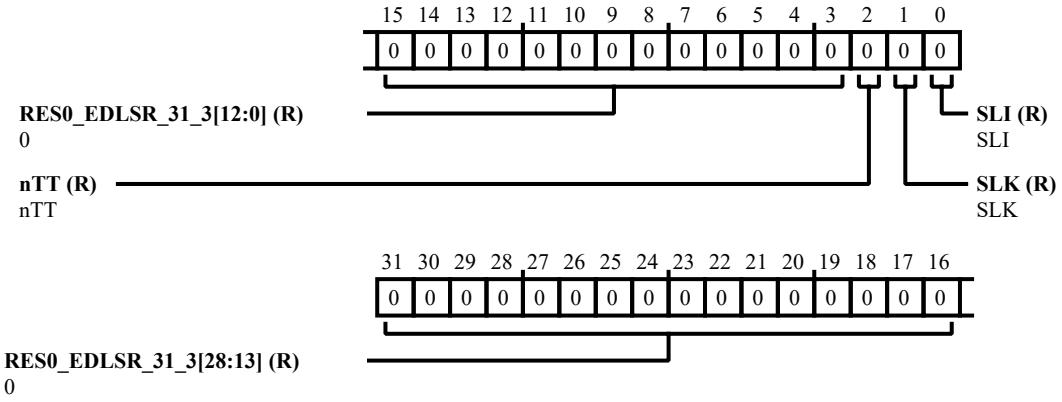

Figure 48-189: A55_CLUSTER_EDLSR Register Diagram

Table 48-187: A55_CLUSTER_EDLSR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:3 (R/NW)	RES0_EDLSR_31_3	0. Reserved, RES0.	
2 (R/NW)	NTT	nTT. Not thirty-two bit access required. RAZ.	
1 (R/NW)	SLK	SLK. Software Lock status for this component. For an access to LSR that is not a memory-mapped access, or when the Software Lock is not implemented, this field is RES0. For memory-mapped accesses when the Software Lock is implemented, possible values of this field are: 0 Lock clear. Writes are permitted to this component's registers. 1 Lock set. Writes to this component's registers are ignored, and reads have no side effects.	
		0	Lock clear. Writes are permitted to this component's registers.
		1	Lock set. Writes to this component's registers are ignored, and reads have no side effects.

Table 48-187: A55_CLUSTER_EDLSR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/NW)	SLI	SLI. Software Lock implemented. For an access to LSR that is not a memory-mapped access, this field is RAZ. For memory-mapped accesses, the value of this field is IMPLEMENTATION DEFINED. Permitted values are: 0 Software Lock not implemented or not memory-mapped access. 1 Software Lock implemented and memory-mapped access.	
		0	Software Lock not implemented or not memory-mapped access.
		1	Software Lock implemented and memory-mapped access.

External Debug Processor Feature Register

Provides information about implemented PE features. For general information about the interpretation of the ID registers see .

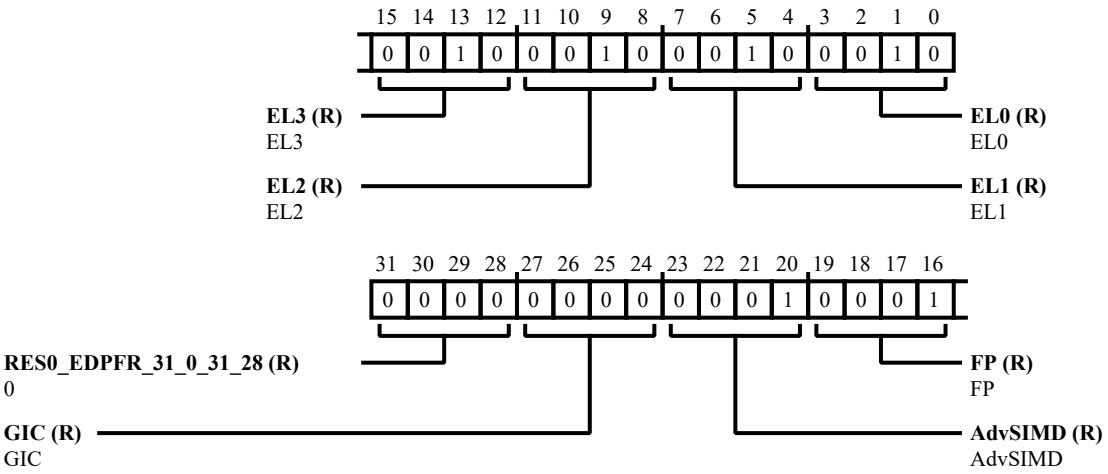

Figure 48-190: A55_CLUSTER_EDPFR_31_0 Register Diagram

Table 48-188: A55_CLUSTER_EDPFR_31_0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:28 (R/NW)	RES0_EDPFR_31_0_31_28	0. Reserved, RES0.	
27:24 (R/NW)	GIC	GIC. System register GIC interface support. Defined values are: 0000 No System register interface to the GIC is supported. 0001 System register interface to versions 3.0 and 4.0 of the GIC CPU interface is supported. All other values are reserved. In an ARMv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64PFR0_EL1.GIC.	
		0	No System register interface to the GIC is supported.
		1	System register interface to versions 3.0 and 4.0 of the GIC CPU interface is supported.
23:20 (R/NW)	ADVSIMD	AdvSIMD. Advanced SIMD. Defined values are: 0000 Advanced SIMD is implemented. 1111 Advanced SIMD is not implemented. All other values are reserved. In an ARMv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64PFR0_EL1.AdvSIMD.	
		0	Advanced SIMD is implemented.
		15	Advanced SIMD is not implemented.

Table 48-188: A55_CLUSTER_EDPFR_31_0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
19:16 (R/NW)	FP	FP. Floating-point. Defined values are: 0000 Floating-point is implemented. 1111 Floating-point is not implemented. All other values are reserved. In an ARMv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64PFR0_EL1.FP.	
		0	Floating-point is implemented.
		15	Floating-point is not implemented.
15:12 (R/NW)	EL3	EL3. AArch64 EL3 Exception level handling. Defined values are: 0000 EL3 is not implemented or cannot be executed in AArch64 state. 0001 EL3 can be executed in AArch64 state only. 0010 EL3 can be executed in either AArch64 or AArch32 state. When the value of EDAA32PFR.EL3 is non-zero, this field must be 0000. All other values are reserved. In an ARMv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64PFR0_EL1.EL3.	
		0	EL3 is not implemented or cannot be executed in AArch64 state.
		1	EL3 can be executed in AArch64 state only.
		2	EL3 can be executed in either AArch64 or AArch32 state.
11:8 (R/NW)	EL2	EL2. AArch64 EL2 Exception level handling. Defined values are: 0000 EL2 is not implemented or cannot be executed in AArch64 state. 0001 EL2 can be executed in AArch64 state only. 0010 EL2 can be executed in either AArch64 or AArch32 state. When the value of EDAA32PFR.EL2 is non-zero, this field must be 0000. All other values are reserved. In an ARMv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64PFR0_EL1.EL2.	
		0	EL2 is not implemented or cannot be executed in AArch64 state.
		1	EL2 can be executed in AArch64 state only.
		2	EL2 can be executed in either AArch64 or AArch32 state.

Table 48-188: A55_CLUSTER_EDPFR_31_0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7:4 (R/NW)	EL1	EL1. AArch64 EL1 Exception level handling. Defined values are: 0000 EL1 can be executed in AArch32 state only. 0001 EL1 can be executed in AArch64 state only. 0010 EL1 can be executed in either AArch64 or AArch32 state. All other values are reserved. In an ARMv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64PFR0_EL1.EL1.	
		0	EL1 can be executed in AArch32 state only.
		1	EL1 can be executed in AArch64 state only.
		2	EL1 can be executed in either AArch64 or AArch32 state.
3:0 (R/NW)	EL0	EL0. AArch64 EL0 Exception level handling. Defined values are: 0000 EL0 can be executed in AArch32 state only. 0001 EL0 can be executed in AArch64 state only. 0010 EL0 can be executed in either AArch64 or AArch32 state. All other values are reserved. In an ARMv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64PFR0_EL1.EL0.	
		0	EL0 can be executed in AArch32 state only.
		1	EL0 can be executed in AArch64 state only.
		2	EL0 can be executed in either AArch64 or AArch32 state.

External Debug Processor Feature Register

Provides information about implemented PE features. For general information about the interpretation of the ID registers see .

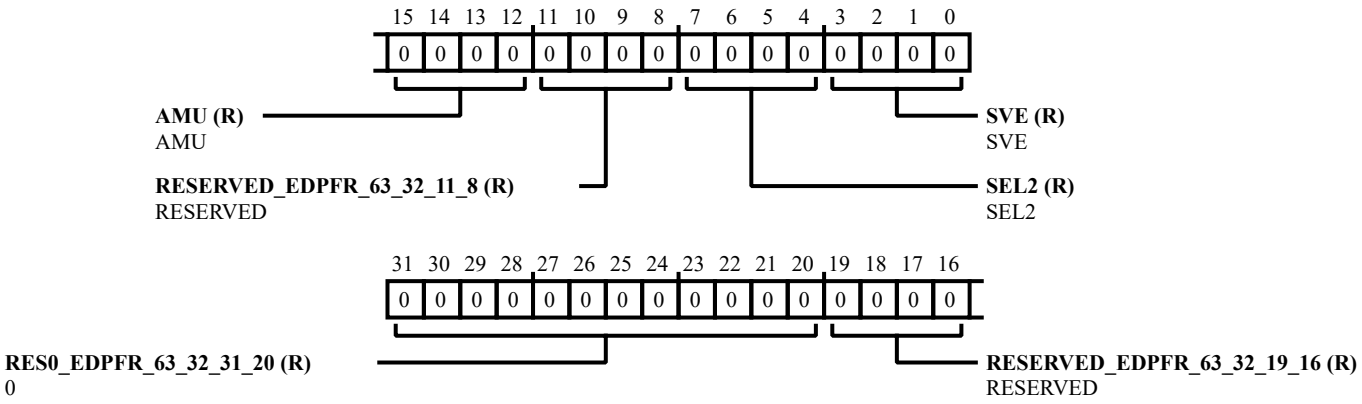

Figure 48-191: A55_CLUSTER_EDPFR_63_32 Register Diagram

Table 48-189: A55_CLUSTER_EDPFR_63_32 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:20 (R/NW)	RES0_EDPFR_63_32_31_20	0. Reserved, RES0.
19:16 (R/NW)	RESERVED_EDPFR_63_32_19_16	RESERVED. Reserved. This field reads as an UNKNOWN value.
15:12 (R/NW)	AMU	AMU. AMU.
11:8 (R/NW)	RESERVED_EDPFR_63_32_11_8	RESERVED. Reserved. This field reads as an UNKNOWN value.
7:4 (R/NW)	SEL2	SEL2. Secure EL2 implemented.
3:0 (R/NW)	SVE	SVE. SVE.

External Debug Peripheral Identification 0 Register

Provides information to identify an external debug component.

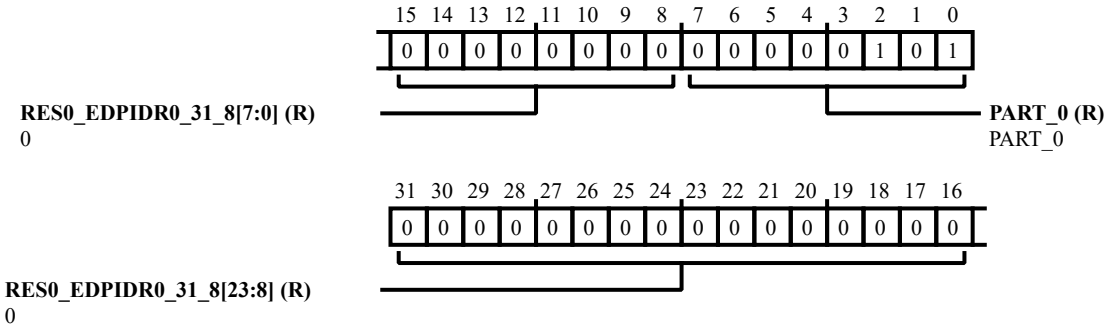

Figure 48-192: A55_CLUSTER_EDPIDR0 Register Diagram

Table 48-190: A55_CLUSTER_EDPIDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_EDPIDR0_31_8	0. Reserved, RES0.
7:0 (R/NW)	PART_0	PART_0. Part number, least significant byte.

External Debug Peripheral Identification 1 Register

Provides information to identify an external debug component.

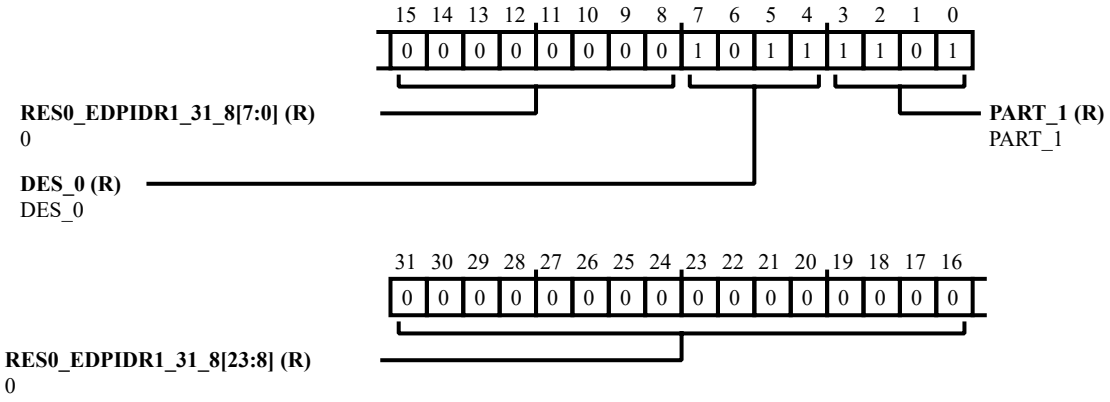

Figure 48-193: A55_CLUSTER_EDPIDR1 Register Diagram

Table 48-191: A55_CLUSTER_EDPIDR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_EDPIDR1_31_8	0. Reserved, RES0.
7:4 (R/NW)	DES_0	DES_0. Designer, least significant nibble of JEP106 ID code. For ARM Limited, this field is 0b1011.
3:0 (R/NW)	PART_1	PART_1. Part number, most significant nibble.

External Debug Peripheral Identification 2 Register

Provides information to identify an external debug component.

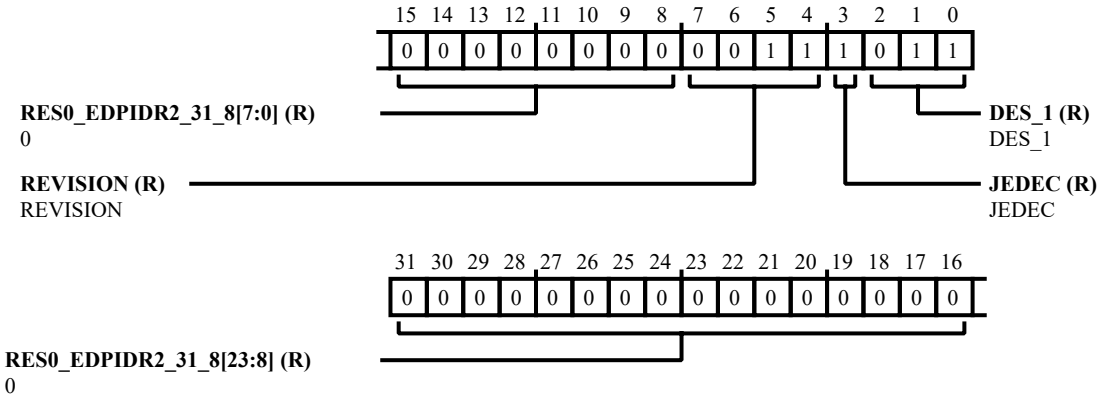

Figure 48-194: A55_CLUSTER_EDPIDR2 Register Diagram

Table 48-192: A55_CLUSTER_EDPIDR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_EDPIDR2_31_8	0. Reserved, RES0.
7:4 (R/NW)	REVISION	REVISION. Part major revision. Parts can also use this field to extend Part number to 16-bits.
3 (R/NW)	JEDEC	JEDEC. RAO. Indicates a JEP106 identity code is used.
2:0 (R/NW)	DES_1	DES_1. Designer, most significant bits of JEP106 ID code. For ARM Limited, this field is 0b011.

External Debug Peripheral Identification 3 Register

Provides information to identify an external debug component.

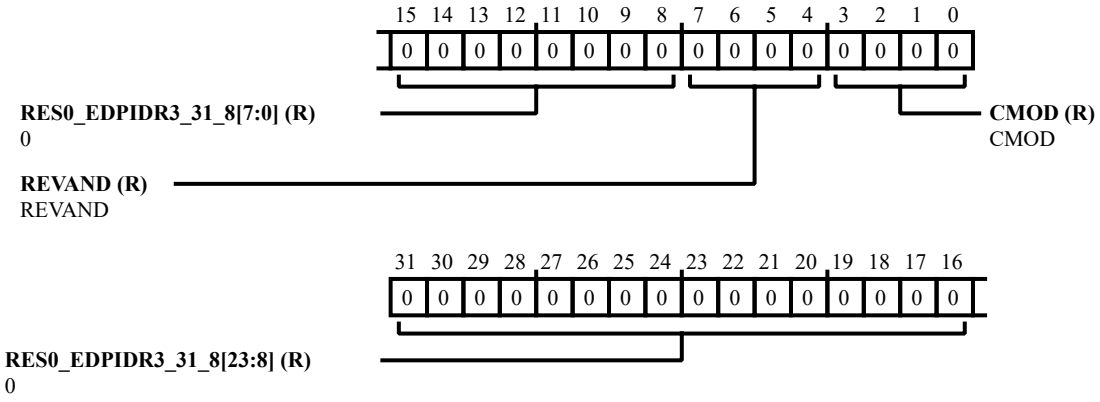

Figure 48-195: A55_CLUSTER_EDPIDR3 Register Diagram

Table 48-193: A55_CLUSTER_EDPIDR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_EDPIDR3_31_8	0. Reserved, RES0.
7:4 (R/NW)	REVAND	REVAND. Part minor revision. Parts using EDPIDR2.REVISION as an extension to the Part number must use this field as a major revision number.
3:0 (R/NW)	CMOD	CMOD. Customer modified. Indicates someone other than the Designer has modified the component.

External Debug Peripheral Identification 4 Register

Provides information to identify an external debug component.

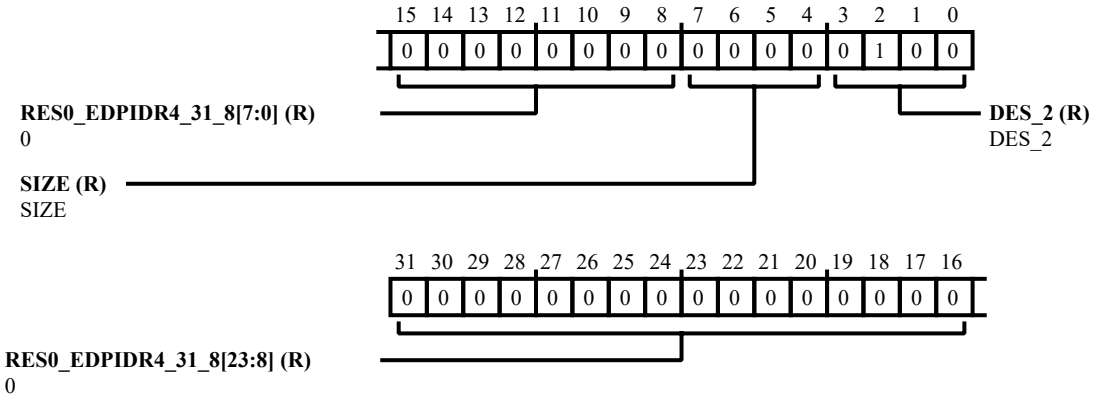

Figure 48-196: A55_CLUSTER_EDPIDR4 Register Diagram

Table 48-194: A55_CLUSTER_EDPIDR4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_EDPIDR4_31_8	0. Reserved, RES0.
7:4 (R/NW)	SIZE	SIZE. Size of the component. RAZ. Log2 of the number of 4KB pages from the start of the component to the end of the component ID registers.
3:0 (R/NW)	DES_2	DES_2. Designer, JEP106 continuation code, least significant nibble. For ARM Limited, this field is 0b0100.

External Debug Peripheral Identification 5 Register

Provides information to identify an external debug component.

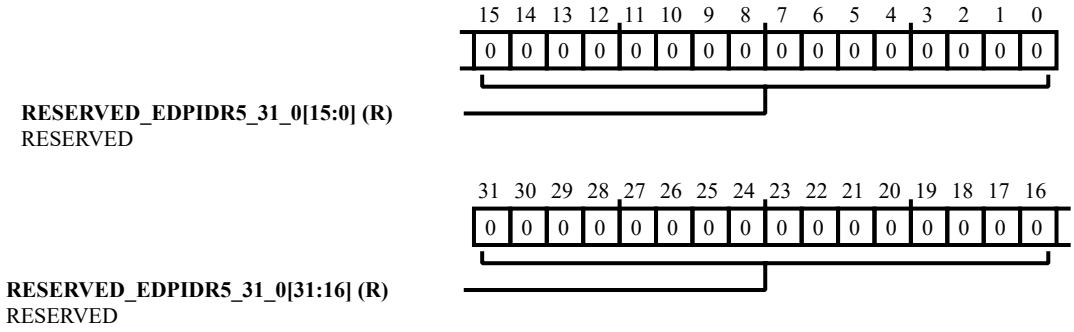

Figure 48-197: A55_CLUSTER_EDPIDR5 Register Diagram

Table 48-195: A55_CLUSTER_EDPIDR5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RESERVED_ED-PIDR5_31_0	RESERVED. Reserved RES0.

External Debug Peripheral Identification 6 Register

Provides information to identify an external debug component.

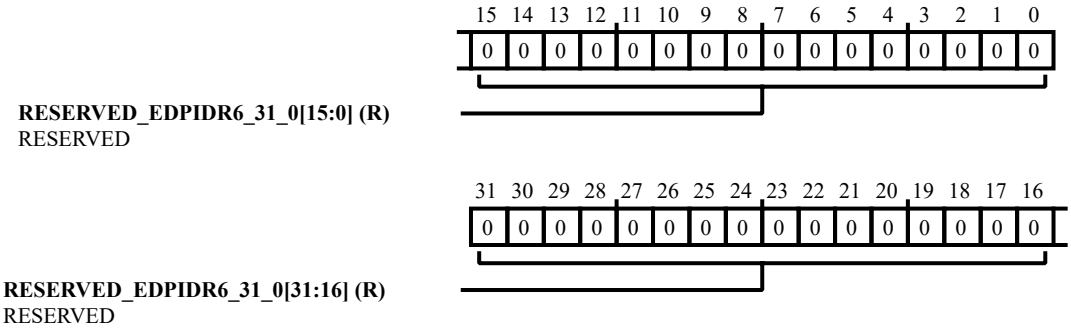

Figure 48-198: A55_CLUSTER_EDPIDR6 Register Diagram

Table 48-196: A55_CLUSTER_EDPIDR6 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RESERVED_ED-PIDR6_31_0	RESERVED. Reserved RES0.

External Debug Peripheral Identification 7 Register

Provides information to identify an external debug component.

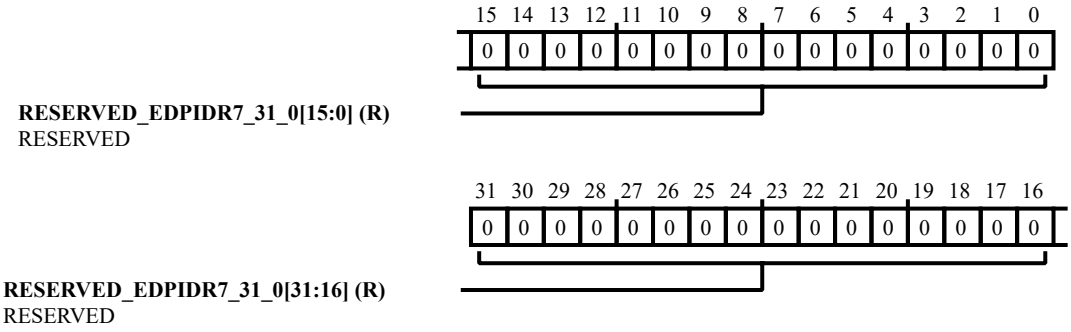

Figure 48-199: A55_CLUSTER_EDPIDR7 Register Diagram

Table 48-197: A55_CLUSTER_EDPIDR7 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RESERVED_ED-PIDR7_31_0	RESERVED. Reserved RES0.

Main ID Register

Provides identification information for the PE, including an implementer code for the device and a device ID number.

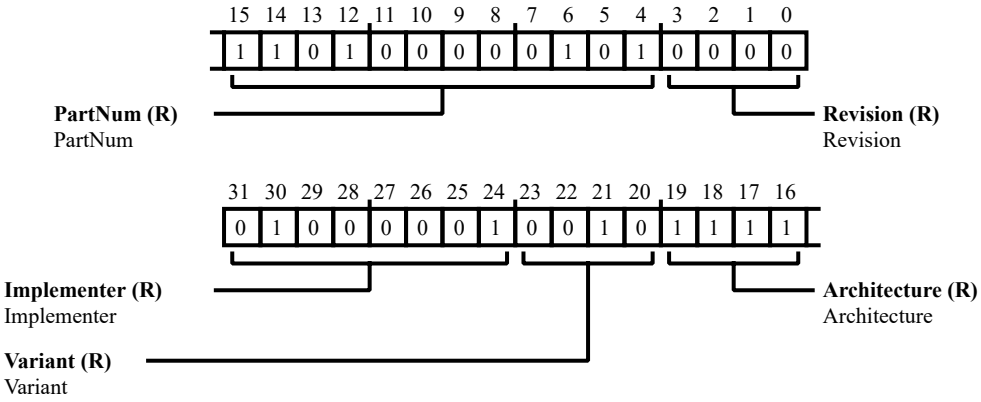

Figure 48-200: A55_CLUSTER_MIDR_EL1 Register Diagram

Table 48-198: A55_CLUSTER_MIDR_EL1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:24 (R/NW)	IMPLEMENTER	Implementer. The Implementer code. This field must hold an implementer code that has been assigned by ARM.	
23:20 (R/NW)	VARIANT	Variant. An IMPLEMENTATION DEFINED variant number. Typically this field is used to distinguish between different product variants or major revisions of a product.	
19:16 (R/NW)	ARCHITECTURE	Architecture. The Architecture used.	
		1	ARMv4.
		2	ARMv4T.
		3	ARMv5 (obsolete).
		4	ARMv5T.
		5	ARMv5TE.
		6	ARMv5TEJ.
		7	ARMv6.
		15	Defined by CPUID scheme.

Table 48-198: A55_CLUSTER_MIDR_EL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
15:4 (R/NW)	PARTNUM	PartNum. An IMPLEMENTATION DEFINED primary part number for the device. On processors implemented by ARM if the top four bits of the primary part number are 0x0 or 0x7 the variant and architecture are encoded differently.
3:0 (R/NW)	REVISION	Revision. An IMPLEMENTATION DEFINED revision number for the device.

Trace Authentication Status Register

Returns the level of tracing that the trace unit can support.

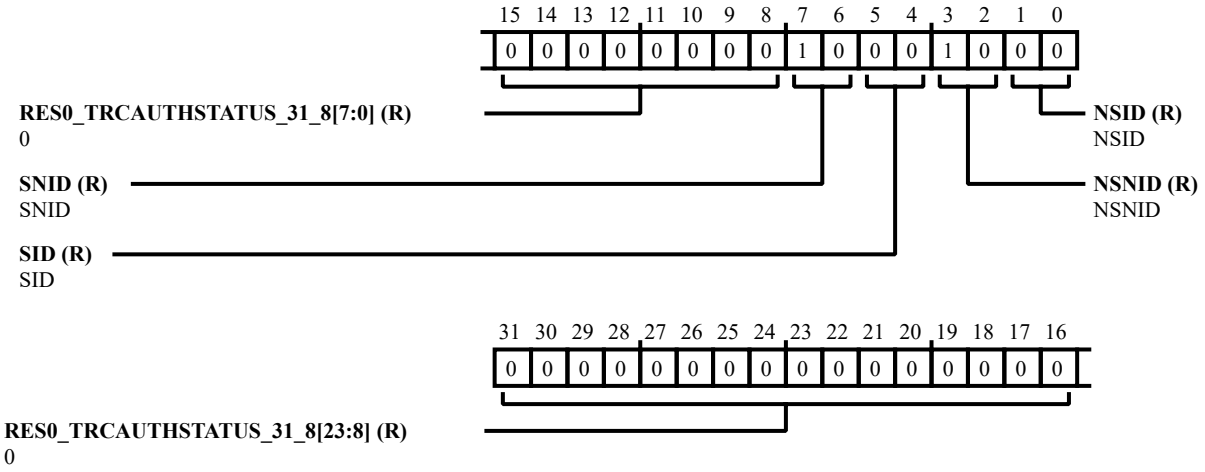

Figure 48-201: A55_CLUSTER_TRCAUTHSTATUS Register Diagram

Table 48-199: A55_CLUSTER_TRCAUTHSTATUS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:8 (R/NW)	RES0_TRCAUTHSTA-TUS_31_8	0. Reserved, RES0.	
7:6 (R/NW)	SNID	SNID. Indicates whether the system enables the trace unit to support Secure non-invasive debug: 00 The trace unit does not implement support for Secure non-invasive debug. 01 Reserved. 10 Secure non-invasive debug is disabled. 11 Secure non-invasive debug is enabled.	
		0	The trace unit does not implement support for Secure non-invasive debug.
		1	Reserved.
		2	Secure non-invasive debug is disabled.
		3	Secure non-invasive debug is enabled.
5:4 (R/NW)	SID	SID. Indicates whether the trace unit supports Secure invasive debug: 00 The trace unit does not support Secure invasive debug. All other values are reserved.	
		0	The trace unit does not support Secure invasive debug.

Table 48-199: A55_CLUSTER_TRCAUTHSTATUS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3:2 (R/NW)	NSNID	NSNID. Indicates whether the system enables the trace unit to support Non-secure non-invasive debug: 00 The trace unit does not implement support for Non-secure non-invasive debug. 01 Reserved. 10 Non-secure non-invasive debug is disabled. 11 Non-secure non-invasive debug is enabled.	
		0	The trace unit does not implement support for Non-secure non-invasive debug.
		1	Reserved.
		2	Non-secure non-invasive debug is disabled.
		3	Non-secure non-invasive debug is enabled.
1:0 (R/NW)	NSID	NSID. Indicates whether the trace unit supports Non-secure invasive debug: 00 The trace unit does not support Non-secure invasive debug. All other values are reserved.	
		0	The trace unit does not support Non-secure invasive debug.

Trace Component ID 0 Register

Return byte 0 of the CoreSight preamble information.

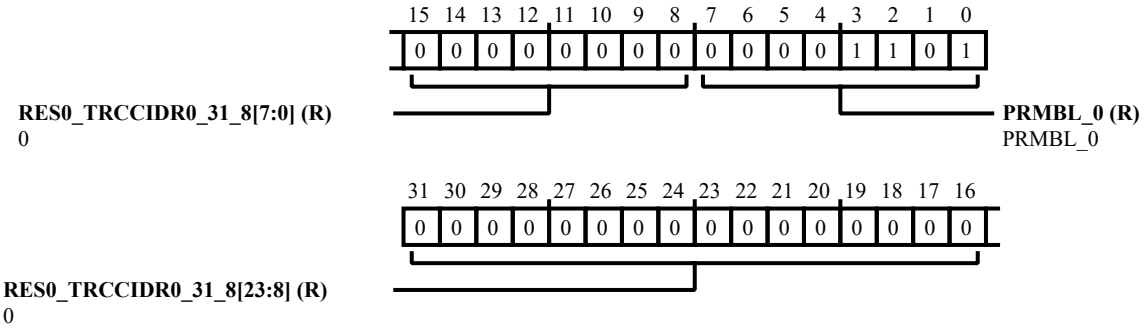

Figure 48-202: A55_CLUSTER_TRCCIDR0 Register Diagram

Table 48-200: A55_CLUSTER_TRCCIDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_TRCCIDR0_31_8	0. Reserved, RES0.
7:0 (R/NW)	PRMBL_0	PRMBL_0. Preamble. Must read as 0x0D.

Trace Component ID 1 Register

Return byte 1 of the CoreSight preamble information.

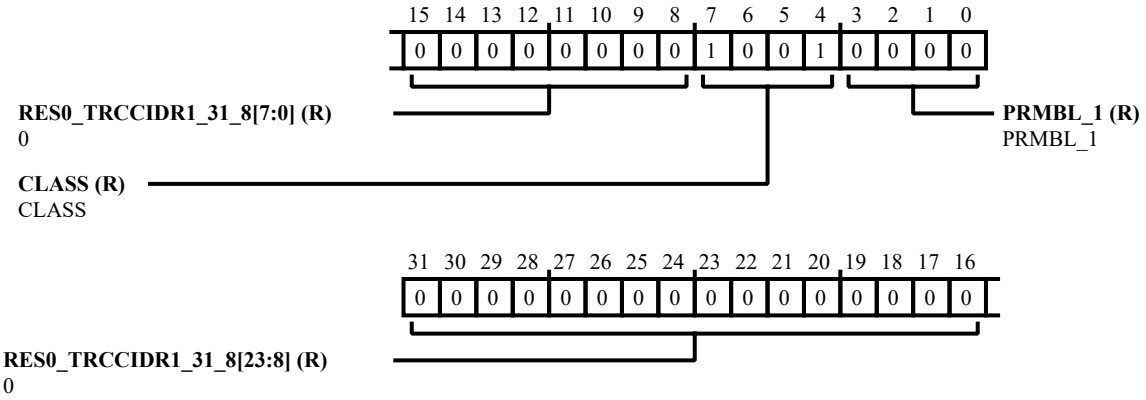

Figure 48-203: A55_CLUSTER_TRCCIDR1 Register Diagram

Table 48-201: A55_CLUSTER_TRCCIDR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_TRCCIDR1_31_8	0. Reserved, RES0.
7:4 (R/NW)	CLASS	CLASS. Component class. Reads as 0x9, to indicate that the ETM is a debug component, with CoreSight architecture compliant management registers.
3:0 (R/NW)	PRMBL_1	PRMBL_1. Preamble. Must read as 0x0.

Trace Component ID 2 Register

Return byte 2 of the CoreSight preamble information.

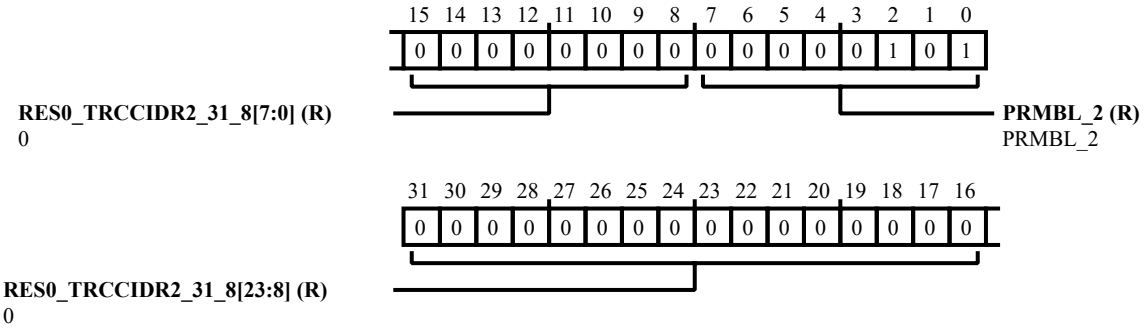

Figure 48-204: A55_CLUSTER_TRCCIDR2 Register Diagram

Table 48-202: A55_CLUSTER_TRCCIDR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_TRCCIDR2_31_8	0. Reserved, RES0.
7:0 (R/NW)	PRMBL_2	PRMBL_2. Preamble. Must read as 0x05.

Trace Component ID 3 Register

Return byte 3 of the CoreSight preamble information.

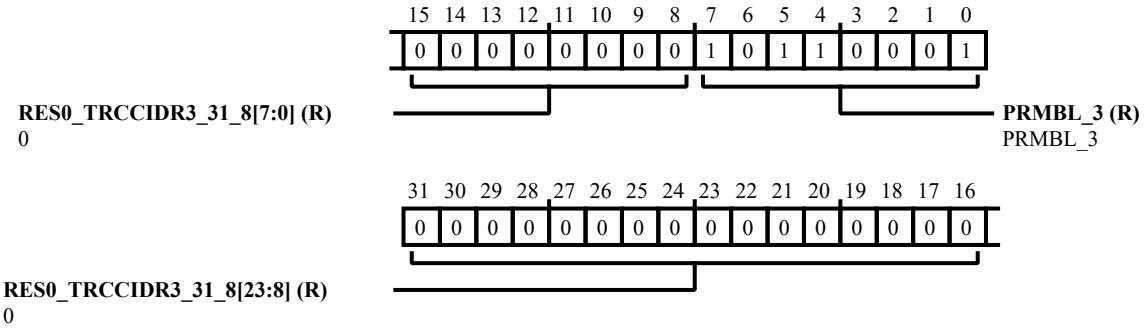

Figure 48-205: A55_CLUSTER_TRCCIDR3 Register Diagram

Table 48-203: A55_CLUSTER_TRCCIDR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_TRCCIDR3_31_8	0. Reserved, RES0.
7:0 (R/NW)	PRMBL_3	PRMBL_3. Preamble. Must read as 0xB1.

Trace Device Affinity 0 Register

Returns the value of the lower 32 bits of MPIDR_EL1 as seen from the highest implemented exception level, unaffected by VMPIDR_EL2. If the trace unit is shared between multiple processors, the value in this register indicates the MPIDR value of the processor that TRCPROCSELR selects.

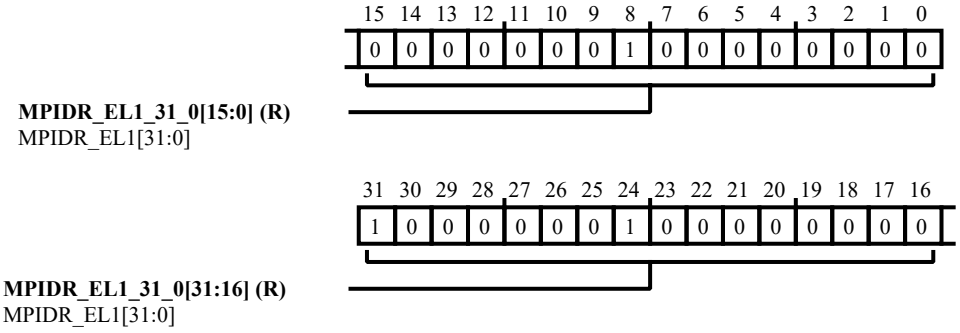

Figure 48-206: A55_CLUSTER_TRCDEVAFF0 Register Diagram

Table 48-204: A55_CLUSTER_TRCDEVAFF0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	MPIDR_EL1_31_0	MPIDR_EL1[31:0]. Read-only copy of the low half of MPIDR_EL1, as seen from the highest implemented exception level.

Trace Device Affinity 1 Register

Returns the value of the upper 32 bits of MPIDR_EL1 as seen from the highest implemented exception level, unaffected by VMPIDR_EL2. If the trace unit is shared between multiple processors, the value in this register indicates the MPIDR value of the processor that TRCPROCSELR selects.

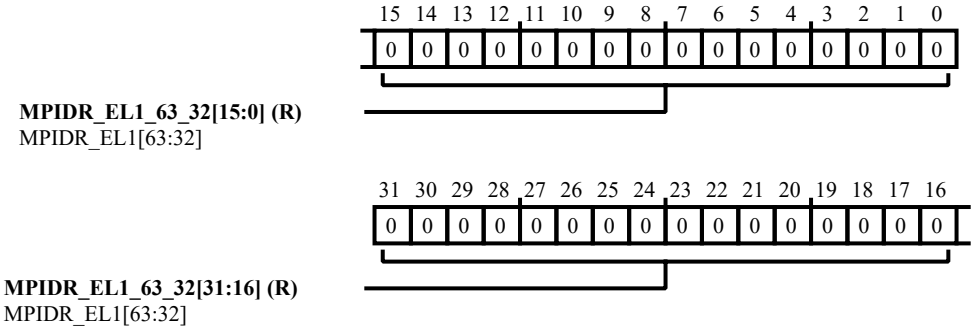

Figure 48-207: A55_CLUSTER_TRCDEVAFF1 Register Diagram

Table 48-205: A55_CLUSTER_TRCDEVAFF1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	MPIDR_EL1_63_32	MPIDR_EL1[63:32]. Read-only copy of the high half of MPIDR_EL1, as seen from the highest implemented exception level.

Trace Device Architecture Register

Identifies the trace unit as an ETMv4 component. This enables debuggers to make some use of a component that conforms to the architecture definition but whose part number is not necessarily recognized.

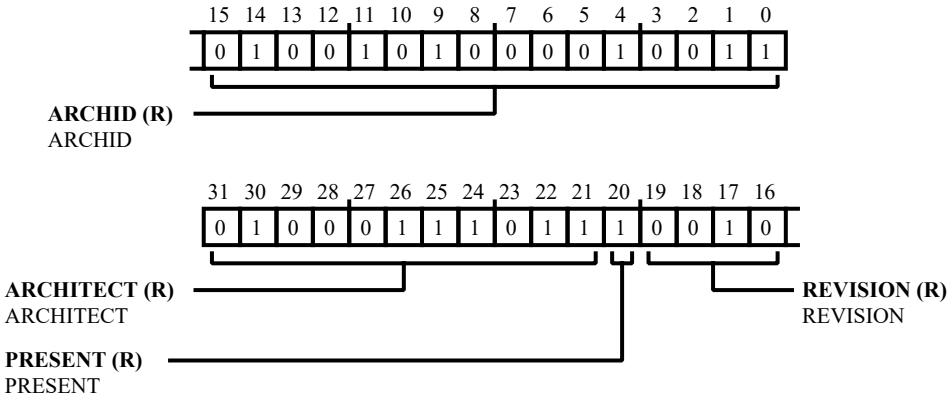

Figure 48-208: A55_CLUSTER_TRCDEVARCH Register Diagram

Table 48-206: A55_CLUSTER_TRCDEVARCH Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:21 (R/NW)	ARCHITECT	ARCHITECT. Defines the architecture of the component. For trace, this is ARM Limited.Bits [31:28] are the JEP 106 continuation code, 0x4.Bits [27:21] are the JEP 106 ID code, 0x3B.
20 (R/NW)	PRESENT	PRESENT. When set to 1, indicates that the DEVARCH is present.This field is RAO.
19:16 (R/NW)	REVISION	REVISION. Defines the architecture revision. For architectures defined by ARM this is the minor revision.For trace, the revision defined by ETMv4 is 0x0.All other values are reserved.
15:0 (R/NW)	ARCHID	ARCHID. Defines this part to be a v8-A debug component. For architectures defined by ARM this is further subdivided.For trace, bits [15:12] are the architecture version, 0x4; bits [11:0] are the architecture part number, 0xA13.This corresponds to trace architecture version ETMv4.

Trace Device ID Register

Returns an IMPLEMENTATION DEFINED CoreSight component capabilities field.

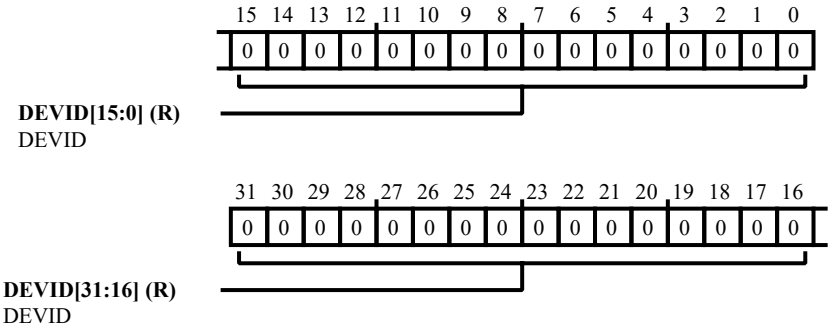

Figure 48-209: A55_CLUSTER_TRCDEVID Register Diagram

Table 48-207: A55_CLUSTER_TRCDEVID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	DEVID	DEVID. Indicates the capabilities of the trace unit. The implemented width of this field and its bit assignments are IMPLEMENTATION DEFINED. Unimplemented bits are RAZ/WI.If a component is configurable then ARM recommends that this field can also indicate which configuration options are implemented that differ from the standard configuration.

Trace Device Type Register

Indicates what type of CoreSight device the trace unit is.

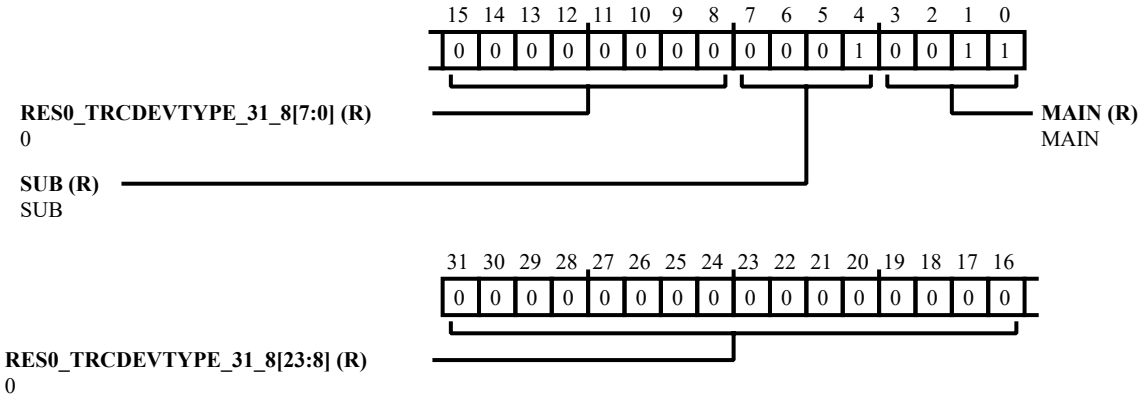

Figure 48-210: A55_CLUSTER_TRCDEVTYPE Register Diagram

Table 48-208: A55_CLUSTER_TRCDEVTYPE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_TRCDEV-TYPE_31_8	0. Reserved, RES0.
7:4 (R/NW)	SUB	SUB. Returns 0x1, to indicate that the ETM generates processor trace.All other values are reserved.
3:0 (R/NW)	MAIN	MAIN. Returns 0x3, to indicate that the ETM is a trace source.All other values are reserved.

Trace Software Lock Access Register

Controls whether the Software Lock is locked. When the Software Lock is locked, the trace unit ignores write accesses from the memory-mapped interface to all ETM registers other than the TRCLAR, and does not change the TRCPDSR.STICKYPD bit if a read access occurs to the TRCPDSR on the memory-mapped interface.

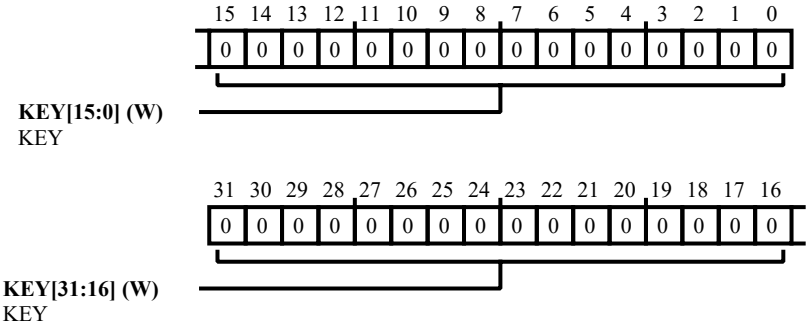

Figure 48-211: A55_CLUSTER_TRCLAR Register Diagram

Table 48-209: A55_CLUSTER_TRCLAR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (RX/W)	KEY	KEY. Writing the key value 0xC5ACCE55 to this field clears the lock, enabling write accesses to this component's registers through a memory-mapped interface.Writing any other value to this register sets the lock, disabling write accesses to this component's registers through a memory mapped interface.Software can use the Software Lock to prevent accidental modification of the trace unit registers by software being debugged. For example, software that accidentally initializes an incorrect region of memory might disable the trace unit and make it impossible to trace the software.

Trace Software Lock Status Register

Trace Software Lock Status Register.

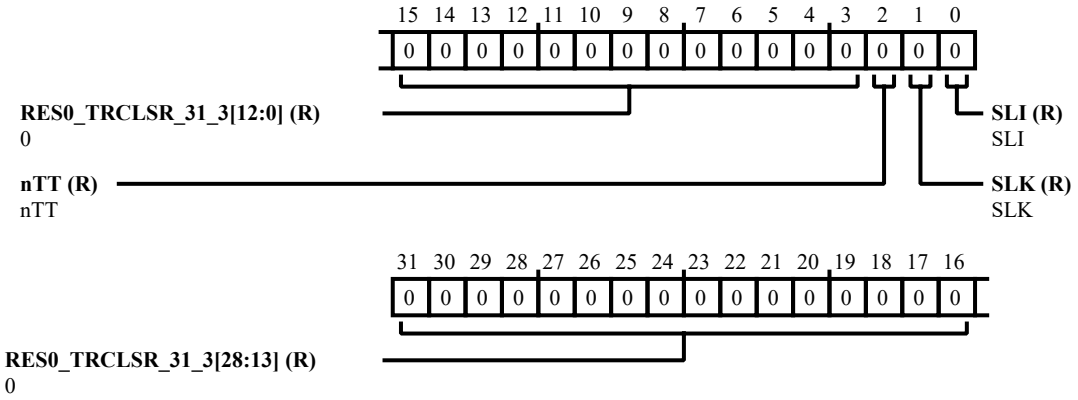

Figure 48-212: A55_CLUSTER_TRCLSR Register Diagram

Table 48-210: A55_CLUSTER_TRCLSR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:3 (R/NW)	RES0_TRCLSR_31_3	0. Reserved, RES0.	
2 (R/NW)	NTT	nTT. Not thirty-two bit access required. RAZ.	
1 (R/NW)	SLK	SLK. Software lock status for this component. Possible values of this field are: 0 Lock clear. Writes are permitted to this component's registers. 1 Lock set. Writes to this component's registers are ignored, and reads have no side effects.	
		0	Lock clear. Writes are permitted to this component's registers.
		1	Lock set. Writes to this component's registers are ignored, and reads have no side effects.
0 (R/NW)	SLI	SLI. Software lock implemented. RAO.	

Trace PowerDown Control Register

Requests the system to provide power to the trace unit.

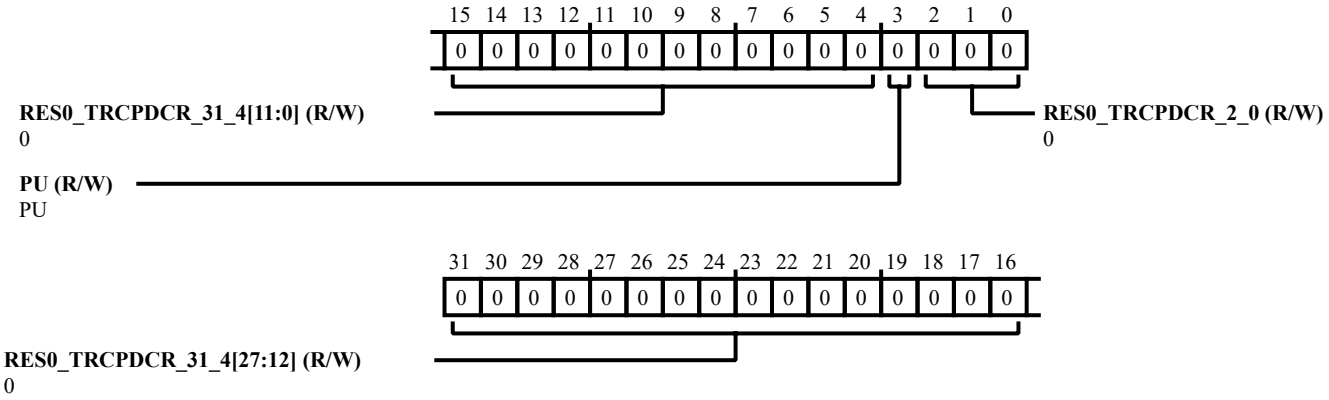

Figure 48-213: A55_CLUSTER_TRCPDCR Register Diagram

Table 48-211: A55_CLUSTER_TRCPDCR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/W)	RES0_TRCPDCR_31_4	0. Reserved, RES0.	
3 (R/W)	PU	PU. Powerup request bit: 0 The system can remove power from the trace unit. The TRCPDSR indicates if the trace unit is powered down. 1 The system must provide power to the trace unit. Typically, a trace unit drives a signal representing the value of this bit to a power controller to request that the trace unit core power domain is powered up. However, if the trace unit and the processor are in the same power domain then the implementation might combine the PU status with a signal from the processor.	
		0	The system can remove power from the trace unit. The TRCPDSR indicates if the trace unit is powered down.
		1	The system must provide power to the trace unit.
2:0 (R/W)	RES0_TRCPDCR_2_0	0. Reserved, RES0.	

Trace Peripheral ID 0 Register

Returns information that helps identify the peripheral. If software reads the TRCPIDR[7:0] register group then it can determine the 64-bit CoreSight Peripheral ID for the ETM.

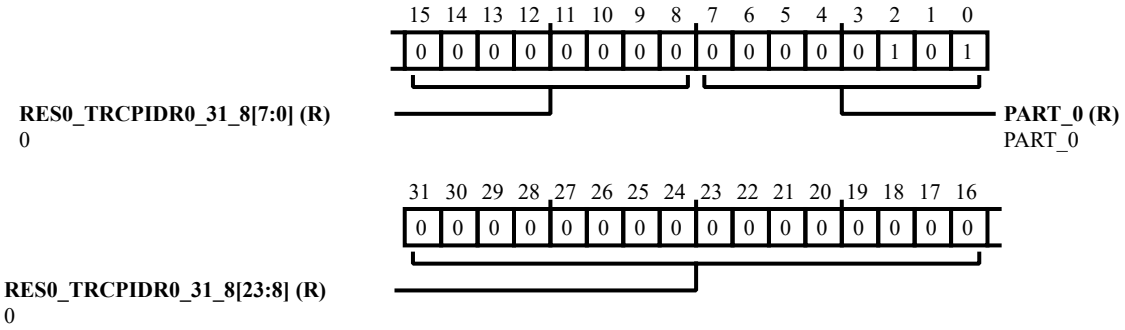

Figure 48-214: A55_CLUSTER_TRCPIDR0 Register Diagram

Table 48-212: A55_CLUSTER_TRCPIDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_TRCPIDR0_31_8	0. Reserved, RES0.
7:0 (R/NW)	PART_0	PART_0. Part number, bits[7:0].

Trace Peripheral ID 1 Register

Returns information that helps identify the peripheral. If software reads the TRCPIDR[7:0] register group then it can determine the 64-bit CoreSight Peripheral ID for the ETM.

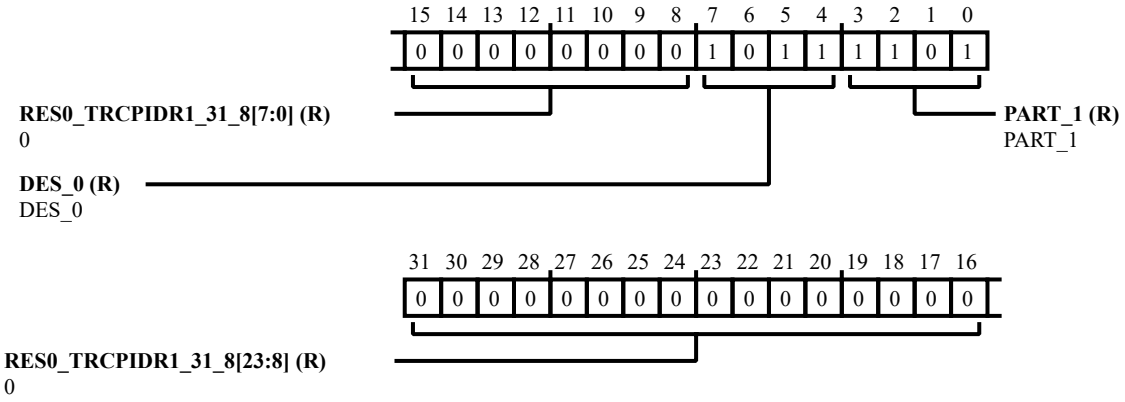

Figure 48-215: A55_CLUSTER_TRCPIDR1 Register Diagram

Table 48-213: A55_CLUSTER_TRCPIDR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_TRCPIDR1_31_8	0. Reserved, RES0.
7:4 (R/NW)	DES_0	DES_0. Designer, bits[3:0] of JEP106 ID code. For ARM Limited, this field is 0b1011.
3:0 (R/NW)	PART_1	PART_1. Part number, bits[11:8].

Trace Peripheral ID 2 Register

Returns information that helps identify the peripheral. If software reads the TRCPIDR[7:0] register group then it can determine the 64-bit CoreSight Peripheral ID for the ETM.

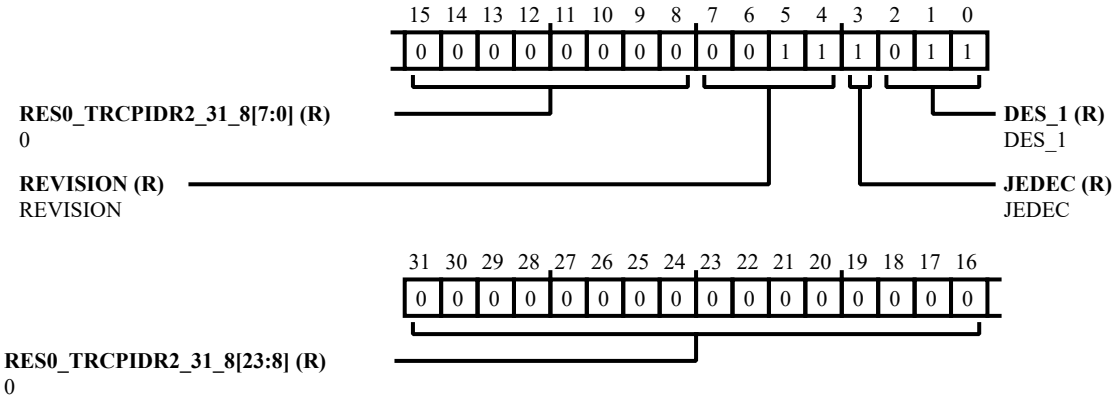

Figure 48-216: A55_CLUSTER_TRCPIDR2 Register Diagram

Table 48-214: A55_CLUSTER_TRCPIDR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_TRCPIDR2_31_8	0. Reserved, RES0.
7:4 (R/NW)	REVISION	REVISION. The IMPLEMENTATION DEFINED revision number for the ETM implementation. See also TRCIDR1.REVISION.
3 (R/NW)	JEDEC	JEDEC. RAO. Indicates a JEP106 identity code is used.
2:0 (R/NW)	DES_1	DES_1. Designer, most significant bits of JEP106 ID code. For ARM Limited, this field is 0b011.

Trace Peripheral ID 3 Register

Returns information that helps identify the peripheral. If software reads the TRCPIDR[7:0] register group then it can determine the 64-bit CoreSight Peripheral ID for the ETM.

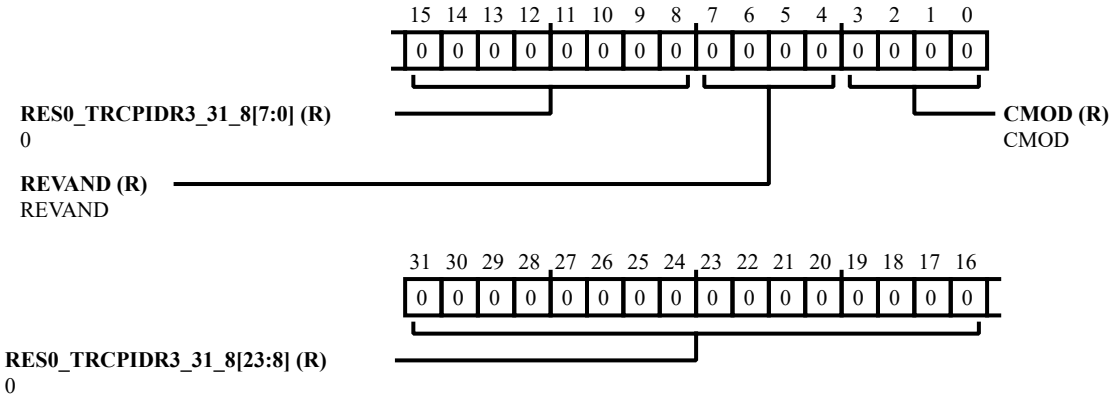

Figure 48-217: A55_CLUSTER_TRCPIDR3 Register Diagram

Table 48-215: A55_CLUSTER_TRCPIDR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_TRCPIDR3_31_8	0. Reserved, RES0.
7:4 (R/NW)	REVAND	REVAND. The IMPLEMENTATION DEFINED manufacturing revision number for the implementation. After silicon is available, if metal fixes are necessary, the manufacturer can alter the top metal layer so that this field can indicate any post-fab silicon changes.
3:0 (R/NW)	CMOD	CMOD. Customer modified. Indicates someone other than the Designer has modified the component.

Trace Peripheral ID 4 Register

Returns information that helps identify the peripheral. If software reads the TRCPIDR[7:0] register group then it can determine the 64-bit CoreSight Peripheral ID for the ETM.

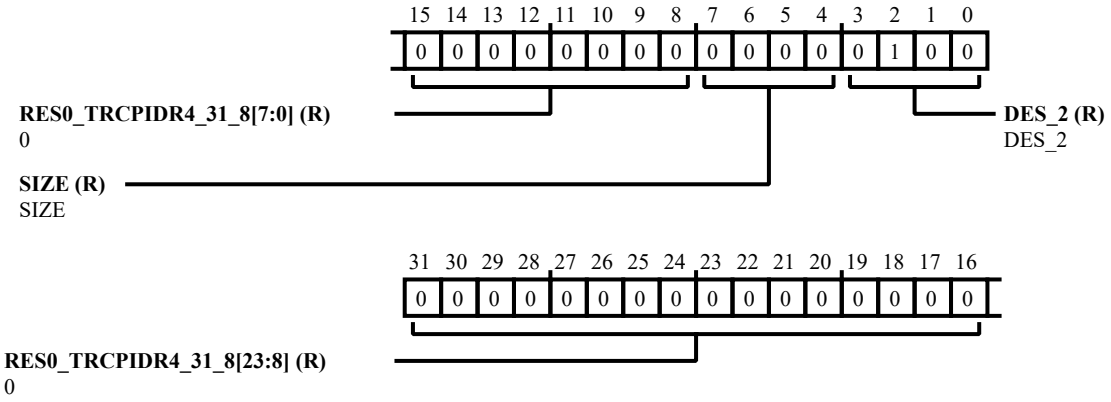

Figure 48-218: A55_CLUSTER_TRCPIDR4 Register Diagram

Table 48-216: A55_CLUSTER_TRCPIDR4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_TRCPIDR4_31_8	0. Reserved, RES0.
7:4 (R/NW)	SIZE	SIZE. Size of the component. RES0. This indicates that the ETM memory map occupies 4KB.
3:0 (R/NW)	DES_2	DES_2. Designer, JEP106 continuation code. For ARM Limited, this field is 0b0100.

Performance Monitors Authentication Status Register

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for Performance Monitors.

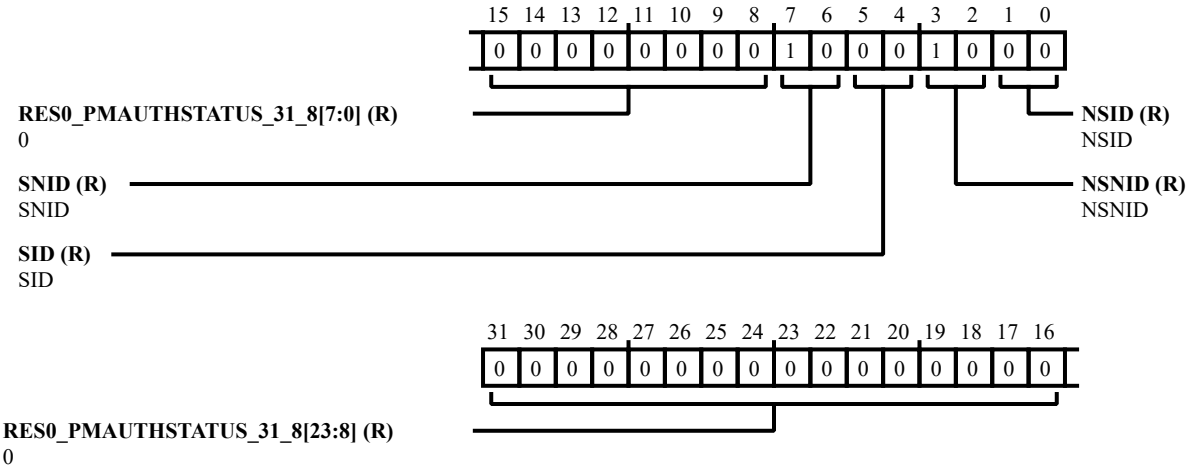

Figure 48-219: A55_CLUSTER_PMAUTHSTATUS Register Diagram

Table 48-217: A55_CLUSTER_PMAUTHSTATUS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:8 (R/NW)	RES0_PMAUTHSTATUS_31_8	0. Reserved, RES0.	
7:6 (R/NW)	SNID	SNID. Holds the same value as DBGAUTHSTATUS_EL1.SNID.	
5:4 (R/NW)	SID	SID. Secure invasive debug. Possible values of this field are: 00 Not implemented. All other values are reserved.	
		0	Not implemented.
3:2 (R/NW)	NSNID	NSNID. Holds the same value as DBGAUTHSTATUS_EL1.NSNID.	
1:0 (R/NW)	NSID	NSID. Non-secure invasive debug. Possible values of this field are: 00 Not implemented. All other values are reserved.	
		0	Not implemented.

Performance Monitors Component Identification 0 Register

Provides information to identify a Performance Monitor component.

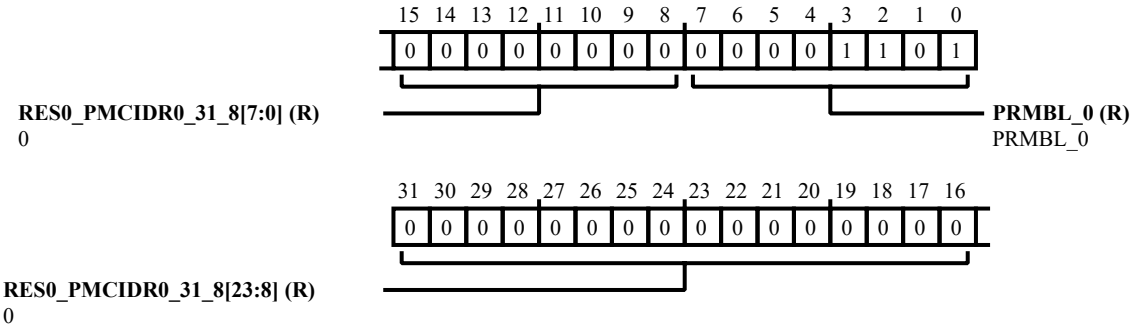

Figure 48-220: A55_CLUSTER_PMCIDR0 Register Diagram

Table 48-218: A55_CLUSTER_PMCIDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_PMCIDR0_31_8	0. Reserved, RES0.
7:0 (R/NW)	PRMBL_0	PRMBL_0. Preamble. Must read as 0x0D.

Performance Monitors Component Identification 1 Register

Provides information to identify a Performance Monitor component.

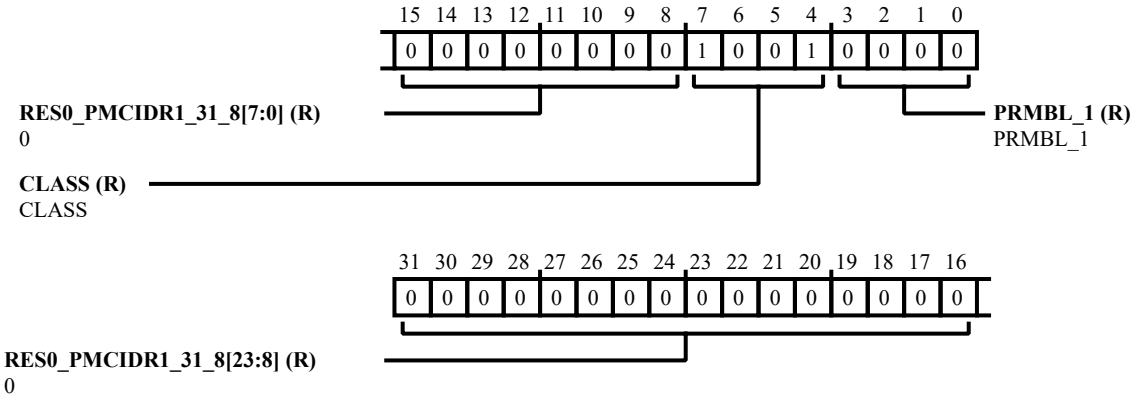

Figure 48-221: A55_CLUSTER_PMCIDR1 Register Diagram

Table 48-219: A55_CLUSTER_PMCIDR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_PMCIDR1_31_8	0. Reserved, RES0.
7:4 (R/NW)	CLASS	CLASS. Component class. Reads as 0x9, debug component.
3:0 (R/NW)	PRMBL_1	PRMBL_1. Preamble. RAZ.

Performance Monitors Component Identification 2 Register

Provides information to identify a Performance Monitor component.

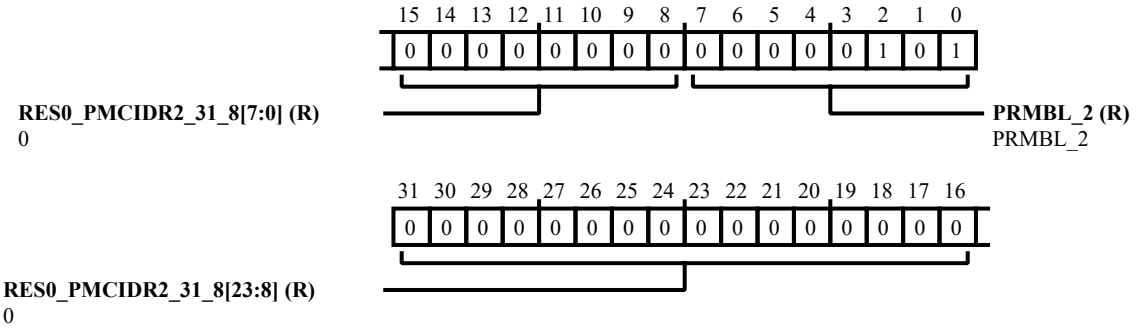

Figure 48-222: A55_CLUSTER_PMCIDR2 Register Diagram

Table 48-220: A55_CLUSTER_PMCIDR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_PMCIDR2_31_8	0. Reserved, RES0.
7:0 (R/NW)	PRMBL_2	PRMBL_2. Preamble. Must read as 0x05.

Performance Monitors Component Identification 3 Register

Provides information to identify a Performance Monitor component.

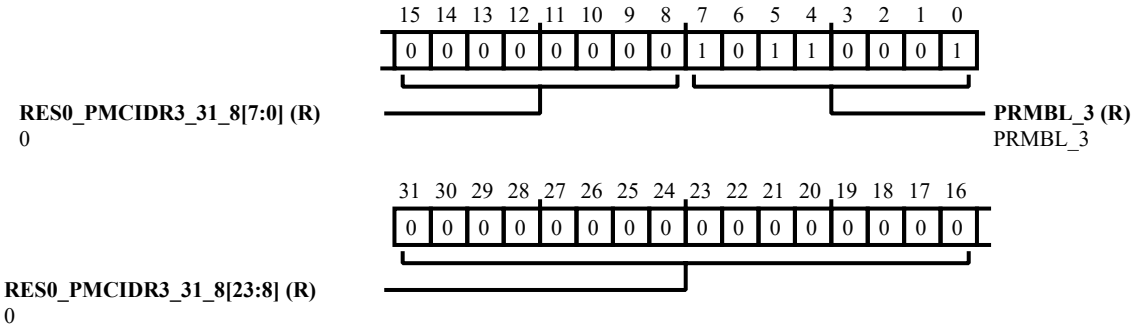

Figure 48-223: A55_CLUSTER_PMCIDR3 Register Diagram

Table 48-221: A55_CLUSTER_PMCIDR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_PMCIDR3_31_8	0. Reserved, RES0.
7:0 (R/NW)	PRMBL_3	PRMBL_3. Preamble. Must read as 0xB1.

Performance Monitors Device Affinity 0 Register

Copy of the low half of the PE MPIDR_EL1 register that allows a debugger to determine which PE in a multiprocessor system the Performance Monitor component relates to.

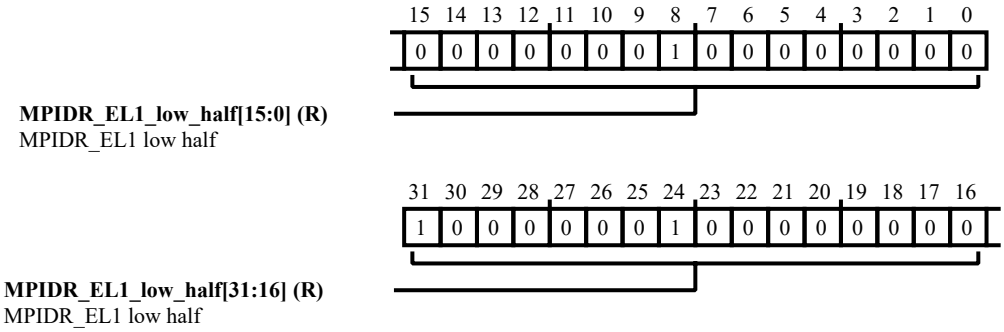

Figure 48-224: A55_CLUSTER_PMDEVAFF0 Register Diagram

Table 48-222: A55_CLUSTER_PMDEVAFF0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	MPIDR_EL1_LOW_HALF	MPIDR_EL1 low half. MPIDR_EL1 low half. Read-only copy of the low half of MPIDR_EL1, as seen from the highest implemented Exception level.

Performance Monitors Device Affinity 1 Register

Copy of the high half of the PE MPIDR_EL1 register that allows a debugger to determine which PE in a multiprocessor system the Performance Monitor component relates to.

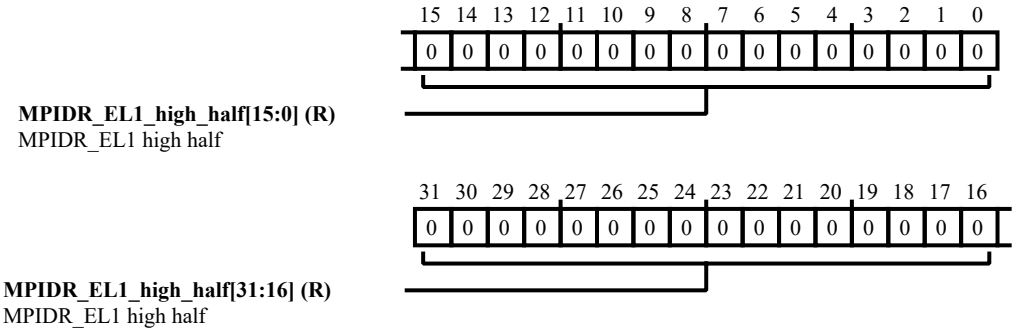

Figure 48-225: A55_CLUSTER_PMDEVAFF1 Register Diagram

Table 48-223: A55_CLUSTER_PMDEVAFF1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	MPIDR_EL1_HIGH_HALF	MPIDR_EL1 high half. MPIDR_EL1 high half. Read-only copy of the high half of MPIDR_EL1, as seen from the highest implemented Exception level.

Performance Monitors Device Architecture Register

Identifies the programmers' model architecture of the Performance Monitor component.

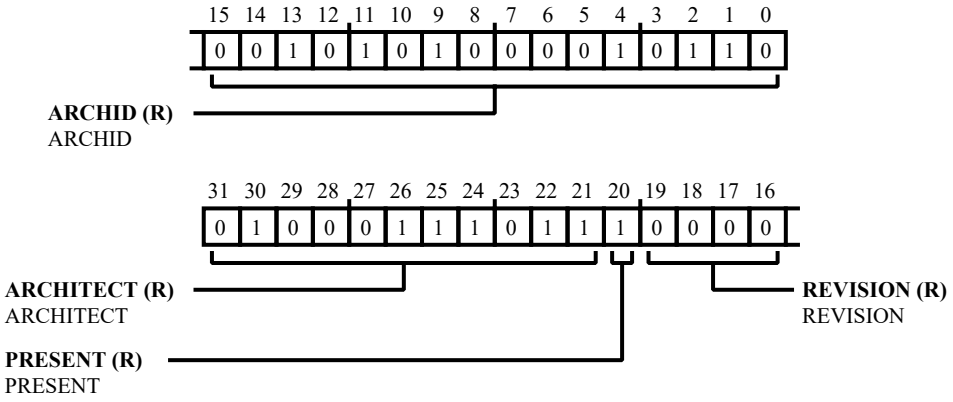

Figure 48-226: A55_CLUSTER_PMDEVARCH Register Diagram

Table 48-224: A55_CLUSTER_PMDEVARCH Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:21 (R/NW)	ARCHITECT	ARCHITECT. Defines the architecture of the component. For Performance Monitors, this is ARM Limited. Bits [31:28] are the JEP106 continuation code, 0x4. Bits [27:21] are the JEP106 ID code, 0x3B.
20 (R/NW)	PRESENT	PRESENT. When set to 1, indicates that the DEVARCH is present. This field is 1 in ARMv8.
19:16 (R/NW)	REVISION	REVISION. Defines the architecture revision. For architectures defined by ARM this is the minor revision. For Performance Monitors, the revision defined by ARMv8 is 0x0. All other values are reserved.
15:0 (R/NW)	ARCHID	ARCHID. Defines this part to be an ARMv8 debug component. For architectures defined by ARM this is further subdivided. For Performance Monitors: Bits [15:12] are the architecture version, 0x2. Bits [11:0] are the architecture part number, 0xA16. This corresponds to Performance Monitors architecture version PMUv3. The PMUv3 memory-mapped programmers' model can be used by devices other than ARMv8 processors. Software must determine whether the PMU is attached to an ARMv8 processor by using the PMDEVAFF0 and PMDEVAFF1 registers to discover the affinity of the PMU to any ARMv8 processors.

Performance Monitors Device Type Register

Indicates to a debugger that this component is part of a PEs performance monitor interface.

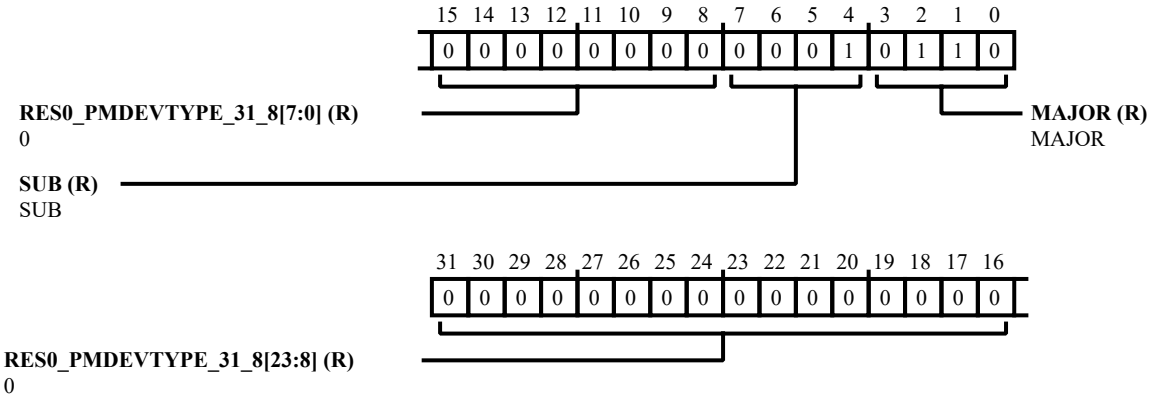

Figure 48-227: A55_CLUSTER_PMDEVTYPE Register Diagram

Table 48-225: A55_CLUSTER_PMDEVTYPE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_PMDEVTYPE_31_8	0. Reserved, RES0.
7:4 (R/NW)	SUB	SUB. Subtype. Must read as 0x1 to indicate this is a component within a PE.
3:0 (R/NW)	MAJOR	MAJOR. Major type. Must read as 0x6 to indicate this is a performance monitor component.

Performance Monitors Lock Access Register

Allows or disallows access to the Performance Monitors registers through a memory-mapped interface.

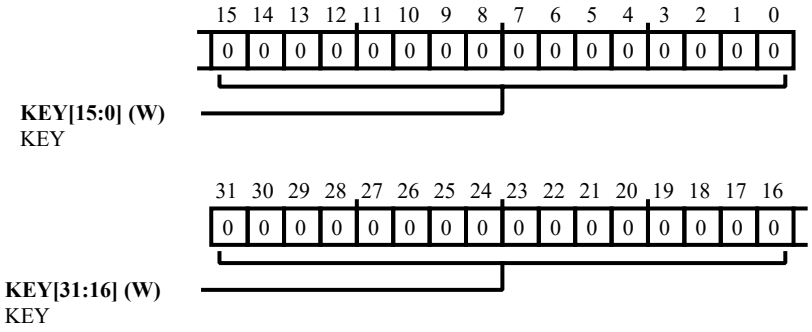

Figure 48-228: A55_CLUSTER_PMLAR Register Diagram

Table 48-226: A55_CLUSTER_PMLAR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (RX/W)	KEY	KEY. Lock Access control. Writing the key value 0xC5ACCE55 to this field unlocks the lock, enabling write accesses to this component's registers through a memory-mapped interface. Writing any other value to this register locks the lock, disabling write accesses to this component's registers through a memory mapped interface.

Performance Monitors Lock Status Register

Indicates the current status of the software lock for Performance Monitors registers.

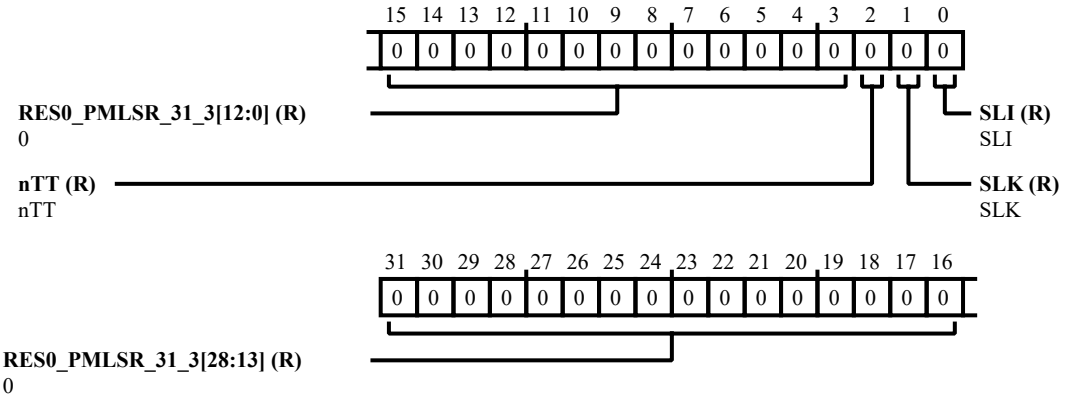

Figure 48-229: A55_CLUSTER_PMLSR Register Diagram

Table 48-227: A55_CLUSTER_PMLSR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:3 (R/NW)	RES0_PMLSR_31_3	0. Reserved, RES0.	
2 (R/NW)	NTT	nTT. Not thirty-two bit access required. RAZ.	
1 (R/NW)	SLK	SLK. Software Lock status for this component. For an access to LSR that is not a memory-mapped access, or when the Software Lock is not implemented, this field is RES0. For memory-mapped accesses when the software lock is implemented, possible values of this field are: 0 Lock clear. Writes are permitted to this component's registers. 1 Lock set. Writes to this component's registers are ignored, and reads have no side effects.	
		0	Lock clear. Writes are permitted to this component's registers.
		1	Lock set. Writes to this component's registers are ignored, and reads have no side effects.

Table 48-227: A55_CLUSTER_PMLSR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
0 (R/NW)	SLI	SLI. Software Lock implemented. For an access to LSR that is not a memory-mapped access, this field is RAZ. For memory-mapped accesses, the value of this field is IMPLEMENTATION DEFINED. Permitted values are: 0 Software Lock not implemented or not memory-mapped access. 1 Software Lock implemented and memory-mapped access.	
		0	Software Lock not implemented or not memory-mapped access.
		1	Software Lock implemented and memory-mapped access.

Performance Monitors Peripheral Identification 0 Register

Provides information to identify a Performance Monitor component.

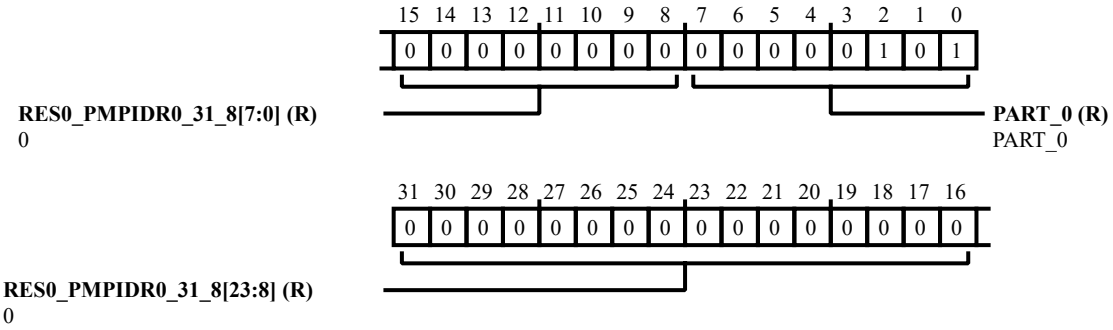

Figure 48-230: A55_CLUSTER_PMPIDR0 Register Diagram

Table 48-228: A55_CLUSTER_PMPIDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_PMPIDR0_31_8	0. Reserved, RES0.
7:0 (R/NW)	PART_0	PART_0. Part number, least significant byte.

Performance Monitors Peripheral Identification 1 Register

Provides information to identify a Performance Monitor component.

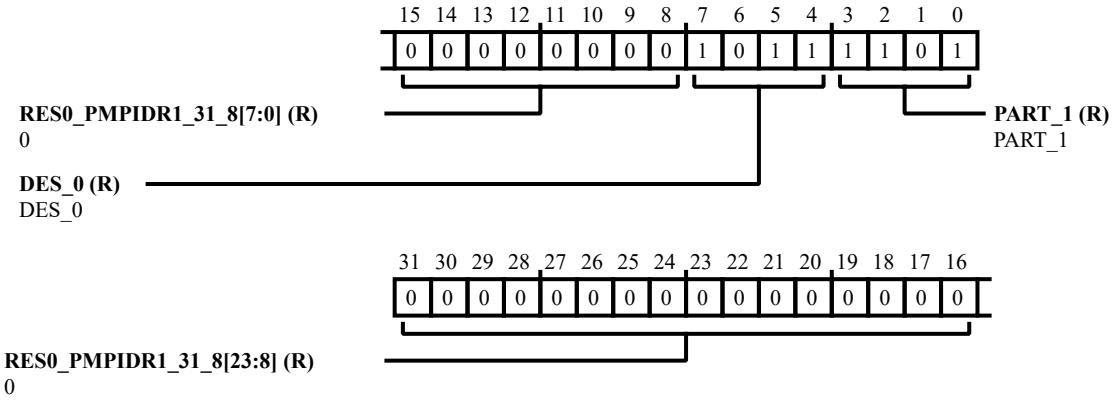

Figure 48-231: A55_CLUSTER_PMPIDR1 Register Diagram

Table 48-229: A55_CLUSTER_PMPIDR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_PMPIDR1_31_8	0. Reserved, RES0.
7:4 (R/NW)	DES_0	DES_0. Designer, least significant nibble of JEP106 ID code. For ARM Limited, this field is 0b1011.
3:0 (R/NW)	PART_1	PART_1. Part number, most significant nibble.

Performance Monitors Peripheral Identification 2 Register

Provides information to identify a Performance Monitor component.

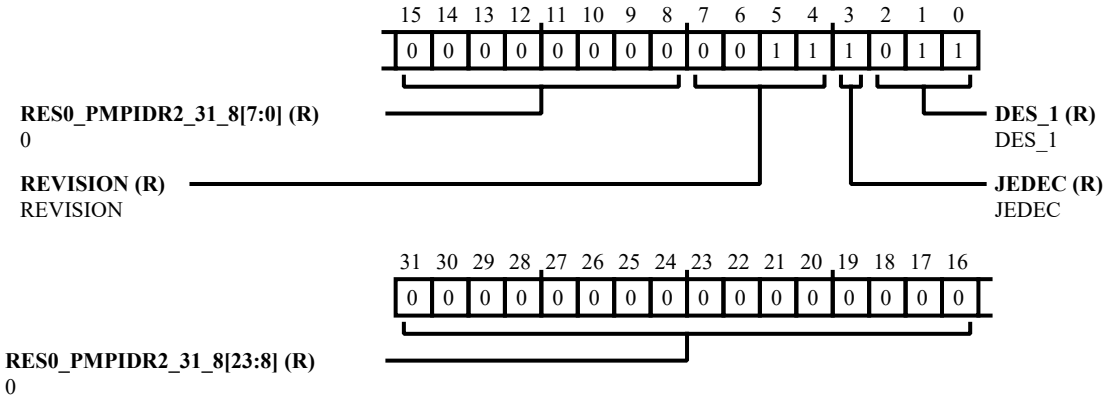

Figure 48-232: A55_CLUSTER_PMPIDR2 Register Diagram

Table 48-230: A55_CLUSTER_PMPIDR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_PMPIDR2_31_8	0. Reserved, RES0.
7:4 (R/NW)	REVISION	REVISION. Part major revision. Parts can also use this field to extend Part number to 16-bits.
3 (R/NW)	JEDEC	JEDEC. RAO. Indicates a JEP106 identity code is used.
2:0 (R/NW)	DES_1	DES_1. Designer, most significant bits of JEP106 ID code. For ARM Limited, this field is 0b011.

Performance Monitors Peripheral Identification 3 Register

Provides information to identify a Performance Monitor component.

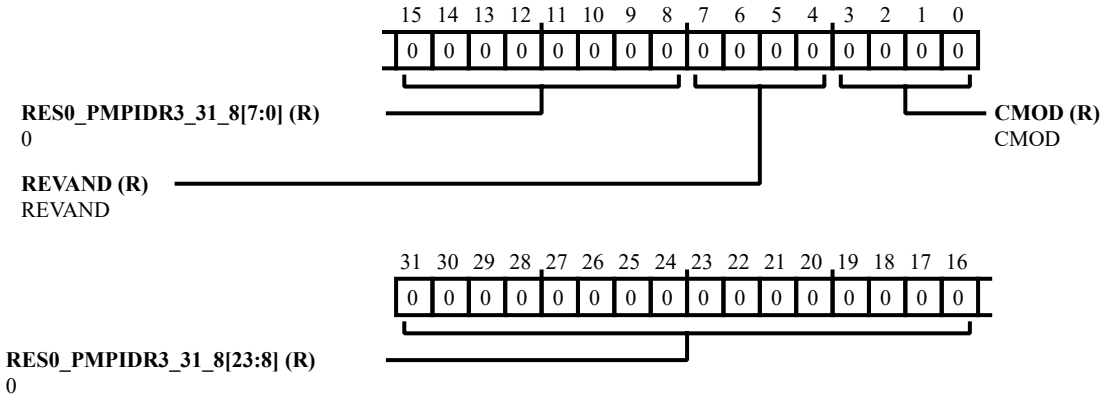

Figure 48-233: A55_CLUSTER_PMPIDR3 Register Diagram

Table 48-231: A55_CLUSTER_PMPIDR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_PMPIDR3_31_8	0. Reserved, RES0.
7:4 (R/NW)	REVAND	REVAND. Part minor revision. Parts using PMPIDR2.REVISION as an extension to the Part number must use this field as a major revision number.
3:0 (R/NW)	CMOD	CMOD. Customer modified. Indicates someone other than the Designer has modified the component.

Performance Monitors Peripheral Identification 4 Register

Provides information to identify a Performance Monitor component.

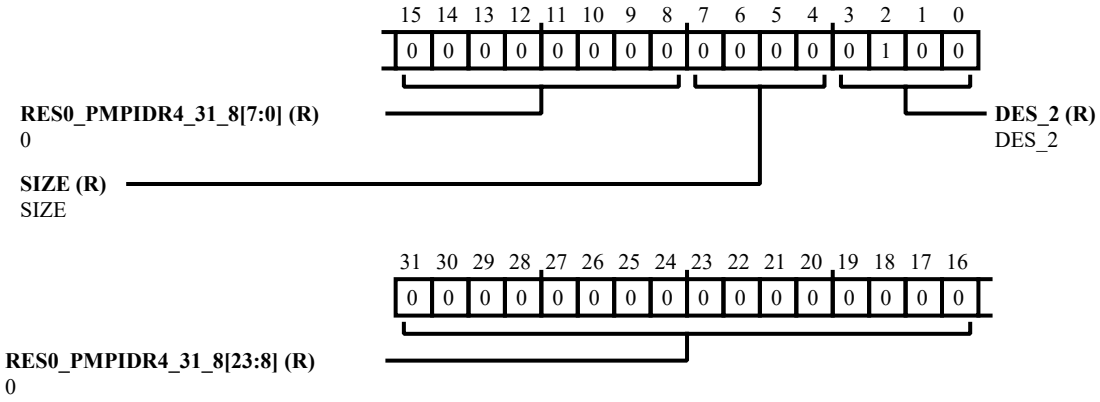

Figure 48-234: A55_CLUSTER_PMPIDR4 Register Diagram

Table 48-232: A55_CLUSTER_PMPIDR4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_PMPIDR4_31_8	0. Reserved, RES0.
7:4 (R/NW)	SIZE	SIZE. Size of the component. RAZ. Log2 of the number of 4KB pages from the start of the component to the end of the component ID registers.
3:0 (R/NW)	DES_2	DES_2. Designer, JEP106 continuation code, least significant nibble. For ARM Limited, this field is 0b0100.

Performance Monitors Peripheral Identification 5 Register

Provides information to identify a Performance Monitor component.

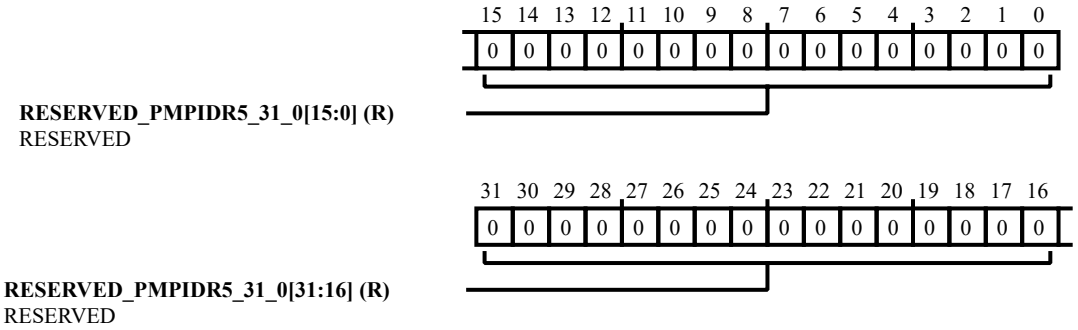

Figure 48-235: A55_CLUSTER_PMPIDR5 Register Diagram

Table 48-233: A55_CLUSTER_PMPIDR5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RESERVED_PMPIDR5_31_0	RESERVED. Reserved RES0.

Performance Monitors Peripheral Identification 6 Register

Provides information to identify a Performance Monitor component.

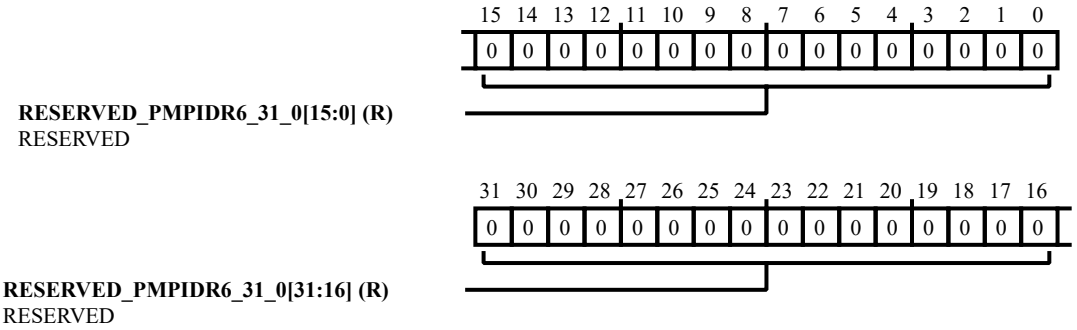

Figure 48-236: A55_CLUSTER_PMPIDR6 Register Diagram

Table 48-234: A55_CLUSTER_PMPIDR6 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RESERVED_PMPIDR6_31_0	RESERVED. Reserved RES0.

Performance Monitors Peripheral Identification 7 Register

Provides information to identify a Performance Monitor component.

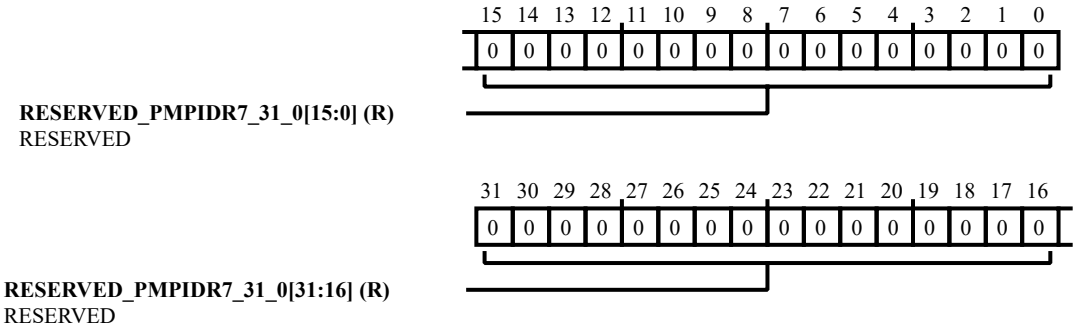

Figure 48-237: A55_CLUSTER_PMPIDR7 Register Diagram

Table 48-235: A55_CLUSTER_PMPIDR7 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RESERVED_PMPIDR7_31_0	RESERVED. Reserved RES0.

Authentication Status Register

AUTHSTATUS reports the required security level and status of the authentication interface. Where functionality changes on a given security level, the change in status must be reported in this register. The effect of each debug level being enabled or disabled is specific to each AP.

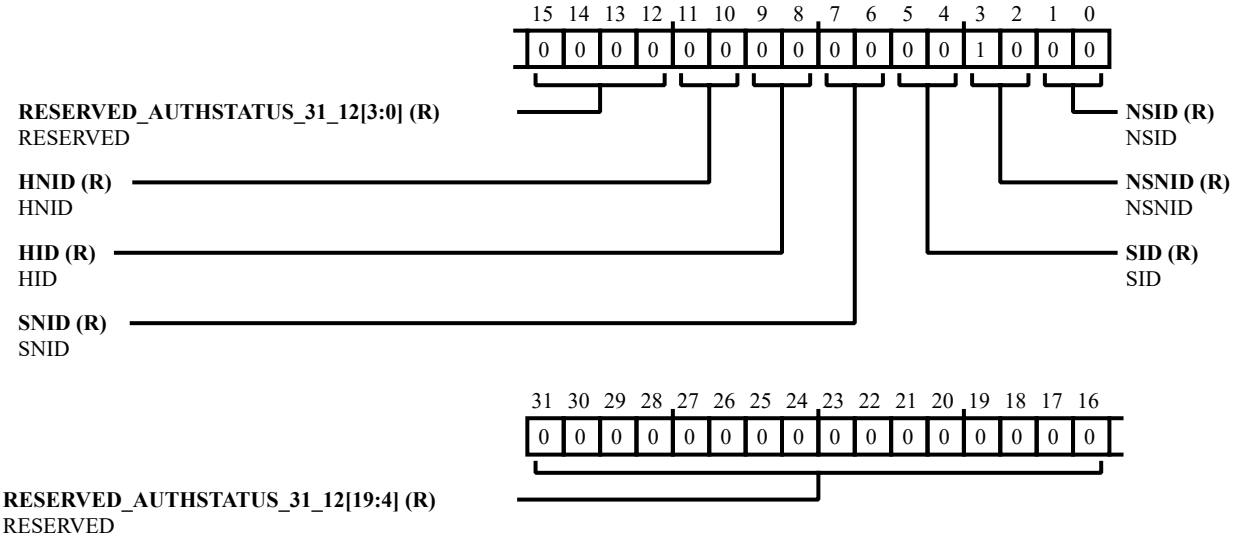

Figure 48-238: A55_CLUSTER_AUTHSTATUS Register Diagram

Table 48-236: A55_CLUSTER_AUTHSTATUS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:12 (R/NW)	RESERVED_AUTHSTATUS_31_12	RESERVED. Reserved RES0.

Table 48-236: A55_CLUSTER_AUTHSTATUS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
11:10 (R/NW)	HNID	HNID. Configuration of hypervisor noninvasive debug.	
		0	Separate controls for hypervisor noninvasive debug are not implemented, or no hypervisor is implemented. For ARMv7 PEs that implement the Virtualization Extensions, and for ARMv8 PEs that implement EL2, if separate controls for hypervisor debug visibility are not implemented, the hypervisor debug visibility is indicated by the relevant Non-secure debug visibility fields NSNID and NSID. See the relevant ARM Architecture Manual for more information about Virtualization Extensions and EL2.
		1	Reserved.
		2	Hypervisor noninvasive debug is implemented and disabled.
		3	If (HIDEN | HNIDEN) & (DBGEN | NIDEN) == TRUE.
9:8 (R/NW)	HID	HID. Configuration of hypervisor invasive debug.	
		0	Separate controls for hypervisor invasive debug are not implemented, or no hypervisor is implemented. For ARMv7 PEs that implement the Virtualization Extensions, and for ARMv8 PEs that implement EL2, if separate controls for hypervisor debug visibility are not implemented, the hypervisor debug visibility is indicated by the relevant Non-secure debug visibility fields NSNID and NSID. See the relevant ARM Architecture Manual for more information about Virtualization Extensions and EL2.
		1	Reserved.
		2	Hypervisor invasive debug is implemented and disabled.
		3	If (HIDEN & DBGEN) == TRUE.

Table 48-236: A55_CLUSTER_AUTHSTATUS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7:6 (R/NW)	SNID	SNID. If Secure noninvasive debug is not supported set this field to 0b00. If Secure noninvasive debug is supported, set this field to 0b11 or 0b10.	
		0	Debug level is not supported.
		1	Reserved.
		2	In all other cases.
		3	If (SPIDEN | SPNIDEN) & (DBGEN | NIDEN) == TRUE.
5:4 (R/NW)	SID	SID. If Secure invasive debug is not supported set this field to 0b00. If Secure invasive debug is supported, set this field to 0b11 or 0b10.	
		0	Debug level is not supported.
		1	Reserved.
		2	In all other cases.
		3	If (SPIDEN & DBGEN) == TRUE.
3:2 (R/NW)	NSNID	NSNID. If Non-secure noninvasive debug is not supported, set this field to 0b00. If Non-secure noninvasive debug is supported, set this field to 0b11 or 0b10.	
		0	Debug level is not supported.
		1	Reserved.
		2	In all other cases.
		3	If (NIDEN | DBGEN) == TRUE.
1:0 (R/NW)	NSID	NSID. If Non-secure invasive debug is not supported, set this field to 0b00. If Non-secure invasive debug is supported, set this field to 0b11 or 0b10.	
		0	Debug level is not supported.
		1	Reserved.
		2	In all other cases.
		3	If DBGEN == TRUE.

Component Identification 0 Register

Component Identification Register.

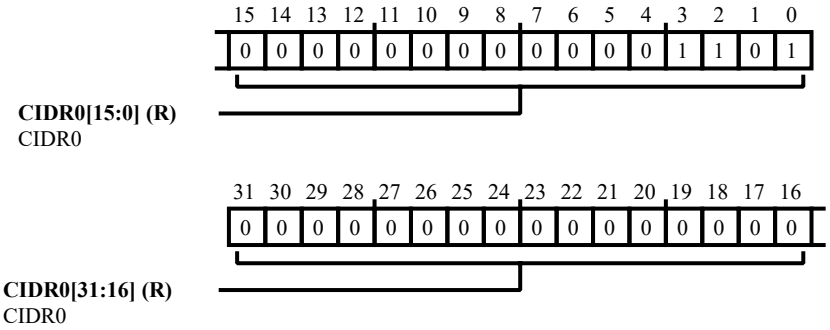

Figure 48-239: A55_CLUSTER_CIDR0 Register Diagram

Table 48-237: A55_CLUSTER_CIDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CIDR0	CIDR0. CIDR0.

Component Identification 1 Register

Component Identification Register.

Table 48-240: A55_CLUSTER_CIDR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CIDR3	CIDR3. CIDR3.

Debug Power Control 0 Register

DBGPCRn is used to indicate whether a power request mechanism is implemented for debug power domain n. Request power to debug power domain n.

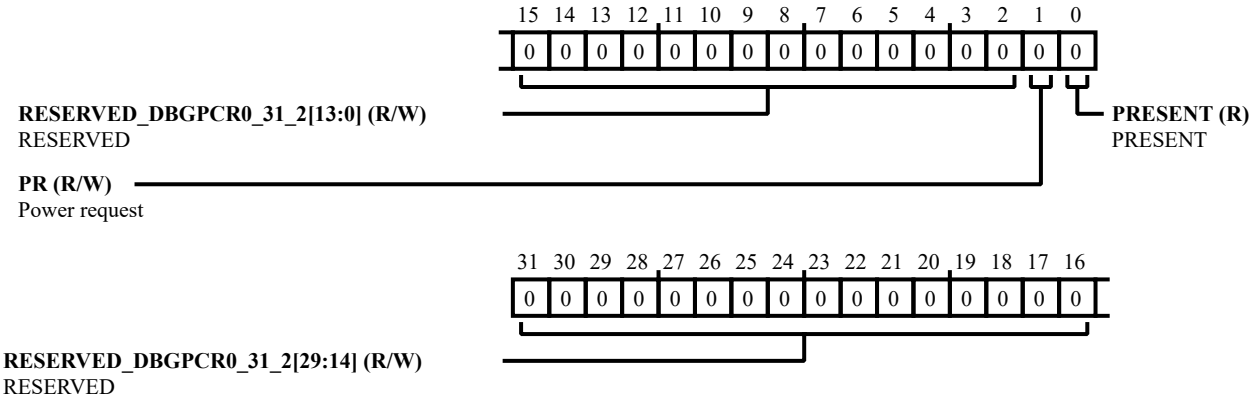

Figure 48-243: A55_CLUSTER_DBGPCR0 Register Diagram

Table 48-241: A55_CLUSTER_DBGPCR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:2 (R/W)	RESERVED_DBGPCR0_31_2	RESERVED. Reserved RES0.	
1 (R/W)	PR	Power request. This field is Reserved if DBGPCRn.PRESENT is b0.	
		0	Power not requested for debug power domain n.
		1	Power requested for debug power domain n.
0 (R/NW)	PRESENT	PRESENT. Power request implemented.	
		0	Power request not implemented for debug power domain n.
		1	Power request implemented for debug power domain n. DBGPCRn.PR and DBGPSRn are implemented.

Debug Power Control 1 Register

DBGPCRn is used to indicate whether a power request mechanism is implemented for debug power domain n. Request power to debug power domain n.

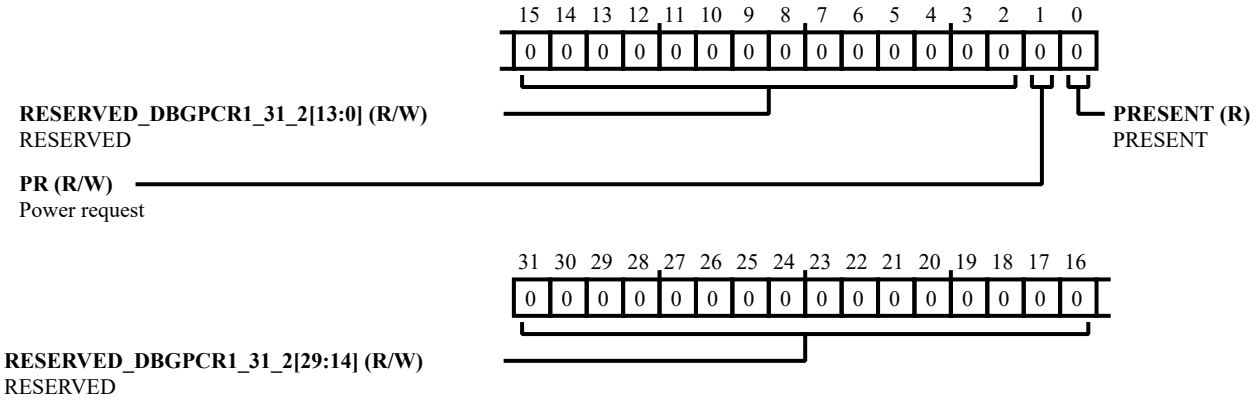

Figure 48-244: A55_CLUSTER_DBGPCR1 Register Diagram

Table 48-242: A55_CLUSTER_DBGPCR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:2 (R/W)	RESERVED_DBGPCR1_31_2	RESERVED. Reserved RES0.	
1 (R/W)	PR	Power request. This field is Reserved if DBGPCRn.PRESENT is b0.	
		0	Power not requested for debug power domain n.
		1	Power requested for debug power domain n.
0 (R/NW)	PRESENT	PRESENT. Power request implemented.	
		0	Power request not implemented for debug power domain n.
		1	Power request implemented for debug power domain n. DBGPCRn.PR and DBGPSRn are implemented.

Debug Power Control 2 Register

DBGPCRn is used to indicate whether a power request mechanism is implemented for debug power domain n. Request power to debug power domain n.

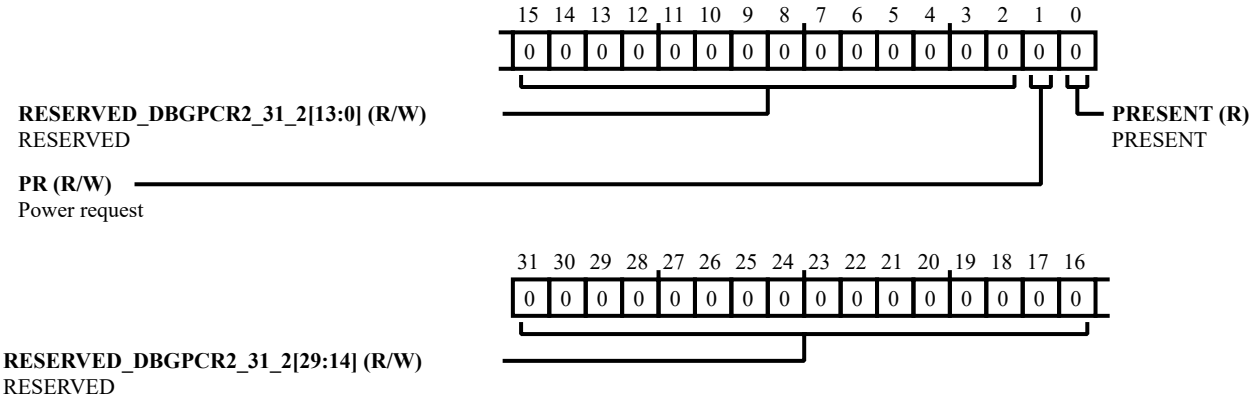

Figure 48-245: A55_CLUSTER_DBGPCR2 Register Diagram

Table 48-243: A55_CLUSTER_DBGPCR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:2 (R/W)	RESERVED_DBGPCR2_31_2	RESERVED. Reserved RES0.	
1 (R/W)	PR	Power request. This field is Reserved if DBGPCRn.PRESENT is b0.	
		0	Power not requested for debug power domain n.
		1	Power requested for debug power domain n.
0 (R/NW)	PRESENT	PRESENT. Power request implemented.	
		0	Power request not implemented for debug power domain n.
		1	Power request implemented for debug power domain n. DBGPCRn.PR and DBGPSRn are implemented.

Debug Power Control 3 Register

DBGPCRn is used to indicate whether a power request mechanism is implemented for debug power domain n. Request power to debug power domain n.

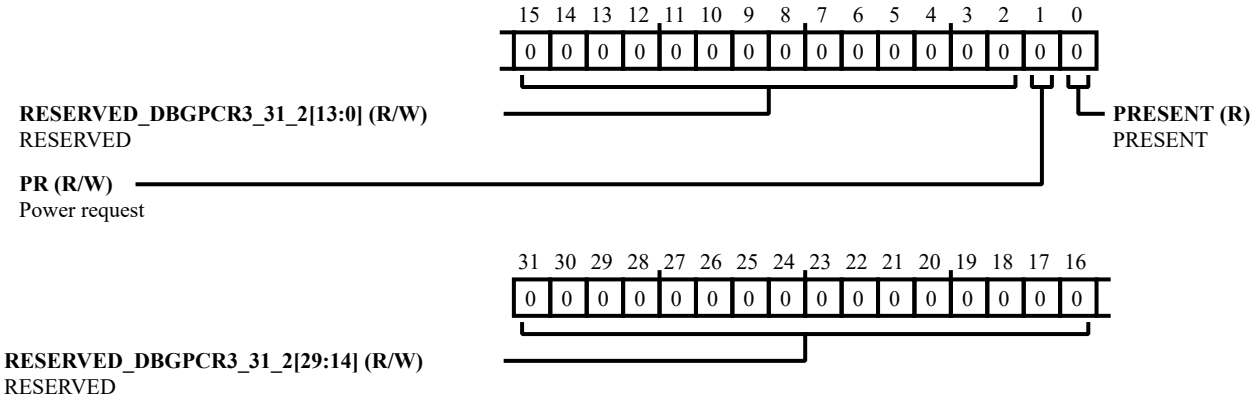

Figure 48-246: A55_CLUSTER_DBGPCR3 Register Diagram

Table 48-244: A55_CLUSTER_DBGPCR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:2 (R/W)	RESERVED_DBGPCR3_31_2	RESERVED. Reserved RES0.	
1 (R/W)	PR	Power request. This field is Reserved if DBGPCRn.PRESENT is b0.	
		0	Power not requested for debug power domain n.
		1	Power requested for debug power domain n.
0 (R/NW)	PRESENT	PRESENT. Power request implemented.	
		0	Power request not implemented for debug power domain n.
		1	Power request implemented for debug power domain n. DBGPCRn.PR and DBGPSRn are implemented.

Debug Power Control 4 Register

DBGPCRn is used to indicate whether a power request mechanism is implemented for debug power domain n. Request power to debug power domain n.

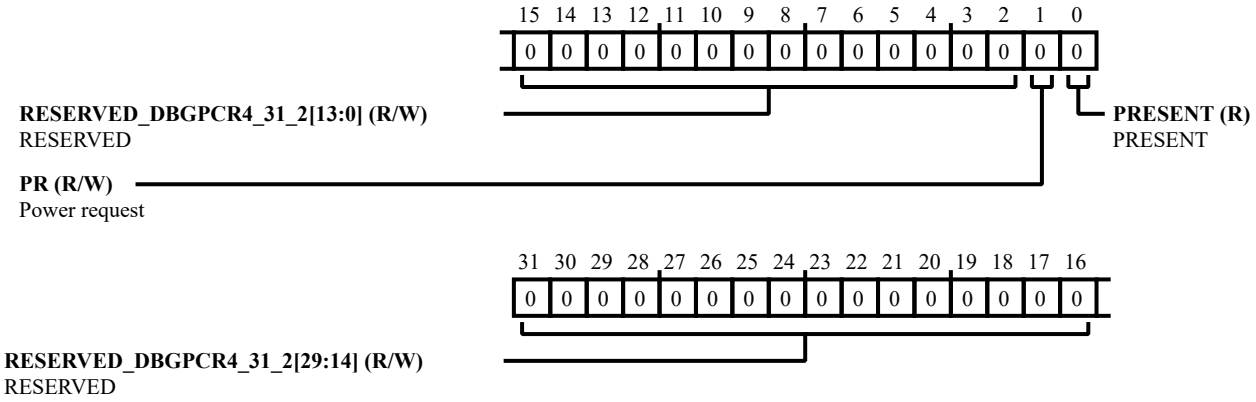

Figure 48-247: A55_CLUSTER_DBGPCR4 Register Diagram

Table 48-245: A55_CLUSTER_DBGPCR4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:2 (R/W)	RESERVED_DBGPCR4_31_2	RESERVED. Reserved RES0.	
1 (R/W)	PR	Power request. This field is Reserved if DBGPCRn.PRESENT is b0.	
		0	Power not requested for debug power domain n.
		1	Power requested for debug power domain n.
0 (R/NW)	PRESENT	PRESENT. Power request implemented.	
		0	Power request not implemented for debug power domain n.
		1	Power request implemented for debug power domain n. DBGPCRn.PR and DBGPSRn are implemented.

Debug Power Control 5 Register

DBGPCRn is used to indicate whether a power request mechanism is implemented for debug power domain n. Request power to debug power domain n.

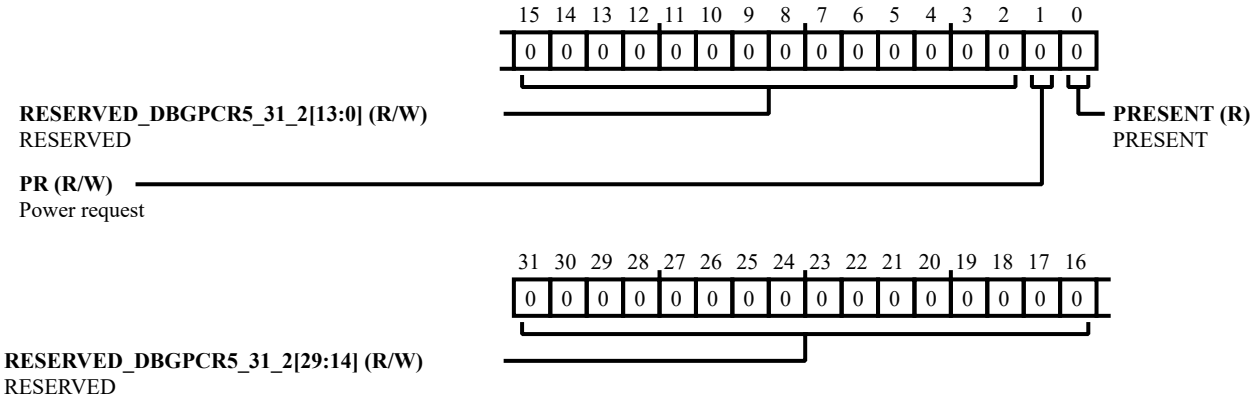

Figure 48-248: A55_CLUSTER_DBGPCR5 Register Diagram

Table 48-246: A55_CLUSTER_DBGPCR5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:2 (R/W)	RESERVED_DBGPCR5_31_2	RESERVED. Reserved RES0.	
1 (R/W)	PR	Power request. This field is Reserved if DBGPCRn.PRESENT is b0.	
		0	Power not requested for debug power domain n.
		1	Power requested for debug power domain n.
0 (R/NW)	PRESENT	PRESENT. Power request implemented.	
		0	Power request not implemented for debug power domain n.
		1	Power request implemented for debug power domain n. DBGPCRn.PR and DBGPSRn are implemented.

Debug Power Control 6 Register

DBGPCRn is used to indicate whether a power request mechanism is implemented for debug power domain n. Request power to debug power domain n.

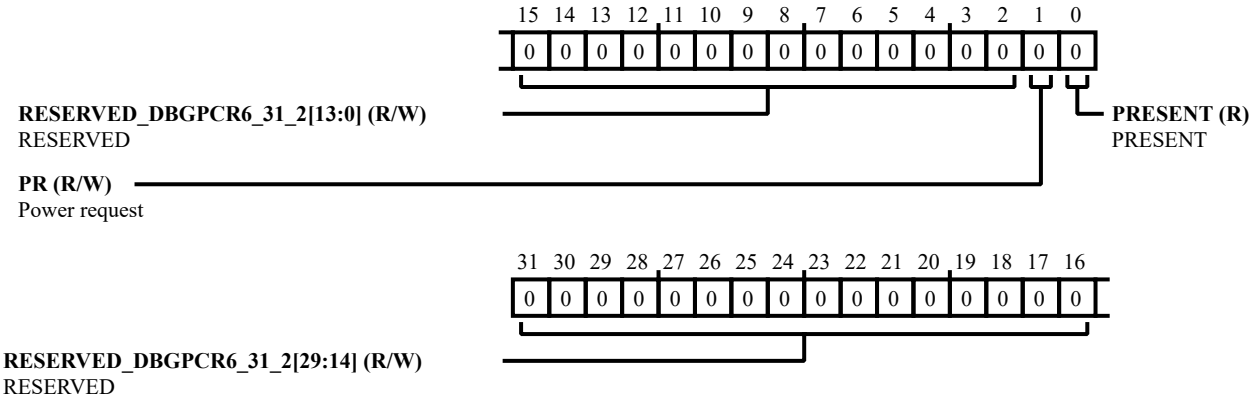

Figure 48-249: A55_CLUSTER_DBGPCR6 Register Diagram

Table 48-247: A55_CLUSTER_DBGPCR6 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:2 (R/W)	RESERVED_DBGPCR6_31_2	RESERVED. Reserved RES0.	
1 (R/W)	PR	Power request. This field is Reserved if DBGPCRn.PRESENT is b0.	
		0	Power not requested for debug power domain n.
		1	Power requested for debug power domain n.
0 (R/NW)	PRESENT	PRESENT. Power request implemented.	
		0	Power request not implemented for debug power domain n.
		1	Power request implemented for debug power domain n. DBGPCRn.PR and DBGPSRn are implemented.

Debug Power Control 7 Register

DBGPCRn is used to indicate whether a power request mechanism is implemented for debug power domain n. Request power to debug power domain n.

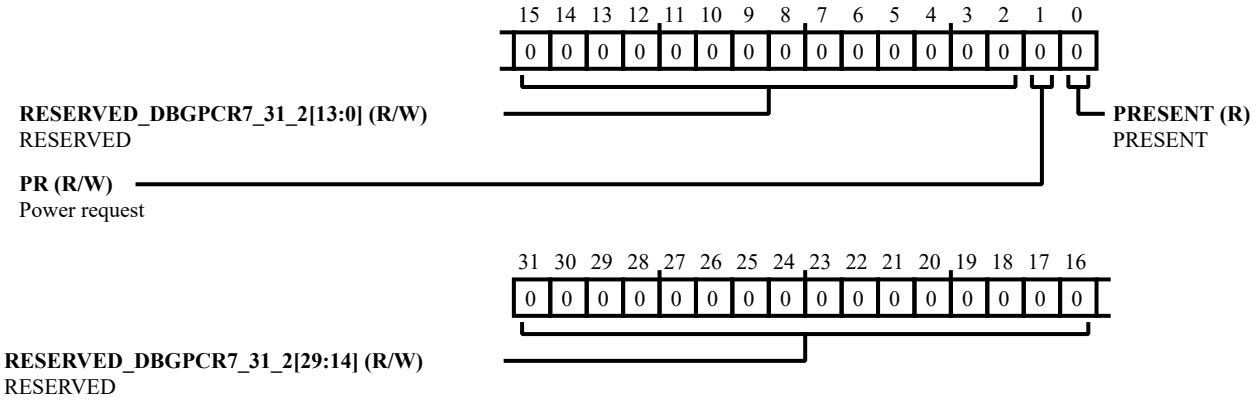

Figure 48-250: A55_CLUSTER_DBGPCR7 Register Diagram

Table 48-248: A55_CLUSTER_DBGPCR7 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:2 (R/W)	RESERVED_DBGPCR7_31_2	RESERVED. Reserved RES0.	
1 (R/W)	PR	Power request. This field is Reserved if DBGPCRn.PRESENT is b0.	
		0	Power not requested for debug power domain n.
		1	Power requested for debug power domain n.
0 (R/NW)	PRESENT	PRESENT. Power request implemented.	
		0	Power request not implemented for debug power domain n.
		1	Power request implemented for debug power domain n. DBGPCRn.PR and DBGPSRn are implemented.

Debug Power Control 8 Register

DBGPCRn is used to indicate whether a power request mechanism is implemented for debug power domain n. Request power to debug power domain n.

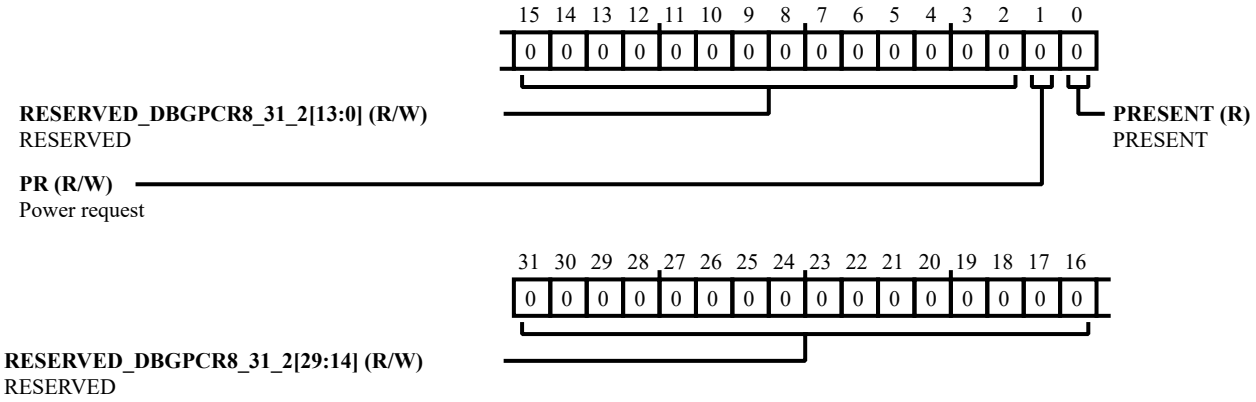

Figure 48-251: A55_CLUSTER_DBGPCR8 Register Diagram

Table 48-249: A55_CLUSTER_DBGPCR8 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:2 (R/W)	RESERVED_DBGPCR8_31_2	RESERVED. Reserved RES0.	
1 (R/W)	PR	Power request. This field is Reserved if DBGPCRn.PRESENT is b0.	
		0	Power not requested for debug power domain n.
		1	Power requested for debug power domain n.
0 (R/NW)	PRESENT	PRESENT. Power request implemented.	
		0	Power request not implemented for debug power domain n.
		1	Power request implemented for debug power domain n. DBGPCRn.PR and DBGPSRn are implemented.

Debug Power Status 0 Register

DBGPSRn is used to indicate the current power status for debug power domain n.

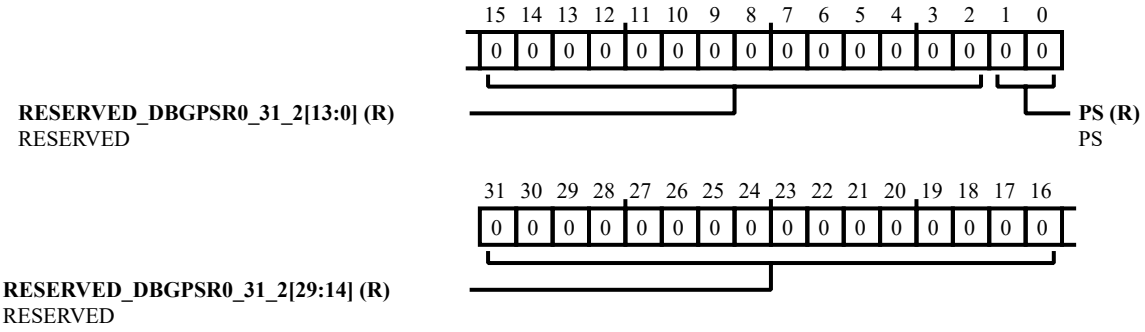

Figure 48-252: A55_CLUSTER_DBGPSR0 Register Diagram

Table 48-250: A55_CLUSTER_DBGPSR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:2 (R/NW)	RESERVED_DBGPSR0_31_2	RESERVED. Reserved RES0.	
1:0 (R/NW)	PS	PS. Power status.	
		0	Debug power domain n might not be powered.
		1	Debug power domain n is powered.
		2	Reserved.
		3	Debug power domain n is powered and must remain powered until DBGPCRn.PR is set to b0.

Debug Power Status 1 Register

DBGPSRn is used to indicate the current power status for debug power domain n.

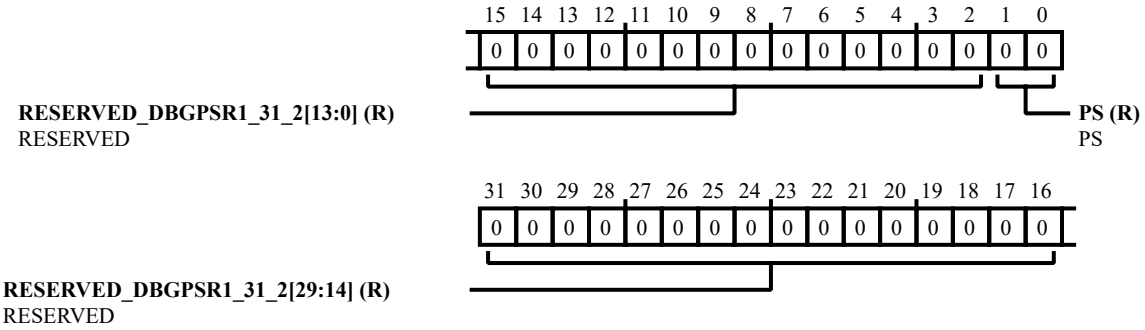

Figure 48-253: A55_CLUSTER_DBGPSR1 Register Diagram

Table 48-251: A55_CLUSTER_DBGPSR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:2 (R/NW)	RESERVED_DBGPSR1_31_2	RESERVED. Reserved RES0.	
1:0 (R/NW)	PS	PS. Power status.	
		0	Debug power domain n might not be powered.
		1	Debug power domain n is powered.
		2	Reserved.
		3	Debug power domain n is powered and must remain powered until DBGPCRn.PR is set to b0.

Debug Power Status 2 Register

DBGPSRn is used to indicate the current power status for debug power domain n.

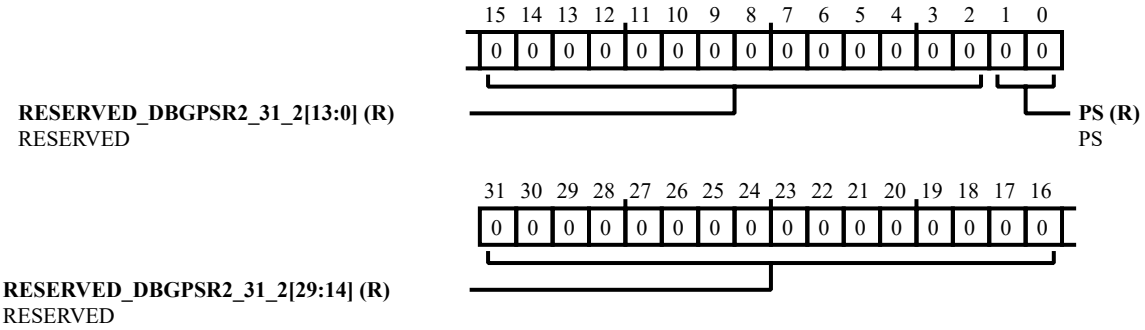

Figure 48-254: A55_CLUSTER_DBGPSR2 Register Diagram

Table 48-252: A55_CLUSTER_DBGPSR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:2 (R/NW)	RESERVED_DBGPSR2_31_2	RESERVED. Reserved RES0.	
1:0 (R/NW)	PS	PS. Power status.	
		0	Debug power domain n might not be powered.
		1	Debug power domain n is powered.
		2	Reserved.
		3	Debug power domain n is powered and must remain powered until DBGPCRn.PR is set to b0.

Debug Power Status 3 Register

DBGPSRn is used to indicate the current power status for debug power domain n.

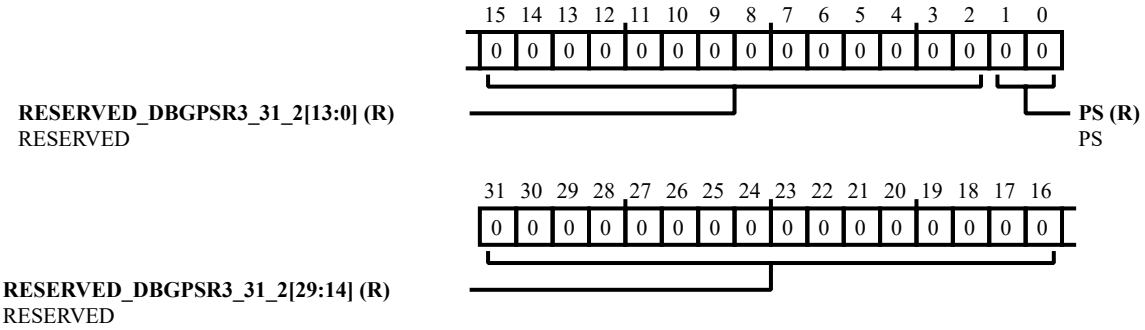

Figure 48-255: A55_CLUSTER_DBGPSR3 Register Diagram

Table 48-253: A55_CLUSTER_DBGPSR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:2 (R/NW)	RESERVED_DBGPSR3_31_2	RESERVED. Reserved RES0.	
1:0 (R/NW)	PS	PS. Power status.	
		0	Debug power domain n might not be powered.
		1	Debug power domain n is powered.
		2	Reserved.
		3	Debug power domain n is powered and must remain powered until DBGPCRn.PR is set to b0.

Debug Power Status 4 Register

DBGPSRn is used to indicate the current power status for debug power domain n.

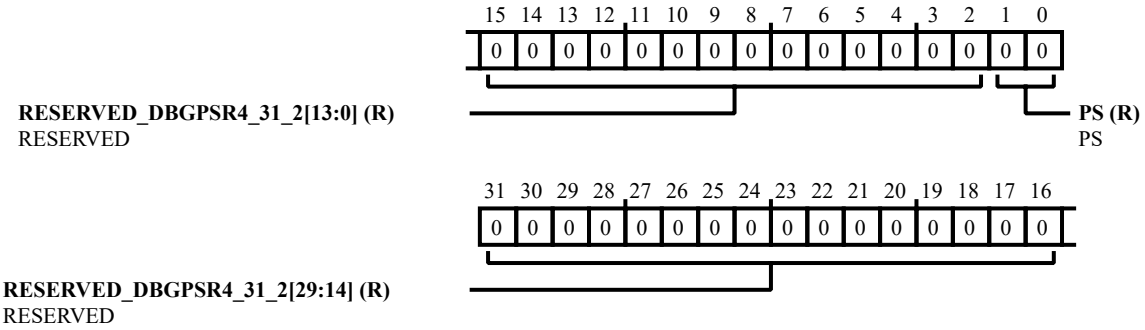

Figure 48-256: A55_CLUSTER_DBGPSR4 Register Diagram

Table 48-254: A55_CLUSTER_DBGPSR4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:2 (R/NW)	RESERVED_DBGPSR4_31_2	RESERVED. Reserved RES0.	
1:0 (R/NW)	PS	PS. Power status.	
		0	Debug power domain n might not be powered.
		1	Debug power domain n is powered.
		2	Reserved.
		3	Debug power domain n is powered and must remain powered until DBGPCRn.PR is set to b0.

Debug Power Status 5 Register

DBGPSRn is used to indicate the current power status for debug power domain n.

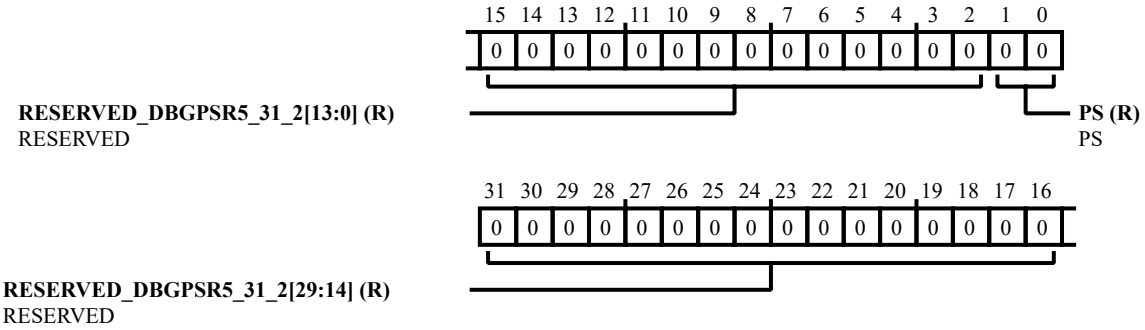

Figure 48-257: A55_CLUSTER_DBGPSR5 Register Diagram

Table 48-255: A55_CLUSTER_DBGPSR5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:2 (R/NW)	RESERVED_DBGPSR5_31_2	RESERVED. Reserved RES0.	
1:0 (R/NW)	PS	PS. Power status.	
		0	Debug power domain n might not be powered.
		1	Debug power domain n is powered.
		2	Reserved.
		3	Debug power domain n is powered and must remain powered until DBGPCRn.PR is set to b0.

Debug Power Status 6 Register

DBGPSRn is used to indicate the current power status for debug power domain n.

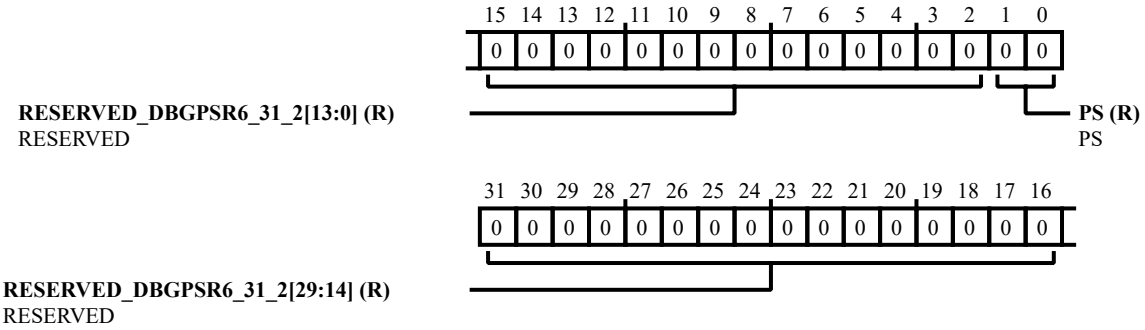

Figure 48-258: A55_CLUSTER_DBGPSR6 Register Diagram

Table 48-256: A55_CLUSTER_DBGPSR6 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:2 (R/NW)	RESERVED_DBGPSR6_31_2	RESERVED. Reserved RES0.	
1:0 (R/NW)	PS	PS. Power status.	
		0	Debug power domain n might not be powered.
		1	Debug power domain n is powered.
		2	Reserved.
		3	Debug power domain n is powered and must remain powered until DBGPCRn.PR is set to b0.

Debug Power Status 7 Register

DBGPSRn is used to indicate the current power status for debug power domain n.

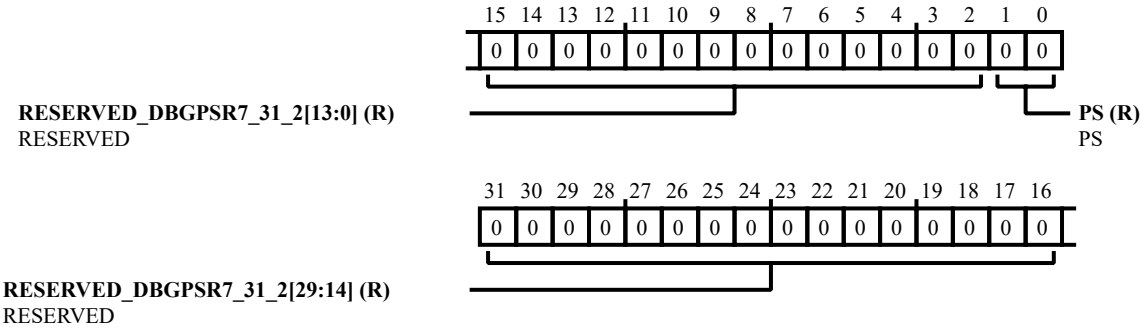

Figure 48-259: A55_CLUSTER_DBGPSR7 Register Diagram

Table 48-257: A55_CLUSTER_DBGPSR7 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:2 (R/NW)	RESERVED_DBGPSR7_31_2	RESERVED. Reserved RES0.	
1:0 (R/NW)	PS	PS. Power status.	
		0	Debug power domain n might not be powered.
		1	Debug power domain n is powered.
		2	Reserved.
		3	Debug power domain n is powered and must remain powered until DBGPCRn.PR is set to b0.

Debug Power Status 8 Register

DBGPSRn is used to indicate the current power status for debug power domain n.

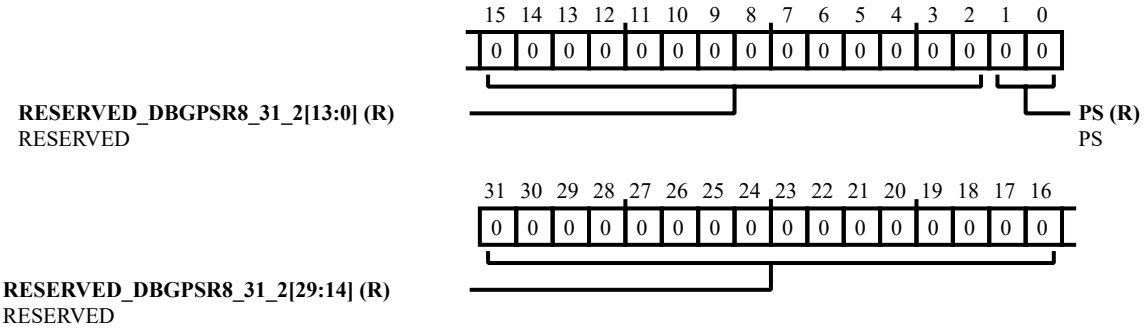

Figure 48-260: A55_CLUSTER_DBGPSR8 Register Diagram

Table 48-258: A55_CLUSTER_DBGPSR8 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:2 (R/NW)	RESERVED_DBGPSR8_31_2	RESERVED. Reserved RES0.	
1:0 (R/NW)	PS	PS. Power status.	
		0	Debug power domain n might not be powered.
		1	Debug power domain n is powered.
		2	Reserved.
		3	Debug power domain n is powered and must remain powered until DBGPCRn.PR is set to b0.

Device Architecture Register

Indicates the component is a ROM table.

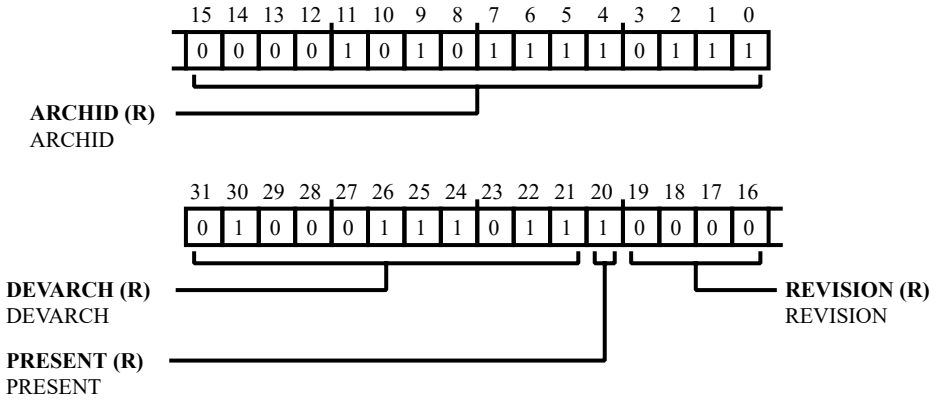

Figure 48-261: A55_CLUSTER_DEVARCH Register Diagram

Table 48-259: A55_CLUSTER_DEVARCH Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:21 (R/NW)	DEVARCH	DEVARCH. ARCHITECT.
20 (R/NW)	PRESENT	PRESENT. PRESENT.
19:16 (R/NW)	REVISION	REVISION. REVISION.
15:0 (R/NW)	ARCHID	ARCHID. indicating a ROM table v0.

Device ID Register

DEVID.

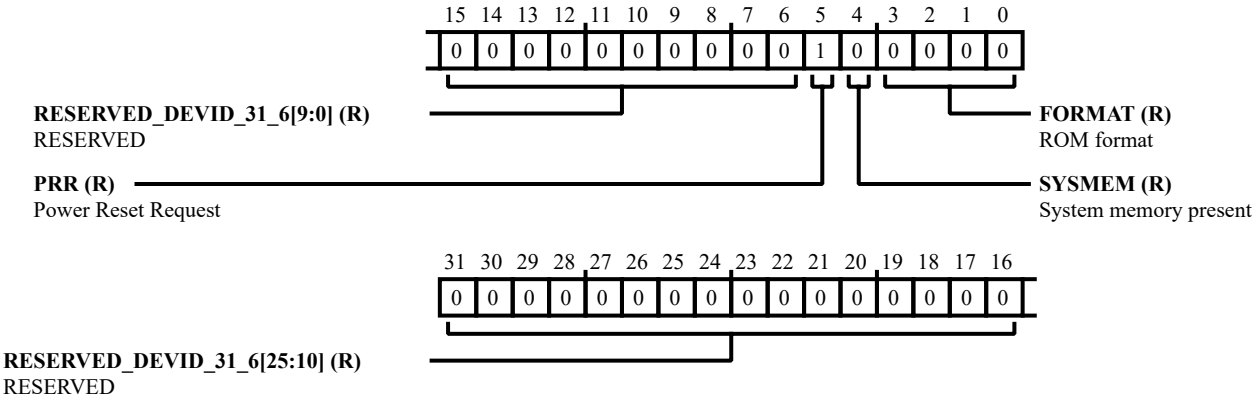

Figure 48-262: A55_CLUSTER_DEVID Register Diagram

Table 48-260: A55_CLUSTER_DEVID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:6 (R/NW)	RESERVED_DEVID_31_6	RESERVED. Reserved RES0.	
5 (R/NW)	PRR	Power Reset Request. Power Reset Request functionality included.	
		0	Power Reset Request functionality not included. If any ROM table entries contain power domain IDs, then a GPR must be present and pointed to by this ROM table. The GPR provides controls to these power domains. PRIDR0 is not implemented.
		1	Power Reset Request functionality included. If any ROM table entries contain power domain IDs, the controls to these power domains is in the Power Reset Request functionality included in this ROM table. PRIDR0 is implemented.
4 (R/NW)	SYSMEM	System memory present. Indicates whether system memory is present on the bus that connects to the ROM Table.	
		0	System memory not present on bus. This is a dedicated debug bus.
		1	System memory is also present on this bus.

Table 48-260: A55_CLUSTER_DEVID Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
3:0 (R/NW)	FORMAT	ROM format. ROM format.	
		0	32-bit Format 0.
		1	64-bit Format 1.

Device Type Register

DEVTYPE.

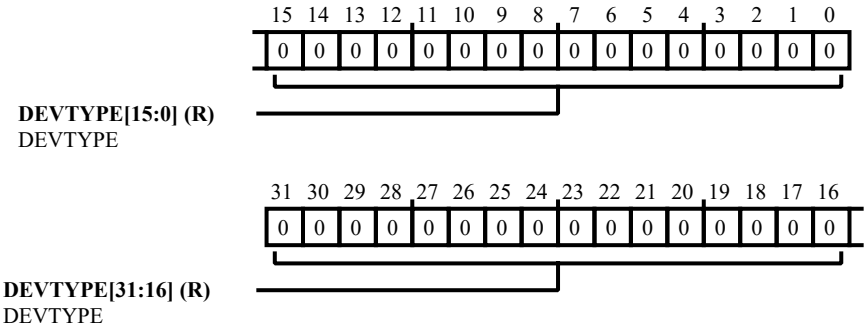

Figure 48-263: A55_CLUSTER_DEVTYPE Register Diagram

Table 48-261: A55_CLUSTER_DEVTYPE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	PIDR7	PIDR7. PIDR7.

Power Reset Identification 0 Register

PRIDR0 indicates the features of the power request functionality.

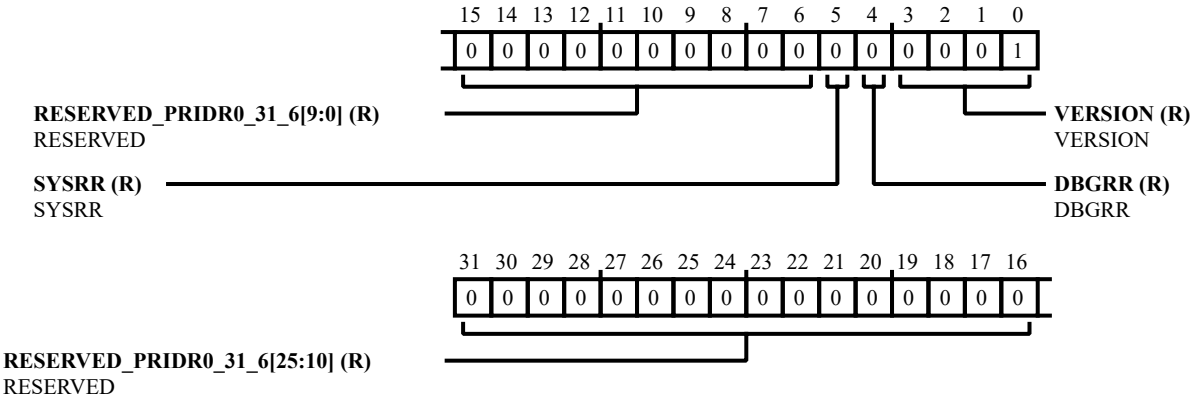

Figure 48-272: A55_CLUSTER_PRIDR0 Register Diagram

Table 48-270: A55_CLUSTER_PRIDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:6 (R/NW)	RESERVED_PRIDR0_31_6	RESERVED. Reserved RES0.	
5 (R/NW)	SYSRR	SYSRR. SYSRR.	
		0	System reset request functionality not implemented.
		1	System reset request functionality implemented. SYSRSTRR and SYSRSTAR implemented.
4 (R/NW)	DBGRR	DBGRR. Indicates whether the debug reset request functionality is present.	
		0	Debug reset request functionality not implemented.
		1	Debug reset request functionality implemented. DBGRSTRR and DBGRSTAR implemented.
3:0 (R/NW)	VERSION	VERSION. Power request functionality version.	
		0	Power request functionality not implemented.
		1	Power request version 0 implemented.

ROM Table Entry 0 Register

ROMENTRYn.

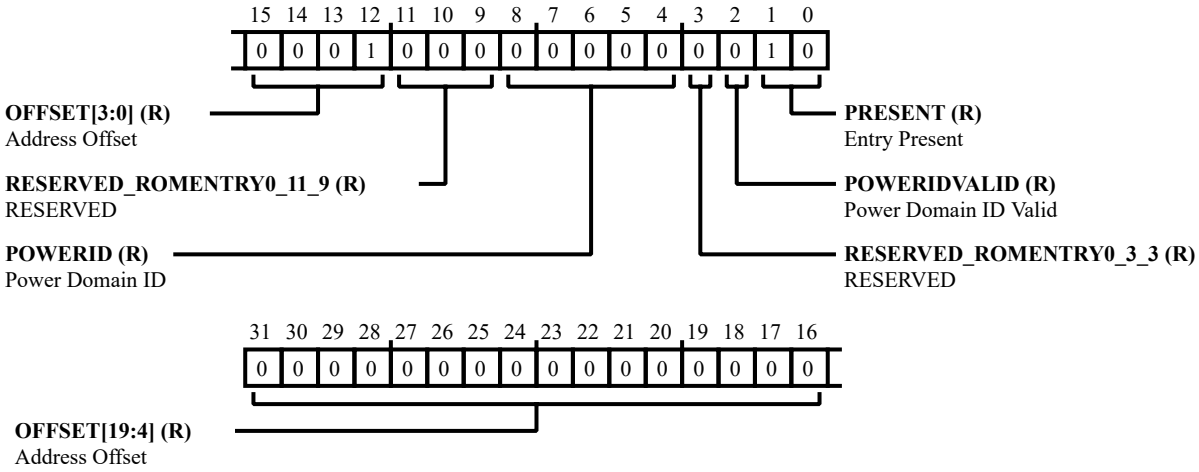

Figure 48-273: A55_CLUSTER_ROMENTRY0 Register Diagram

Table 48-271: A55_CLUSTER_ROMENTRY0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:12 (R/NW)	OFFSET	Address Offset. Base address of the highest 4KB block for that component, relative to the ROM address.	
11:9 (R/NW)	RESERVED_ROMEN-TRY0_11_9	RESERVED. Reserved RES0.	
		0	Reserved.
8:4 (R/NW)	POWERID	Power Domain ID. Indicates the power domain ID of the component.	
3 (R/NW)	RESERVED_ROMEN-TRY0_3_3	RESERVED. Reserved RES0.	
		0	Reserved.
2 (R/NW)	POWERIDVALID	Power Domain ID Valid. Indicates if the POWERID field valid.	
		0	Power domain ID not provided.
		1	Power domain ID provided in POWERID.

Table 48-271: A55_CLUSTER_ROMENTRY0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1:0 (R/NW)	PRESENT	Entry Present. Set if corresponding unit exists.	
		0	ROM entry not present. All other fields in this entry must be zero. This is the final entry in the ROM table.
		1	Reserved.
		2	ROM entry not present. This is not the final entry in the ROM table. All other fields in this entry are UNKNOWN.
		3	ROM entry present.

ROM Table Entry 1 Register

ROMENTRYn.

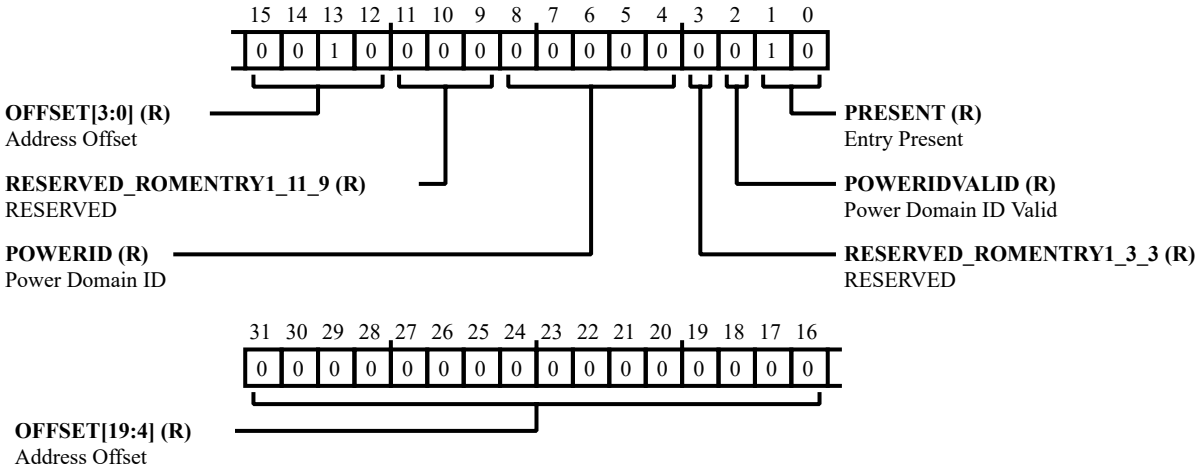

Figure 48-274: A55_CLUSTER_ROMENTRY1 Register Diagram

Table 48-272: A55_CLUSTER_ROMENTRY1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:12 (R/NW)	OFFSET	Address Offset. Base address of the highest 4KB block for that component, relative to the ROM address.	
11:9 (R/NW)	RESERVED_ROMEN-TRY1_11_9	RESERVED. Reserved RES0.	
		0	Reserved.
8:4 (R/NW)	POWERID	Power Domain ID. Indicates the power domain ID of the component.	
3 (R/NW)	RESERVED_ROMEN-TRY1_3_3	RESERVED. Reserved RES0.	
		0	Reserved.
2 (R/NW)	POWERIDVALID	Power Domain ID Valid. Indicates if the POWERID field valid.	
		0	Power domain ID not provided.
		1	Power domain ID provided in POWERID.

Table 48-272: A55_CLUSTER_ROMENTRY1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1:0 (R/NW)	PRESENT	Entry Present. Set if corresponding unit exists.	
		0	ROM entry not present. All other fields in this entry must be zero. This is the final entry in the ROM table.
		1	Reserved.
		2	ROM entry not present. This is not the final entry in the ROM table. All other fields in this entry are UNKNOWN.
		3	ROM entry present.

ROM Table Entry 10 Register

ROMENTRYn.

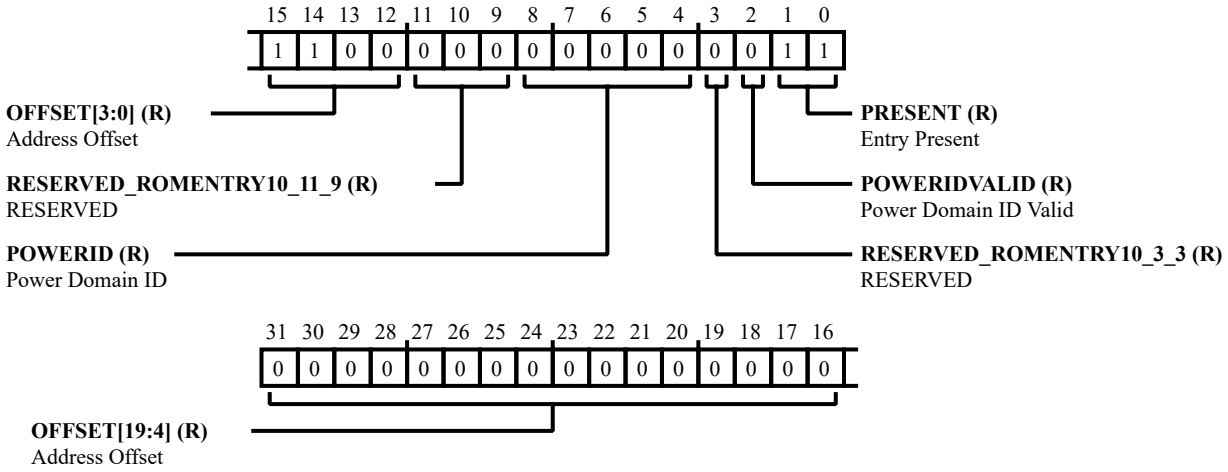

Figure 48-275: A55_CLUSTER_ROMENTRY10 Register Diagram

Table 48-273: A55_CLUSTER_ROMENTRY10 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:12 (R/NW)	OFFSET	Address Offset. Base address of the highest 4KB block for that component, relative to the ROM address.	
11:9 (R/NW)	RESERVED_ROMEN-TRY10_11_9	RESERVED. Reserved RES0.	
		0	Reserved.
8:4 (R/NW)	POWERID	Power Domain ID. Indicates the power domain ID of the component.	
3 (R/NW)	RESERVED_ROMEN-TRY10_3_3	RESERVED. Reserved RES0.	
		0	Reserved.
2 (R/NW)	POWERIDVALID	Power Domain ID Valid. Indicates if the POWERID field valid.	
		0	Power domain ID not provided.
		1	Power domain ID provided in POWERID.

Table 48-273: A55_CLUSTER_ROMENTRY10 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1:0 (R/NW)	PRESENT	Entry Present. Set if corresponding unit exists.	
		0	ROM entry not present. All other fields in this entry must be zero. This is the final entry in the ROM table.
		1	Reserved.
		2	ROM entry not present. This is not the final entry in the ROM table. All other fields in this entry are UNKNOWN.
		3	ROM entry present.

ROM Table Entry 11 Register

ROMENTRYn.

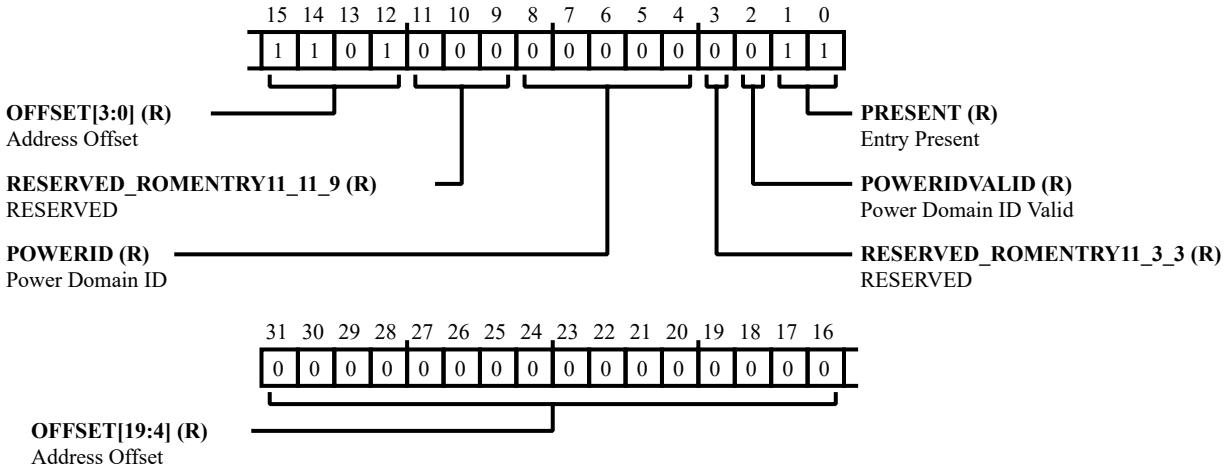

Figure 48-276: A55_CLUSTER_ROMENTRY11 Register Diagram

Table 48-274: A55_CLUSTER_ROMENTRY11 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:12 (R/NW)	OFFSET	Address Offset. Base address of the highest 4KB block for that component, relative to the ROM address.	
11:9 (R/NW)	RESERVED_ROMEN-TRY11_11_9	RESERVED. Reserved RES0.	
		0	Reserved.
8:4 (R/NW)	POWERID	Power Domain ID. Indicates the power domain ID of the component.	
3 (R/NW)	RESERVED_ROMEN-TRY11_3_3	RESERVED. Reserved RES0.	
		0	Reserved.
2 (R/NW)	POWERIDVALID	Power Domain ID Valid. Indicates if the POWERID field valid.	
		0	Power domain ID not provided.
		1	Power domain ID provided in POWERID.

Table 48-274: A55_CLUSTER_ROMENTRY11 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1:0 (R/NW)	PRESENT	Entry Present. Set if corresponding unit exists.	
		0	ROM entry not present. All other fields in this entry must be zero. This is the final entry in the ROM table.
		1	Reserved.
		2	ROM entry not present. This is not the final entry in the ROM table. All other fields in this entry are UNKNOWN.
		3	ROM entry present.

ROM Table Entry 12 Register

ROMENTRYn.

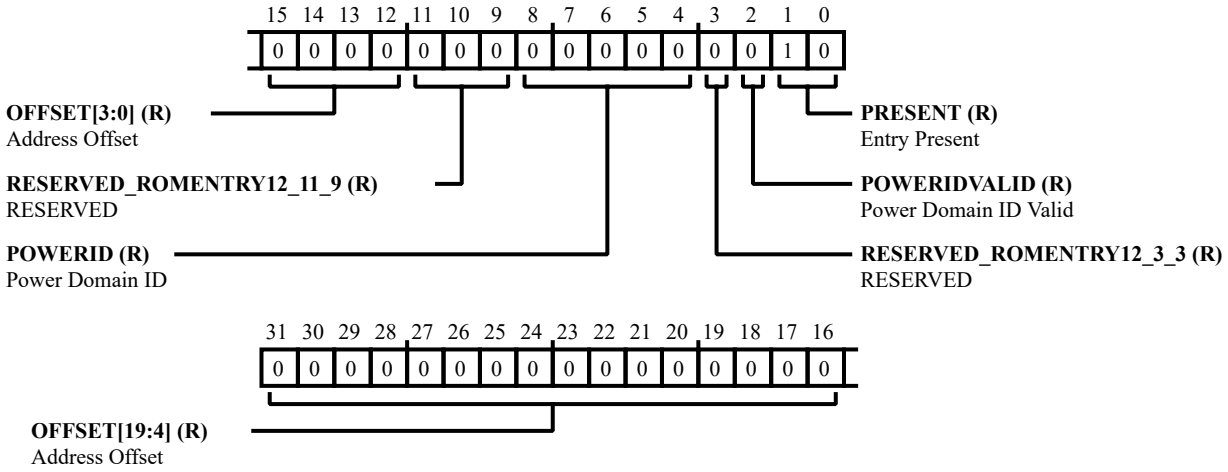

Figure 48-277: A55_CLUSTER_ROMENTRY12 Register Diagram

Bit No. (Access)	Bit Name	Description/Enumeration	
31:12 (R/NW)	OFFSET	Address Offset. Base address of the highest 4KB block for that component, relative to the ROM address.	
11:9 (R/NW)	RESERVED_ROMEN-TRY12_11_9	RESERVED. Reserved RES0.	
		0	Reserved.
8:4 (R/NW)	POWERID	Power Domain ID. Indicates the power domain ID of the component.	
3 (R/NW)	RESERVED_ROMEN-TRY12_3_3	RESERVED. Reserved RES0.	
		0	Reserved.
2 (R/NW)	POWERIDVALID	Power Domain ID Valid. Indicates if the POWERID field valid.	
		0	Power domain ID not provided.
		1	Power domain ID provided in POWERID.

Table 48-275: A55_CLUSTER_ROMENTRY12 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1:0 (R/NW)	PRESENT	Entry Present. Set if corresponding unit exists.	
		0	ROM entry not present. All other fields in this entry must be zero. This is the final entry in the ROM table.
		1	Reserved.
		2	ROM entry not present. This is not the final entry in the ROM table. All other fields in this entry are UNKNOWN.
		3	ROM entry present.

ROM Table Entry 13 Register

ROMENTRYn.

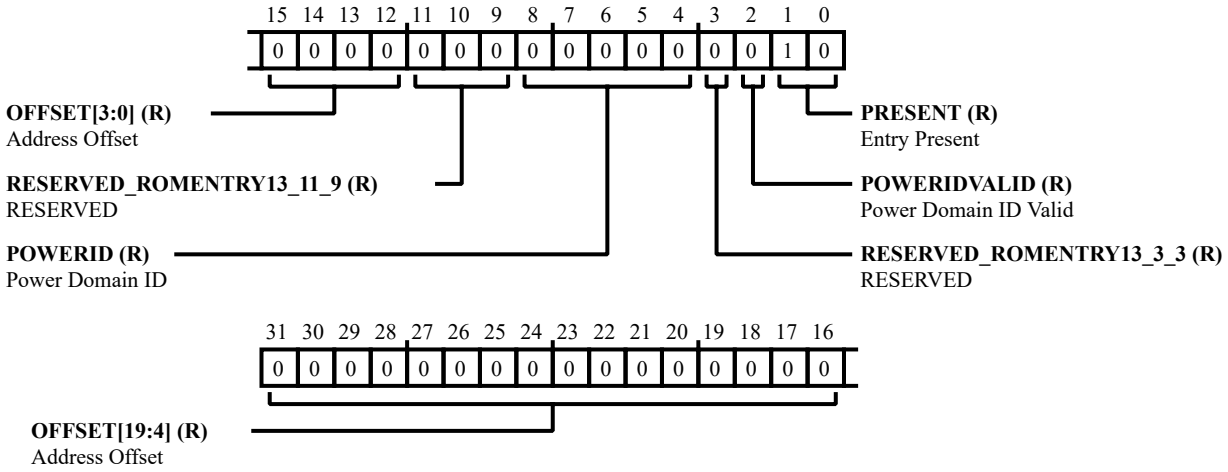

Figure 48-278: A55_CLUSTER_ROMENTRY13 Register Diagram

Table 48-276: A55_CLUSTER_ROMENTRY13 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:12 (R/NW)	OFFSET	Address Offset. Base address of the highest 4KB block for that component, relative to the ROM address.	
11:9 (R/NW)	RESERVED_ROMEN-TRY13_11_9	RESERVED. Reserved RES0.	
		0	Reserved.
8:4 (R/NW)	POWERID	Power Domain ID. Indicates the power domain ID of the component.	
3 (R/NW)	RESERVED_ROMEN-TRY13_3_3	RESERVED. Reserved RES0.	
		0	Reserved.
2 (R/NW)	POWERIDVALID	Power Domain ID Valid. Indicates if the POWERID field valid.	
		0	Power domain ID not provided.
		1	Power domain ID provided in POWERID.

Table 48-276: A55_CLUSTER_ROMENTRY13 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1:0 (R/NW)	PRESENT	Entry Present. Set if corresponding unit exists.	
		0	ROM entry not present. All other fields in this entry must be zero. This is the final entry in the ROM table.
		1	Reserved.
		2	ROM entry not present. This is not the final entry in the ROM table. All other fields in this entry are UNKNOWN.
		3	ROM entry present.

ROM Table Entry 14 Register

ROMENTRYn.

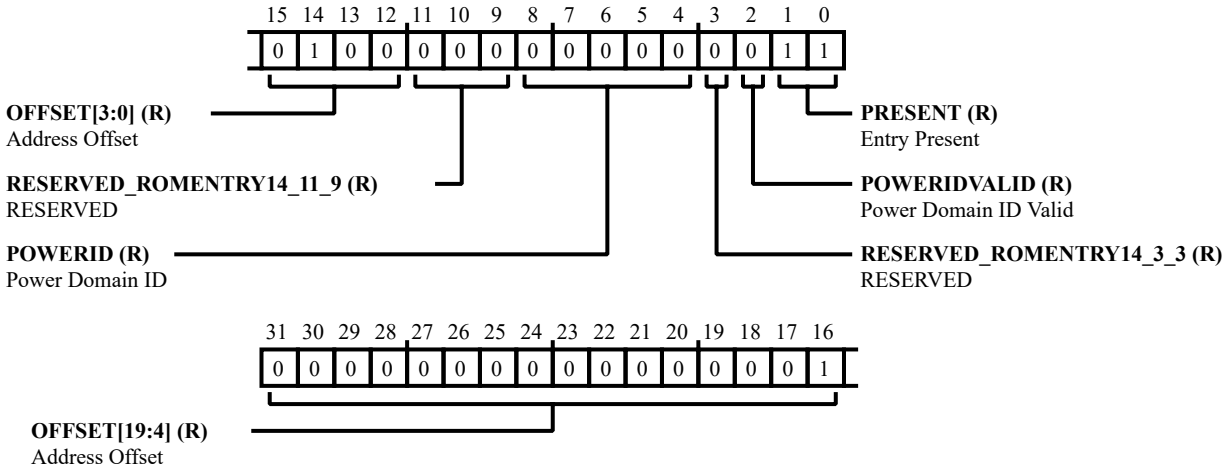

Figure 48-279: A55_CLUSTER_ROMENTRY14 Register Diagram

Table 48-277: A55_CLUSTER_ROMENTRY14 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:12 (R/NW)	OFFSET	Address Offset. Base address of the highest 4KB block for that component, relative to the ROM address.	
11:9 (R/NW)	RESERVED_ROMEN-TRY14_11_9	RESERVED. Reserved RES0.	
		0	Reserved.
8:4 (R/NW)	POWERID	Power Domain ID. Indicates the power domain ID of the component.	
3 (R/NW)	RESERVED_ROMEN-TRY14_3_3	RESERVED. Reserved RES0.	
		0	Reserved.
2 (R/NW)	POWERIDVALID	Power Domain ID Valid. Indicates if the POWERID field valid.	
		0	Power domain ID not provided.
		1	Power domain ID provided in POWERID.

Table 48-277: A55_CLUSTER_ROMENTRY14 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1:0 (R/NW)	PRESENT	Entry Present. Set if corresponding unit exists.	
		0	ROM entry not present. All other fields in this entry must be zero. This is the final entry in the ROM table.
		1	Reserved.
		2	ROM entry not present. This is not the final entry in the ROM table. All other fields in this entry are UNKNOWN.
		3	ROM entry present.

ROM Table Entry 15 Register

ROMENTRYn.

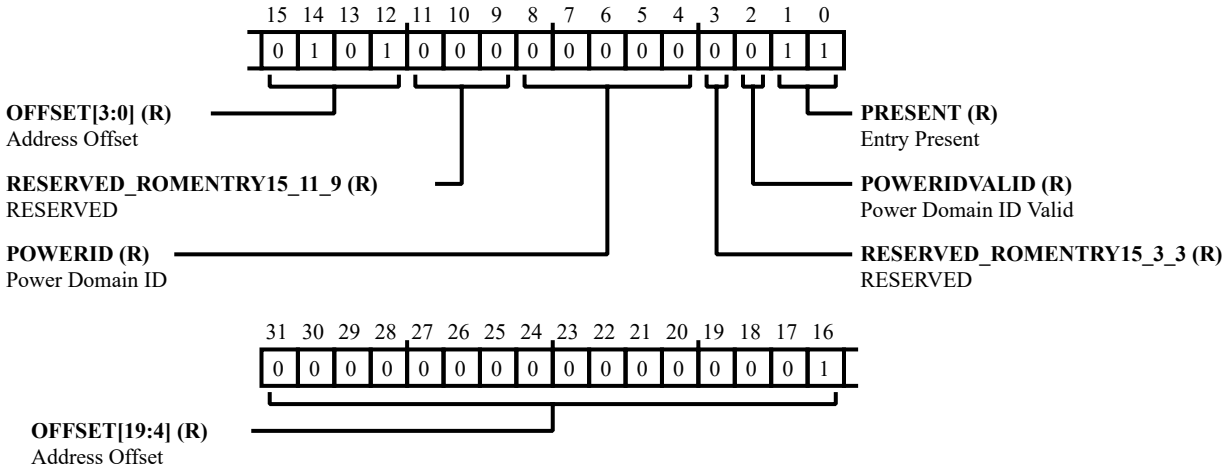

Figure 48-280: A55_CLUSTER_ROMENTRY15 Register Diagram

Table 48-278: A55_CLUSTER_ROMENTRY15 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:12 (R/NW)	OFFSET	Address Offset. Base address of the highest 4KB block for that component, relative to the ROM address.	
11:9 (R/NW)	RESERVED_ROMEN-TRY15_11_9	RESERVED. Reserved RES0.	
		0	Reserved.
8:4 (R/NW)	POWERID	Power Domain ID. Indicates the power domain ID of the component.	
3 (R/NW)	RESERVED_ROMEN-TRY15_3_3	RESERVED. Reserved RES0.	
		0	Reserved.
2 (R/NW)	POWERIDVALID	Power Domain ID Valid. Indicates if the POWERID field valid.	
		0	Power domain ID not provided.
		1	Power domain ID provided in POWERID.

Table 48-278: A55_CLUSTER_ROMENTRY15 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1:0 (R/NW)	PRESENT	Entry Present. Set if corresponding unit exists.	
		0	ROM entry not present. All other fields in this entry must be zero. This is the final entry in the ROM table.
		1	Reserved.
		2	ROM entry not present. This is not the final entry in the ROM table. All other fields in this entry are UNKNOWN.
		3	ROM entry present.

		0	ROM entry not present. All other fields in this entry must be zero. This is the final entry in the ROM table.
		1	Reserved.
		2	ROM entry not present. This is not the final entry in the ROM table. All other fields in this entry are UNKNOWN.
		3	ROM entry present.

ROM Table Entry 5 Register

ROMENTRYn.

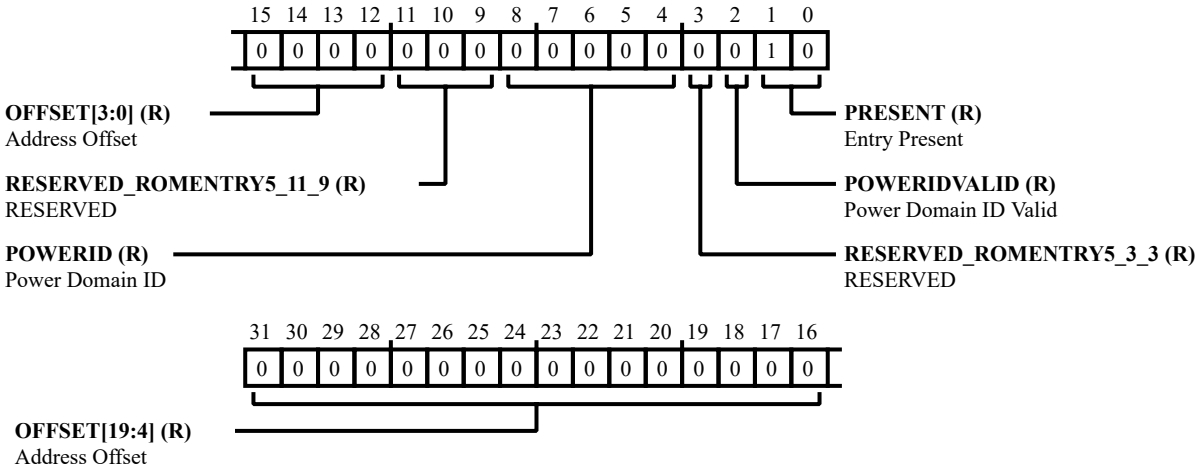

Figure 48-318: A55_CLUSTER_ROMENTRY5 Register Diagram

Table 48-316: A55_CLUSTER_ROMENTRY5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:12 (R/NW)	OFFSET	Address Offset. Base address of the highest 4KB block for that component, relative to the ROM address.	
11:9 (R/NW)	RESERVED_ROMEN-TRY5_11_9	RESERVED. Reserved RES0.	
		0	Reserved.
8:4 (R/NW)	POWERID	Power Domain ID. Indicates the power domain ID of the component.	
3 (R/NW)	RESERVED_ROMEN-TRY5_3_3	RESERVED. Reserved RES0.	
		0	Reserved.
2 (R/NW)	POWERIDVALID	Power Domain ID Valid. Indicates if the POWERID field valid.	
		0	Power domain ID not provided.
		1	Power domain ID provided in POWERID.

Table 48-316: A55_CLUSTER_ROMENTRY5 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1:0 (R/NW)	PRESENT	Entry Present. Set if corresponding unit exists.	
		0	ROM entry not present. All other fields in this entry must be zero. This is the final entry in the ROM table.
		1	Reserved.
		2	ROM entry not present. This is not the final entry in the ROM table. All other fields in this entry are UNKNOWN.
		3	ROM entry present.

ROM Table Entry 50 Register

		1	Reserved.
		2	ROM entry not present. This is not the final entry in the ROM table. All other fields in this entry are UNKNOWN.
		3	ROM entry present.

ROM Table Entry 67 Register

ROMENTRYn.

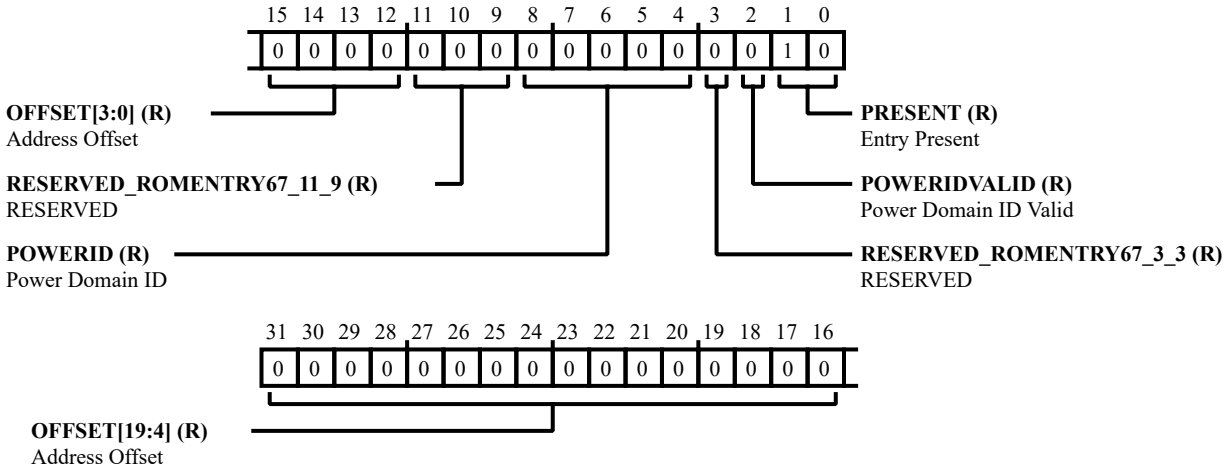

Figure 48-337: A55_CLUSTER_ROMENTRY67 Register Diagram

Table 48-335: A55_CLUSTER_ROMENTRY67 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:12 (R/NW)	OFFSET	Address Offset. Base address of the highest 4KB block for that component, relative to the ROM address.	
11:9 (R/NW)	RESERVED_ROMEN-TRY67_11_9	RESERVED. Reserved RES0.	
		0	Reserved.
8:4 (R/NW)	POWERID	Power Domain ID. Indicates the power domain ID of the component.	
3 (R/NW)	RESERVED_ROMEN-TRY67_3_3	RESERVED. Reserved RES0.	
		0	Reserved.
2 (R/NW)	POWERIDVALID	Power Domain ID Valid. Indicates if the POWERID field valid.	
		0	Power domain ID not provided.
		1	Power domain ID provided in POWERID.

Table 48-335: A55_CLUSTER_ROMENTRY67 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1:0 (R/NW)	PRESENT	Entry Present. Set if corresponding unit exists.	
		0	ROM entry not present. All other fields in this entry must be zero. This is the final entry in the ROM table.
		1	Reserved.
		2	ROM entry not present. This is not the final entry in the ROM table. All other fields in this entry are UNKNOWN.
		3	ROM entry present.

ROM Table Entry 68 Register

ROMENTRYn.

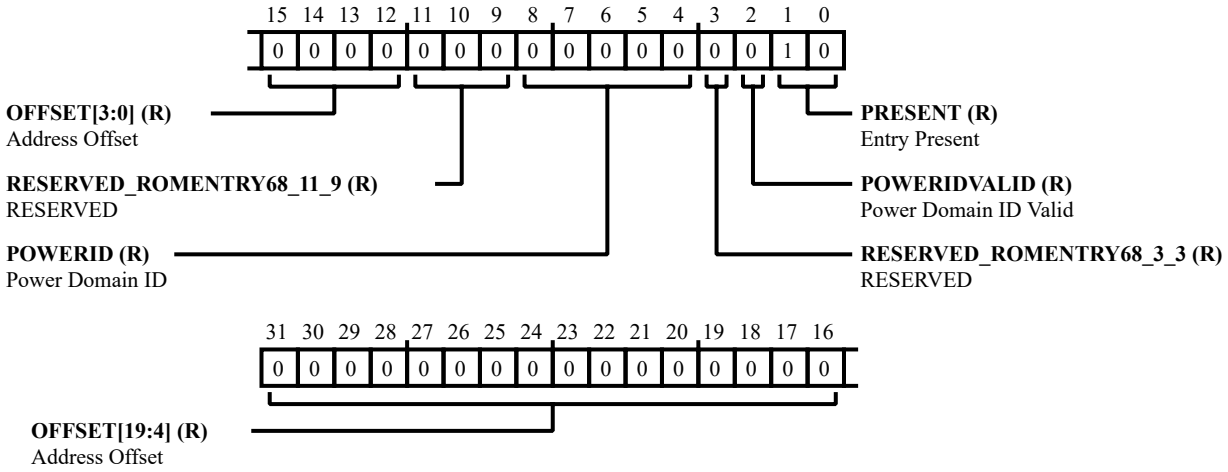

Figure 48-338: A55_CLUSTER_ROMENTRY68 Register Diagram

Table 48-336: A55_CLUSTER_ROMENTRY68 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:12 (R/NW)	OFFSET	Address Offset. Base address of the highest 4KB block for that component, relative to the ROM address.	
11:9 (R/NW)	RESERVED_ROMEN-TRY68_11_9	RESERVED. Reserved RES0.	
		0	Reserved.
8:4 (R/NW)	POWERID	Power Domain ID. Indicates the power domain ID of the component.	
3 (R/NW)	RESERVED_ROMEN-TRY68_3_3	RESERVED. Reserved RES0.	
		0	Reserved.
2 (R/NW)	POWERIDVALID	Power Domain ID Valid. Indicates if the POWERID field valid.	
		0	Power domain ID not provided.
		1	Power domain ID provided in POWERID.

Table 48-336: A55_CLUSTER_ROMENTRY68 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1:0 (R/NW)	PRESENT	Entry Present. Set if corresponding unit exists.	
		0	ROM entry not present. All other fields in this entry must be zero. This is the final entry in the ROM table.
		1	Reserved.
		2	ROM entry not present. This is not the final entry in the ROM table. All other fields in this entry are UNKNOWN.
		3	ROM entry present.

ROM Table Entry 69 Register

ROMENTRYn.

		1	Reserved.
		2	ROM entry not present. This is not the final entry in the ROM table. All other fields in this entry are UNKNOWN.
		3	ROM entry present.

ADSP-2184x SOC600CTI_TRACE Register Descriptions

Your module description, here. (SOC600CTI_TRACE) contains the following registers.

Table 48-353: ADSP-2184x SOC600CTI_TRACE Register List

Name	Description
SOC600CTI_TRACE_ASICCTRL	External Multiplexer Control register.
SOC600CTI_TRACE_AUTHSTATUS	Authentication Status Register.
SOC600CTI_TRACE_CIDR0	Component Identification Register 0.
SOC600CTI_TRACE_CIDR1	Component Identification Register 1.
SOC600CTI_TRACE_CIDR2	Component Identification Register 2.
SOC600CTI_TRACE_CIDR3	Component Identification Register 3.
SOC600CTI_TRACE_CLAIMCLR	Claim Tag Clear Register.
SOC600CTI_TRACE_CLAIMSET	Claim Tag Set Register.
SOC600CTI_TRACE_CTIAPPCLEAR	CTI Application Channel Clear register.
SOC600CTI_TRACE_CTIAPPPULSE	CTI Application Channel Pulse register.
SOC600CTI_TRACE_CTIAPPSET	CTI Application Channel Set register.
SOC600CTI_TRACE_CTICHINSTATUS	CTI Channel Input Status register.
SOC600CTI_TRACE_CTICHOUTSTATUS	CTI Channel Output Status register.
SOC600CTI_TRACE_CTICONTROL	CTI Control register.
SOC600CTI_TRACE_CTIGATE	Enable CTI Channel Gate register.
SOC600CTI_TRACE_CTIINEN0	CTI Trigger 0 to Channel Enable register.
SOC600CTI_TRACE_CTIINEN1	CTI Trigger 1 to Channel Enable register.

Table 48-353: ADSP-2184x SOC600CTI_TRACE Register List (Continued)

Name	Description
SOC600CTI_TRACE_CTIINEN2	CTI Trigger 2 to Channel Enable register.
SOC600CTI_TRACE_CTIINEN3	CTI Trigger 3 to Channel Enable register.
SOC600CTI_TRACE_CTIINEN4	CTI Trigger 4 to Channel Enable register.
SOC600CTI_TRACE_CTIINEN5	CTI Trigger 5 to Channel Enable register.
SOC600CTI_TRACE_CTIINEN6	CTI Trigger 6 to Channel Enable register.
SOC600CTI_TRACE_CTIINTACK	CTI Interrupt Acknowledge register.
SOC600CTI_TRACE_CTIOUTEN0	CTI Channel to Trigger 0 Enable register.
SOC600CTI_TRACE_CTIOUTEN1	CTI Channel to Trigger 1 Enable register.
SOC600CTI_TRACE_CTIOUTEN2	CTI Channel to Trigger 2 Enable register.
SOC600CTI_TRACE_CTIOUTEN3	CTI Channel to Trigger 3 Enable register.
SOC600CTI_TRACE_CTIOUTEN4	CTI Channel to Trigger 4 Enable register.
SOC600CTI_TRACE_CTIOUTEN5	CTI Channel to Trigger 5 Enable register.
SOC600CTI_TRACE_CTITRIGINSTATUS	CTI Trigger Input Status register.
SOC600CTI_TRACE_CTITRIGOUTSTATUS	CTI Trigger Output Status register.
SOC600CTI_TRACE_DEVAFF0	Device Affinity register 0.
SOC600CTI_TRACE_DEVAFF1	Device Affinity register 1.
SOC600CTI_TRACE_DEVARCH	Device Architecture Register.
SOC600CTI_TRACE_DEVID	Device Configuration Register.
SOC600CTI_TRACE_DEVTYPE	Device Type Identifier Register.
SOC600CTI_TRACE_ITCHIN	Integration Test Channel Input register.
SOC600CTI_TRACE_ITCHOUT	Integration Test Channel Output register.
SOC600CTI_TRACE_ITCTRL	Integration Mode Control Register.
SOC600CTI_TRACE_ITTRIGIN	Integration Test Trigger Input register.
SOC600CTI_TRACE_ITTRIGOUT	Integration Test Trigger Output register.
SOC600CTI_TRACE_PIDR0	Peripheral Identification Register 0.
SOC600CTI_TRACE_PIDR1	Peripheral Identification Register 1.
SOC600CTI_TRACE_PIDR2	Peripheral Identification Register 2.
SOC600CTI_TRACE_PIDR3	Peripheral Identification Register 3.
SOC600CTI_TRACE_PIDR4	Peripheral Identification Register 4.
SOC600CTI_TRACE_PIDR5	Peripheral Identification Register 5.
SOC600CTI_TRACE_PIDR6	Peripheral Identification Register 6.

Table 48-353: ADSP-2184x SOC600CTI_TRACE Register List (Continued)

Name	Description
SOC600CTI_TRACE_PIDR7	Peripheral Identification Register 7.

External Multiplexer Control register.

I/O port control.

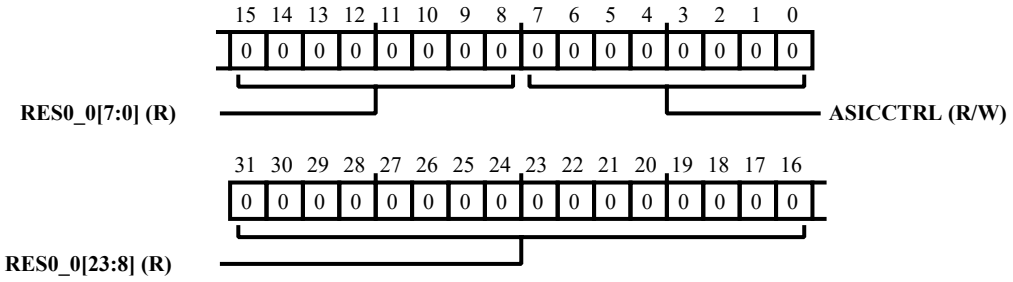

Figure 48-355: SOC600CTI_TRACE_ASICCTRL Register Diagram

Table 48-354: SOC600CTI_TRACE_ASICCTRL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
7:0 (R/W)	ASICCTRL	. Set and clear external output signal.	
		0	Clear output bit to 0.
		1	Set output bit to 1.

Authentication Status Register.

Reports the current status of the authentication control signals.

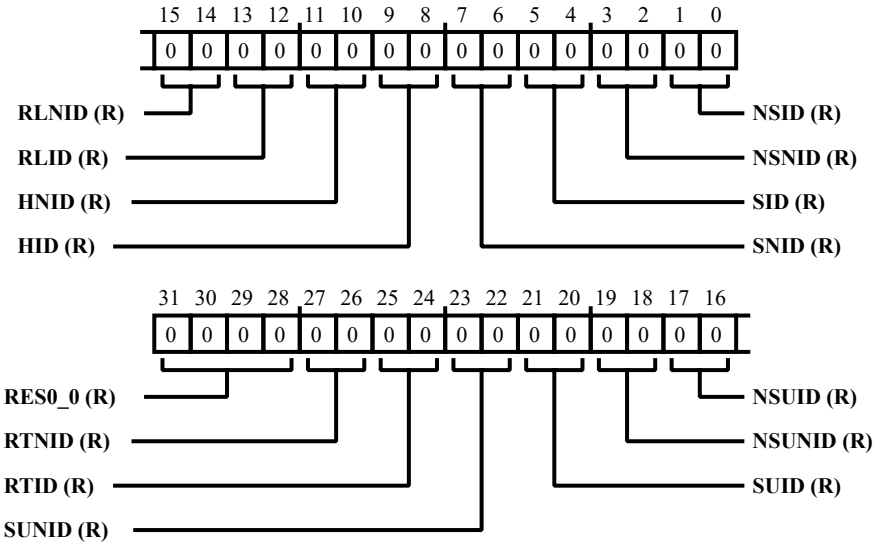

Figure 48-356: SOC600CTI_TRACE_AUTHSTATUS Register Diagram

Table 48-355: SOC600CTI_TRACE_AUTHSTATUS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:28 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
27:26 (R/NW)	RTNID	. Root non-invasive debug.	
		0	Separate Root non-invasive debug enable not implemented or Root state non-invasive debug features not implemented.
		1	Reserved.
		2	Implemented and disabled.
		3	Implemented and enabled.

Table 48-355: SOC600CTI_TRACE_AUTHSTATUS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
25:24 (R/NW)	RTID	. Root invasive debug.	
		0	Separate Root invasive debug enable not implemented or Root state invasive debug features not implemented.
		1	Reserved.
		2	Implemented and disabled.
		3	Implemented and enabled.
23:22 (R/NW)	SUNID	. Secure unprivileged non-invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.
21:20 (R/NW)	SUID	. Secure unprivileged invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.
19:18 (R/NW)	NSUNID	. Non-secure unprivileged non-invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.
17:16 (R/NW)	NSUID	. Non-secure unprivileged invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.

Table 48-355: SOC600CTI_TRACE_AUTHSTATUS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15:14 (R/NW)	RLNID	. Realm non-invasive debug.	
		0	Separate Realm non-invasive debug enable not implemented or Realm state non-invasive debug features not implemented.
		1	Reserved.
		2	Implemented and disabled.
		3	Implemented and enabled.
13:12 (R/NW)	RLID	. Realm invasive debug.	
		0	Separate Realm invasive debug enable not implemented or Realm state invasive debug features not implemented.
		1	Reserved.
		2	Implemented and disabled.
		3	Implemented and enabled.
11:10 (R/NW)	HNID	. Hypervisor non-invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.
9:8 (R/NW)	HID	. Hypervisor invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.

Table 48-355: SOC600CTI_TRACE_AUTHSTATUS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7:6 (R/NW)	SNID	. Secure non-invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.
5:4 (R/NW)	SID	. Secure invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.
3:2 (R/NW)	NSNID	. Non-secure non-invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.
1:0 (R/NW)	NSID	. Non-secure invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.

Component Identification Register 0.

The CIDR0 register is part of the set of component identification registers.

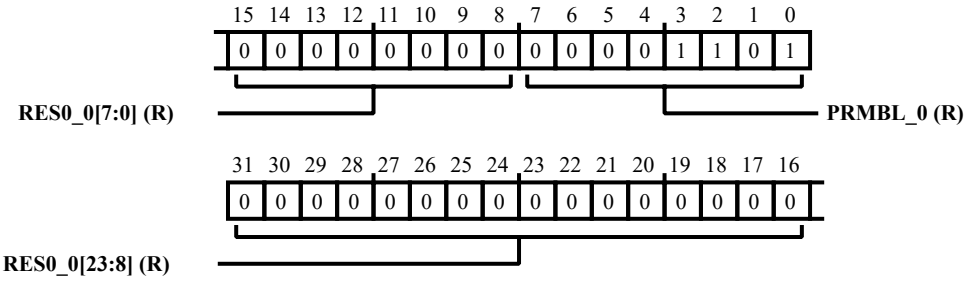

Figure 48-357: SOC600CTI_TRACE_CIDR0 Register Diagram

Table 48-356: SOC600CTI_TRACE_CIDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PRMBL_0	. Preamble. Returns 0x0D.

Component Identification Register 1.

The CIDR1 register is part of the set of component identification registers.

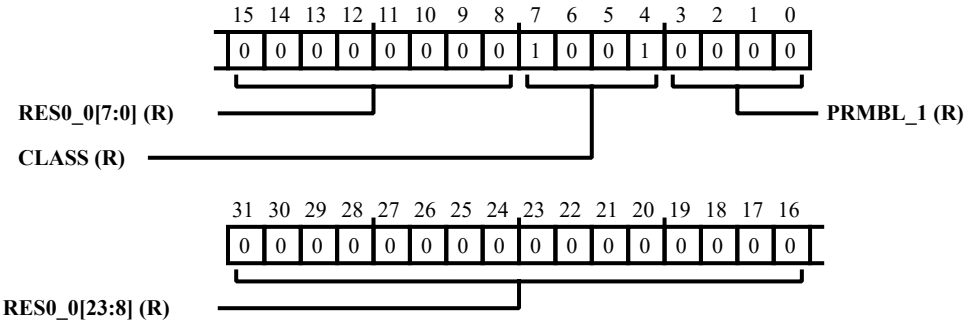

Figure 48-358: SOC600CTI_TRACE_CIDR1 Register Diagram

Table 48-357: SOC600CTI_TRACE_CIDR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
7:4 (R/NW)	CLASS	. Component class.	
		9	CoreSight component.
		15	CoreLink, PrimeCell, or system component.
3:0 (R/NW)	PRMBL_1	. Preamble. Returns 0x0.	

Component Identification Register 2.

The CIDR2 register is part of the set of component identification registers.

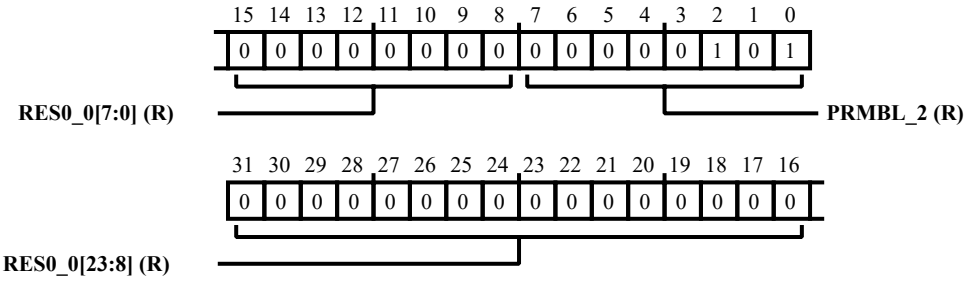

Figure 48-359: SOC600CTI_TRACE_CIDR2 Register Diagram

Table 48-358: SOC600CTI_TRACE_CIDR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PRMBL_2	. Preamble. Returns 0x05.

Component Identification Register 3.

The CIDR3 register is part of the set of component identification registers.

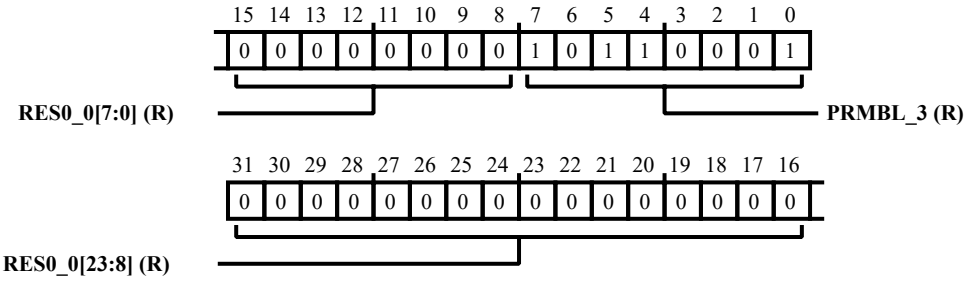

Figure 48-360: SOC600CTI_TRACE_CIDR3 Register Diagram

Table 48-359: SOC600CTI_TRACE_CIDR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PRMBL_3	. Preamble. Returns 0xB1.

Claim Tag Clear Register.

This register forms one half of the claim tag value. On writes, this location enables individual bits to be cleared. On reads, it returns the current claim tag value.

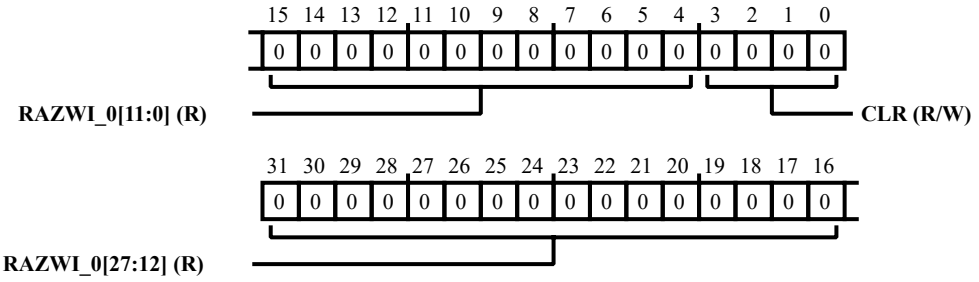

Figure 48-361: SOC600CTI_TRACE_CLAIMCLR Register Diagram

Table 48-360: SOC600CTI_TRACE_CLAIMCLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:4 (R/NW)	RAZWI_0	. RAZ/WI.
3:0 (R/W)	CLR	. A bit-programmable register bank that clears the claim tag value. It is zero at reset. It is used by software agents to signal to each other ownership of the hardware. It has no direct effect on the hardware itself.

Claim Tag Set Register.

This register forms one half of the claim tag value. On writes, this location enables individual bits to be set. On reads, it returns the number of bits that can be set.

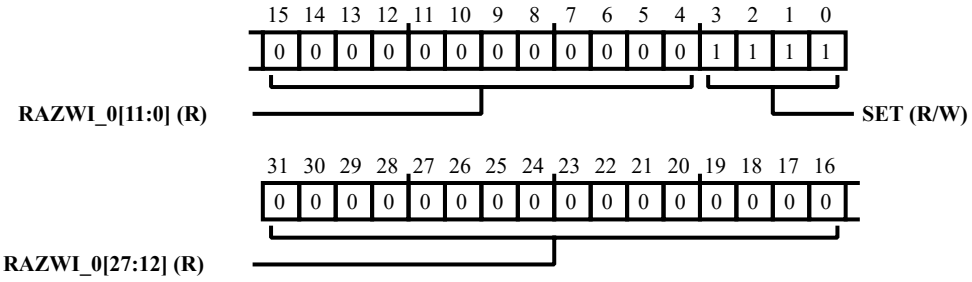

Figure 48-362: SOC600CTI_TRACE_CLAIMSET Register Diagram

Table 48-361: SOC600CTI_TRACE_CLAIMSET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:4 (R/NW)	RAZWI_0	. RAZ/WI.
3:0 (R/W)	SET	. A bit-programmable register bank that sets the claim tag value. A read returns a logic 1 for all implemented locations.

CTI Application Channel Clear register.

The CTIAPPCLEAR register allows software to clear any channel output. Software can use this register to clear a channel event in place of a hardware source on a trigger input. This register must not be used in a system where all events are sent as single-cycle pulses. It is only retained for compatibility with older systems and software. The register is implemented before the CTIGATE register. Therefore, for the channel event to propagate outside the CTI, the corresponding CTIGATE bit must be set to 1.

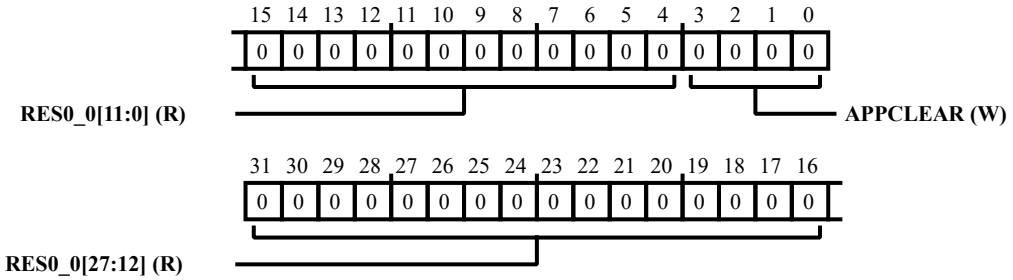

Figure 48-363: SOC600CTI_TRACE_CTIAPPCLEAR Register Diagram

Table 48-362: SOC600CTI_TRACE_CTIAPPCLEAR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (RX/W)	APPCLEAR	. Clears the corresponding internal channel flag.	
		0	No effect.
		1	Clears the channel output.

CTI Application Channel Pulse register.

The application channel pulse register allows software to pulse any channel output. This register can be used by software to pulse a channel event in place of a hardware source on a trigger input. The register is implemented before the CTIGATE register so, for the channel event to propagate outside the CTI, it is necessary for the corresponding CTIGATE bit to be 1.

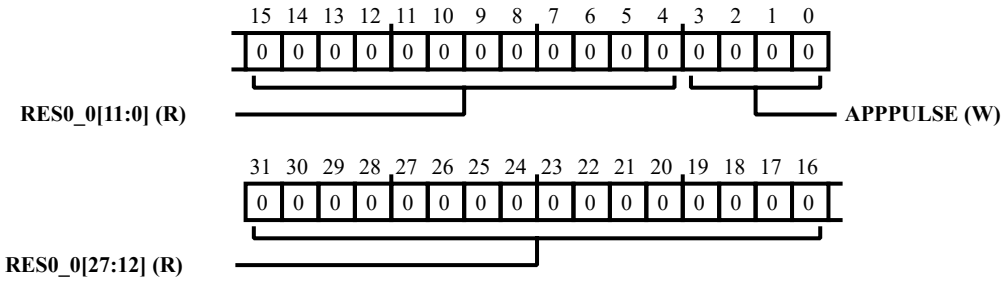

Figure 48-364: SOC600CTI_TRACE_CTIAPPPULSE Register Diagram

Table 48-363: SOC600CTI_TRACE_CTIAPPPULSE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (RX/W)	APPPULSE	. Pulses the channel outputs.	
		0	No effect.
		1	Pulse channel event for one clk cycle.

CTI Application Channel Set register.

The CTIAPPSET register allows software to set any channel output. Software can use this register to generate a channel event in place of a hardware source on a trigger input. This register must not be used in a system where all events are sent as single-cycle pulses. It is only retained for compatibility with older systems and software. The register is implemented before the CTIGATE register. Therefore, for the channel event to propagate outside the CTI, the corresponding CTIGATE bit must be set to 1.

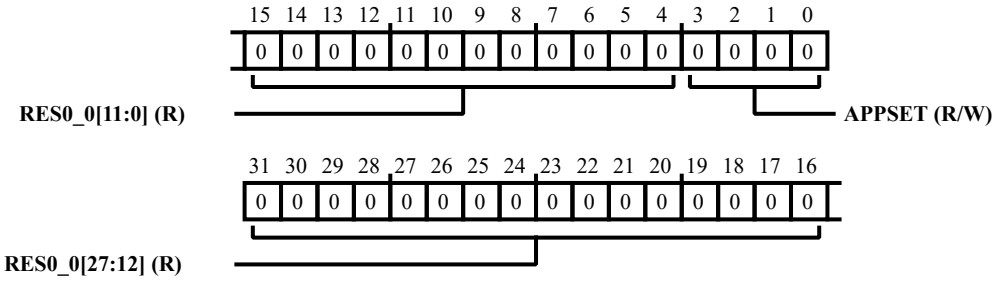

Figure 48-365: SOC600CTI_TRACE_CTIAPPSET Register Diagram

Table 48-364: SOC600CTI_TRACE_CTIAPPSET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (R/W)	APPSET	. Sets the corresponding internal channel flag:.	
		0	Read: application channel is inactive. Write: has no effect.
		1	Read: application channel is active. Write: sets the channel output.

CTI Channel Input Status register.

Channel input status. If the channel input is driven by a source that generates single cycle pulses, this register is generally read as 0.

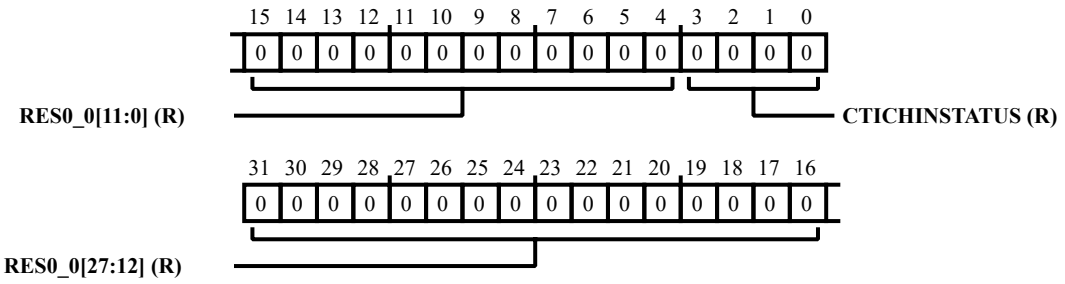

Figure 48-366: SOC600CTI_TRACE_CTICHINSTATUS Register Diagram

Table 48-365: SOC600CTI_TRACE_CTICHINSTATUS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (R/NW)	CTICHINSTATUS	. Channel input status.	
		0	One bit per channel input. 0 means that the input is LOW.
		1	One bit per channel input. 1 means that the input is HIGH.

CTI Channel Output Status register.

Channel output status. The register only has meaning if the trigger source drives static levels, rather than pulses.

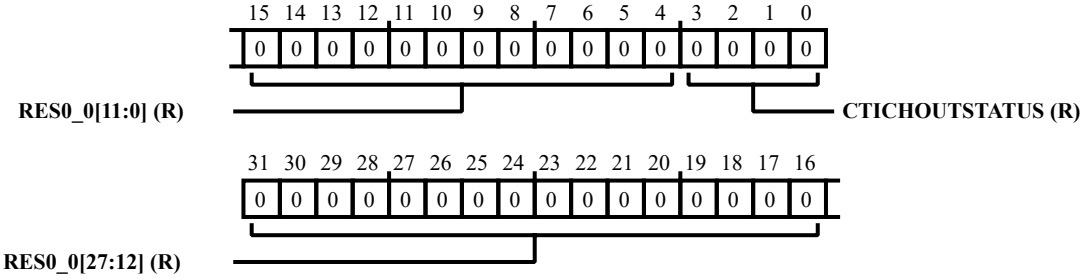

Figure 48-367: SOC600CTI_TRACE_CTICHOUTSTATUS Register Diagram

Table 48-366: SOC600CTI_TRACE_CTICHOUTSTATUS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (R/NW)	CTICHOUTSTATUS	. Channel output status.	
		0	One bit per channel output. 0 means that the output is LOW.
		1	One bit per channel output. 1 means that the output is HIGH.

CTI Control register.

The CTICONTROL register enables and disables the CTI.

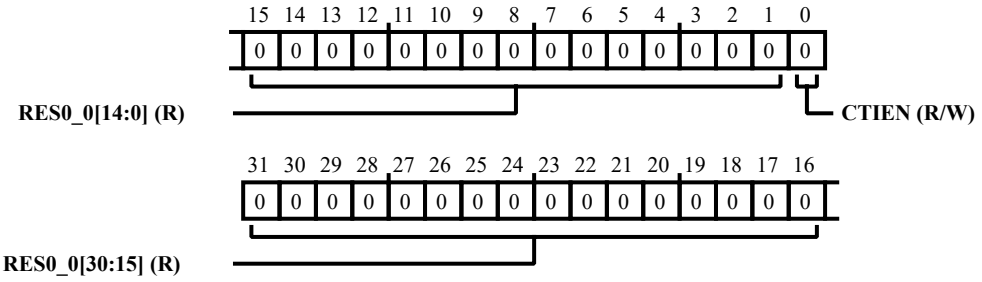

Figure 48-368: SOC600CTI_TRACE_CTICONTROL Register Diagram

Table 48-367: SOC600CTI_TRACE_CTICONTROL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:1 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
0 (R/W)	CTIEN	. Enable control:.	
		0	CTI disabled.
		1	CTI enabled.

Enable CTI Channel Gate register.

Channel output gate.

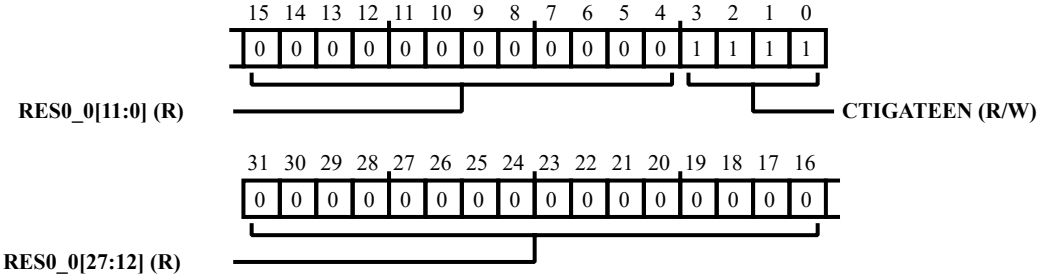

Figure 48-369: SOC600CTI_TRACE_CTIGATE Register Diagram

Table 48-368: SOC600CTI_TRACE_CTIGATE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (R/W)	CTIGATEEN	. Enables the propagation of channel events out of the CTI, one bit per channel.	
		0	Disable a channel from propagating.
		1	Enable channel propagation.

CTI Trigger 0 to Channel Enable register.

This register maps trigger inputs to channels in the cross trigger system. The CTIINEN registers are bit maps that allow the trigger input to be mapped to any channel output, including none (0x0) and all (2^CHANNEL_WIDTH - 1). There is one register per trigger input, so it is possible to map any combination of trigger inputs to any channel outputs.

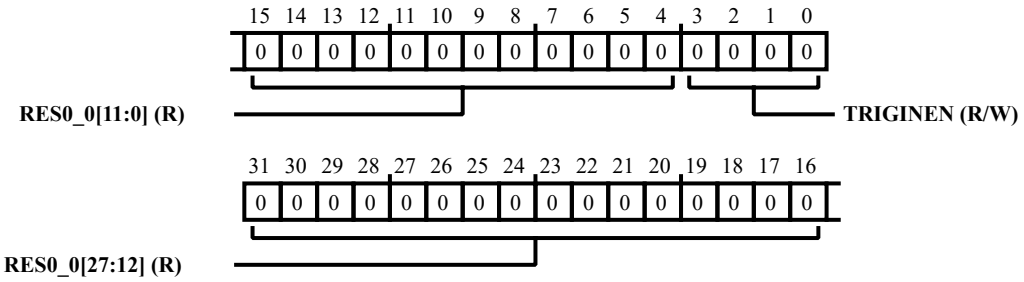

Figure 48-370: SOC600CTI_TRACE_CTIINEN0 Register Diagram

Table 48-369: SOC600CTI_TRACE_CTIINEN0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (R/W)	TRIGINEN	. Trigger input to channel mapping.	
		0	Input trigger 0 events are ignored by the corresponding channel.
		1	When an event is received on event_in[0], generate an event on the channel corresponding to this bit.

CTI Trigger 1 to Channel Enable register.

This register maps trigger inputs to channels in the cross trigger system. The CTIINEN registers are bit maps that allow the trigger input to be mapped to any channel output, including none (0x0) and all (2^CHANNEL_WIDTH - 1). There is one register per trigger input, so it is possible to map any combination of trigger inputs to any channel outputs.

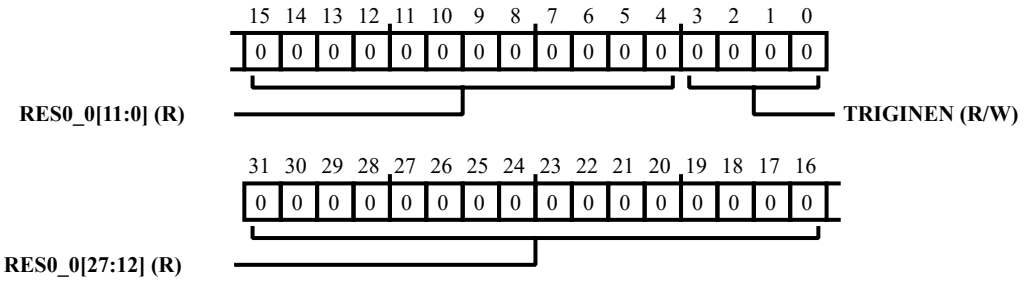

Figure 48-371: SOC600CTI_TRACE_CTIINEN1 Register Diagram

Table 48-370: SOC600CTI_TRACE_CTIINEN1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (R/W)	TRIGINEN	. Trigger input to channel mapping.	
		0	Input trigger 1 events are ignored by the corresponding channel.
		1	When an event is received on event_in[1], generate an event on the channel corresponding to this bit.

CTI Trigger 2 to Channel Enable register.

This register maps trigger inputs to channels in the cross trigger system. The CTIINEN registers are bit maps that allow the trigger input to be mapped to any channel output, including none (0x0) and all (2^CHANNEL_WIDTH - 1). There is one register per trigger input, so it is possible to map any combination of trigger inputs to any channel outputs.

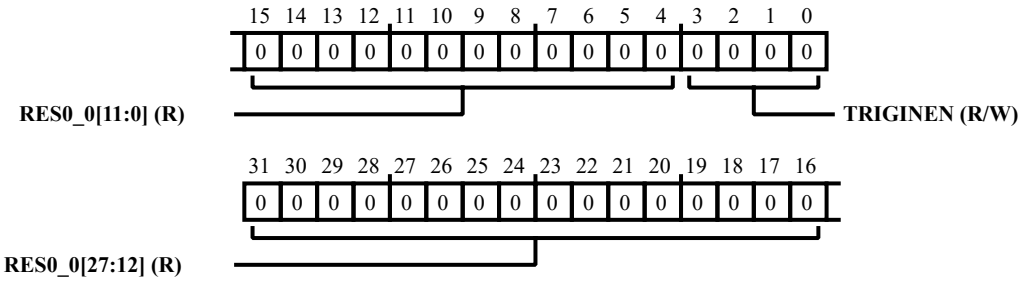

Figure 48-372: SOC600CTI_TRACE_CTIINEN2 Register Diagram

Table 48-371: SOC600CTI_TRACE_CTIINEN2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (R/W)	TRIGINEN	. Trigger input to channel mapping.	
		0	Input trigger 2 events are ignored by the corresponding channel.
		1	When an event is received on event_in[2], generate an event on the channel corresponding to this bit.

CTI Trigger 3 to Channel Enable register.

This register maps trigger inputs to channels in the cross trigger system. The CTIINEN registers are bit maps that allow the trigger input to be mapped to any channel output, including none (0x0) and all (2^CHANNEL_WIDTH - 1). There is one register per trigger input, so it is possible to map any combination of trigger inputs to any channel outputs.

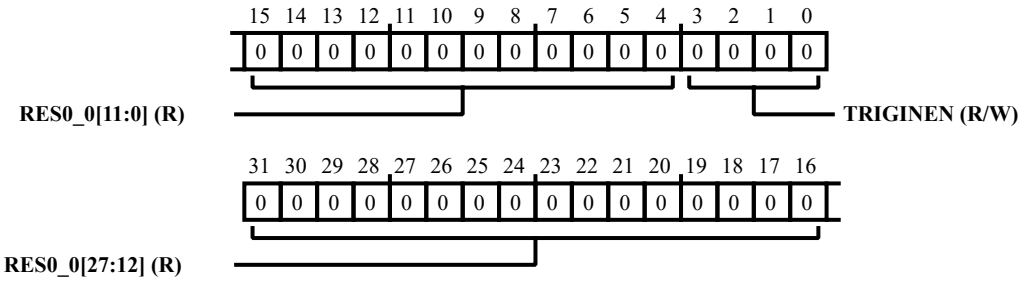

Figure 48-373: SOC600CTI_TRACE_CTIINEN3 Register Diagram

Table 48-372: SOC600CTI_TRACE_CTIINEN3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (R/W)	TRIGINEN	. Trigger input to channel mapping.	
		0	Input trigger 3 events are ignored by the corresponding channel.
		1	When an event is received on event_in[3], generate an event on the channel corresponding to this bit.

CTI Trigger 4 to Channel Enable register.

This register maps trigger inputs to channels in the cross trigger system. The CTIINEN registers are bit maps that allow the trigger input to be mapped to any channel output, including none (0x0) and all (2^CHANNEL_WIDTH - 1). There is one register per trigger input, so it is possible to map any combination of trigger inputs to any channel outputs.

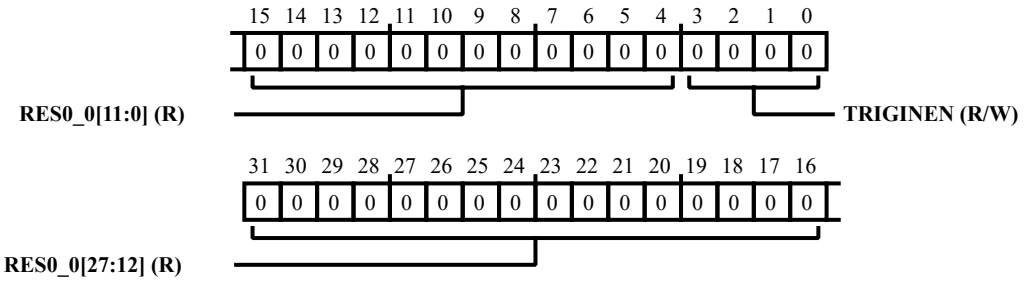

Figure 48-374: SOC600CTI_TRACE_CTIINEN4 Register Diagram

Table 48-373: SOC600CTI_TRACE_CTIINEN4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (R/W)	TRIGINEN	. Trigger input to channel mapping.	
		0	Input trigger 4 events are ignored by the corresponding channel.
		1	When an event is received on event_in[4], generate an event on the channel corresponding to this bit.

CTI Trigger 5 to Channel Enable register.

This register maps trigger inputs to channels in the cross trigger system. The CTIINEN registers are bit maps that allow the trigger input to be mapped to any channel output, including none (0x0) and all (2^CHANNEL_WIDTH - 1). There is one register per trigger input, so it is possible to map any combination of trigger inputs to any channel outputs.

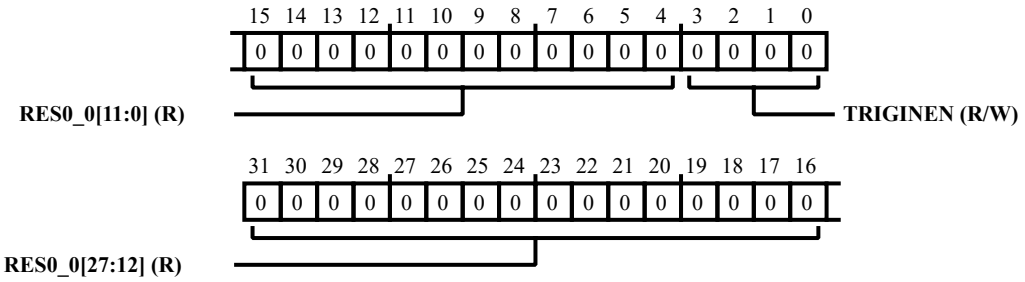

Figure 48-375: SOC600CTI_TRACE_CTIINEN5 Register Diagram

Table 48-374: SOC600CTI_TRACE_CTIINEN5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (R/W)	TRIGINEN	. Trigger input to channel mapping.	
		0	Input trigger 5 events are ignored by the corresponding channel.
		1	When an event is received on event_in[5], generate an event on the channel corresponding to this bit.

CTI Trigger 6 to Channel Enable register.

This register maps trigger inputs to channels in the cross trigger system. The CTIINEN registers are bit maps that allow the trigger input to be mapped to any channel output, including none (0x0) and all (2^CHANNEL_WIDTH - 1). There is one register per trigger input, so it is possible to map any combination of trigger inputs to any channel outputs.

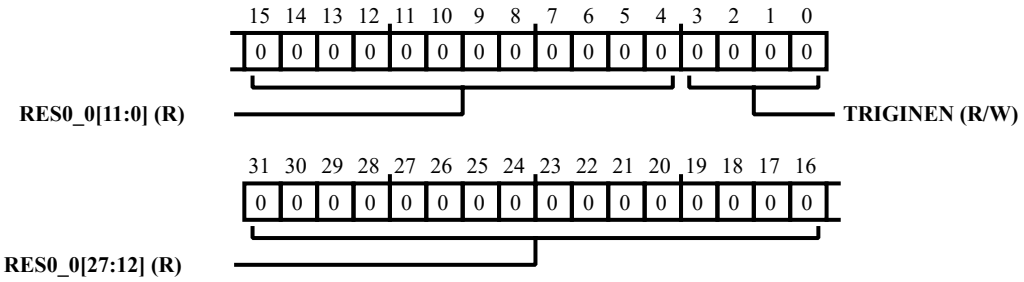

Figure 48-376: SOC600CTI_TRACE_CTIINEN6 Register Diagram

Table 48-375: SOC600CTI_TRACE_CTIINEN6 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (R/W)	TRIGINEN	. Trigger input to channel mapping.	
		0	Input trigger 6 events are ignored by the corresponding channel.
		1	When an event is received on event_in[6], generate an event on the channel corresponding to this bit.

CTI Interrupt Acknowledge register.

The CTIINTACK register acknowledges trigger outputs. It is a bit map that allows selective clearing of trigger output events. If the SW_HANDSHAKE parameter for a trigger output is set, indicating that the output latches HIGH when an event is sent to that output, then the output remains HIGH until the corresponding INTACK bit is written to a 1. A write of a bit to 0 has no effect. This allows different software threads to be responsible for clearing different trigger outputs without needing to perform a read-modify-write operation to find which bits are set.

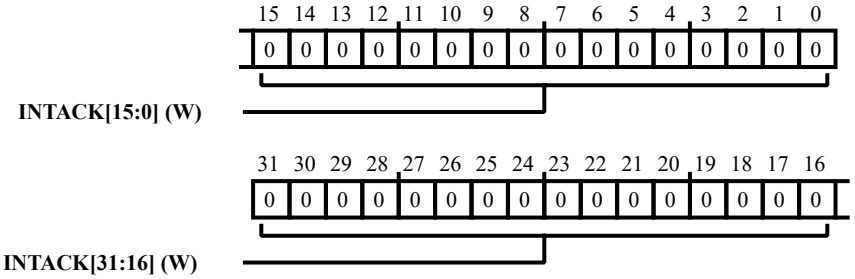

Figure 48-377: SOC600CTI_TRACE_CTIINTACK Register Diagram

Table 48-376: SOC600CTI_TRACE_CTIINTACK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (RX/W)	INTACK	. Acknowledges the corresponding event_out output.

CTI Channel to Trigger 0 Enable register.

This register maps channels in the cross trigger system to trigger outputs. The CTIOUTEN registers are bit maps that allow any channel input to be mapped to the trigger output, including none (0x0) and all (2^CHANNEL_WIDTH - 1). There is one register per trigger output so it is possible to map any channel input to any combination of trigger outputs.

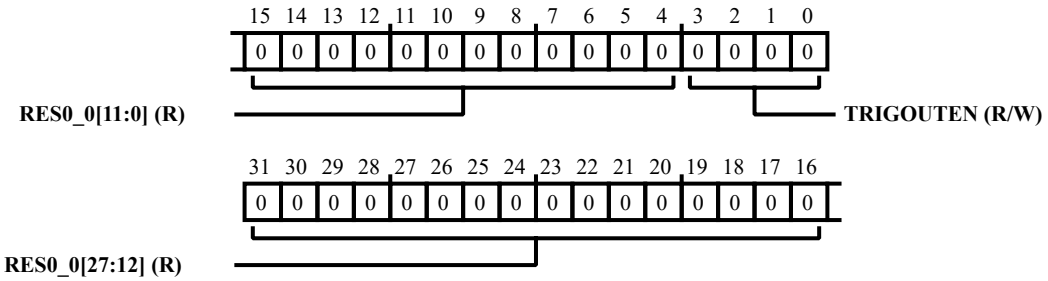

Figure 48-378: SOC600CTI_TRACE_CTIOUTEN0 Register Diagram

Table 48-377: SOC600CTI_TRACE_CTIOUTEN0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (R/W)	TRIGOUTEN	. Channel to trigger output mapping.	
		0	The corresponding channel is ignored by the output trigger0.
		1	When an event occurs on the channel corresponding to this bit, generate an event on event_out[0].

CTI Channel to Trigger 1 Enable register.

This register maps channels in the cross trigger system to trigger outputs. The CTIOUTEN registers are bit maps that allow any channel input to be mapped to the trigger output, including none (0x0) and all (2^CHANNEL_WIDTH - 1). There is one register per trigger output so it is possible to map any channel input to any combination of trigger outputs.

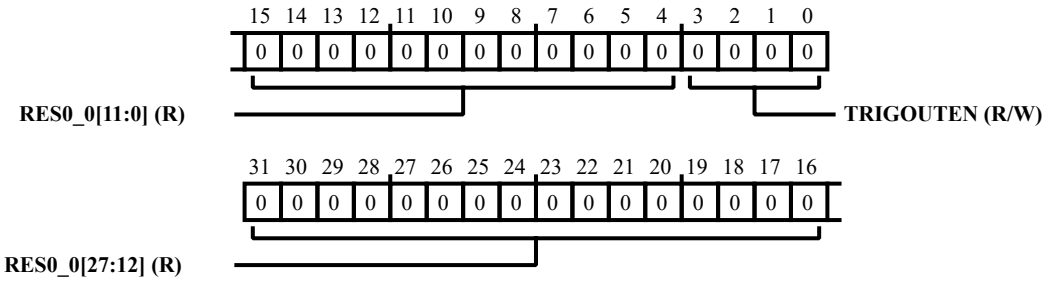

Figure 48-379: SOC600CTI_TRACE_CTIOUTEN1 Register Diagram

Table 48-378: SOC600CTI_TRACE_CTIOUTEN1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (R/W)	TRIGOUTEN	. Channel to trigger output mapping.	
		0	The corresponding channel is ignored by the output trigger1.
		1	When an event occurs on the channel corresponding to this bit, generate an event on event_out[1].

CTI Channel to Trigger 2 Enable register.

This register maps channels in the cross trigger system to trigger outputs. The CTIOUTEN registers are bit maps that allow any channel input to be mapped to the trigger output, including none (0x0) and all (2^CHANNEL_WIDTH - 1). There is one register per trigger output so it is possible to map any channel input to any combination of trigger outputs.

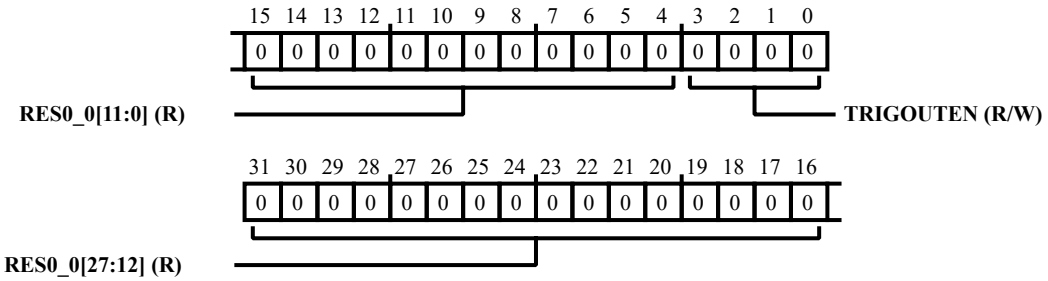

Figure 48-380: SOC600CTI_TRACE_CTIOUTEN2 Register Diagram

Table 48-379: SOC600CTI_TRACE_CTIOUTEN2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (R/W)	TRIGOUTEN	. Channel to trigger output mapping.	
		0	The corresponding channel is ignored by the output trigger2.
		1	When an event occurs on the channel corresponding to this bit, generate an event on event_out[2].

CTI Channel to Trigger 3 Enable register.

This register maps channels in the cross trigger system to trigger outputs. The CTIOUTEN registers are bit maps that allow any channel input to be mapped to the trigger output, including none (0x0) and all (2^CHANNEL_WIDTH - 1). There is one register per trigger output so it is possible to map any channel input to any combination of trigger outputs.

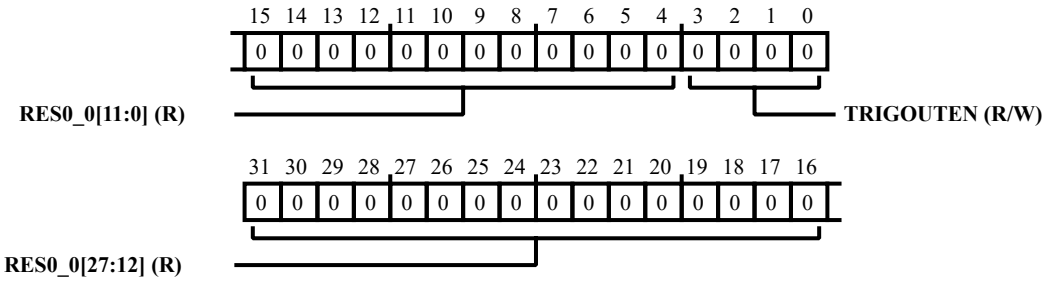

Figure 48-381: SOC600CTI_TRACE_CTIOUTEN3 Register Diagram

Table 48-380: SOC600CTI_TRACE_CTIOUTEN3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (R/W)	TRIGOUTEN	. Channel to trigger output mapping.	
		0	The corresponding channel is ignored by the output trigger3.
		1	When an event occurs on the channel corresponding to this bit, generate an event on event_out[3].

CTI Channel to Trigger 4 Enable register.

This register maps channels in the cross trigger system to trigger outputs. The CTIOUTEN registers are bit maps that allow any channel input to be mapped to the trigger output, including none (0x0) and all (2^CHANNEL_WIDTH - 1). There is one register per trigger output so it is possible to map any channel input to any combination of trigger outputs.

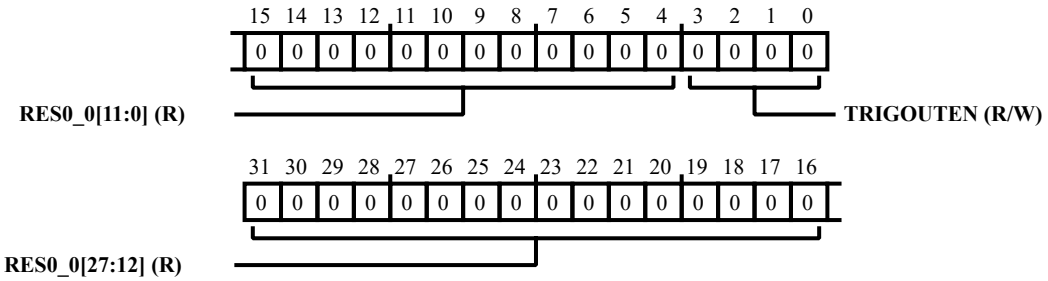

Figure 48-382: SOC600CTI_TRACE_CTIOUTEN4 Register Diagram

Table 48-381: SOC600CTI_TRACE_CTIOUTEN4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (R/W)	TRIGOUTEN	. Channel to trigger output mapping.	
		0	The corresponding channel is ignored by the output trigger4.
		1	When an event occurs on the channel corresponding to this bit, generate an event on event_out[4].

CTI Channel to Trigger 5 Enable register.

This register maps channels in the cross trigger system to trigger outputs. The CTIOUTEN registers are bit maps that allow any channel input to be mapped to the trigger output, including none (0x0) and all (2^CHANNEL_WIDTH - 1). There is one register per trigger output so it is possible to map any channel input to any combination of trigger outputs.

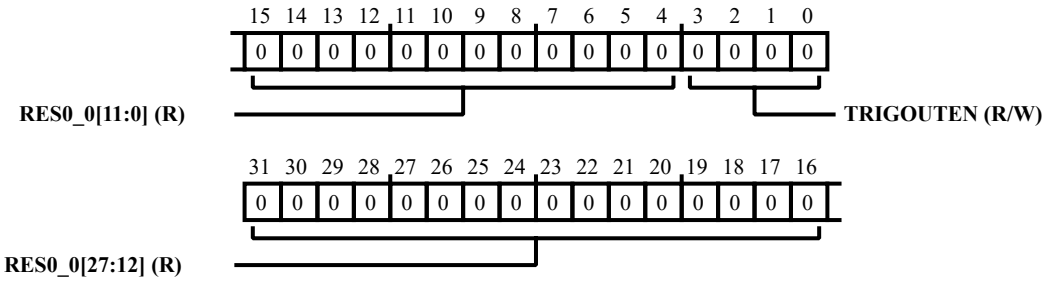

Figure 48-383: SOC600CTI_TRACE_CTIOUTEN5 Register Diagram

Table 48-382: SOC600CTI_TRACE_CTIOUTEN5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (R/W)	TRIGOUTEN	. Channel to trigger output mapping.	
		0	The corresponding channel is ignored by the output trigger5.
		1	When an event occurs on the channel corresponding to this bit, generate an event on event_out[5].

CTI Trigger Input Status register.

Trigger input status. If the event_in input is driven by a source that generates single cycle pulses, this register is generally read as 0.

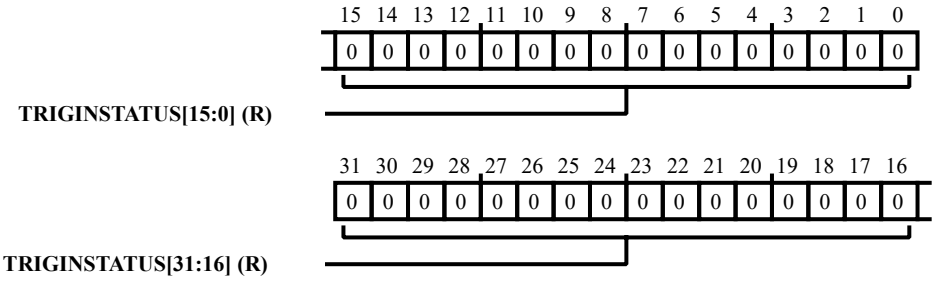

Figure 48-384: SOC600CTI_TRACE_CTITRIGINSTATUS Register Diagram

Table 48-383: SOC600CTI_TRACE_CTITRIGINSTATUS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:0 (R/NW)	TRIGINSTATUS	. Trigger input status.	
		0	One bit per trigger input. 0 means that the input is LOW.
		1	One bit per trigger input. 1 means that the input is HIGH.

CTI Trigger Output Status register.

Trigger output status. The register only has meaning if the trigger source drives static levels, rather than pulses.

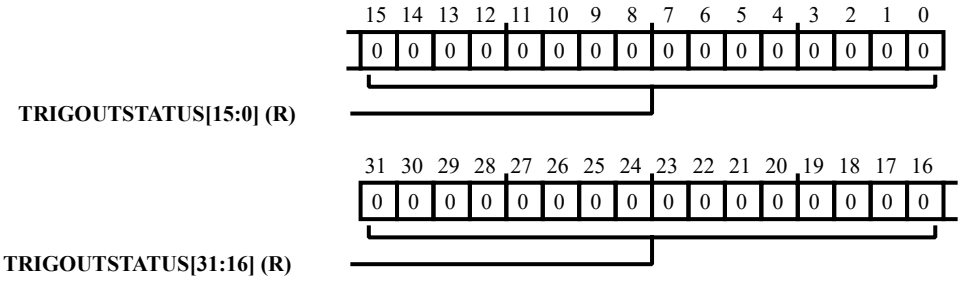

Figure 48-385: SOC600CTI_TRACE_CTITRIGOUTSTATUS Register Diagram

Table 48-384: SOC600CTI_TRACE_CTITRIGOUTSTATUS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:0 (R/NW)	TRIGOUTSTATUS	. Trigger output status.	
		0	One bit per trigger output. 0 means that the output is LOW.
		1	One bit per trigger output. 1 means that the output is HIGH.

Device Affinity register 0.

Enables a debugger to determine if two components have an affinity with each other.

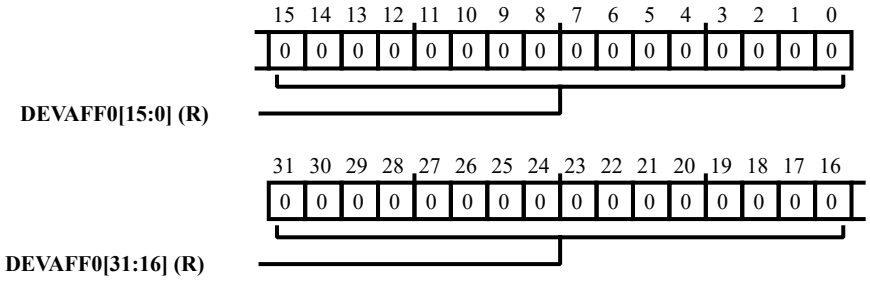

Figure 48-386: SOC600CTI_TRACE_DEVAFF0 Register Diagram

Table 48-385: SOC600CTI_TRACE_DEVAFF0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	DEVAFF0	. Lower 32-bits of DEVAFF. The value is set by the devaff[31:0] tie-off inputs.

Device Affinity register 1.

Enables a debugger to determine if two components have an affinity with each other.

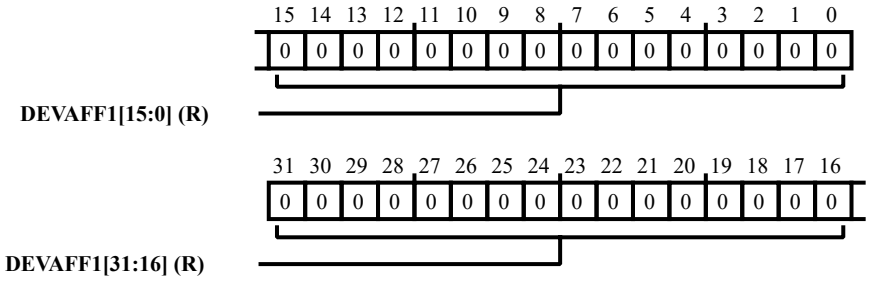

Figure 48-387: SOC600CTI_TRACE_DEVAFF1 Register Diagram

Table 48-386: SOC600CTI_TRACE_DEVAFF1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	DEVAFF1	. Upper 32-bits of DEVAFF. The value is set by the devaff[63:32] tie-off inputs.

Device Architecture Register.

Identifies the architect and architecture of a CoreSight component. The architect might differ from the designer of a component, for example Arm defines the architecture but another company designs and implements the component.

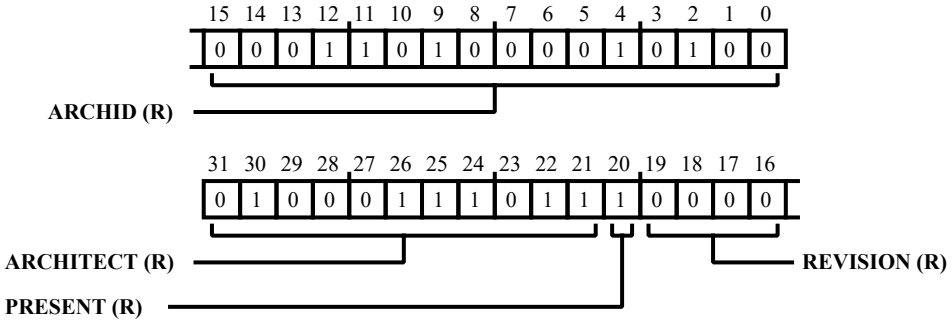

Figure 48-388: SOC600CTI_TRACE_DEVARCH Register Diagram

Table 48-387: SOC600CTI_TRACE_DEVARCH Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:21 (R/NW)	ARCHITECT	. Defines the architect of the component.	
		571	Arm.
20 (R/NW)	PRESENT	. Indicates the presence of this register.	
		0	DEVARCH is not present.
		1	DEVARCH is present.
19:16 (R/NW)	REVISION	. Architecture revision. Returns the revision of the architecture that the ARCHID field specifies.	
15:0 (R/NW)	ARCHID	. Architecture ID. Returns a value that identifies the architecture of the component.	
		2583	Memory Access Port v2 architecture.
		2599	JTAG Access Port v2 architecture.
		2631	Unknown Access Port v2 architecture.
		2807	CoreSight ROM architecture.
		6676	CTI architecture.

Device Configuration Register.

This register is IMPLEMENTATION DEFINED for each Part Number and Designer. The register indicates the capabilities of the component.

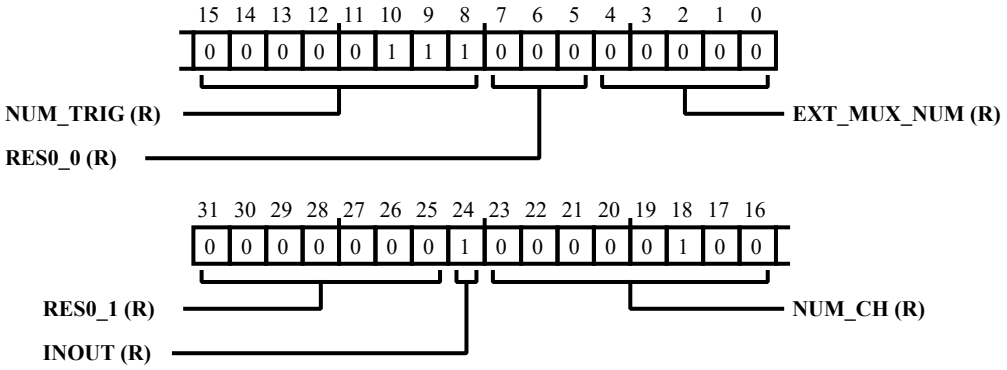

Figure 48-389: SOC600CTI_TRACE_DEVID Register Diagram

Table 48-388: SOC600CTI_TRACE_DEVID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:25 (R/NW)	RES0_1	. Reserved bit or field with SBZP behavior.
24 (R/NW)	INOUT	. Indicates channel inputs are also masked by the CTIGATE register. Always 1.
23:16 (R/NW)	NUM_CH	. The number of channels. Always either 4 or 16, set by CHANNEL_WIDTH.
15:8 (R/NW)	NUM_TRIG	. Indicates the maximum number of triggers - the maximum of the two parameters, NUM_EVENT_RECEIVERS and NUM_EVENT_TRANSMITTERS.
7:5 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
4:0 (R/NW)	EXT_MUX_NUM	. Indicates the value of the EXT_MUX_NUM parameter, which determines if there is any external multiplexing on the trigger inputs and outputs. 0 indicates no multiplexing.

Device Type Identifier Register.

A debugger can use this register to get information about a component that has an unrecognized Part number.

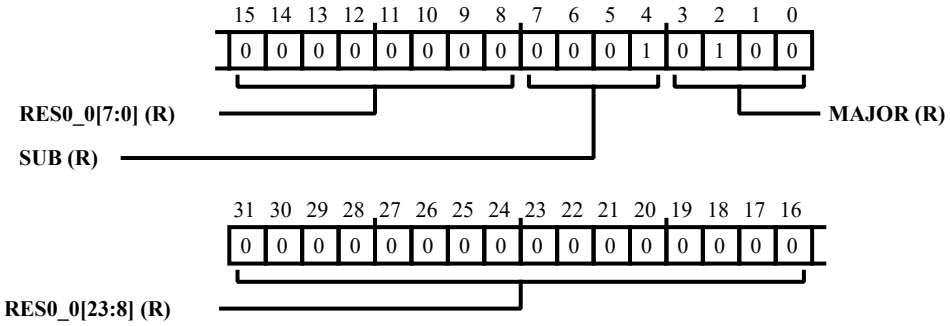

Figure 48-390: SOC600CTI_TRACE_DEVTYPE Register Diagram

Table 48-389: SOC600CTI_TRACE_DEVTYPE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:4 (R/NW)	SUB	. Minor classification. Returns 0x1, indicating this component is a Trigger-Matrix.
3:0 (R/NW)	MAJOR	. Major classification. Returns 0x4, indicating this component performs Debug Control.

Integration Test Channel Input register.

Integration test mode register, used to view channel events. The integration test register includes a latch that is set when a pulse is received on a channel input. When read, a register bit reads as 1 if the channel has received a pulse since it was last read. The act of reading the register automatically clears the 1 to a 0. When performing integration testing it is therefore important to coordinate the setting of event latches and reading/clearing them.

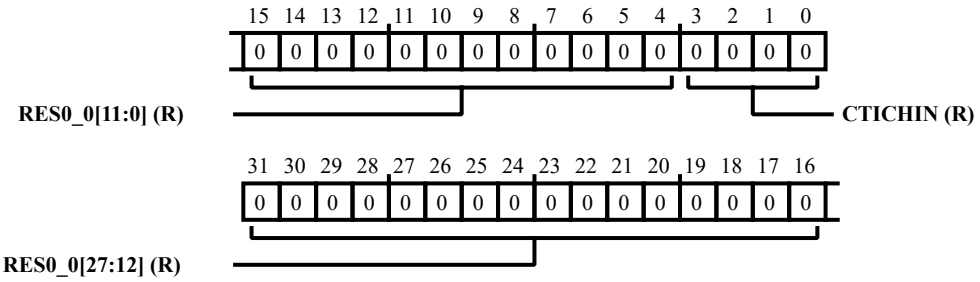

Figure 48-391: SOC600CTI_TRACE_ITCHIN Register Diagram

Table 48-390: SOC600CTI_TRACE_ITCHIN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
3:0 (R/NW)	CTICHIN	. Reads the latched value of the channel inputs.

Integration Test Channel Output register.

Integration test mode register, used to generate channel events. Writing to the register creates a single pulse on the output. ITCHOUT is self-clearing.

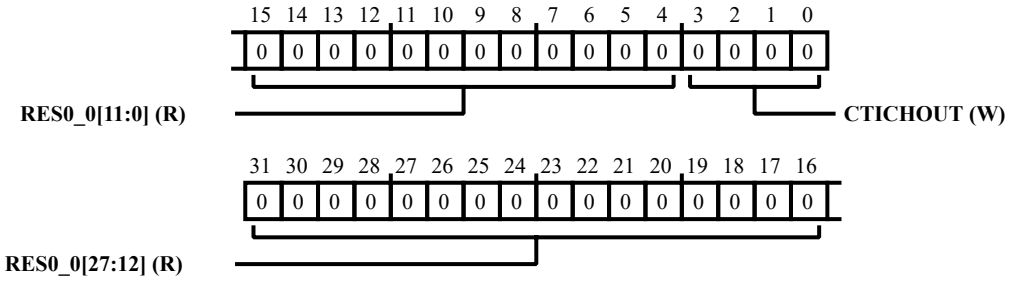

Figure 48-392: SOC600CTI_TRACE_ITCHOUT Register Diagram

Table 48-391: SOC600CTI_TRACE_ITCHOUT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (RX/W)	CTICHOUT	. Pulses the channel outputs.	
		0	No effect.
		1	Pulse channel event for one clk cycle.

Integration Mode Control Register.

The Integration Mode Control register is used to switch between functional mode and integration mode. After switching to integration mode and performing integration tests or topology detection, reset the system to ensure correct behavior of CoreSight and other connected system components.

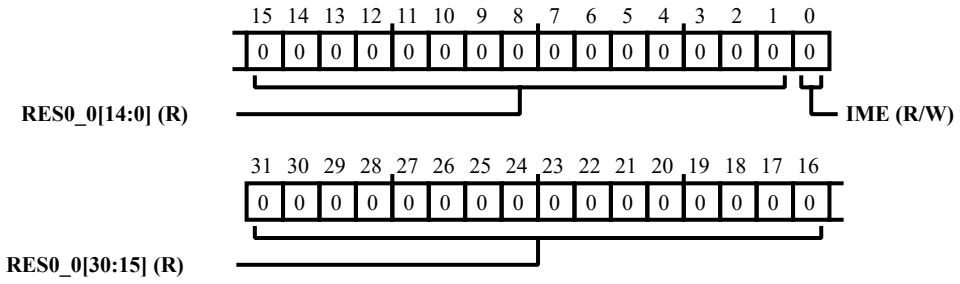

Figure 48-393: SOC600CTI_TRACE_ITCTRL Register Diagram

Table 48-392: SOC600CTI_TRACE_ITCTRL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:1 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
0 (R/W)	IME	. Integration Mode Enable.	
		0	The component must enter functional mode.
		1	The component must enter integration mode, and enable support for topology detection and integration testing.

Integration Test Trigger Input register.

Integration test mode register, used to view trigger events. The integration test register includes a latch that is set when a pulse is received on a trigger input. When read, a register bit reads as 1 if the trigger input has received a pulse since it was last read. The act of reading the register automatically clears the 1 to a 0. When performing integration testing it is therefore important to coordinate the setting of event latches and reading/clearing them.

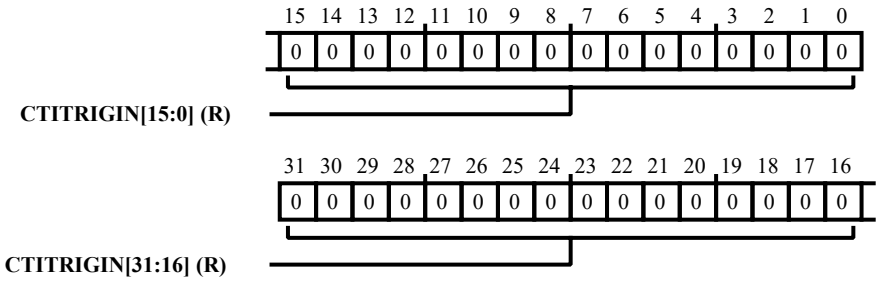

Figure 48-394: SOC600CTI_TRACE_ITTRIGIN Register Diagram

Table 48-393: SOC600CTI_TRACE_ITTRIGIN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CTITRIGIN	. Reads the latched value of the trigger inputs.

Integration Test Trigger Output register.

Integration test mode register, used to generate trigger events.

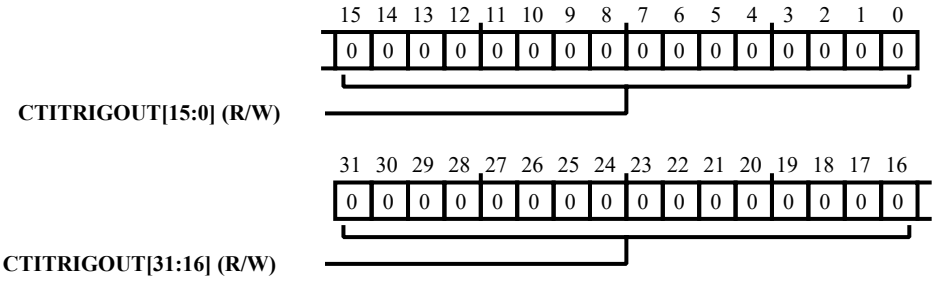

Figure 48-395: SOC600CTI_TRACE_ITTRIGOUT Register Diagram

Table 48-394: SOC600CTI_TRACE_ITTRIGOUT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:0 (R/W)	CTITRIGOUT	. Set/clear trigger output signal. Reads return the value in the register if SW_HANDSHAKE=1, otherwise 0 is returned if SW_HANDSHAKE=0. Writes:.	
		0	Clears the trigger output if SW_HANDSHAKE=1, no effect if SW_HANDSHAKE=0.
		1	Sets the trigger output if SW_HANDSHAKE=1, pulses trigger output if SW_HANDSHAKE=0.

Peripheral Identification Register 0.

The PIDR0 register is part of the set of peripheral identification registers.

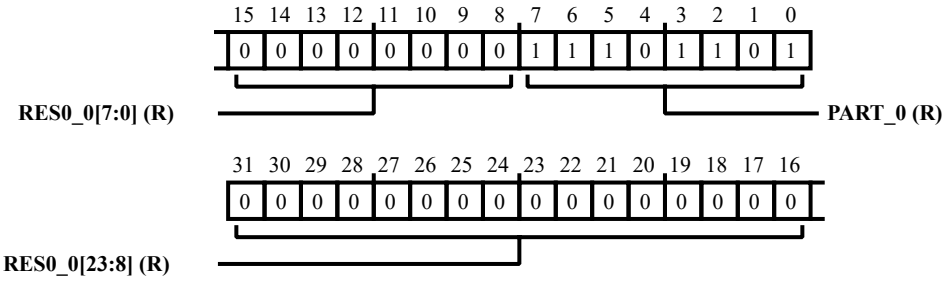

Figure 48-396: SOC600CTI_TRACE_PIDR0 Register Diagram

Table 48-395: SOC600CTI_TRACE_PIDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PART_0	. Part number, bits[7:0]. Taken together with PIDR1.PART_1 it indicates the component. The Part Number is selected by the designer of the component.

Peripheral Identification Register 1.

The PIDR1 register is part of the set of peripheral identification registers.

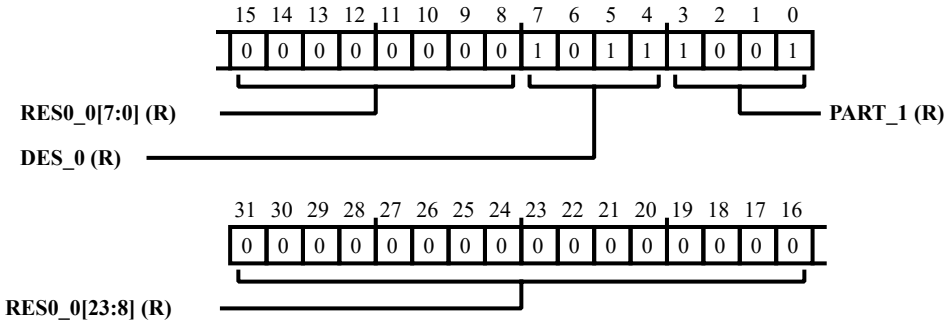

Figure 48-397: SOC600CTI_TRACE_PIDR1 Register Diagram

Table 48-396: SOC600CTI_TRACE_PIDR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:4 (R/NW)	DES_0	. JEP106 identification code, bits[3:0]. Together, with PIDR4.DES_2 and PIDR2.DES_1, they indicate the designer of the component and not the implementer, except where the two are the same.
3:0 (R/NW)	PART_1	. Part number, bits[11:8]. Taken together with PIDR0.PART_0 it indicates the component. The Part Number is selected by the designer of the component.

Peripheral Identification Register 2.

The PIDR2 register is part of the set of peripheral identification registers.

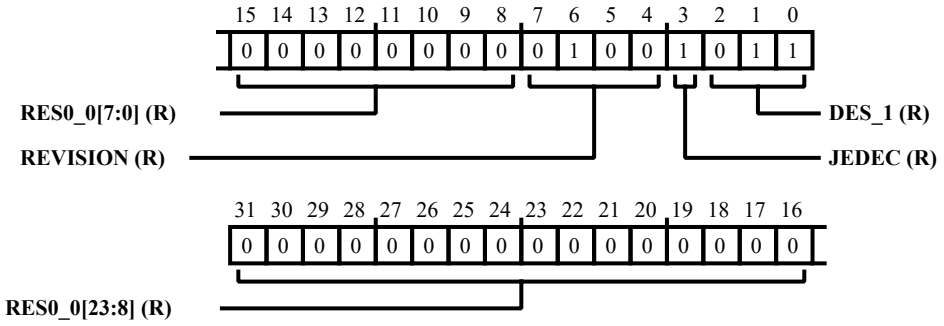

Figure 48-398: SOC600CTI_TRACE_PIDR2 Register Diagram

Table 48-397: SOC600CTI_TRACE_PIDR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:4 (R/NW)	REVISION	. Revision. It is an incremental value starting at 0x0 for the first design of a component. See the Component list in Chapter 1 for information on the RTL revision of the component.
3 (R/NW)	JEDEC	. 1 - Always set. Indicates that a JEDEC assigned value is used.
2:0 (R/NW)	DES_1	. JEP106 identification code, bits[6:4]. Together, with PIDR4.DES_2 and PIDR1.DES_0, they indicate the designer of the component and not the implementer, except where the two are the same.

Peripheral Identification Register 3.

The PIDR3 register is part of the set of peripheral identification registers.

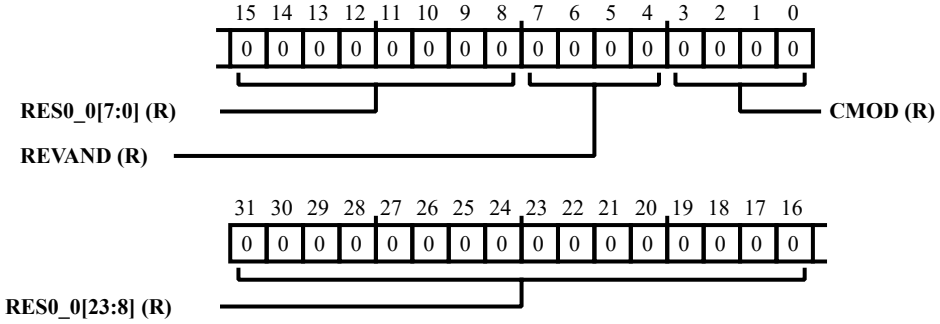

Figure 48-399: SOC600CTI_TRACE_PIDR3 Register Diagram

Table 48-398: SOC600CTI_TRACE_PIDR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:4 (R/NW)	REVAND	. This field indicates minor errata fixes specific to this design, for example metal fixes after implementation. In most cases this field is 0x0.
3:0 (R/NW)	CMOD	. Customer Modified. Where the component is reusable IP, this value indicates if the customer has modified the behavior of the component. In most cases this field is 0x0.

Peripheral Identification Register 4.

The PIDR4 register is part of the set of peripheral identification registers.

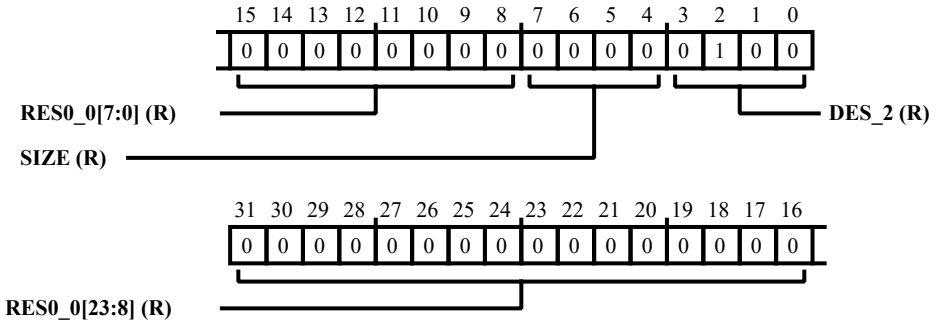

Figure 48-400: SOC600CTI_TRACE_PIDR4 Register Diagram

Table 48-399: SOC600CTI_TRACE_PIDR4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:4 (R/NW)	SIZE	. Indicates the memory size that is used by this component. Returns 0 indicating that the component uses an UNKNOWN number of 4KB blocks. Using the SIZE field to indicate the size of the component is deprecated.
3:0 (R/NW)	DES_2	. JEP106 continuation code. Together, with PIDR2.DES_1 and PIDR1.DES_0, they indicate the designer of the component and not the implementer, except where the two are the same.

Peripheral Identification Register 5.

The PIDR5 register is part of the set of peripheral identification registers.

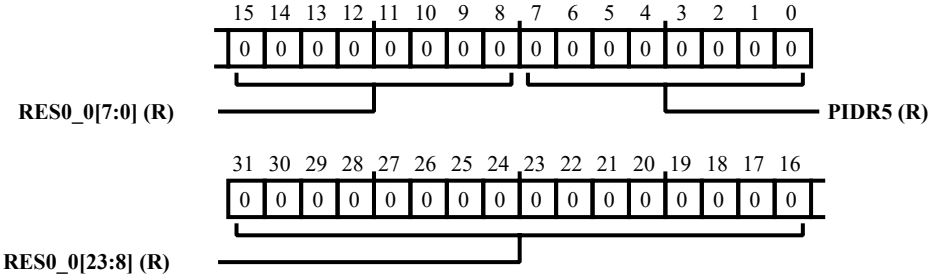

Figure 48-401: SOC600CTI_TRACE_PIDR5 Register Diagram

Table 48-400: SOC600CTI_TRACE_PIDR5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PIDR5	. Reserved.

Peripheral Identification Register 6.

The PIDR6 register is part of the set of peripheral identification registers.

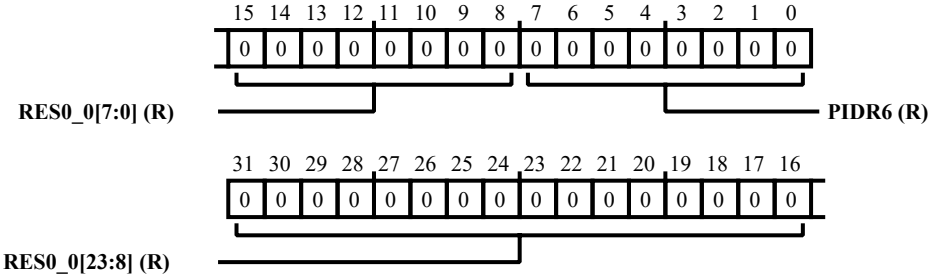

Figure 48-402: SOC600CTI_TRACE_PIDR6 Register Diagram

Table 48-401: SOC600CTI_TRACE_PIDR6 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PIDR6	. Reserved.

Peripheral Identification Register 7.

The PIDR7 register is part of the set of peripheral identification registers.

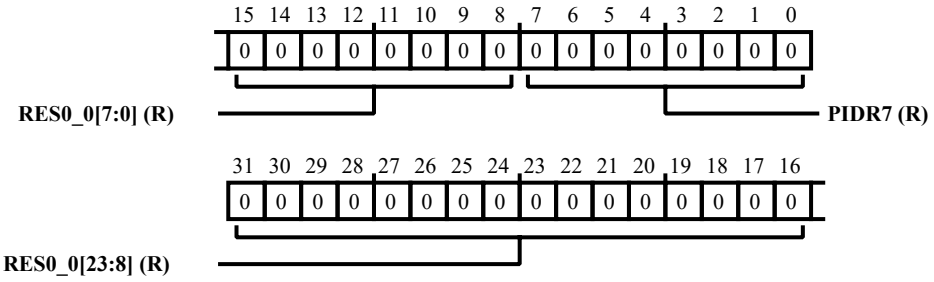

Figure 48-403: SOC600CTI_TRACE_PIDR7 Register Diagram

Table 48-402: SOC600CTI_TRACE_PIDR7 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PIDR7	. Reserved.

ADSP-2184x SYSCTI Register Descriptions

Your module description, here. (SYSCTI) contains the following registers.

Table 48-403: ADSP-2184x SYSCTI Register List

Name	Description
SYSCTI_ASICCTRL	External Multiplexer Control register.
SYSCTI_AUTHSTATUS	Authentication Status Register.
SYSCTI_CIDR0	Component Identification Register 0.
SYSCTI_CIDR1	Component Identification Register 1.
SYSCTI_CIDR2	Component Identification Register 2.
SYSCTI_CIDR3	Component Identification Register 3.
SYSCTI_CLAIMCLR	Claim Tag Clear Register.
SYSCTI_CLAIMSET	Claim Tag Set Register.
SYSCTI_CTIAPPCLEAR	CTI Application Channel Clear register.
SYSCTI_CTIAPPPULSE	CTI Application Channel Pulse register.

Table 48-403: ADSP-2184x SYSCTI Register List (Continued)

Name	Description
SYSCTI_CTIAPPSET	CTI Application Channel Set register.
SYSCTI_CTICHINSTATUS	CTI Channel Input Status register.
SYSCTI_CTICHOUTSTATUS	CTI Channel Output Status register.
SYSCTI_CTICONTROL	CTI Control register.
SYSCTI_CTIGATE	Enable CTI Channel Gate register.
SYSCTI_CTIINEN0	CTI Trigger 0 to Channel Enable register.
SYSCTI_CTIINEN1	CTI Trigger 1 to Channel Enable register.
SYSCTI_CTIINEN2	CTI Trigger 2 to Channel Enable register.
SYSCTI_CTIINEN3	CTI Trigger 3 to Channel Enable register.
SYSCTI_CTIINEN4	CTI Trigger 4 to Channel Enable register.
SYSCTI_CTIINEN5	CTI Trigger 5 to Channel Enable register.
SYSCTI_CTIINEN6	CTI Trigger 6 to Channel Enable register.
SYSCTI_CTIINEN7	CTI Trigger 7 to Channel Enable register.
SYSCTI_CTIINTACK	CTI Interrupt Acknowledge register.
SYSCTI_CTIOUTEN0	CTI Channel to Trigger 0 Enable register.
SYSCTI_CTIOUTEN1	CTI Channel to Trigger 1 Enable register.
SYSCTI_CTIOUTEN10	CTI Channel to Trigger 10 Enable register.
SYSCTI_CTIOUTEN11	CTI Channel to Trigger 11 Enable register.
SYSCTI_CTIOUTEN12	CTI Channel to Trigger 12 Enable register.
SYSCTI_CTIOUTEN13	CTI Channel to Trigger 13 Enable register.
SYSCTI_CTIOUTEN2	CTI Channel to Trigger 2 Enable register.
SYSCTI_CTIOUTEN3	CTI Channel to Trigger 3 Enable register.
SYSCTI_CTIOUTEN4	CTI Channel to Trigger 4 Enable register.
SYSCTI_CTIOUTEN5	CTI Channel to Trigger 5 Enable register.
SYSCTI_CTIOUTEN6	CTI Channel to Trigger 6 Enable register.
SYSCTI_CTIOUTEN7	CTI Channel to Trigger 7 Enable register.
SYSCTI_CTIOUTEN8	CTI Channel to Trigger 8 Enable register.
SYSCTI_CTIOUTEN9	CTI Channel to Trigger 9 Enable register.
SYSCTI_CTITRIGINSTATUS	CTI Trigger Input Status register.
SYSCTI_CTITRIGOUTSTATUS	CTI Trigger Output Status register.
SYSCTI_DEVAFF0	Device Affinity register 0.

Table 48-403: ADSP-2184x SYSCTI Register List (Continued)

Name	Description
SYSCTI_DEVAFF1	Device Affinity register 1.
SYSCTI_DEVARCH	Device Architecture Register.
SYSCTI_DEVID	Device Configuration Register.
SYSCTI_DEVTYPE	Device Type Identifier Register.
SYSCTI_ITCHIN	Integration Test Channel Input register.
SYSCTI_ITCHOUT	Integration Test Channel Output register.
SYSCTI_ITCTRL	Integration Mode Control Register.
SYSCTI_ITTRIGIN	Integration Test Trigger Input register.
SYSCTI_ITTRIGOUT	Integration Test Trigger Output register.
SYSCTI_PIDR0	Peripheral Identification Register 0.
SYSCTI_PIDR1	Peripheral Identification Register 1.
SYSCTI_PIDR2	Peripheral Identification Register 2.
SYSCTI_PIDR3	Peripheral Identification Register 3.
SYSCTI_PIDR4	Peripheral Identification Register 4.
SYSCTI_PIDR5	Peripheral Identification Register 5.
SYSCTI_PIDR6	Peripheral Identification Register 6.
SYSCTI_PIDR7	Peripheral Identification Register 7.

External Multiplexer Control register.

I/O port control.

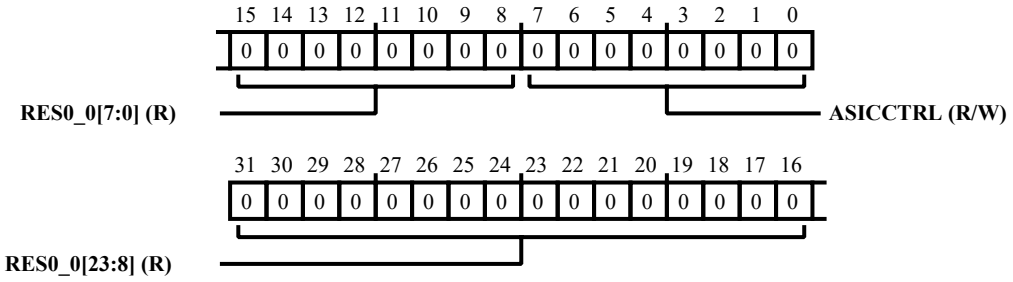

Figure 48-404: SYSCTI_ASICCTRL Register Diagram

Table 48-404: SYSCTI_ASICCTRL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
7:0 (R/W)	ASICCTRL	. Set and clear external output signal.	
		0	Clear output bit to 0.
		1	Set output bit to 1.

Authentication Status Register.

Reports the current status of the authentication control signals.

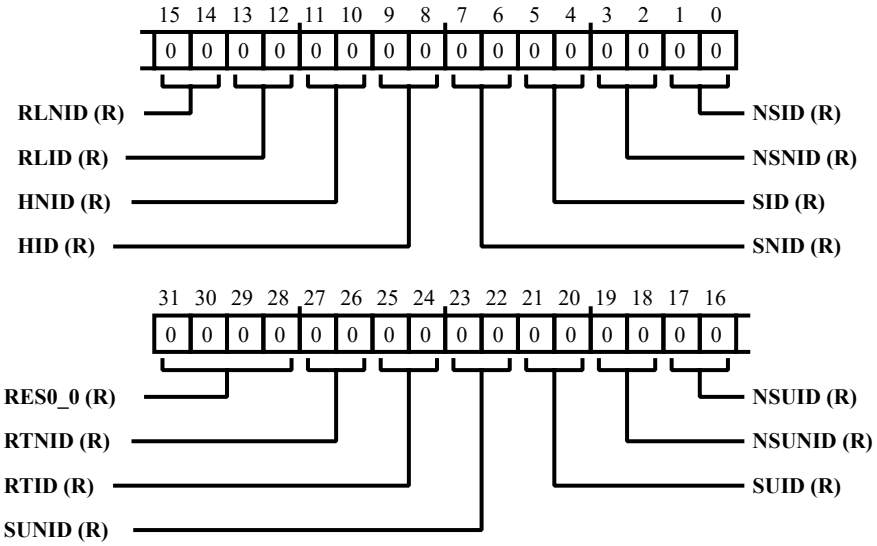

Figure 48-405: SYSCTI_AUTHSTATUS Register Diagram

Table 48-405: SYSCTI_AUTHSTATUS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:28 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
27:26 (R/NW)	RTNID	. Root non-invasive debug.	
		0	Separate Root non-invasive debug enable not implemented or Root state non-invasive debug features not implemented.
		1	Reserved.
		2	Implemented and disabled.
		3	Implemented and enabled.

Table 48-405: SYSCTI_AUTHSTATUS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
25:24 (R/NW)	RTID	. Root invasive debug.	
		0	Separate Root invasive debug enable not implemented or Root state invasive debug features not implemented.
		1	Reserved.
		2	Implemented and disabled.
		3	Implemented and enabled.
23:22 (R/NW)	SUNID	. Secure unprivileged non-invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.
21:20 (R/NW)	SUID	. Secure unprivileged invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.
19:18 (R/NW)	NSUNID	. Non-secure unprivileged non-invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.
17:16 (R/NW)	NSUID	. Non-secure unprivileged invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.

Table 48-405: SYSCTI_AUTHSTATUS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15:14 (R/NW)	RLNID	. Realm non-invasive debug.	
		0	Separate Realm non-invasive debug enable not implemented or Realm state non-invasive debug features not implemented.
		1	Reserved.
		2	Implemented and disabled.
		3	Implemented and enabled.
13:12 (R/NW)	RLID	. Realm invasive debug.	
		0	Separate Realm invasive debug enable not implemented or Realm state invasive debug features not implemented.
		1	Reserved.
		2	Implemented and disabled.
		3	Implemented and enabled.
11:10 (R/NW)	HNID	. Hypervisor non-invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.
9:8 (R/NW)	HID	. Hypervisor invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.

Table 48-405: SYSCTI_AUTHSTATUS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7:6 (R/NW)	SNID	. Secure non-invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.
5:4 (R/NW)	SID	. Secure invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.
3:2 (R/NW)	NSNID	. Non-secure non-invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.
1:0 (R/NW)	NSID	. Non-secure invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.

Component Identification Register 0.

The CIDR0 register is part of the set of component identification registers.

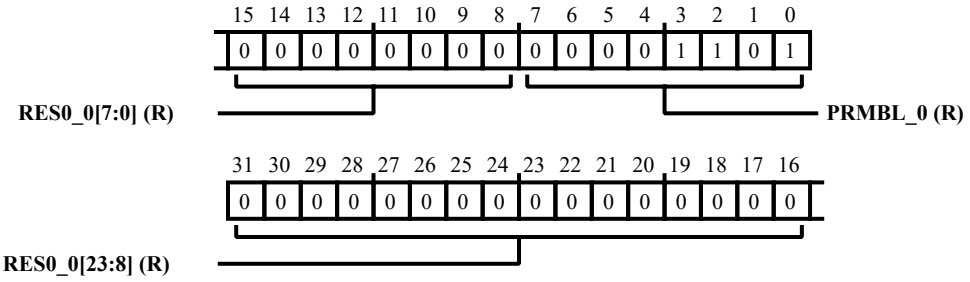

Figure 48-406: SYSCTI_CIDR0 Register Diagram

Table 48-406: SYSCTI_CIDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PRMBL_0	. Preamble. Returns 0x0D.

Component Identification Register 1.

The CIDR1 register is part of the set of component identification registers.

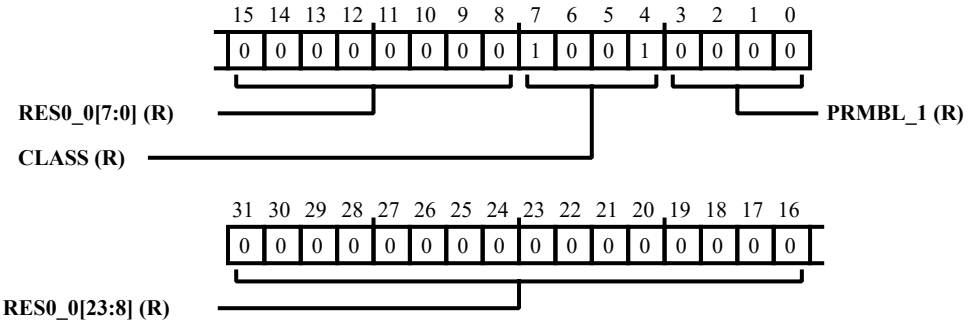

Figure 48-407: SYSCTI_CIDR1 Register Diagram

Table 48-407: SYSCTI_CIDR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
7:4 (R/NW)	CLASS	. Component class.	
		9	CoreSight component.
		15	CoreLink, PrimeCell, or system component.
3:0 (R/NW)	PRMBL_1	. Preamble. Returns 0x0.	

Component Identification Register 2.

The CIDR2 register is part of the set of component identification registers.

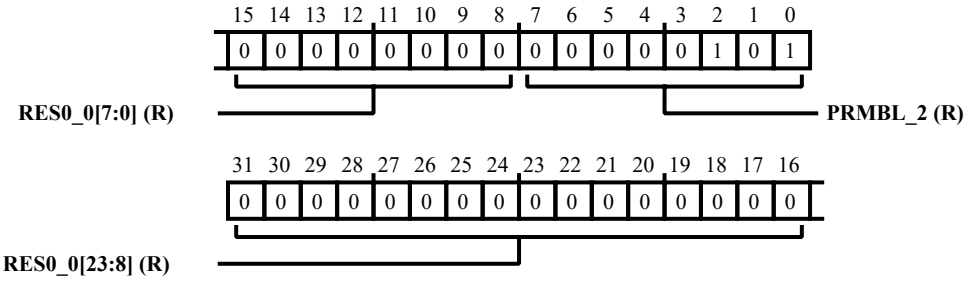

Figure 48-408: SYSCTI_CIDR2 Register Diagram

Table 48-408: SYSCTI_CIDR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PRMBL_2	. Preamble. Returns 0x05.

Component Identification Register 3.

The CIDR3 register is part of the set of component identification registers.

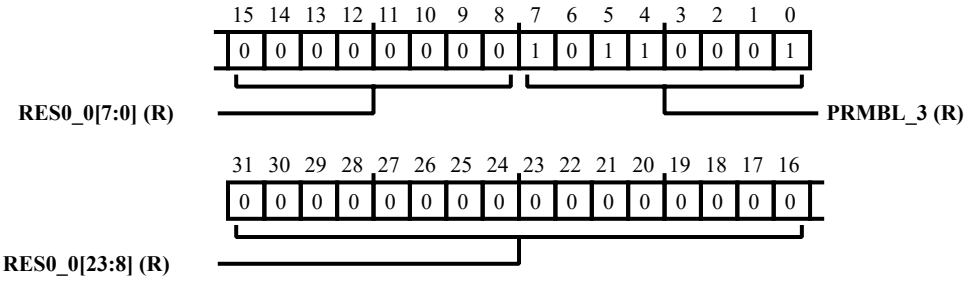

Figure 48-409: SYSCTI_CIDR3 Register Diagram

Table 48-409: SYSCTI_CIDR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PRMBL_3	. Preamble. Returns 0xB1.

Claim Tag Clear Register.

This register forms one half of the claim tag value. On writes, this location enables individual bits to be cleared. On reads, it returns the current claim tag value.

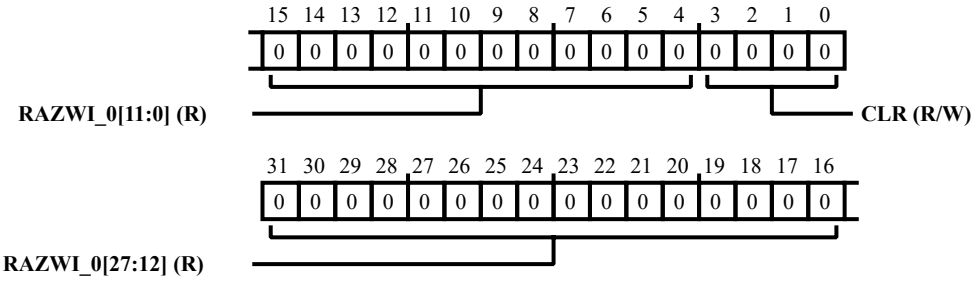

Figure 48-410: SYSCTI_CLAIMCLR Register Diagram

Table 48-410: SYSCTI_CLAIMCLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:4 (R/NW)	RAZWI_0	. RAZ/WI.
3:0 (R/W)	CLR	. A bit-programmable register bank that clears the claim tag value. It is zero at reset. It is used by software agents to signal to each other ownership of the hardware. It has no direct effect on the hardware itself.

Claim Tag Set Register.

This register forms one half of the claim tag value. On writes, this location enables individual bits to be set. On reads, it returns the number of bits that can be set.

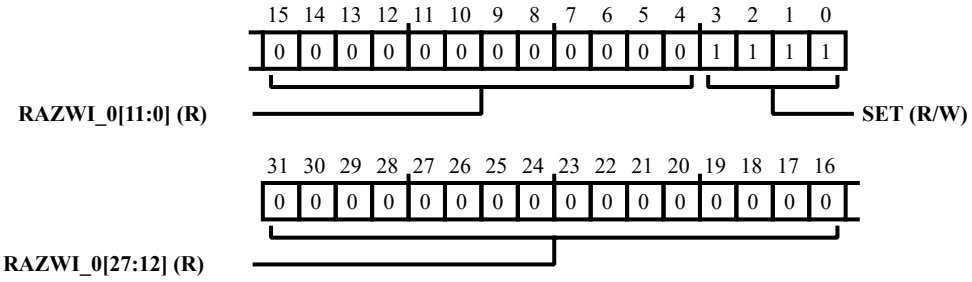

Figure 48-411: SYSCTI_CLAIMSET Register Diagram

Table 48-411: SYSCTI_CLAIMSET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:4 (R/NW)	RAZWI_0	. RAZ/WI.
3:0 (R/W)	SET	. A bit-programmable register bank that sets the claim tag value. A read returns a logic 1 for all implemented locations.

CTI Application Channel Clear register.

The CTIAPPCLEAR register allows software to clear any channel output. Software can use this register to clear a channel event in place of a hardware source on a trigger input. This register must not be used in a system where all events are sent as single-cycle pulses. It is only retained for compatibility with older systems and software. The register is implemented before the CTIGATE register. Therefore, for the channel event to propagate outside the CTI, the corresponding CTIGATE bit must be set to 1.

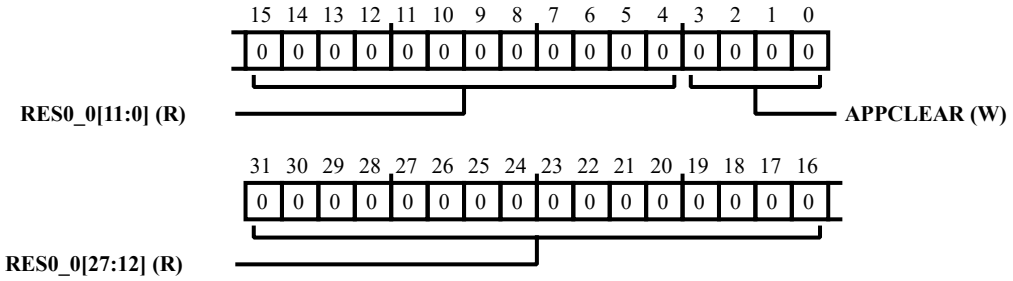

Figure 48-412: SYSCTI_CTIAPPCLEAR Register Diagram

Table 48-412: SYSCTI_CTIAPPCLEAR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (RX/W)	APPCLEAR	. Clears the corresponding internal channel flag.	
		0	No effect.
		1	Clears the channel output.

CTI Application Channel Pulse register.

The application channel pulse register allows software to pulse any channel output. This register can be used by software to pulse a channel event in place of a hardware source on a trigger input. The register is implemented before the CTIGATE register so, for the channel event to propagate outside the CTI, it is necessary for the corresponding CTIGATE bit to be 1.

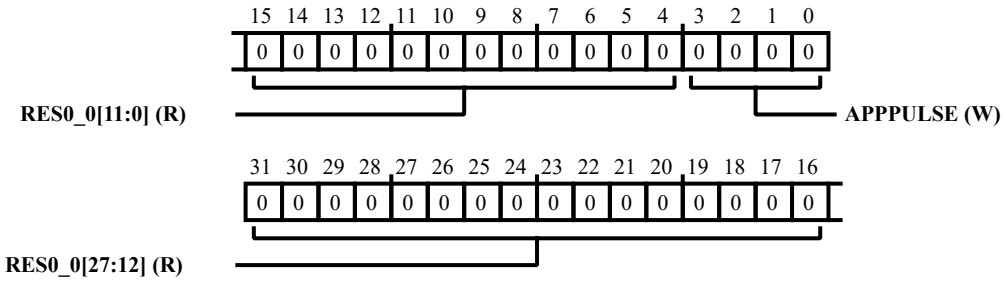

Figure 48-413: SYSCTI_CTIAPPPULSE Register Diagram

Table 48-413: SYSCTI_CTIAPPPULSE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (RX/W)	APPPULSE	. Pulses the channel outputs.	
		0	No effect.
		1	Pulse channel event for one clk cycle.

CTI Application Channel Set register.

The CTIAPPSET register allows software to set any channel output. Software can use this register to generate a channel event in place of a hardware source on a trigger input. This register must not be used in a system where all events are sent as single-cycle pulses. It is only retained for compatibility with older systems and software. The register is implemented before the CTIGATE register. Therefore, for the channel event to propagate outside the CTI, the corresponding CTIGATE bit must be set to 1.

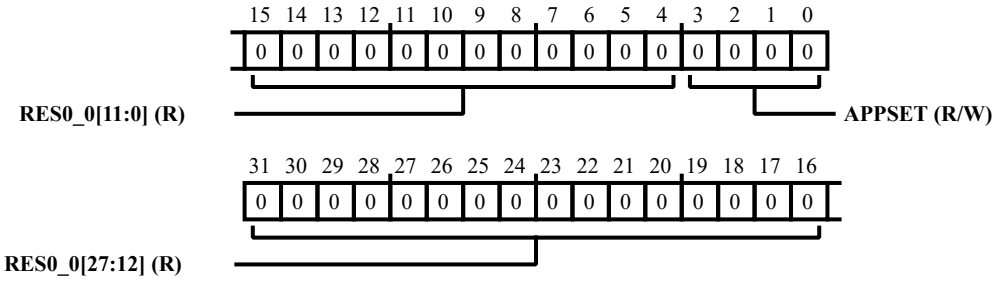

Figure 48-414: SYSCTI_CTIAPPSET Register Diagram

Table 48-414: SYSCTI_CTIAPPSET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (R/W)	APPSET	. Sets the corresponding internal channel flag:.	
		0	Read: application channel is inactive. Write: has no effect.
		1	Read: application channel is active. Write: sets the channel output.

CTI Channel Input Status register.

Channel input status. If the channel input is driven by a source that generates single cycle pulses, this register is generally read as 0.

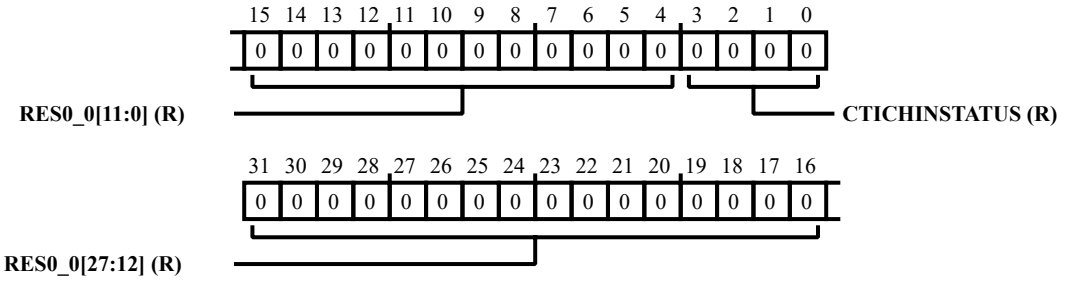

Figure 48-415: SYSCTI_CTICHINSTATUS Register Diagram

Table 48-415: SYSCTI_CTICHINSTATUS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (R/NW)	CTICHINSTATUS	. Channel input status.	
		0	One bit per channel input. 0 means that the input is LOW.
		1	One bit per channel input. 1 means that the input is HIGH.

CTI Channel Output Status register.

Channel output status. The register only has meaning if the trigger source drives static levels, rather than pulses.

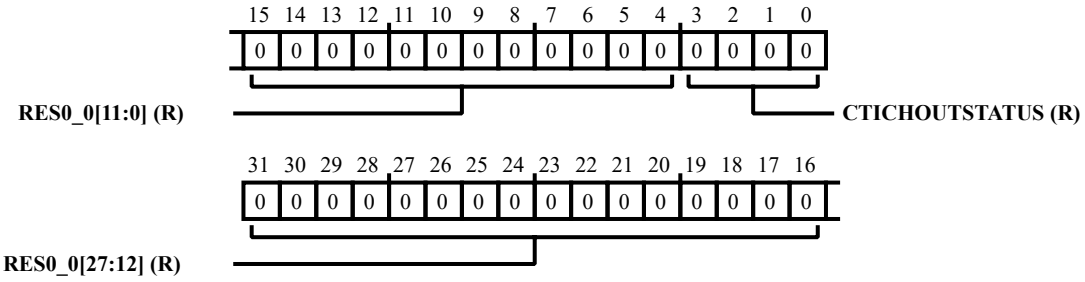

Figure 48-416: SYSCTI_CTICHOUTSTATUS Register Diagram

Table 48-416: SYSCTI_CTICHOUTSTATUS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (R/NW)	CTICHOUTSTATUS	. Channel output status.	
		0	One bit per channel output. 0 means that the output is LOW.
		1	One bit per channel output. 1 means that the output is HIGH.

CTI Control register.

The CTICONTROL register enables and disables the CTI.

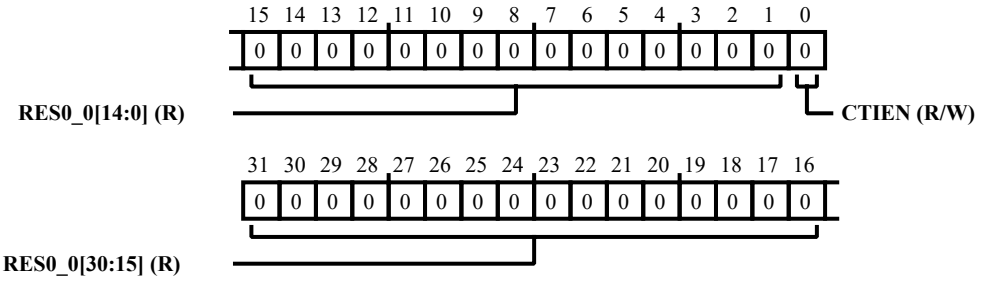

Figure 48-417: SYSCTI_CTICONTROL Register Diagram

Table 48-417: SYSCTI_CTICONTROL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:1 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
0 (R/W)	CTIEN	. Enable control:.	
		0	CTI disabled.
		1	CTI enabled.

Enable CTI Channel Gate register.

Channel output gate.

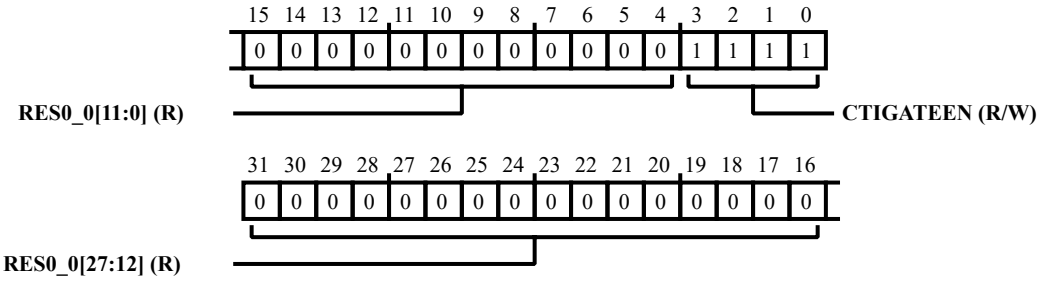

Figure 48-418: SYSCTI_CTIGATE Register Diagram

Table 48-418: SYSCTI_CTIGATE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (R/W)	CTIGATEEN	. Enables the propagation of channel events out of the CTI, one bit per channel.	
		0	Disable a channel from propagating.
		1	Enable channel propagation.

CTI Trigger 0 to Channel Enable register.

This register maps trigger inputs to channels in the cross trigger system. The CTIINEN registers are bit maps that allow the trigger input to be mapped to any channel output, including none (0x0) and all (2^CHANNEL_WIDTH - 1). There is one register per trigger input, so it is possible to map any combination of trigger inputs to any channel outputs.

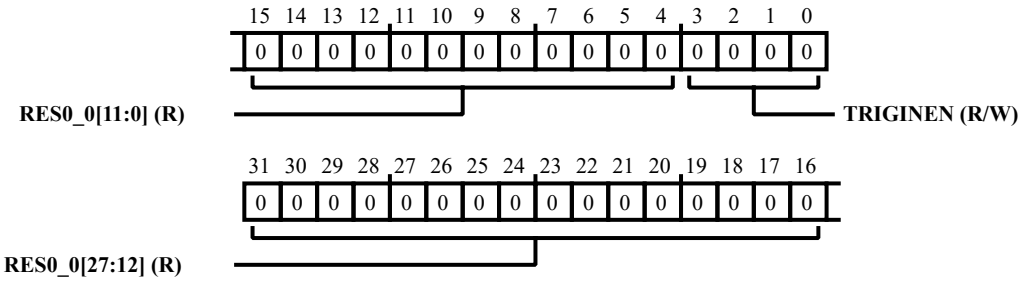

Figure 48-419: SYSCTI_CTIINEN0 Register Diagram

Table 48-419: SYSCTI_CTIINEN0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (R/W)	TRIGINEN	. Trigger input to channel mapping.	
		0	Input trigger 0 events are ignored by the corresponding channel.
		1	When an event is received on event_in[0], generate an event on the channel corresponding to this bit.

CTI Trigger 1 to Channel Enable register.

This register maps trigger inputs to channels in the cross trigger system. The CTIINEN registers are bit maps that allow the trigger input to be mapped to any channel output, including none (0x0) and all (2^CHANNEL_WIDTH - 1). There is one register per trigger input, so it is possible to map any combination of trigger inputs to any channel outputs.

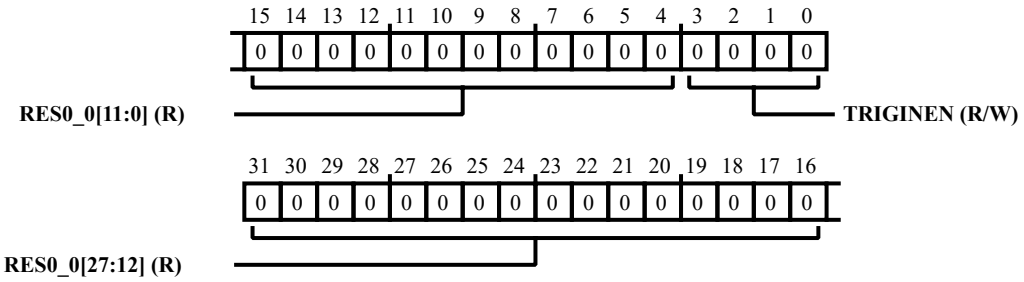

Figure 48-420: SYSCTI_CTIINEN1 Register Diagram

Table 48-420: SYSCTI_CTIINEN1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (R/W)	TRIGINEN	. Trigger input to channel mapping.	
		0	Input trigger 1 events are ignored by the corresponding channel.
		1	When an event is received on event_in[1], generate an event on the channel corresponding to this bit.

CTI Trigger 2 to Channel Enable register.

This register maps trigger inputs to channels in the cross trigger system. The CTIINEN registers are bit maps that allow the trigger input to be mapped to any channel output, including none (0x0) and all (2^CHANNEL_WIDTH - 1). There is one register per trigger input, so it is possible to map any combination of trigger inputs to any channel outputs.

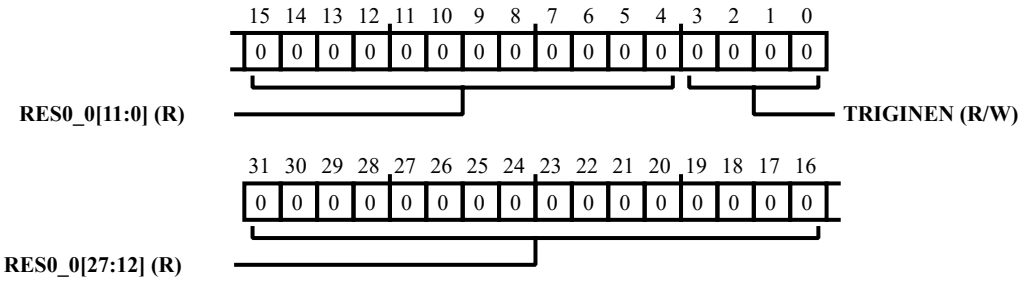

Figure 48-421: SYSCTI_CTIINEN2 Register Diagram

Table 48-421: SYSCTI_CTIINEN2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (R/W)	TRIGINEN	. Trigger input to channel mapping.	
		0	Input trigger 2 events are ignored by the corresponding channel.
		1	When an event is received on event_in[2], generate an event on the channel corresponding to this bit.

CTI Trigger 3 to Channel Enable register.

This register maps trigger inputs to channels in the cross trigger system. The CTIINEN registers are bit maps that allow the trigger input to be mapped to any channel output, including none (0x0) and all (2^CHANNEL_WIDTH - 1). There is one register per trigger input, so it is possible to map any combination of trigger inputs to any channel outputs.

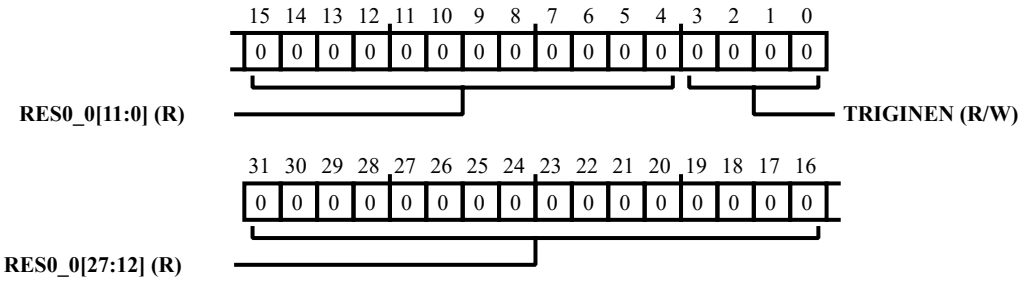

Figure 48-422: SYSCTI_CTIINEN3 Register Diagram

Table 48-422: SYSCTI_CTIINEN3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (R/W)	TRIGINEN	. Trigger input to channel mapping.	
		0	Input trigger 3 events are ignored by the corresponding channel.
		1	When an event is received on event_in[3], generate an event on the channel corresponding to this bit.

CTI Trigger 4 to Channel Enable register.

This register maps trigger inputs to channels in the cross trigger system. The CTIINEN registers are bit maps that allow the trigger input to be mapped to any channel output, including none (0x0) and all (2^CHANNEL_WIDTH - 1). There is one register per trigger input, so it is possible to map any combination of trigger inputs to any channel outputs.

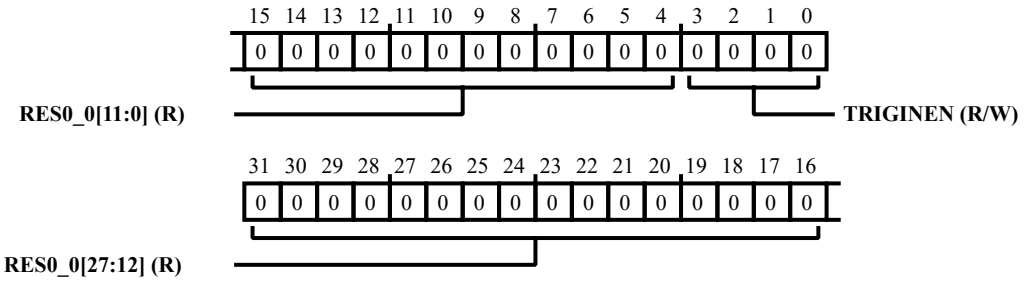

Figure 48-423: SYSCTI_CTIINEN4 Register Diagram

Table 48-423: SYSCTI_CTIINEN4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (R/W)	TRIGINEN	. Trigger input to channel mapping.	
		0	Input trigger 4 events are ignored by the corresponding channel.
		1	When an event is received on event_in[4], generate an event on the channel corresponding to this bit.

CTI Trigger 5 to Channel Enable register.

This register maps trigger inputs to channels in the cross trigger system. The CTIINEN registers are bit maps that allow the trigger input to be mapped to any channel output, including none (0x0) and all (2^CHANNEL_WIDTH - 1). There is one register per trigger input, so it is possible to map any combination of trigger inputs to any channel outputs.

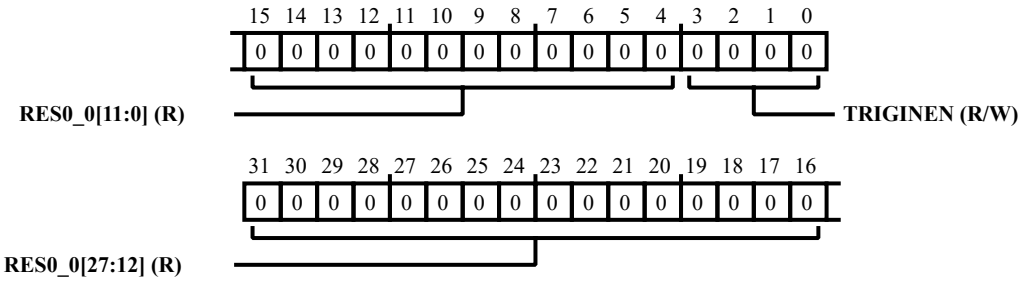

Figure 48-424: SYSCTI_CTIINEN5 Register Diagram

Table 48-424: SYSCTI_CTIINEN5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (R/W)	TRIGINEN	. Trigger input to channel mapping.	
		0	Input trigger 5 events are ignored by the corresponding channel.
		1	When an event is received on event_in[5], generate an event on the channel corresponding to this bit.

CTI Trigger 6 to Channel Enable register.

This register maps trigger inputs to channels in the cross trigger system. The CTIINEN registers are bit maps that allow the trigger input to be mapped to any channel output, including none (0x0) and all (2^CHANNEL_WIDTH - 1). There is one register per trigger input, so it is possible to map any combination of trigger inputs to any channel outputs.

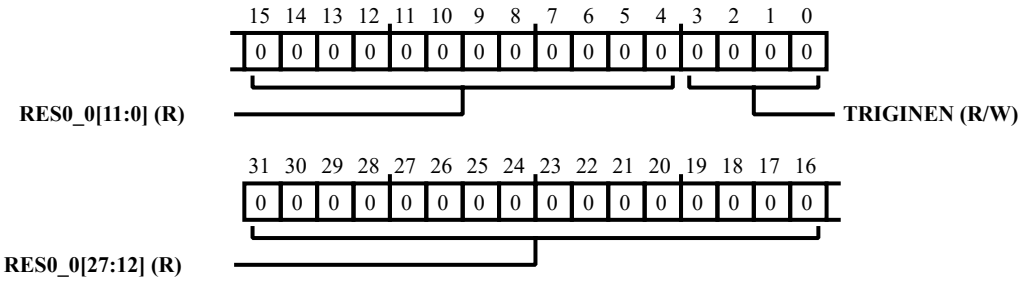

Figure 48-425: SYSCTI_CTIINEN6 Register Diagram

Table 48-425: SYSCTI_CTIINEN6 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (R/W)	TRIGINEN	. Trigger input to channel mapping.	
		0	Input trigger 6 events are ignored by the corresponding channel.
		1	When an event is received on event_in[6], generate an event on the channel corresponding to this bit.

CTI Trigger 7 to Channel Enable register.

This register maps trigger inputs to channels in the cross trigger system. The CTIINEN registers are bit maps that allow the trigger input to be mapped to any channel output, including none (0x0) and all (2^CHANNEL_WIDTH - 1). There is one register per trigger input, so it is possible to map any combination of trigger inputs to any channel outputs.

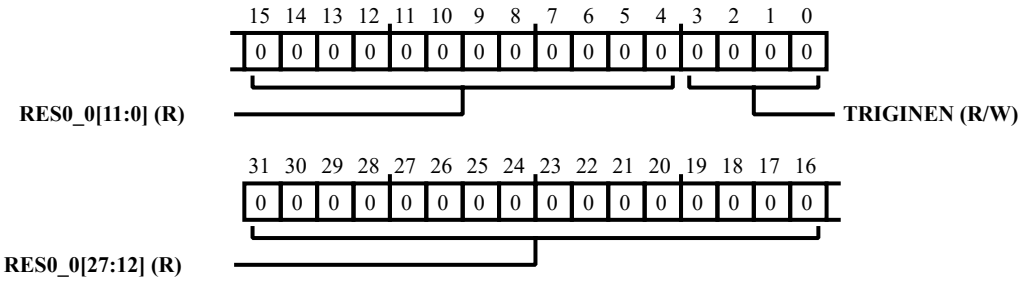

Figure 48-426: SYSCTI_CTIINEN7 Register Diagram

Table 48-426: SYSCTI_CTIINEN7 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (R/W)	TRIGINEN	. Trigger input to channel mapping.	
		0	Input trigger 7 events are ignored by the corresponding channel.
		1	When an event is received on event_in[7], generate an event on the channel corresponding to this bit.

CTI Interrupt Acknowledge register.

The CTIINTACK register acknowledges trigger outputs. It is a bit map that allows selective clearing of trigger output events. If the SW_HANDSHAKE parameter for a trigger output is set, indicating that the output latches HIGH when an event is sent to that output, then the output remains HIGH until the corresponding INTACK bit is written to a 1. A write of a bit to 0 has no effect. This allows different software threads to be responsible for clearing different trigger outputs without needing to perform a read-modify-write operation to find which bits are set.

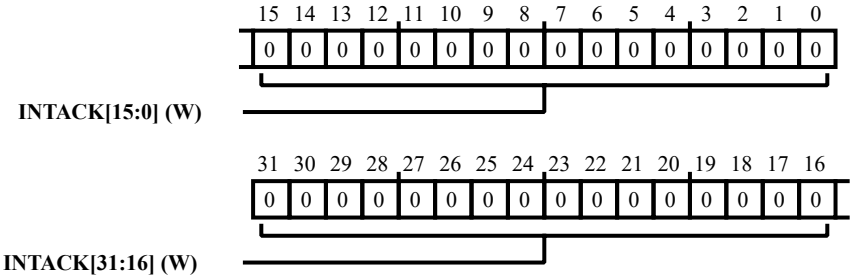

Figure 48-427: SYSCTI_CTIINTACK Register Diagram

Table 48-427: SYSCTI_CTIINTACK Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (RX/W)	INTACK	. Acknowledges the corresponding event_out output.

CTI Channel to Trigger 0 Enable register.

This register maps channels in the cross trigger system to trigger outputs. The CTIOUTEN registers are bit maps that allow any channel input to be mapped to the trigger output, including none (0x0) and all (2^CHANNEL_WIDTH - 1). There is one register per trigger output so it is possible to map any channel input to any combination of trigger outputs.

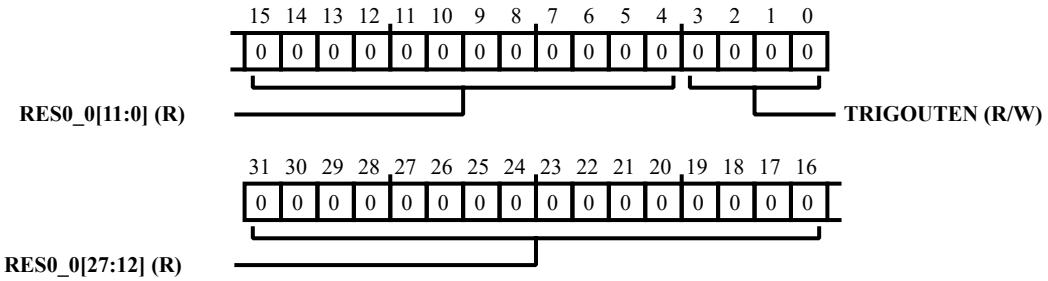

Figure 48-428: SYSCTI_CTIOUTEN0 Register Diagram

Table 48-428: SYSCTI_CTIOUTEN0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (R/W)	TRIGOUTEN	. Channel to trigger output mapping.	
		0	The corresponding channel is ignored by the output trigger0.
		1	When an event occurs on the channel corresponding to this bit, generate an event on event_out[0].

CTI Channel to Trigger 1 Enable register.

This register maps channels in the cross trigger system to trigger outputs. The CTIOUTEN registers are bit maps that allow any channel input to be mapped to the trigger output, including none (0x0) and all (2^CHANNEL_WIDTH - 1). There is one register per trigger output so it is possible to map any channel input to any combination of trigger outputs.

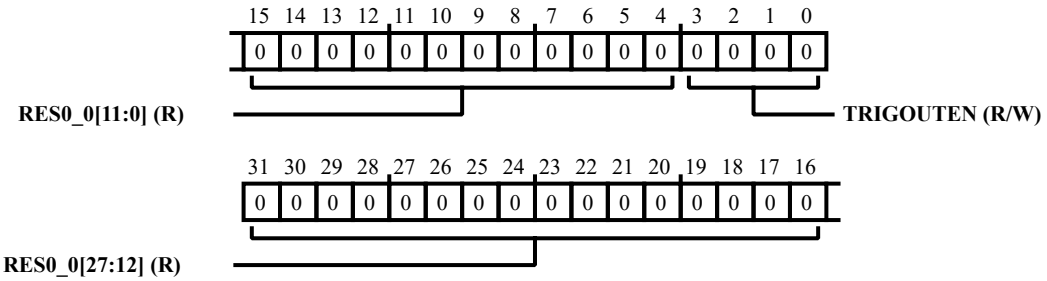

Figure 48-429: SYSCTI_CTIOUTEN1 Register Diagram

Table 48-429: SYSCTI_CTIOUTEN1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (R/W)	TRIGOUTEN	. Channel to trigger output mapping.	
		0	The corresponding channel is ignored by the output trigger1.
		1	When an event occurs on the channel corresponding to this bit, generate an event on event_out[1].

CTI Channel to Trigger 10 Enable register.

This register maps channels in the cross trigger system to trigger outputs. The CTIOUTEN registers are bit maps that allow any channel input to be mapped to the trigger output, including none (0x0) and all (2^CHANNEL_WIDTH - 1). There is one register per trigger output so it is possible to map any channel input to any combination of trigger outputs.

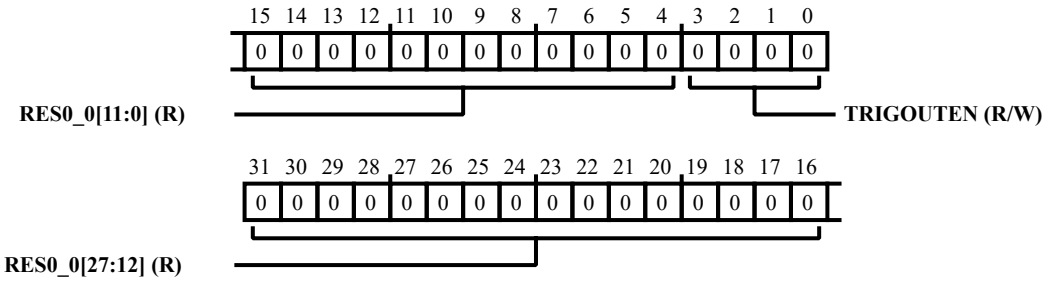

Figure 48-430: SYSCTI_CTIOUTEN10 Register Diagram

Table 48-430: SYSCTI_CTIOUTEN10 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (R/W)	TRIGOUTEN	. Channel to trigger output mapping.	
		0	The corresponding channel is ignored by the output trigger10.
		1	When an event occurs on the channel corresponding to this bit, generate an event on event_out[10].

CTI Channel to Trigger 11 Enable register.

This register maps channels in the cross trigger system to trigger outputs. The CTIOUTEN registers are bit maps that allow any channel input to be mapped to the trigger output, including none (0x0) and all (2^CHANNEL_WIDTH - 1). There is one register per trigger output so it is possible to map any channel input to any combination of trigger outputs.

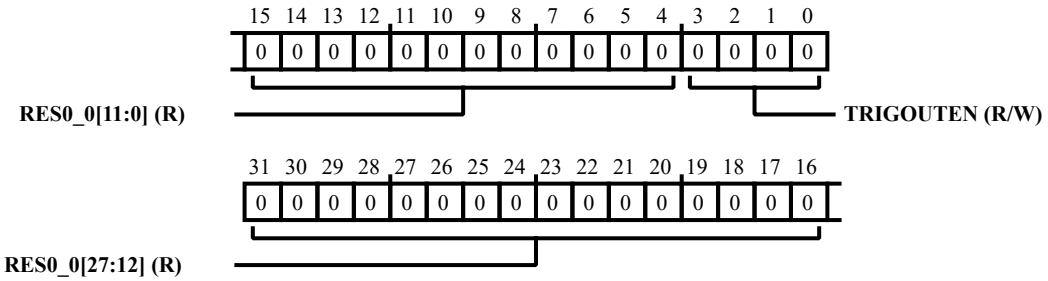

Figure 48-431: SYSCTI_CTIOUTEN11 Register Diagram

Table 48-431: SYSCTI_CTIOUTEN11 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (R/W)	TRIGOUTEN	. Channel to trigger output mapping.	
		0	The corresponding channel is ignored by the output trigger11.
		1	When an event occurs on the channel corresponding to this bit, generate an event on event_out[11].

CTI Channel to Trigger 12 Enable register.

This register maps channels in the cross trigger system to trigger outputs. The CTIOUTEN registers are bit maps that allow any channel input to be mapped to the trigger output, including none (0x0) and all (2^CHANNEL_WIDTH - 1). There is one register per trigger output so it is possible to map any channel input to any combination of trigger outputs.

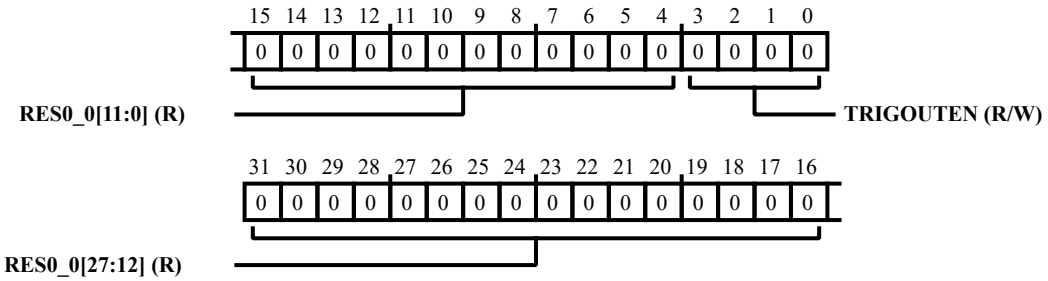

Figure 48-432: SYSCTI_CTIOUTEN12 Register Diagram

Table 48-432: SYSCTI_CTIOUTEN12 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (R/W)	TRIGOUTEN	. Channel to trigger output mapping.	
		0	The corresponding channel is ignored by the output trigger12.
		1	When an event occurs on the channel corresponding to this bit, generate an event on event_out[12].

CTI Channel to Trigger 13 Enable register.

This register maps channels in the cross trigger system to trigger outputs. The CTIOUTEN registers are bit maps that allow any channel input to be mapped to the trigger output, including none (0x0) and all (2^CHANNEL_WIDTH - 1). There is one register per trigger output so it is possible to map any channel input to any combination of trigger outputs.

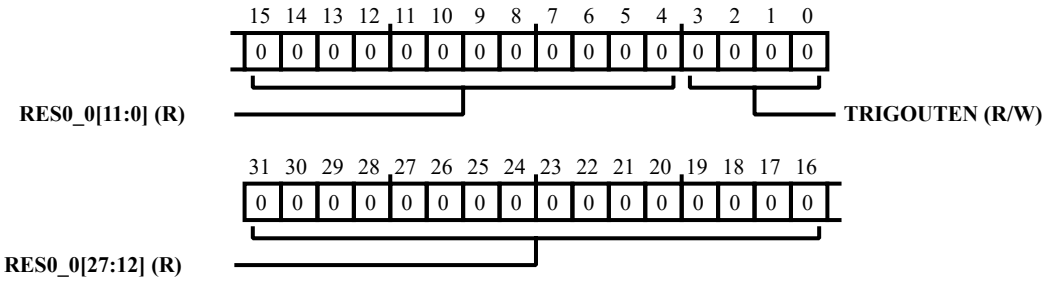

Figure 48-433: SYSCTI_CTIOUTEN13 Register Diagram

Table 48-433: SYSCTI_CTIOUTEN13 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (R/W)	TRIGOUTEN	. Channel to trigger output mapping.	
		0	The corresponding channel is ignored by the output trigger13.
		1	When an event occurs on the channel corresponding to this bit, generate an event on event_out[13].

CTI Channel to Trigger 2 Enable register.

This register maps channels in the cross trigger system to trigger outputs. The CTIOUTEN registers are bit maps that allow any channel input to be mapped to the trigger output, including none (0x0) and all (2^CHANNEL_WIDTH - 1). There is one register per trigger output so it is possible to map any channel input to any combination of trigger outputs.

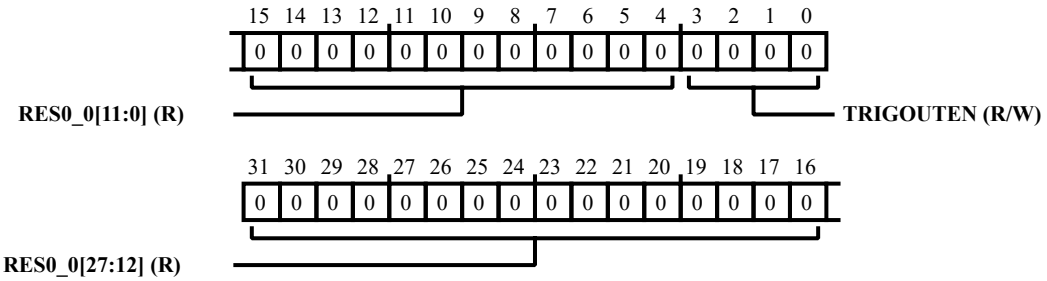

Figure 48-434: SYSCTI_CTIOUTEN2 Register Diagram

Table 48-434: SYSCTI_CTIOUTEN2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (R/W)	TRIGOUTEN	. Channel to trigger output mapping.	
		0	The corresponding channel is ignored by the output trigger2.
		1	When an event occurs on the channel corresponding to this bit, generate an event on event_out[2].

CTI Channel to Trigger 3 Enable register.

This register maps channels in the cross trigger system to trigger outputs. The CTIOUTEN registers are bit maps that allow any channel input to be mapped to the trigger output, including none (0x0) and all (2^CHANNEL_WIDTH - 1). There is one register per trigger output so it is possible to map any channel input to any combination of trigger outputs.

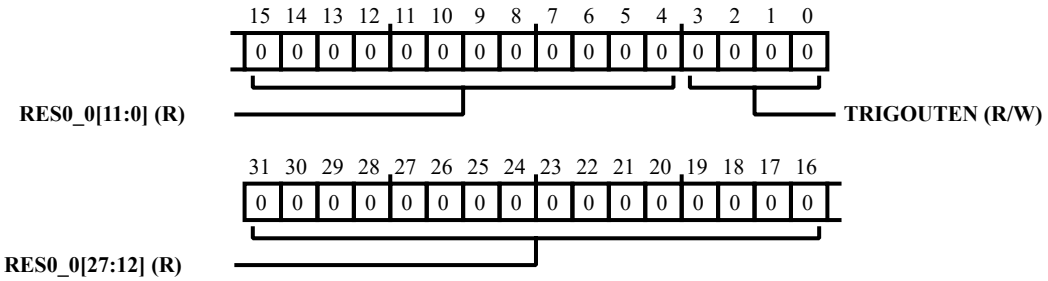

Figure 48-435: SYSCTI_CTIOUTEN3 Register Diagram

Table 48-435: SYSCTI_CTIOUTEN3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (R/W)	TRIGOUTEN	. Channel to trigger output mapping.	
		0	The corresponding channel is ignored by the output trigger3.
		1	When an event occurs on the channel corresponding to this bit, generate an event on event_out[3].

CTI Channel to Trigger 4 Enable register.

This register maps channels in the cross trigger system to trigger outputs. The CTIOUTEN registers are bit maps that allow any channel input to be mapped to the trigger output, including none (0x0) and all (2^CHANNEL_WIDTH - 1). There is one register per trigger output so it is possible to map any channel input to any combination of trigger outputs.

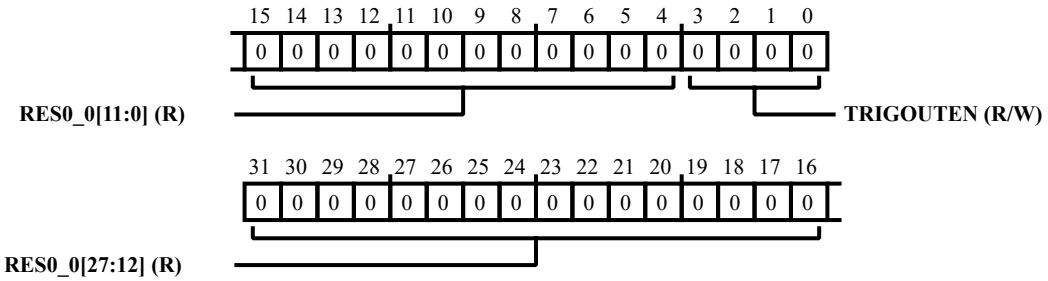

Figure 48-436: SYSCTI_CTIOUTEN4 Register Diagram

Table 48-436: SYSCTI_CTIOUTEN4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (R/W)	TRIGOUTEN	. Channel to trigger output mapping.	
		0	The corresponding channel is ignored by the output trigger4.
		1	When an event occurs on the channel corresponding to this bit, generate an event on event_out[4].

CTI Channel to Trigger 5 Enable register.

This register maps channels in the cross trigger system to trigger outputs. The CTIOUTEN registers are bit maps that allow any channel input to be mapped to the trigger output, including none (0x0) and all (2^CHANNEL_WIDTH - 1). There is one register per trigger output so it is possible to map any channel input to any combination of trigger outputs.

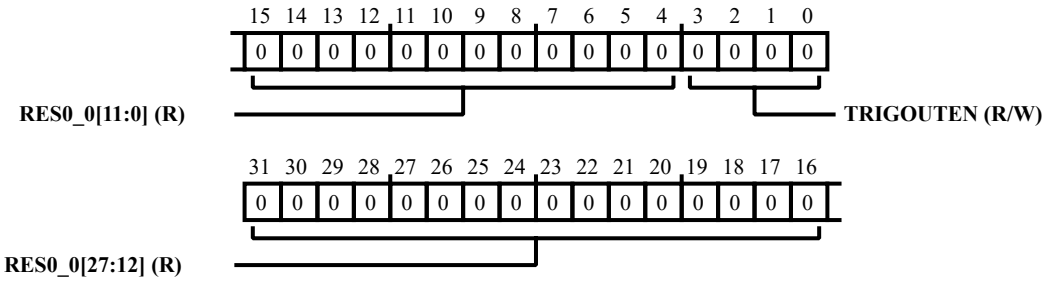

Figure 48-437: SYSCTI_CTIOUTEN5 Register Diagram

Table 48-437: SYSCTI_CTIOUTEN5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (R/W)	TRIGOUTEN	. Channel to trigger output mapping.	
		0	The corresponding channel is ignored by the output trigger5.
		1	When an event occurs on the channel corresponding to this bit, generate an event on event_out[5].

CTI Channel to Trigger 6 Enable register.

This register maps channels in the cross trigger system to trigger outputs. The CTIOUTEN registers are bit maps that allow any channel input to be mapped to the trigger output, including none (0x0) and all (2^CHANNEL_WIDTH - 1). There is one register per trigger output so it is possible to map any channel input to any combination of trigger outputs.

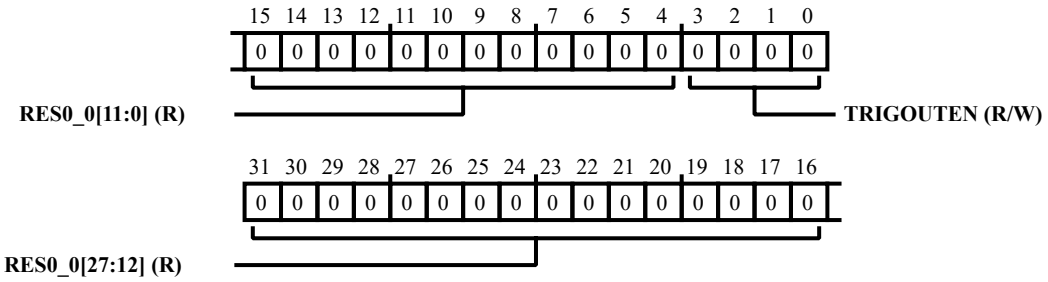

Figure 48-438: SYSCTI_CTIOUTEN6 Register Diagram

Table 48-438: SYSCTI_CTIOUTEN6 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (R/W)	TRIGOUTEN	. Channel to trigger output mapping.	
		0	The corresponding channel is ignored by the output trigger6.
		1	When an event occurs on the channel corresponding to this bit, generate an event on event_out[6].

CTI Channel to Trigger 7 Enable register.

This register maps channels in the cross trigger system to trigger outputs. The CTIOUTEN registers are bit maps that allow any channel input to be mapped to the trigger output, including none (0x0) and all (2^CHANNEL_WIDTH - 1). There is one register per trigger output so it is possible to map any channel input to any combination of trigger outputs.

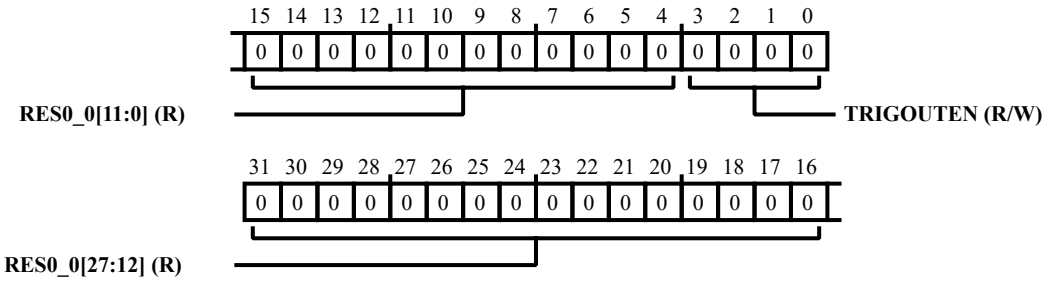

Figure 48-439: SYSCTI_CTIOUTEN7 Register Diagram

Table 48-439: SYSCTI_CTIOUTEN7 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (R/W)	TRIGOUTEN	. Channel to trigger output mapping.	
		0	The corresponding channel is ignored by the output trigger7.
		1	When an event occurs on the channel corresponding to this bit, generate an event on event_out[7].

CTI Channel to Trigger 8 Enable register.

This register maps channels in the cross trigger system to trigger outputs. The CTIOUTEN registers are bit maps that allow any channel input to be mapped to the trigger output, including none (0x0) and all (2^CHANNEL_WIDTH - 1). There is one register per trigger output so it is possible to map any channel input to any combination of trigger outputs.

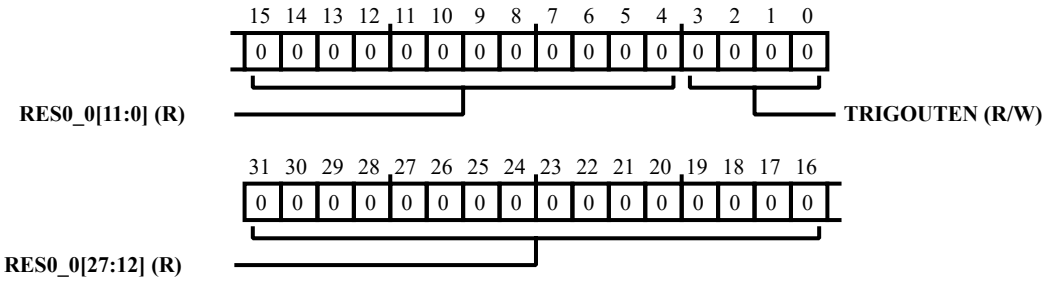

Figure 48-440: SYSCTI_CTIOUTEN8 Register Diagram

Table 48-440: SYSCTI_CTIOUTEN8 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (R/W)	TRIGOUTEN	. Channel to trigger output mapping.	
		0	The corresponding channel is ignored by the output trigger8.
		1	When an event occurs on the channel corresponding to this bit, generate an event on event_out[8].

CTI Channel to Trigger 9 Enable register.

This register maps channels in the cross trigger system to trigger outputs. The CTIOUTEN registers are bit maps that allow any channel input to be mapped to the trigger output, including none (0x0) and all (2^CHANNEL_WIDTH - 1). There is one register per trigger output so it is possible to map any channel input to any combination of trigger outputs.

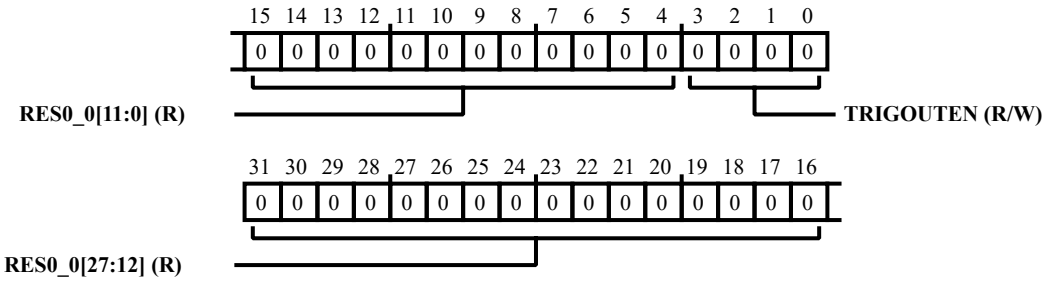

Figure 48-441: SYSCTI_CTIOUTEN9 Register Diagram

Table 48-441: SYSCTI_CTIOUTEN9 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (R/W)	TRIGOUTEN	. Channel to trigger output mapping.	
		0	The corresponding channel is ignored by the output trigger9.
		1	When an event occurs on the channel corresponding to this bit, generate an event on event_out[9].

CTI Trigger Input Status register.

Trigger input status. If the event_in input is driven by a source that generates single cycle pulses, this register is generally read as 0.

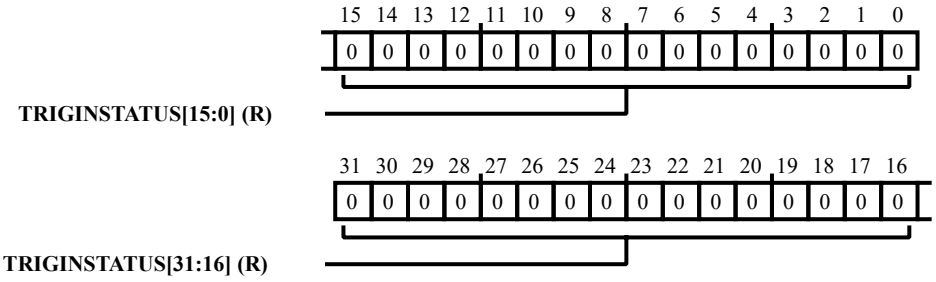

Figure 48-442: SYSCTI_CTITRIGINSTATUS Register Diagram

Table 48-442: SYSCTI_CTITRIGINSTATUS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:0 (R/NW)	TRIGINSTATUS	. Trigger input status.	
		0	One bit per trigger input. 0 means that the input is LOW.
		1	One bit per trigger input. 1 means that the input is HIGH.

CTI Trigger Output Status register.

Trigger output status. The register only has meaning if the trigger source drives static levels, rather than pulses.

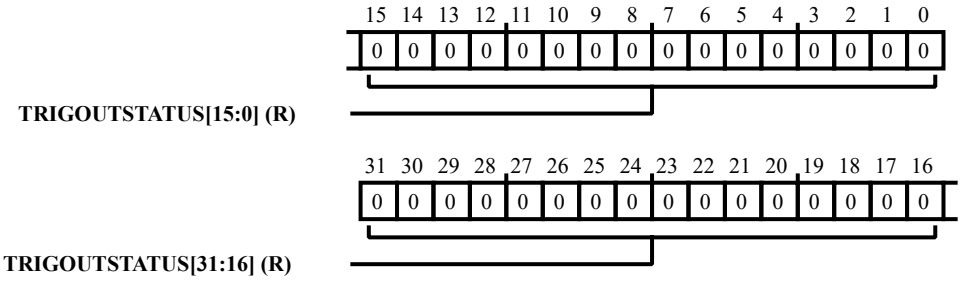

Figure 48-443: SYSCTI_CTITRIGOUTSTATUS Register Diagram

Table 48-443: SYSCTI_CTITRIGOUTSTATUS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:0 (R/NW)	TRIGOUTSTATUS	. Trigger output status.	
		0	One bit per trigger output. 0 means that the output is LOW.
		1	One bit per trigger output. 1 means that the output is HIGH.

Device Affinity register 0.

Enables a debugger to determine if two components have an affinity with each other.

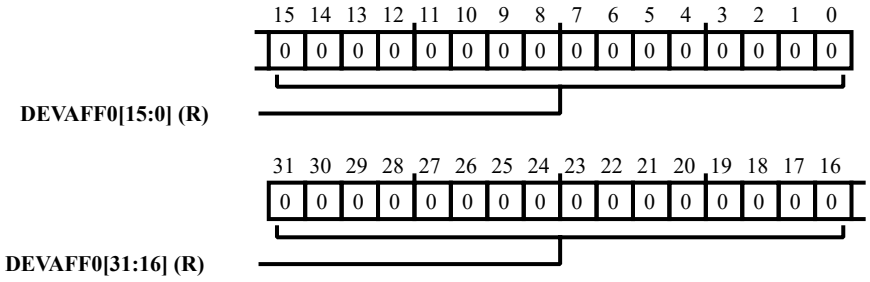

Figure 48-444: SYSCTI_DEVAFF0 Register Diagram

Table 48-444: SYSCTI_DEVAFF0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	DEVAFF0	. Lower 32-bits of DEVAFF. The value is set by the devaff[31:0] tie-off inputs.

Device Affinity register 1.

Enables a debugger to determine if two components have an affinity with each other.

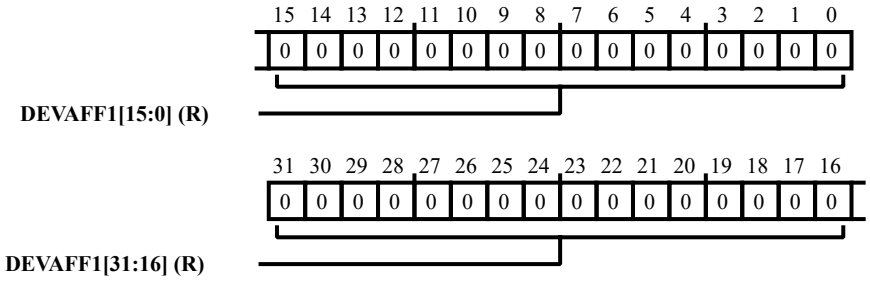

Figure 48-445: SYSCTI_DEVAFF1 Register Diagram

Table 48-445: SYSCTI_DEVAFF1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	DEVAFF1	. Upper 32-bits of DEVAFF. The value is set by the devaff[63:32] tie-off inputs.

Device Architecture Register.

Identifies the architect and architecture of a CoreSight component. The architect might differ from the designer of a component, for example Arm defines the architecture but another company designs and implements the component.

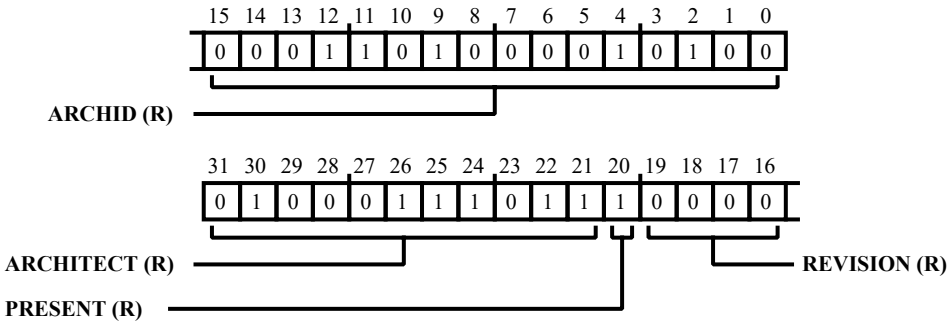

Figure 48-446: SYSCTI_DEVARCH Register Diagram

Table 48-446: SYSCTI_DEVARCH Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:21 (R/NW)	ARCHITECT	. Defines the architect of the component.	
		571	Arm.
20 (R/NW)	PRESENT	. Indicates the presence of this register.	
		0	DEVARCH is not present.
		1	DEVARCH is present.
19:16 (R/NW)	REVISION	. Architecture revision. Returns the revision of the architecture that the ARCHID field specifies.	
15:0 (R/NW)	ARCHID	. Architecture ID. Returns a value that identifies the architecture of the component.	
		2583	Memory Access Port v2 architecture.
		2599	JTAG Access Port v2 architecture.
		2631	Unknown Access Port v2 architecture.
		2807	CoreSight ROM architecture.
		6676	CTI architecture.

Device Configuration Register.

This register is IMPLEMENTATION DEFINED for each Part Number and Designer. The register indicates the capabilities of the component.

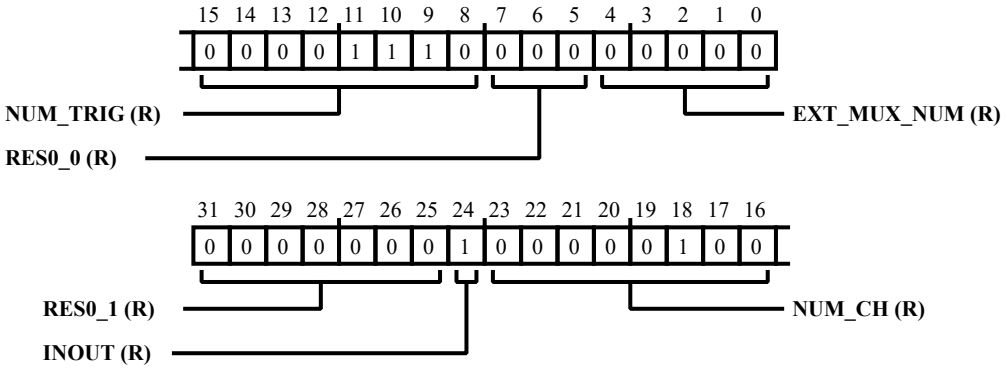

Figure 48-447: SYSCTI_DEVID Register Diagram

Table 48-447: SYSCTI_DEVID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:25 (R/NW)	RES0_1	. Reserved bit or field with SBZP behavior.
24 (R/NW)	INOUT	. Indicates channel inputs are also masked by the CTIGATE register. Always 1.
23:16 (R/NW)	NUM_CH	. The number of channels. Always either 4 or 16, set by CHANNEL_WIDTH.
15:8 (R/NW)	NUM_TRIG	. Indicates the maximum number of triggers - the maximum of the two parameters, NUM_EVENT_RECEIVERS and NUM_EVENT_TRANSMITTERS.
7:5 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
4:0 (R/NW)	EXT_MUX_NUM	. Indicates the value of the EXT_MUX_NUM parameter, which determines if there is any external multiplexing on the trigger inputs and outputs. 0 indicates no multiplexing.

Device Type Identifier Register.

A debugger can use this register to get information about a component that has an unrecognized Part number.

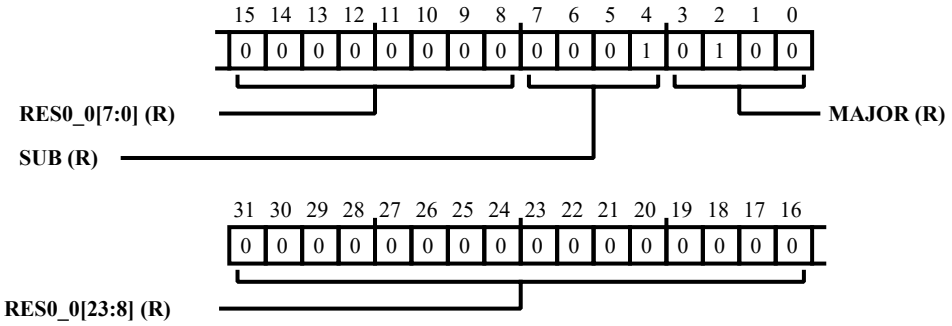

Figure 48-448: SYSCTI_DEVTYPE Register Diagram

Table 48-448: SYSCTI_DEVTYPE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:4 (R/NW)	SUB	. Minor classification. Returns 0x1, indicating this component is a Trigger-Matrix.
3:0 (R/NW)	MAJOR	. Major classification. Returns 0x4, indicating this component performs Debug Control.

Integration Test Channel Input register.

Integration test mode register, used to view channel events. The integration test register includes a latch that is set when a pulse is received on a channel input. When read, a register bit reads as 1 if the channel has received a pulse since it was last read. The act of reading the register automatically clears the 1 to a 0. When performing integration testing it is therefore important to coordinate the setting of event latches and reading/clearing them.

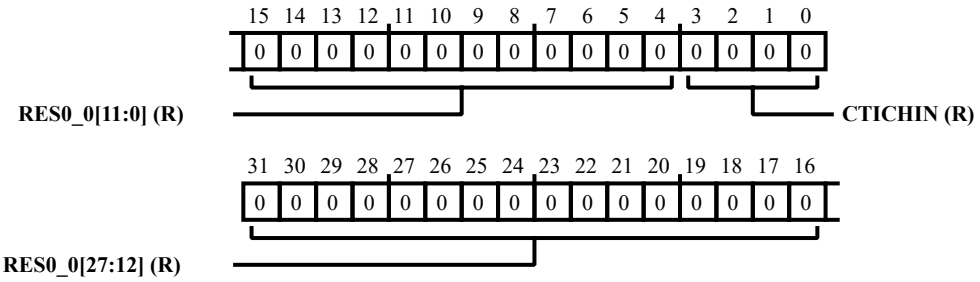

Figure 48-449: SYSCTI_ITCHIN Register Diagram

Table 48-449: SYSCTI_ITCHIN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
3:0 (R/NW)	CTICHIN	. Reads the latched value of the channel inputs.

Integration Test Channel Output register.

Integration test mode register, used to generate channel events. Writing to the register creates a single pulse on the output. ITCHOUT is self-clearing.

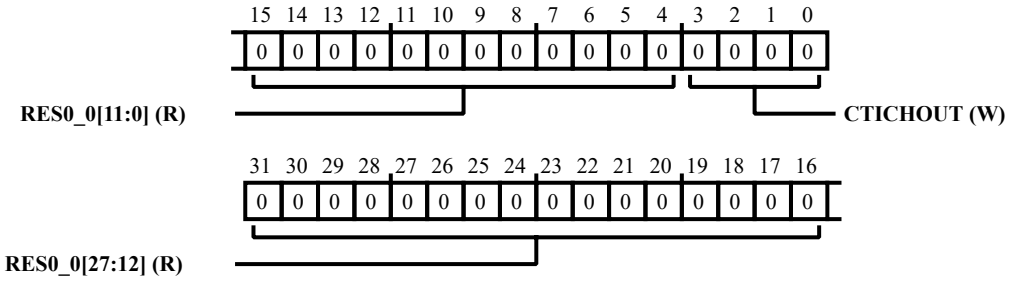

Figure 48-450: SYSCTI_ITCHOUT Register Diagram

Table 48-450: SYSCTI_ITCHOUT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3:0 (RX/W)	CTICHOUT	. Pulses the channel outputs.	
		0	No effect.
		1	Pulse channel event for one clk cycle.

Integration Mode Control Register.

The Integration Mode Control register is used to switch between functional mode and integration mode. After switching to integration mode and performing integration tests or topology detection, reset the system to ensure correct behavior of CoreSight and other connected system components.

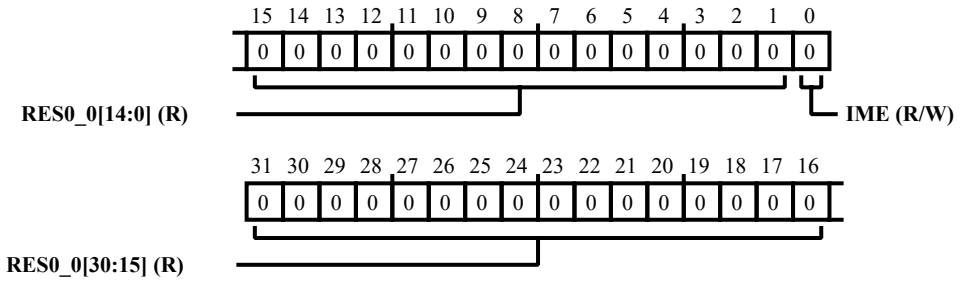

Figure 48-451: SYSCTI_ITCTRL Register Diagram

Table 48-451: SYSCTI_ITCTRL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:1 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
0 (R/W)	IME	. Integration Mode Enable.	
		0	The component must enter functional mode.
		1	The component must enter integration mode, and enable support for topology detection and integration testing.

Integration Test Trigger Input register.

Integration test mode register, used to view trigger events. The integration test register includes a latch that is set when a pulse is received on a trigger input. When read, a register bit reads as 1 if the trigger input has received a pulse since it was last read. The act of reading the register automatically clears the 1 to a 0. When performing integration testing it is therefore important to coordinate the setting of event latches and reading/clearing them.

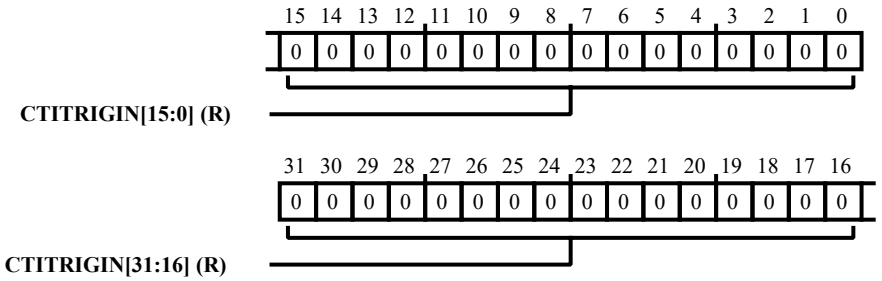

Figure 48-452: SYSCTI_ITTRIGIN Register Diagram

Table 48-452: SYSCTI_ITTRIGIN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CTITRIGIN	. Reads the latched value of the trigger inputs.

Integration Test Trigger Output register.

Integration test mode register, used to generate trigger events.

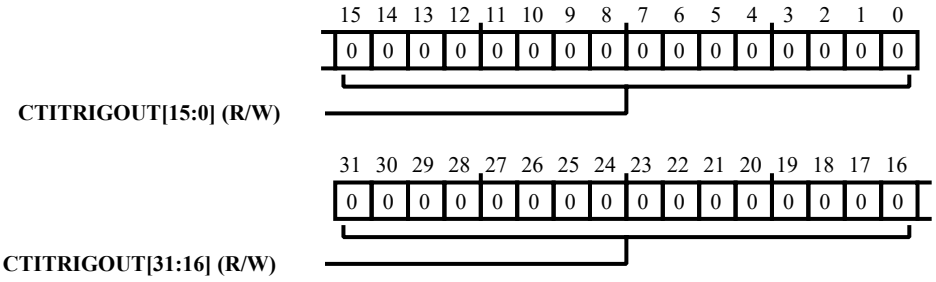

Figure 48-453: SYSCTI_ITTRIGOUT Register Diagram

Table 48-453: SYSCTI_ITTRIGOUT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:0 (R/W)	CTITRIGOUT	. Set/clear trigger output signal. Reads return the value in the register if SW_HANDSHAKE=1, otherwise 0 is returned if SW_HANDSHAKE=0. Writes:.	
		0	Clears the trigger output if SW_HANDSHAKE=1, no effect if SW_HANDSHAKE=0.
		1	Sets the trigger output if SW_HANDSHAKE=1, pulses trigger output if SW_HANDSHAKE=0.

Peripheral Identification Register 0.

The PIDR0 register is part of the set of peripheral identification registers.

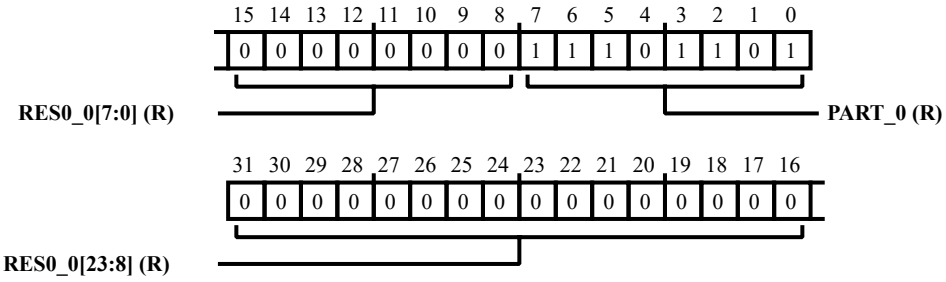

Figure 48-454: SYSCTI_PIDR0 Register Diagram

Table 48-454: SYSCTI_PIDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PART_0	. Part number, bits[7:0]. Taken together with PIDR1.PART_1 it indicates the component. The Part Number is selected by the designer of the component.

Peripheral Identification Register 1.

The PIDR1 register is part of the set of peripheral identification registers.

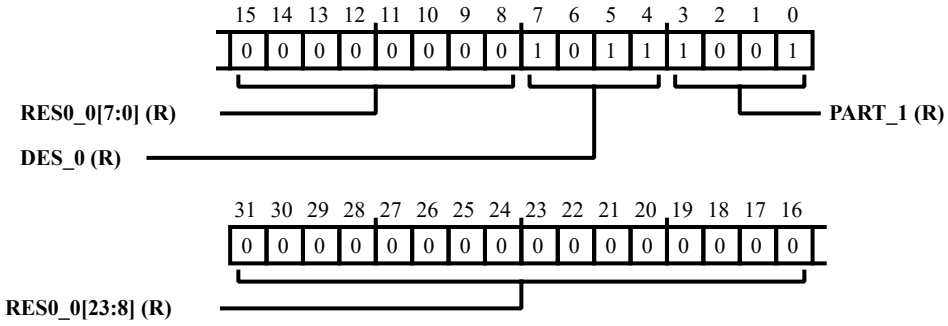

Figure 48-455: SYSCTI_PIDR1 Register Diagram

Table 48-455: SYSCTI_PIDR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:4 (R/NW)	DES_0	. JEP106 identification code, bits[3:0]. Together, with PIDR4.DES_2 and PIDR2.DES_1, they indicate the designer of the component and not the implementer, except where the two are the same.
3:0 (R/NW)	PART_1	. Part number, bits[11:8]. Taken together with PIDR0.PART_0 it indicates the component. The Part Number is selected by the designer of the component.

Peripheral Identification Register 2.

The PIDR2 register is part of the set of peripheral identification registers.

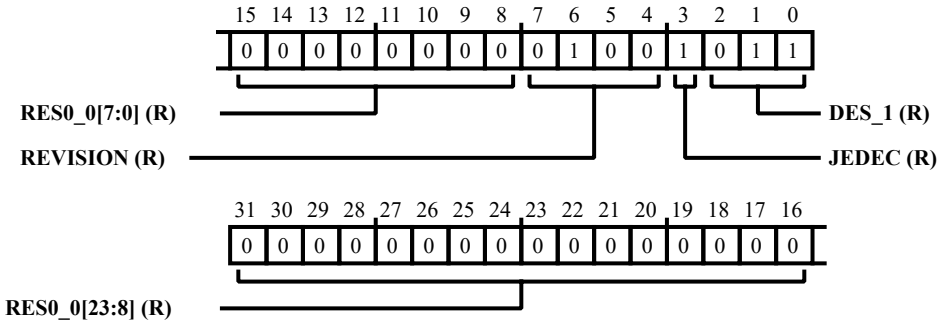

Figure 48-456: SYSCTI_PIDR2 Register Diagram

Table 48-456: SYSCTI_PIDR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:4 (R/NW)	REVISION	. Revision. It is an incremental value starting at 0x0 for the first design of a component. See the Component list in Chapter 1 for information on the RTL revision of the component.
3 (R/NW)	JEDEC	. 1 - Always set. Indicates that a JEDEC assigned value is used.
2:0 (R/NW)	DES_1	. JEP106 identification code, bits[6:4]. Together, with PIDR4.DES_2 and PIDR1.DES_0, they indicate the designer of the component and not the implementer, except where the two are the same.

Peripheral Identification Register 3.

The PIDR3 register is part of the set of peripheral identification registers.

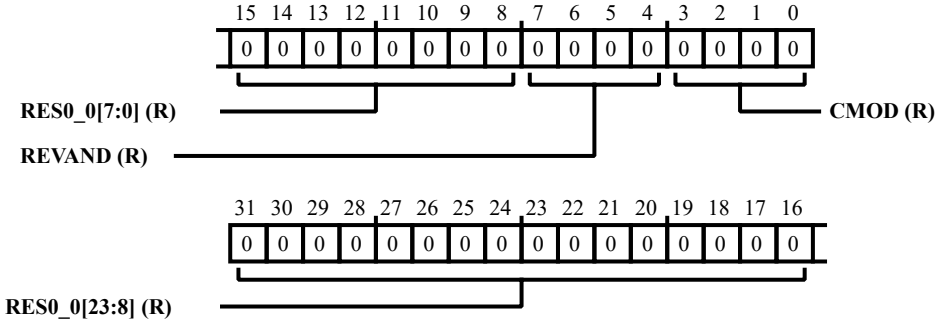

Figure 48-457: SYSCTI_PIDR3 Register Diagram

Table 48-457: SYSCTI_PIDR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:4 (R/NW)	REVAND	. This field indicates minor errata fixes specific to this design, for example metal fixes after implementation. In most cases this field is 0x0.
3:0 (R/NW)	CMOD	. Customer Modified. Where the component is reusable IP, this value indicates if the customer has modified the behavior of the component. In most cases this field is 0x0.

Peripheral Identification Register 4.

The PIDR4 register is part of the set of peripheral identification registers.

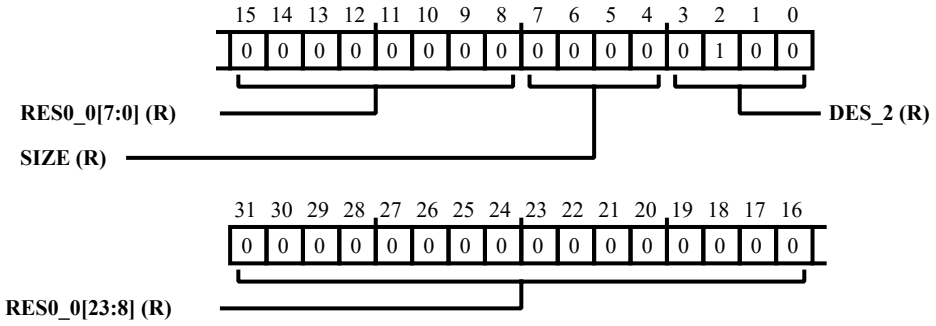

Figure 48-458: SYSCTI_PIDR4 Register Diagram

Table 48-458: SYSCTI_PIDR4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:4 (R/NW)	SIZE	. Indicates the memory size that is used by this component. Returns 0 indicating that the component uses an UNKNOWN number of 4KB blocks. Using the SIZE field to indicate the size of the component is deprecated.
3:0 (R/NW)	DES_2	. JEP106 continuation code. Together, with PIDR2.DES_1 and PIDR1.DES_0, they indicate the designer of the component and not the implementer, except where the two are the same.

Peripheral Identification Register 5.

The PIDR5 register is part of the set of peripheral identification registers.

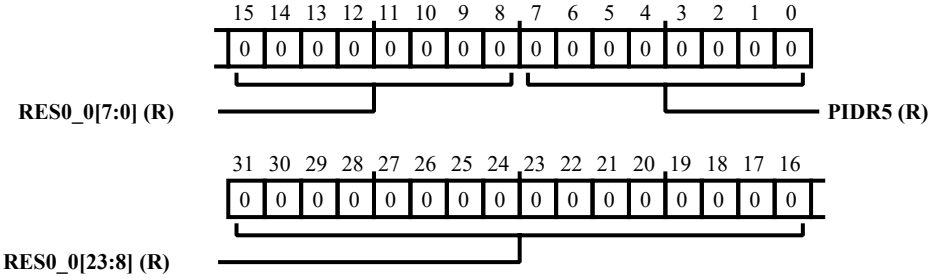

Figure 48-459: SYSCTI_PIDR5 Register Diagram

Table 48-459: SYSCTI_PIDR5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PIDR5	. Reserved.

Peripheral Identification Register 6.

The PIDR6 register is part of the set of peripheral identification registers.

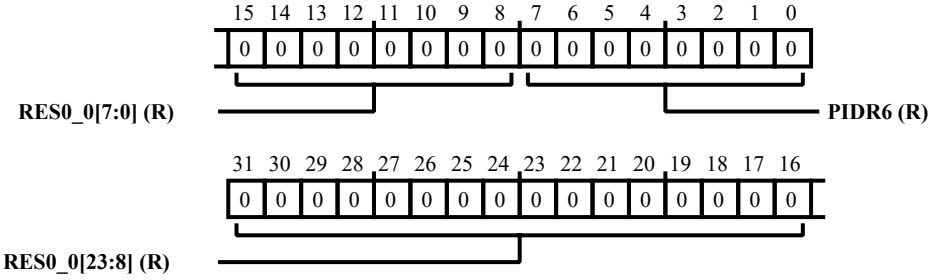

Figure 48-460: SYSCTI_PIDR6 Register Diagram

Table 48-460: SYSCTI_PIDR6 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PIDR6	. Reserved.

Peripheral Identification Register 7.

The PIDR7 register is part of the set of peripheral identification registers.

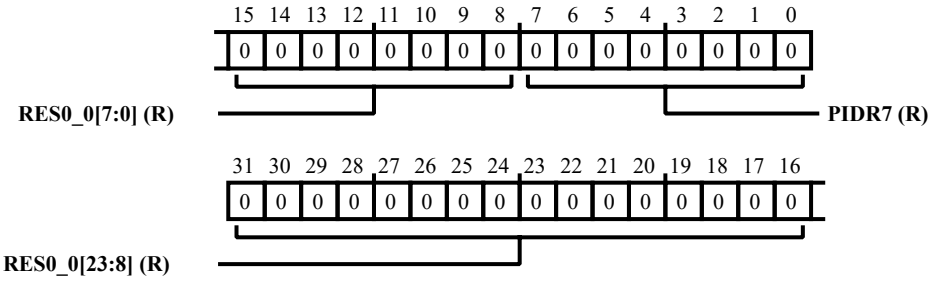

Figure 48-461: SYSCTI_PIDR7 Register Diagram

Table 48-461: SYSCTI_PIDR7 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PIDR7	. Reserved.

ADSP-2184x TAPC Register Descriptions

TAPC (TAPC) contains the following registers.

Table 48-462: ADSP-2184x TAPC Register List

Name	Description
TAPC_DBGCTL	Debug Control Register
TAPC_IDCODE	IDCODE Register
TAPC_SDBGKEY0	Secure Debug Key 0 Register
TAPC_SDBGKEY1	Secure Debug Key 1 Register
TAPC_SDBGKEY2	Secure Debug Key 2 Register
TAPC_SDBGKEY3	Secure Debug Key 3 Register
TAPC_SDBGKEY4	Secure Debug Key 4 Register
TAPC_SDBGKEY5	Secure Debug Key 5 Register
TAPC_SDBGKEY6	Secure Debug Key 6 Register
TAPC_SDBGKEY7	Secure Debug Key 7 Register

Table 48-462: ADSP-2184x TAPC Register List (Continued)

Name	Description
TAPC_SDBGKEY_CTL	Secure Debug Key Control Register
TAPC_SDBGKEY_STAT	Secure Debug Key Status Register
TAPC_USERCODE	USERCODE Register

Debug Control Register

The TAPC_DBGCTL register creates authentication signals to all CoreSight components in the system such as DBGEN, NIDEN, SPNIDEN and SPIDEN.

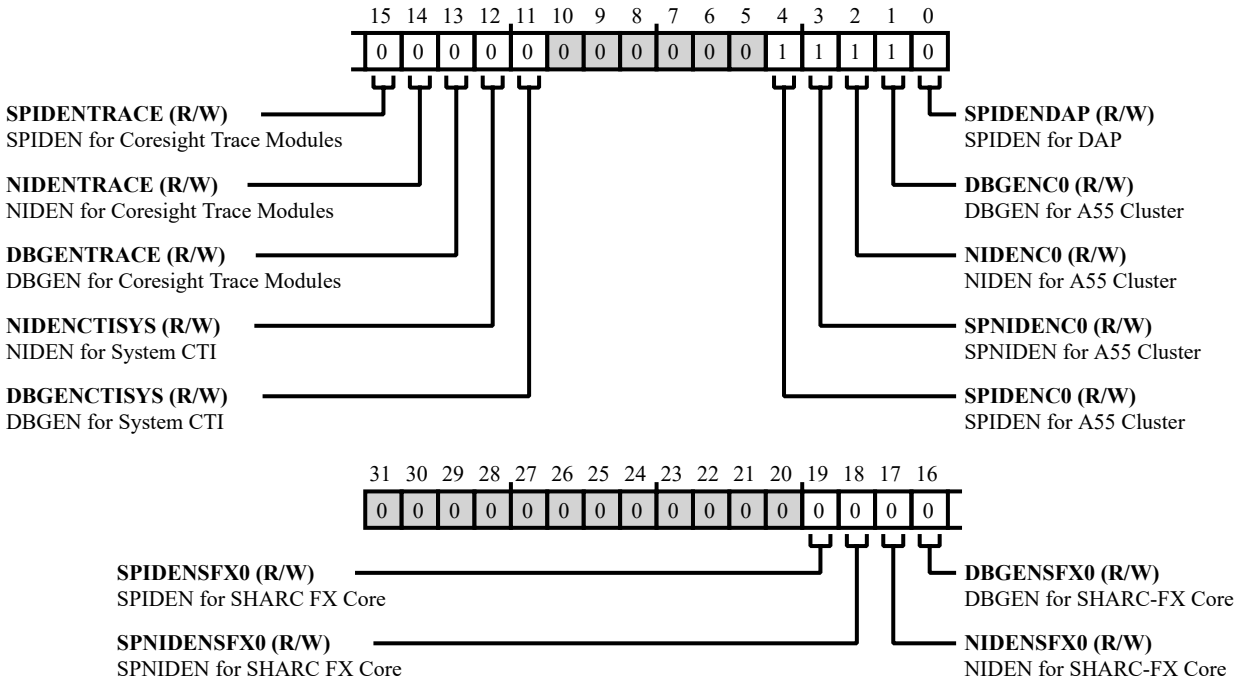

Figure 48-462: TAPC_DBGCTL Register Diagram

Table 48-463: TAPC_DBGCTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
19 (R/W)	SPIDENSFX0	SPIDEN for SHARC FX Core. Secure Privileged Invasive Debug Enable for SHARC-FX Core
18 (R/W)	SPNIDENSFX0	SPNIDEN for SHARC FX Core. Secure Privileged Non-Invasive Debug Enable for SHARC-FX Core
17 (R/W)	NIDENSFX0	NIDEN for SHARC-FX Core. Non Invasive Debug Enable for SHARC FX Core
16 (R/W)	DBGENSFX0	DBGEN for SHARC-FX Core. Debug Enable for SHARC-FX Core
15 (R/W)	SPIDENTRACE	SPIDEN for Coresight Trace Modules.
14 (R/W)	NIDENTRACE	NIDEN for Coresight Trace Modules.

Table 48-463: TAPC_DBGCTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
13 (R/W)	DBGENTRACE	DBGEN for Coresight Trace Modules.
12 (R/W)	NIDENCTISYS	NIDEN for System CTI.
11 (R/W)	DBGENCTISYS	DBGEN for System CTI.
4 (R/W)	SPIDENC0	SPIDEN for A55 Cluster.
3 (R/W)	SPNIDENC0	SPNIDEN for A55 Cluster.
2 (R/W)	NIDENC0	NIDEN for A55 Cluster.
1 (R/W)	DBGENC0	DBGEN for A55 Cluster.
0 (R/W)	SPIDENDAP	SPIDEN for DAP.

IDCODE Register

The TAPC_IDCODE register holds the IDCODE. The bit field is defined as follows.

IDCODE[31:28] = 0x1* – REVID

IDCODE[27:12] = 0x280B – JTAG ID

IDCODE[11:1] = 0x65 – Manufacturer ID

IDCODE[0] = 0x1

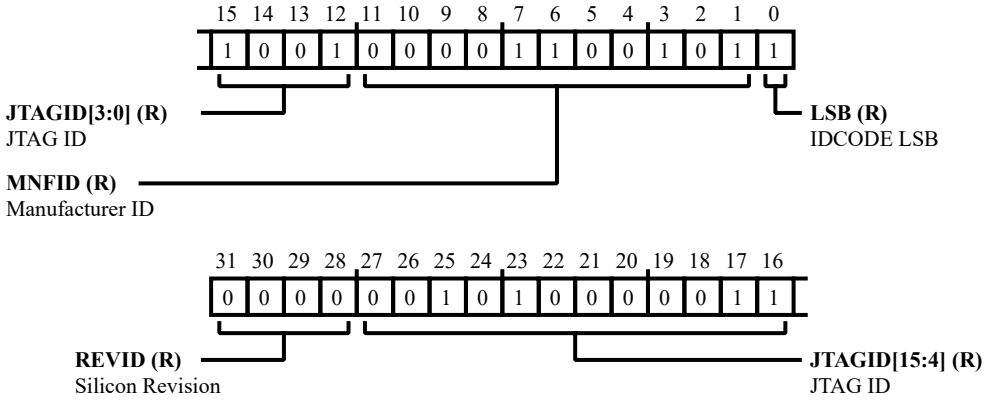

Figure 48-463: TAPC_IDCODE Register Diagram

Table 48-464: TAPC_IDCODE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:28 (R/NW)	REVID	Silicon Revision. The TAPC_IDCODE.REVID bit field holds the silicon revision. See the processor anomaly list for details.
27:12 (R/NW)	JTAGID	JTAG ID.
11:1 (R/NW)	MNFID	Manufacturer ID.
0 (R/NW)	LSB	IDCODE LSB.

Secure Debug Key 0 Register

The TAPC_SDBGKEY0 register allows a locked part to unlock debug access through the JTAG or SWD interfaces. A debug key of 128 bits needs to be written into the Secure Debug Key registers (TAPC_SDBGKEY0, TAPC_SDBGKEY1, TAPC_SDBGKEY2, TAPC_SDBGKEY3) in the TAPC through the peripheral bus interface.

These registers hold the value of the key against which a matching key provided by the debug user is compared to enable a debug session. The task of writing these registers is performed (initially) by boot ROM code which copies a customer-selected key from the Flash memory info block to these registers.

An SDBGKEY value of all 0's is always an invalid key, a value of all 1's match the default value of the Secure Debug Key Compare registers and requires no entry in these registers. It is recommended programs have a significant number of 0's and 1's in a pseudo-random pattern throughout the 128-bit code for maximum protection.

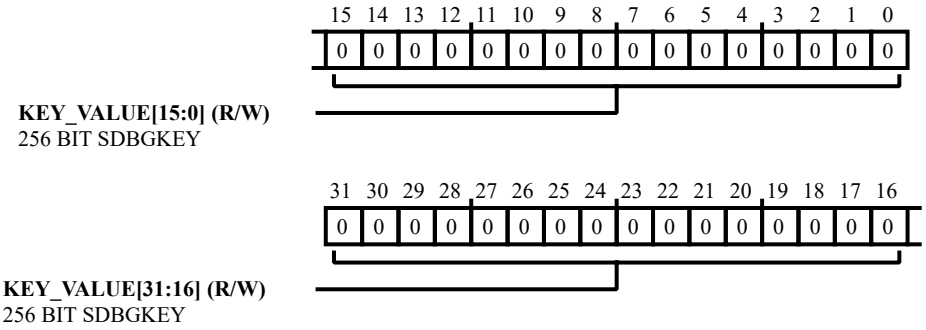

Figure 48-464: TAPC_SDBGKEY0 Register Diagram

Table 48-465: TAPC_SDBGKEY0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	KEY_VALUE	256 BIT SDBGKEY. The TAPC_SDBGKEY0.KEY_VALUE bit field holds the value of the key against which a matching key provided by the debug user is compared to enable a debug session.

Secure Debug Key 1 Register

The TAPC_SDBGKEY1 register allows a locked part to unlock debug access through the JTAG or SWD interfaces. See the TAPC_SDBGKEY0 register description for more information.

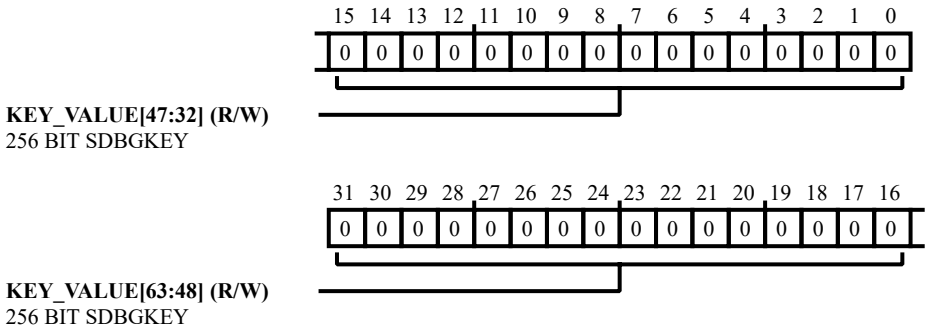

Figure 48-465: TAPC_SDBGKEY1 Register Diagram

Table 48-466: TAPC_SDBGKEY1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	KEY_VALUE	256 BIT SDBGKEY. The TAPC_SDBGKEY1.KEY_VALUE bit field holds the value of the key against which a matching key provided by the debug user is compared to enable a debug session.

Secure Debug Key 2 Register

The TAPC_SDBGKEY2 register allows a locked part to unlock debug access through the JTAG or SWD interfaces. See the TAPC_SDBGKEY0 register description for more information.

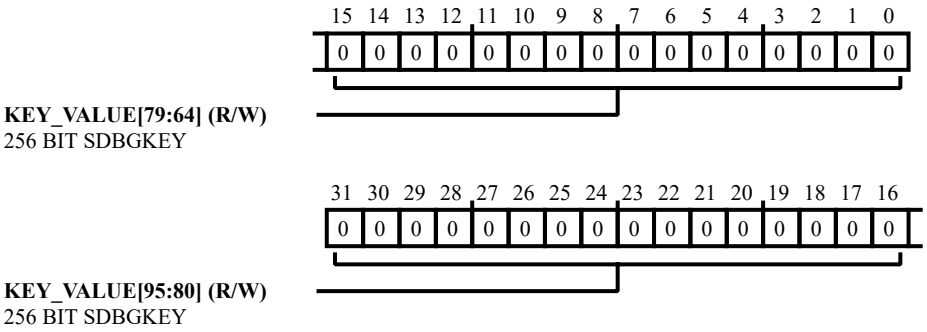

Figure 48-466: TAPC_SDBGKEY2 Register Diagram

Table 48-467: TAPC_SDBGKEY2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	KEY_VALUE	256 BIT SDBGKEY. The TAPC_SDBGKEY2.KEY_VALUE bit field holds the value of the key against which a matching key provided by the debug user is compared to enable a debug session.

Secure Debug Key 3 Register

The TAPC_SDBGKEY3 register allows a locked part to unlock debug access through the JTAG or SWD interfaces. See the TAPC_SDBGKEY0 register description for more information.

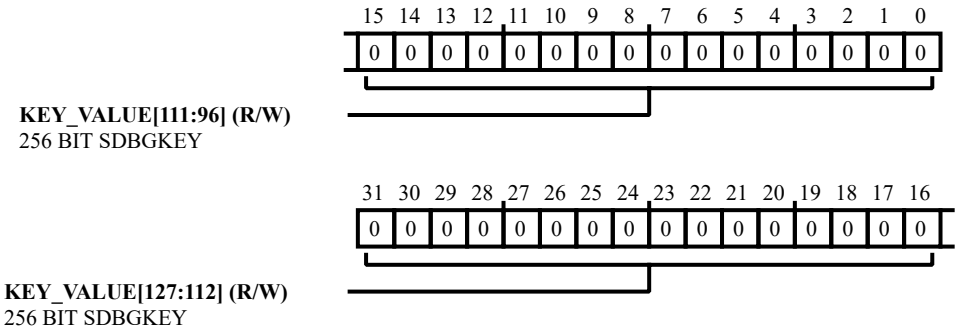

Figure 48-467: TAPC_SDBGKEY3 Register Diagram

Table 48-468: TAPC_SDBGKEY3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	KEY_VALUE	256 BIT SDBGKEY. The TAPC_SDBGKEY3.KEY_VALUE bit field holds the value of the key against which a matching key provided by the debug user is compared to enable a debug session.

Secure Debug Key 4 Register

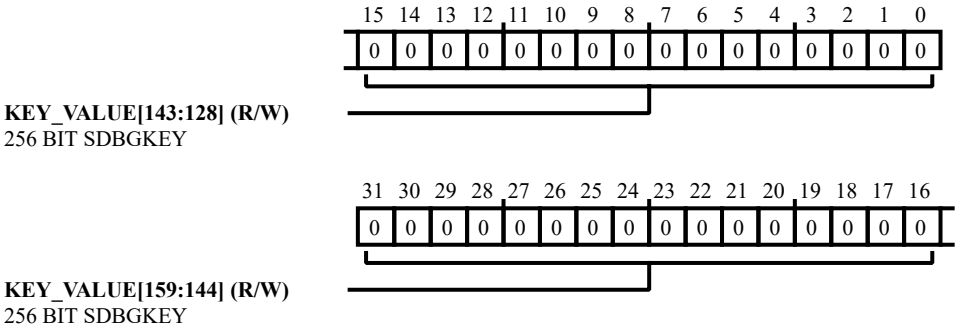

Figure 48-468: TAPC_SDBGKEY4 Register Diagram

Table 48-469: TAPC_SDBGKEY4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	KEY_VALUE	256 BIT SDBGKEY. The `TAPC_SDBGKEY4.KEY_VALUE` bit field holds the value of the key against which a matching key provided by the debug user is compared to enable a debug session.

Secure Debug Key 5 Register

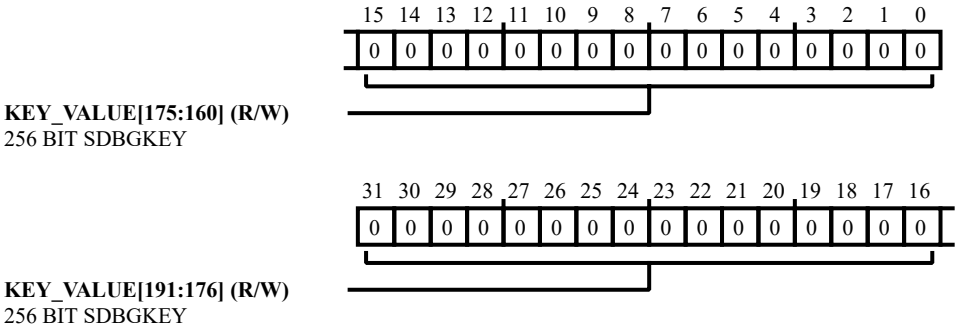

Figure 48-469: TAPC_SDBGKEY5 Register Diagram

Table 48-470: TAPC_SDBGKEY5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	KEY_VALUE	256 BIT SDBGKEY. The `TAPC_SDBGKEY5.KEY_VALUE` bit field holds the value of the key against which a matching key provided by the debug user is compared to enable a debug session.

Secure Debug Key 6 Register

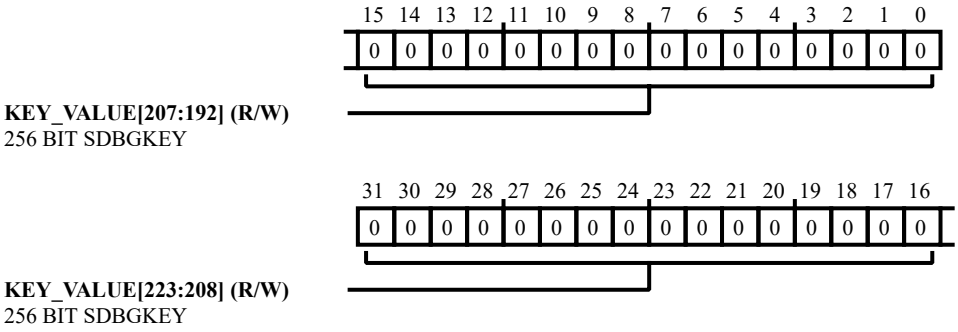

Figure 48-470: TAPC_SDBGKEY6 Register Diagram

Table 48-471: TAPC_SDBGKEY6 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	KEY_VALUE	256 BIT SDBGKEY. The `TAPC_SDBGKEY6.KEY_VALUE` bit field holds the value of the key against which a matching key provided by the debug user is compared to enable a debug session.

Secure Debug Key 7 Register

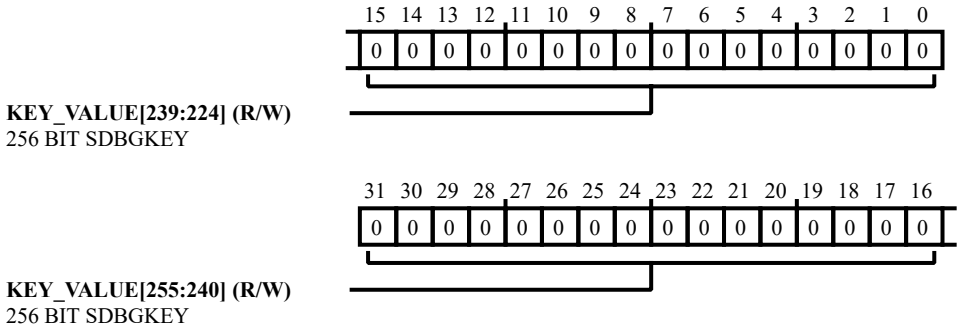

Figure 48-471: TAPC_SDBGKEY7 Register Diagram

Table 48-472: TAPC_SDBGKEY7 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	KEY_VALUE	256 BIT SDBGKEY. The `TAPC_SDBGKEY7.KEY_VALUE` bit field holds the value of the key against which a matching key provided by the debug user is compared to enable a debug session.

Secure Debug Key Control Register

The TAPC_SDBGKEY_CTL register contains a bit to configure configure validity for the secure debug keys.

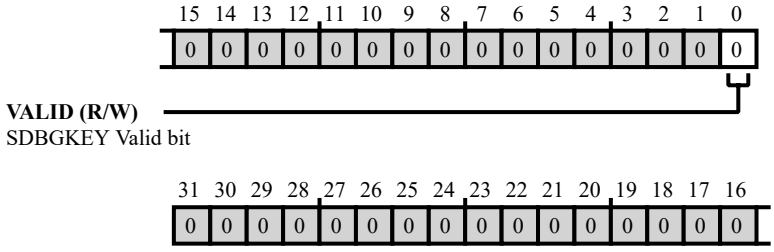

Figure 48-472: TAPC_SDBGKEY_CTL Register Diagram

Table 48-473: TAPC_SDBGKEY_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W)	VALID	SDBGKEY Valid bit.

Secure Debug Key Status Register

The TAPC_SDBGKEY_STAT register contains the PASS/FAIL status of the secure debug key match.

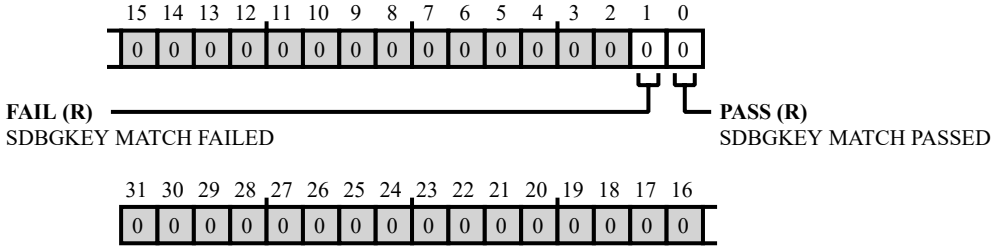

Figure 48-473: TAPC_SDBGKEY_STAT Register Diagram

Table 48-474: TAPC_SDBGKEY_STAT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
1 (R/NW)	FAIL	SDBGKEY MATCH FAILED.
0 (R/NW)	PASS	SDBGKEY MATCH PASSED.

USERCODE Register

The TAPC_USERCODE register stores the 32-bit USERCODE value for the SoC debug unit.

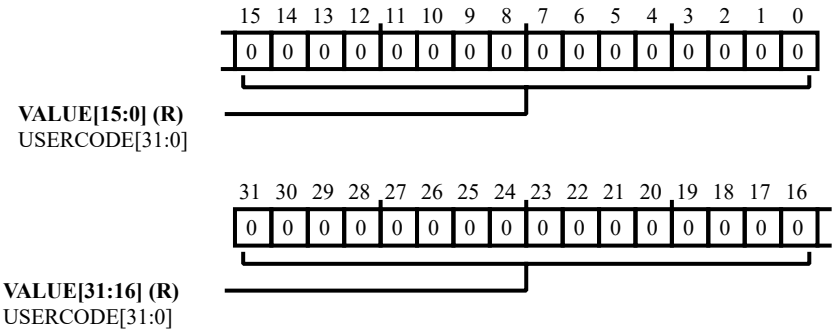

Figure 48-474: TAPC_USERCODE Register Diagram

Table 48-475: TAPC_USERCODE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	VALUE	USERCODE[31:0].

ADSP-2184x TRACE Register Descriptions

Your module description, here. (TRACE) contains the following registers.

Table 48-476: ADSP-2184x TRACE Register List

Name	Description
TRACE_AUTHSTATUS	Authentication Status Register.
TRACE_CIDR0	Component Identification Register 0.
TRACE_CIDR1	Component Identification Register 1.
TRACE_CIDR2	Component Identification Register 2.
TRACE_CIDR3	Component Identification Register 3.
TRACE_CLAIMCLR	Claim Tag Clear Register.
TRACE_CLAIMSET	Claim Tag Set Register.
TRACE_CSPSR	Current Port Size Register.
TRACE_CTPMR	Current Test Patterns/Modes Register.
TRACE_DEVARCH	Device Architecture Register.
TRACE_DEVID	Device Configuration Register.

Table 48-476: ADSP-2184x TRACE Register List (Continued)

Name	Description
TRACE_DEVTYPE	Device Type Identifier Register.
TRACE_EXTCTLIN	External Control Port In Register.
TRACE_EXTCTLOUT	External Control Port Out Register.
TRACE_FFCR	Formatter and Flush Control Register.
TRACE_FFSR	Formatter and Flush Status Register.
TRACE_FSCR	Formatter Synchronization Count Register.
TRACE_ITATBCTR0	Integration Test ATB Control Register 0.
TRACE_ITATBCTR1	Integration Test ATB Control Register 1.
TRACE_ITATBCTR2	Integration Test ATB Control Register 2.
TRACE_ITATBDATA0	Integration Test ATB Data Register 0.
TRACE_ITCTRL	Integration Mode Control Register.
TRACE_ITOUTCTR	Integration Test Output Control Register.
TRACE_ITTRFLIN	Integration Test Trigger In and Flush In Register.
TRACE_PIDR0	Peripheral Identification Register 0.
TRACE_PIDR1	Peripheral Identification Register 1.
TRACE_PIDR2	Peripheral Identification Register 2.
TRACE_PIDR3	Peripheral Identification Register 3.
TRACE_PIDR4	Peripheral Identification Register 4.
TRACE_PIDR5	Peripheral Identification Register 5.
TRACE_PIDR6	Peripheral Identification Register 6.
TRACE_PIDR7	Peripheral Identification Register 7.
TRACE_SSPSR	Supported Port Size Register.
TRACE_STMR	Supported Trigger Modes Register.
TRACE_STPMR	Supported Test Patterns/Modes Register.
TRACE_TCMR	Trigger Counter Multiplier Register.
TRACE_TCVR	Trigger Counter Value Register.
TRACE_TPRCR	Test Pattern Repeat Counter Register.

Authentication Status Register.

Reports the current status of the authentication control signals.

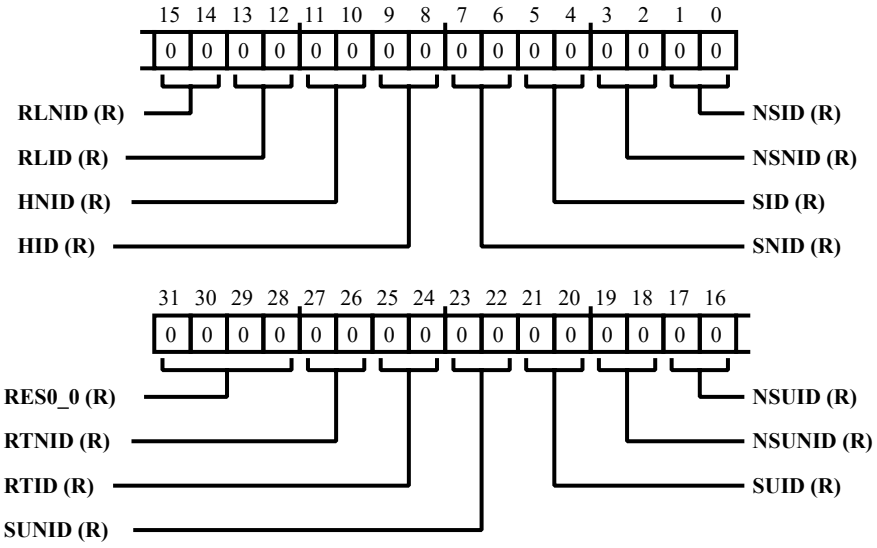

Figure 48-475: TRACE_AUTHSTATUS Register Diagram

Table 48-477: TRACE_AUTHSTATUS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:28 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
27:26 (R/NW)	RTNID	. Root non-invasive debug.	
		0	Separate Root non-invasive debug enable not implemented or Root state non-invasive debug features not implemented.
		1	Reserved.
		2	Implemented and disabled.
		3	Implemented and enabled.

Table 48-477: TRACE_AUTHSTATUS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
25:24 (R/NW)	RTID	. Root invasive debug.	
		0	Separate Root invasive debug enable not implemented or Root state invasive debug features not implemented.
		1	Reserved.
		2	Implemented and disabled.
		3	Implemented and enabled.
23:22 (R/NW)	SUNID	. Secure unprivileged non-invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.
21:20 (R/NW)	SUID	. Secure unprivileged invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.
19:18 (R/NW)	NSUNID	. Non-secure unprivileged non-invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.
17:16 (R/NW)	NSUID	. Non-secure unprivileged invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.

Table 48-477: TRACE_AUTHSTATUS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15:14 (R/NW)	RLNID	. Realm non-invasive debug.	
		0	Separate Realm non-invasive debug enable not implemented or Realm state non-invasive debug features not implemented.
		1	Reserved.
		2	Implemented and disabled.
		3	Implemented and enabled.
13:12 (R/NW)	RLID	. Realm invasive debug.	
		0	Separate Realm invasive debug enable not implemented or Realm state invasive debug features not implemented.
		1	Reserved.
		2	Implemented and disabled.
		3	Implemented and enabled.
11:10 (R/NW)	HNID	. Hypervisor non-invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.
9:8 (R/NW)	HID	. Hypervisor invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.

Table 48-477: TRACE_AUTHSTATUS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7:6 (R/NW)	SNID	. Secure non-invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.
5:4 (R/NW)	SID	. Secure invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.
3:2 (R/NW)	NSNID	. Non-secure non-invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.
1:0 (R/NW)	NSID	. Non-secure invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.

Component Identification Register 0.

The CIDR0 register is part of the set of component identification registers.

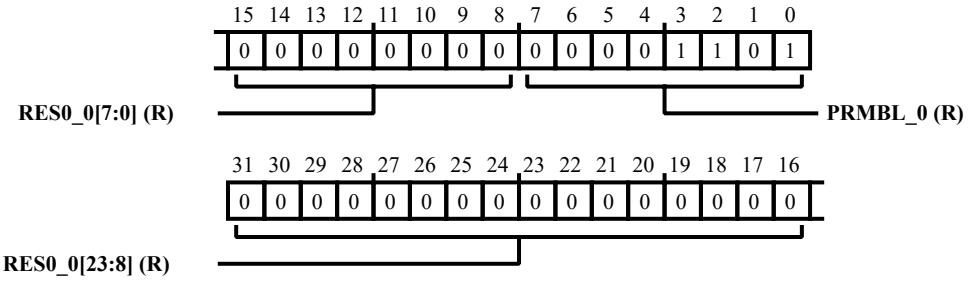

Figure 48-476: TRACE_CIDR0 Register Diagram

Table 48-478: TRACE_CIDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PRMBL_0	. Preamble. Returns 0x0D.

Component Identification Register 1.

The CIDR1 register is part of the set of component identification registers.

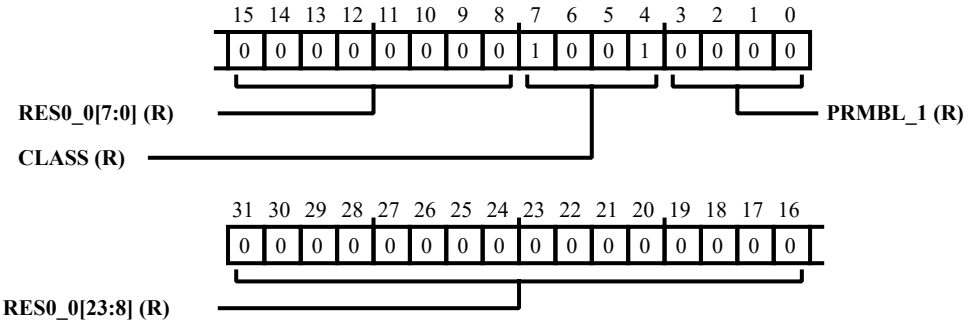

Figure 48-477: TRACE_CIDR1 Register Diagram

Table 48-479: TRACE_CIDR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
7:4 (R/NW)	CLASS	. Component class.	
		9	CoreSight component.
		15	CoreLink, PrimeCell, or system component.
3:0 (R/NW)	PRMBL_1	. Preamble. Returns 0x0.	

Component Identification Register 2.

The CIDR2 register is part of the set of component identification registers.

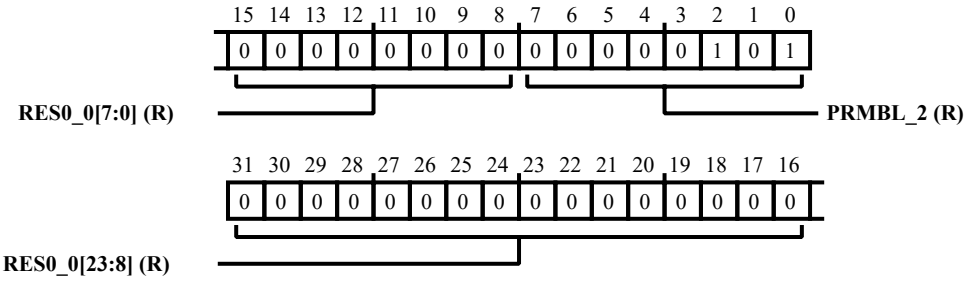

Figure 48-478: TRACE_CIDR2 Register Diagram

Table 48-480: TRACE_CIDR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PRMBL_2	. Preamble. Returns 0x05.

Component Identification Register 3.

The CIDR3 register is part of the set of component identification registers.

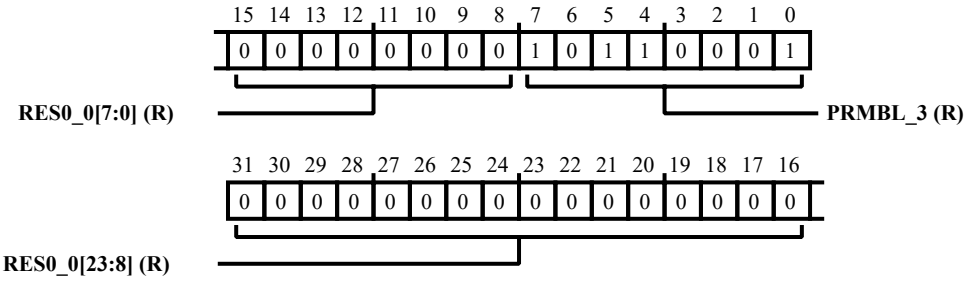

Figure 48-479: TRACE_CIDR3 Register Diagram

Table 48-481: TRACE_CIDR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PRMBL_3	. Preamble. Returns 0xB1.

Claim Tag Clear Register.

This register forms one half of the claim tag value. On writes, this location enables individual bits to be cleared. On reads, it returns the current claim tag value.

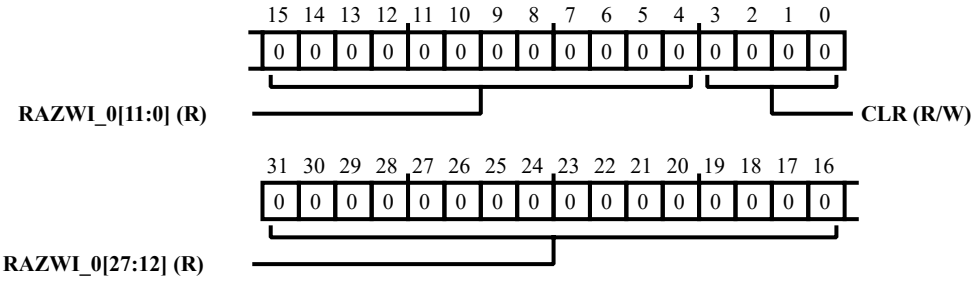

Figure 48-480: TRACE_CLAIMCLR Register Diagram

Table 48-482: TRACE_CLAIMCLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:4 (R/NW)	RAZWI_0	. RAZ/WI.
3:0 (R/W)	CLR	. A bit-programmable register bank that clears the claim tag value. It is zero at reset. It is used by software agents to signal to each other ownership of the hardware. It has no direct effect on the hardware itself.

Claim Tag Set Register.

This register forms one half of the claim tag value. On writes, this location enables individual bits to be set. On reads, it returns the number of bits that can be set.

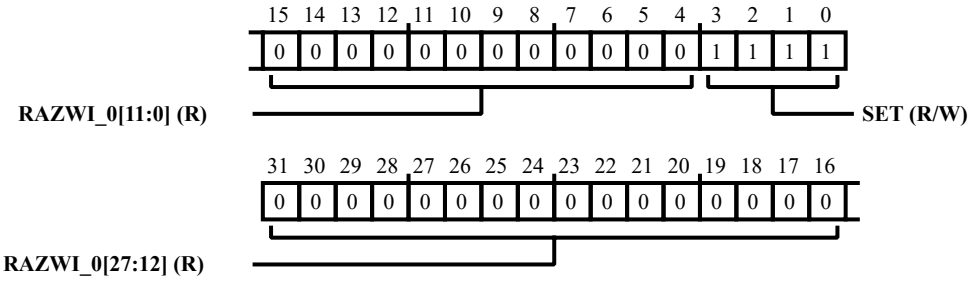

Figure 48-481: TRACE_CLAIMSET Register Diagram

Table 48-483: TRACE_CLAIMSET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:4 (R/NW)	RAZWI_0	. RAZ/WI.
3:0 (R/W)	SET	. A bit-programmable register bank that sets the claim tag value. A read returns a logic 1 for all implemented locations.

Current Port Size Register.

The CSPSR register shows the currently selected size of the tracedata port. It has the same format as the Supported Port Size Register but only one bit is set to show the currently selected port size. If a bit that is indicated as not supported in the SSPSR is set in the CSPSR, it can corrupt the output trace stream, in trace capture mode, and the trace patterns in pattern generation mode. If more than one bit is set, this register indicates the programmed size. However, the port size is internally resolved to the highest order set bit. This register must not be modified while the trace port is still active, or without correctly stopping the formatter. If this happens, it can result in data not being aligned to the port width, for example, data on an 8-bit trace port might not be byte aligned. For the register access to complete on APB clocking on traceclkin is needed.

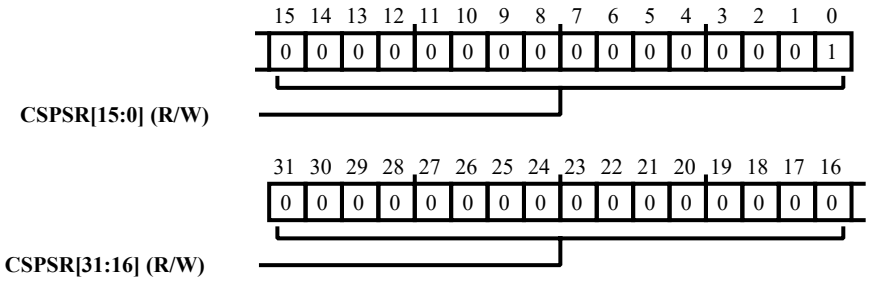

Figure 48-482: TRACE_CSPSR Register Diagram

Table 48-484: TRACE_CSPSR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	CSPSR	. Currently selected size of the tracedata port.

Current Test Patterns/Modes Register.

The CTPMR register indicates the current test pattern or mode selected. Only one of the two mode bits, bits[17:16], can be set at any one time, but a multiple number of bits for the patterns can be set using bits [3:0]. When timed mode is selected, after the allotted number of cycles is reached, the mode automatically switches to off mode. The pattern with higher bit index is output first when multiple patterns are selected. When no pattern is selected then a default pattern (00/00) is used instead. In continuous mode, the pattern generator continues to send patterns until CTPMR.PCONTEN bit is cleared by software. If multiple patterns are enabled, after sending out all enabled patterns, the pattern generator switches back to the first pattern type and continues to do so until stopped by software. When no pattern is selected then the default pattern (00/00) is used instead. Writing to this register when timed or continuous pattern mode is already enabled causes the current pattern generation to be abandoned and to be restarted with the new pattern mode and new pattern set. Writing to TPRCR or CSPSR when timed or continuous pattern mode is already enabled causes the current pattern generation to be abandoned and to be restarted. The reset value of this register is 0x00000000 which indicates off mode with no selected patterns. For the register access to complete on APB clocking on traceclkin is needed.

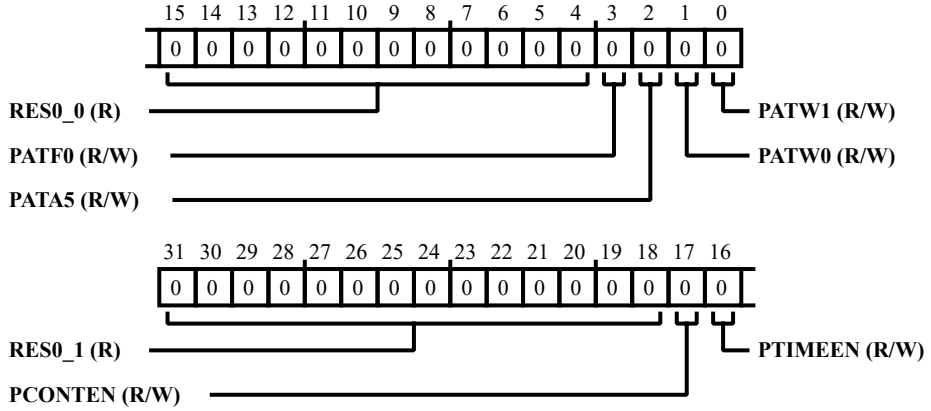

Figure 48-483: TRACE_CTPMR Register Diagram

Table 48-485: TRACE_CTPMR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:18 (R/NW)	RES0_1	. Reserved bit or field with SBZP behavior.	
17 (R/W)	PCONTEN	. Continuous Pattern Mode. Indicates whether continuous pattern mode is enabled:.	
		0	Mode disabled.
		1	Mode enabled.

Table 48-485: TRACE_CTPMR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
16 (R/W)	PTIMEEN	. Timed Pattern Mode. Indicates whether timed pattern mode is enabled:.	
		0	Mode disabled.
		1	Mode enabled.
15:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
3 (R/W)	PATF0	. FF/00 Pattern. Indicates whether the FF/00 pattern is enabled as output over the Trace Port. All pins toggle simultaneously as 1-0-1-0.	
		0	Pattern disabled.
		1	Pattern enabled.
2 (R/W)	PATA5	. 55/AA Pattern. Indicates whether the 55/AApattern is enabled as output over the Trace Port. The odd numbered pins toggle as 0-1-0-1, while the even numbered pins toggle as 1-0-1-0, simultaneously.	
		0	Pattern disabled.
		1	Pattern enabled.
1 (R/W)	PATW0	. Walking 0 Pattern. Indicates whether the walking 0s pattern is enabled as output over the Trace port. To start with, all pins are set to 1, except tracedata[0] which is driven LOW. In each subsequent cycle, the 0 bit shifts to its left by 1 position and eventually rotates around from its starting position, based on the CSPSR value, to tracedata[0], provided the pattern mode remains enabled for a sufficient number of cycles. When timed mode is selected, after the allotted number of cycles is reached (See TPRCR, 0x208), the wsmode automatically switches to off mode. The pattern with higher bit index is output first when multiple patterns are selected.	
		0	Pattern disabled.
		1	Pattern enabled.
0 (R/W)	PATW1	. Walking 1s Pattern. Indicates whether the walking 1s pattern is enabled as output over the Trace Port. It is similar to the walking 0s pattern except that tracedata[0] is set to 1 to start with and all other bits are 0. It is this set bit that rotates through all the selected pins of the tracedata port.	
		0	Pattern disabled.
		1	Pattern enabled.

Device Architecture Register.

Identifies the architect and architecture of a CoreSight component. The architect might differ from the designer of a component, for example Arm defines the architecture but another company designs and implements the component.

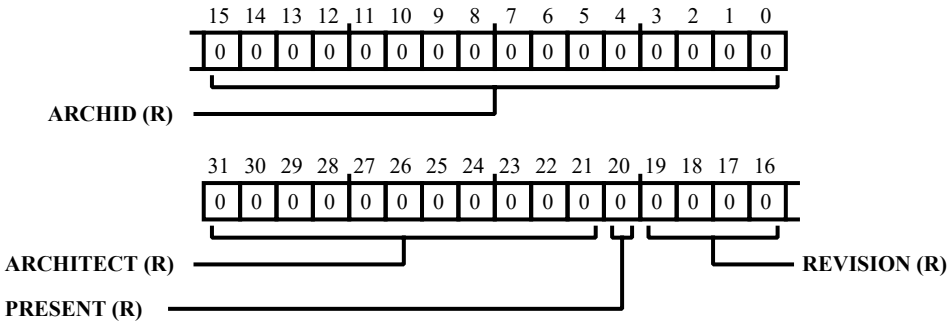

Figure 48-484: TRACE_DEVARCH Register Diagram

Table 48-486: TRACE_DEVARCH Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:21 (R/NW)	ARCHITECT	. Defines the architect of the component.	
		571	Arm.
20 (R/NW)	PRESENT	. Indicates the presence of this register.	
		0	DEVARCH is not present.
		1	DEVARCH is present.
19:16 (R/NW)	REVISION	. Architecture revision. Returns the revision of the architecture that the ARCHID field specifies.	
15:0 (R/NW)	ARCHID	. Architecture ID. Returns a value that identifies the architecture of the component.	
		2583	Memory Access Port v2 architecture.
		2599	JTAG Access Port v2 architecture.
		2631	Unknown Access Port v2 architecture.
		2807	CoreSight ROM architecture.
		6676	CTI architecture.

Device Configuration Register.

This register is IMPLEMENTATION DEFINED for each Part Number and Designer. The register indicates the capabilities of the component.

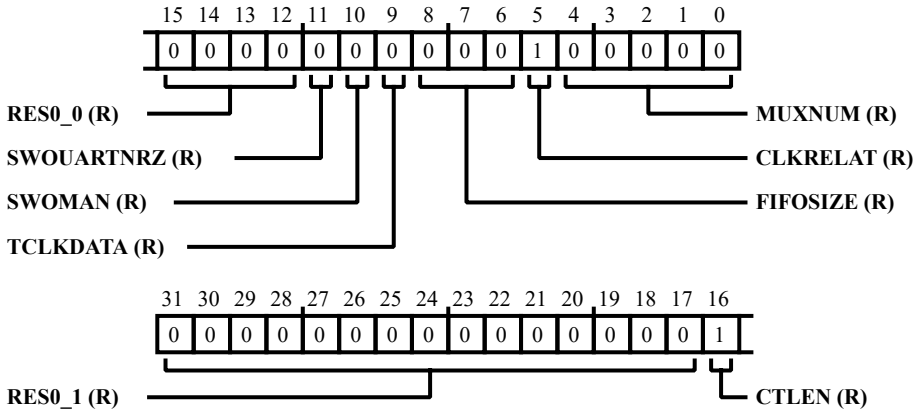

Figure 48-485: TRACE_DEVID Register Diagram

Table 48-487: TRACE_DEVID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:17 (R/NW)	RES0_1	. Reserved bit or field with SBZP behavior.
16 (R/NW)	CTLEN	. Trace Capture Enable support. Reads 0x1, which indicates that the CTL register is implemented and the software can enable and disable trace capture by programming the CTL register.
15:12 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
11 (R/NW)	SWOUARTNRZ	. Serial Wire Output, UART or NRZ support. Reads 0x0, which indicates that Serial Wire Output, UART or NRZ, is not supported.
10 (R/NW)	SWOMAN	. Serial Wire Output, Manchester-encoded format support. Reads 0x0, which indicates that Serial Wire Output, Manchester-encoded format, is not supported.
9 (R/NW)	TCLKDATA	. Trace Clock Plus Data support. Reads 0x0, which indicates that trace clock and data is supported.

Table 48-487: TRACE_DEVID Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
8:6 (R/NW)	FIFOSIZE	. FIFO size in powers of 2. Reads 0x0, indicating that the FIFO size is implementation-defined and is not visible in the programmers model.
5 (R/NW)	CLKRELAT	. Relationship between clk and traceclkin. Reads 0x1 which indicates that these two clocks are asynchronous.
4:0 (R/NW)	MUXNUM	. Indicates a hidden level of input multiplexing. When non-zero, this value indicates the type of multiplexing on the input to the ATB. Currently only 0x00 is supported, that is, no multiplexing is present. This value helps detect the ATB structure.

Device Type Identifier Register.

A debugger can use this register to get information about a component that has an unrecognized Part number.

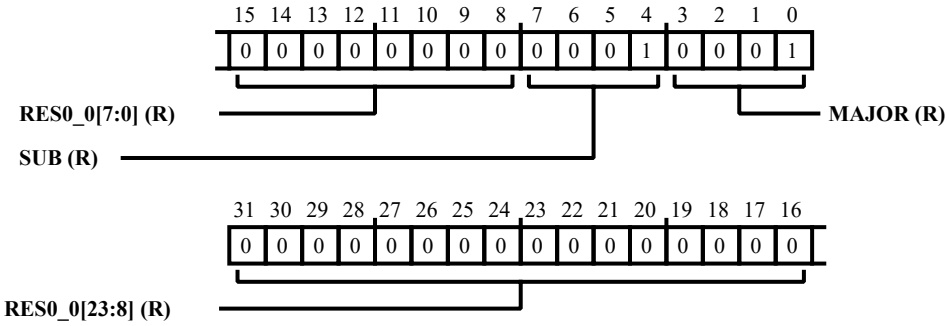

Figure 48-486: TRACE_DEVTYPE Register Diagram

Table 48-488: TRACE_DEVTYPE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:4 (R/NW)	SUB	. Minor classification. Returns 0x1, indicating this component is a Trace Port.
3:0 (R/NW)	MAJOR	. Major classification. Returns 0x1, indicating this component is a Trace Sink.

External Control Port In Register.

Indicates the current status of external control input port extctl_in[7:0]. It can be used as a feedback mechanism for any serializers, pin sharing multiplexers, or other solutions that might be added to the trace output pins either for pin control or a high-speed trace port solution.

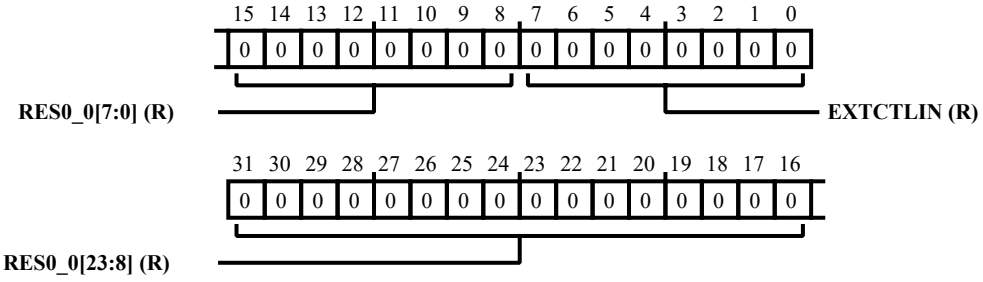

Figure 48-487: TRACE_EXTCTLIN Register Diagram

Table 48-489: TRACE_EXTCTLIN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	EXTCTLIN	. This 8-bit field shows the current status of external control input port extctl_in[7:0]. The reset value depends on the external source driving this port.

External Control Port Out Register.

Value to be driven on external control output port extctl_out[7:0]. It can be used as a control mechanism for any serializers, pin sharing multiplexers, or other solutions that might be added to the trace output pins either for pin control or a high-speed trace port solution.

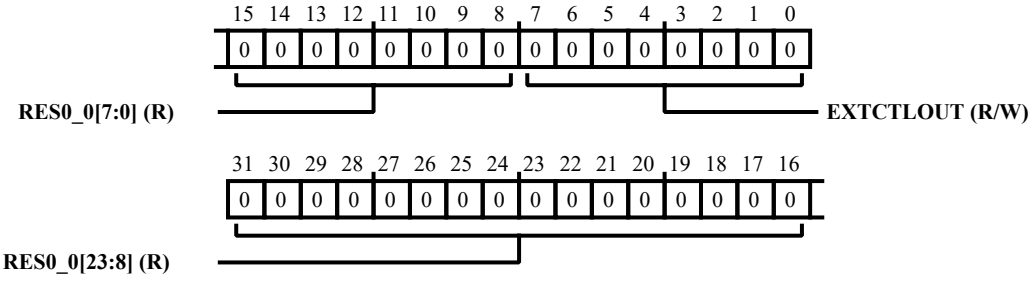

Figure 48-488: TRACE_EXTCTLOUT Register Diagram

Table 48-490: TRACE_EXTCTLOUT Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/W)	EXTCTLOUT	. This 8-bit field holds the value to be driven on the external control output port extctl_out[7:0].

Formatter and Flush Control Register.

The FFCR controls the generation of stop, trigger and flush events. The insertion of a flush completion packet and the insertion of a trigger packet in the formatted trace is enabled here. In bypass mode formatting is disabled and triggers are indicated on tracectl pin, bits[1:0] must be 0b00. In normal mode formatting is enabled and triggers are indicated on tracectl pin, bits[1:0] must be 0b01. In continuous mode formatting is enabled and triggers are embedded in the trace stream with Triger Byte ID 0x7D with a single byte of data payload = 0x00, bits[1:0] must be 0b10. Setting both bits is the same as setting bit[1]. All three flush-generating conditions can be enabled together. However, if a second or third flush event is generated from another condition then the current flush completes before the next flush is serviced. Flush from flushin takes priority over flush from trigger, which in turn completes before a manuallyactivated flush. All trigger indication conditions can be enabled simultaneously although this can cause the appearance of multiple triggers if flush using trigger is also enabled. Both Stop On settings can be enabled although if Flush on Trigger is set up, none of the flushed data is stored. ARM recommends that you change the trace port width without enabling continuous mode. Enabling continuous mode causes data to be sent from the trace port and modifying the port size can result in data not being aligned.

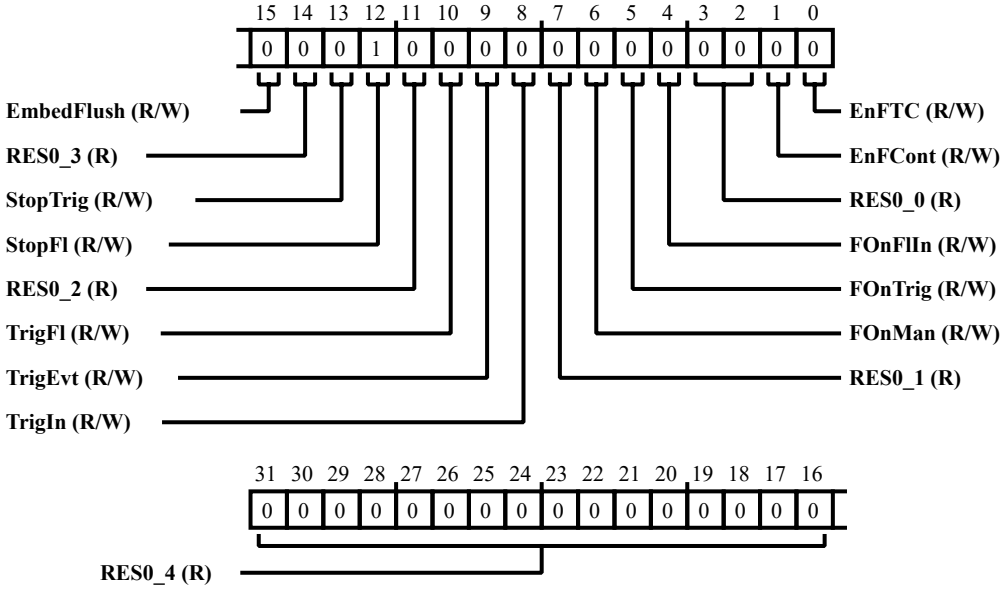

Figure 48-489: TRACE_FFCR Register Diagram

Table 48-491: TRACE_FFCR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:16 (R/NW)	RES0_4	. Reserved bit or field with SBZP behavior.

Table 48-491: TRACE_FFCR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15 (R/W)	EMBEDFLUSH	. Embed flush completion packet, Flush ID. Enables insertion of Flush ID 0x7B with a single byte of data payload = 0x00 in the output trace, after the last flush data byte, when a flush completes on the ATB receiver interface. This bit is effective only in Normal and Continuous formatter modes. In Bypass mode, the Flush ID insertion remains disabled and this bit is ignored.	
		0	Disable Flush ID insertion.
		1	Enable Flush ID insertion.
14 (R/NW)	RES0_3	. Reserved bit or field with SBZP behavior.	
13 (R/W)	STOPTRIG	. Stop on Trigger Event. Stops the formatter after a trigger event is observed.	
		0	Disable stopping the formatter after a trigger event is observed.
		1	Enable stopping the formatter after a trigger event is observed.
12 (R/W)	STOPFL	. Stop on Flush Completion. Forces the FIFO to drain off any partially completed packets after a flush completion and stops the formatter.	
		0	Disable stopping the formatter when afready_rx is received.
		1	Enable stopping the formatter when afready_rx is received.
11 (R/NW)	RES0_2	. Reserved bit or field with SBZP behavior.	
10 (R/W)	TRIGFL	. Trigger on Flush Completion.	
		0	Disable trigger indication on flush completion, that is, when afready_rx is high.
		1	Enable trigger indication on flush completion.
9 (R/W)	TRIGEVT	. Trigger on Trigger Event. Indicates a trigger when the trigger counter reaches 0 while decrementing. If FFCR.StopTrig is set, this bit is ignored.	
		0	Disable trigger indication on trigger event.
		1	Enable trigger indication on trigger event.

Table 48-491: TRACE_FFCR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8 (R/W)	TRIGIN	. Trigger on trigin.	
		0	Disable trigger indication when trigin is asserted.
		1	Enable trigger indication when trigin is asserted.
7 (R/NW)	RES0_1	. Reserved bit or field with SBZP behavior.	
6 (R/W)	FONMAN	. Flush Manual. Writing 1 to this bit generates a flush request on afvalid_rx pin, writing 0 has no effect. It is automatically cleared when the generated flush request completes and afready_rx is received by the TPIU. Reading this bit returns its current value.	
5 (R/W)	FONTRIG	. Flush on Trigger Event. Initiates a flush request when a trigger event occurs. A trigger event occurs when the trigger counter reaches 0 while decrementing, or, if the TCVR is 0x0 and trigin goes HIGH.	
		0	Disable generation of flush when a trigger event occurs.
		1	Enable generation of flush when a trigger event occurs.
4 (R/W)	FONFLIN	. Flush on flushin.	
		0	Disable generation of flush using flushin input.
		1	Enable generation of flush using flushin input.
3:2 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
1 (R/W)	ENFCONT	. Enable Continuous Formatting Mode and Enable Formatter. The trigger packets are embedded in the trace stream. This bit can only be changed when FFSR.FtStopped is HIGH.	
0 (R/W)	ENFTC	. Enable Formatter. The trigger packets are not embedded in the trace stream and the trace disable cycles and triggers are indicated by tracectl pin where present. This bit can only be changed when FFSR.FtStopped is HIGH.	

Formatter and Flush Status Register.

The FFSR indicates the current status of formatter and flush features available in the TPIU.

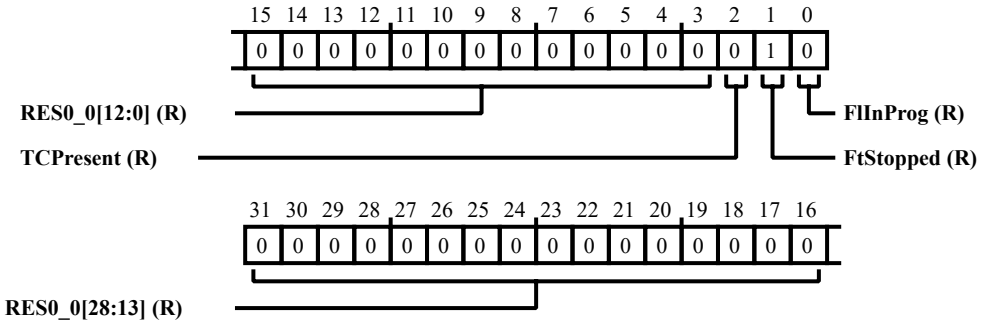

Figure 48-490: TRACE_FFSR Register Diagram

Table 48-492: TRACE_FFSR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:3 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
2 (R/NW)	TCPRESENT	. Indicates whether the tracectl pin is available for use, based on the tie-off value of tpctl_valid.	
		0	tracectl pin not present. The data formatter must be used and in continuous mode.
		1	tracectl pin present.
1 (R/NW)	FTSTOPPED	. The formatter has received a stop request and all trace data and post-amble is sent. Any further trace on the ATB interface is dropped and atready_rx is asserted.	
		0	Formatter running.
		1	Formatter stopped.
0 (R/NW)	FLINPROG	. Indicates whether a flush is in progress. It is set when the TPIU sends a flush request on its ATB receiver interface. The bit remains set until the ATB flush is complete and the last byte of flush data, including the flush ID payload if FFCR.EmbedFlush is set, has been output on the trace port.	
		0	No ongoing flush.
		1	Flush in progress.

Formatter Synchronization Count Register.

The FSCR register indicates the maximum number of formatter frames sent to Trace Port after which a synchronization packet must be inserted. The register value indicates the programmed counter value and not the current state of the counter. The TPIU uses a frame sync counter that contains the number of formatter frames since the last frame synchronization packet. The counter is a 12-bit counter with a maximum count value of 4096. This equates to synchronization every 65536 bytes (4096 packets x 16 bytes per packet). On reset, the FSCR is set up for a synchronization packet every 1024 bytes, that is every 64 formatter frames. If the formatter is configured in continuous mode, full and half-word sync frames are inserted during normal operation. In this case, the counter value is the maximum number of complete frames between full synchronization packets. For the register access to complete on APB clocking on traceclkin is needed.

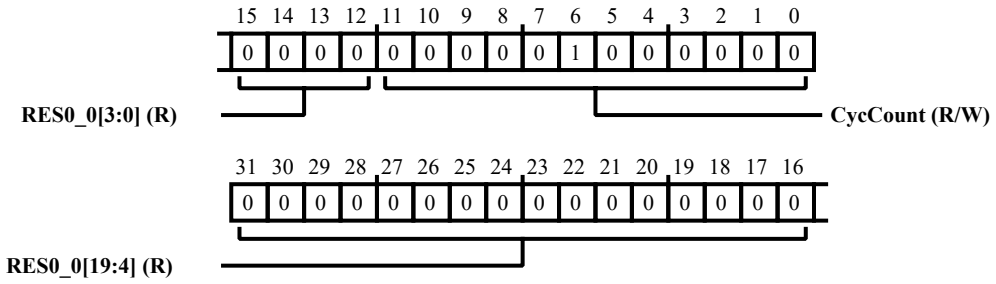

Figure 48-491: TRACE_FSCR Register Diagram

Table 48-493: TRACE_FSCR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:12 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
11:0 (R/W)	CYCCOUNT	. 12-bit counter value to indicate the number of complete frames between full synchronization packets. It is also used to send periodic synchronization requests to the ATB transmitter using syncreq_rx output. If this field is programmed as 0x0, the synchronization counter is disabled. If this field is programmed with 0x1-0x7 the programmed value is 0x8. The reset value is 0x040, that is, 64 frames = 1024 bytes.

Integration Test ATB Control Register 0.

This register indicates the values of atvalid_rx, afready_rx, and atbytes_rx inputs in integration mode. Reads are allowed even in functional mode, but the register is disabled and does not get updated even if the inputs change. The reset value depends on an external source driving these inputs.

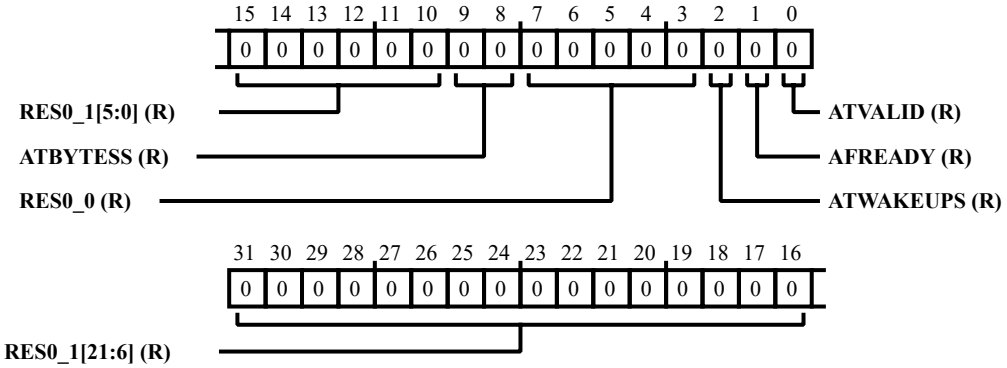

Figure 48-492: TRACE_ITATBCTR0 Register Diagram

Table 48-494: TRACE_ITATBCTR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:10 (R/NW)	RES0_1	. Reserved bit or field with SBZP behavior.
9:8 (R/NW)	ATBYTESS	. Reads the value of atbytes_rx[1:0] in integration mode.
7:3 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
2 (R/NW)	ATWAKEUPS	. Reads the value of atwakeup_rx in integration mode.
1 (R/NW)	AFREADY	. Reads the value of afready_rx in integration mode.
0 (R/NW)	ATVALID	. Reads the value of atvalid_rx in integration mode.

Integration Test ATB Control Register 1.

This register indicates the value of the atid_rx input in integration mode. Reads are allowed even in functional mode, but the register is disabled and does not get updated even if the inputs change. The reset value depends on external source driving these inputs.

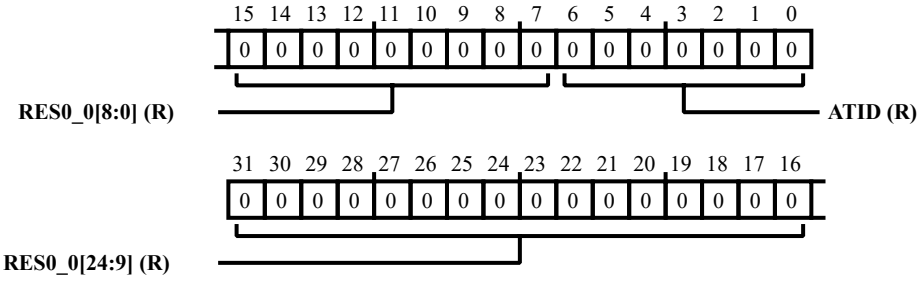

Figure 48-493: TRACE_ITATBCTR1 Register Diagram

Table 48-495: TRACE_ITATBCTR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:7 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
6:0 (R/NW)	ATID	. Reads the value of atid_rx[6:0] in integration mode.

Integration Test ATB Control Register 2.

This register enables control of the atready_rx, afvalid_rx, and syncreq_rx outputs in integration mode. Writes to this register are allowed in integration mode as well as functional mode. However, the programmed value is driven to the outputs only in integration mode.

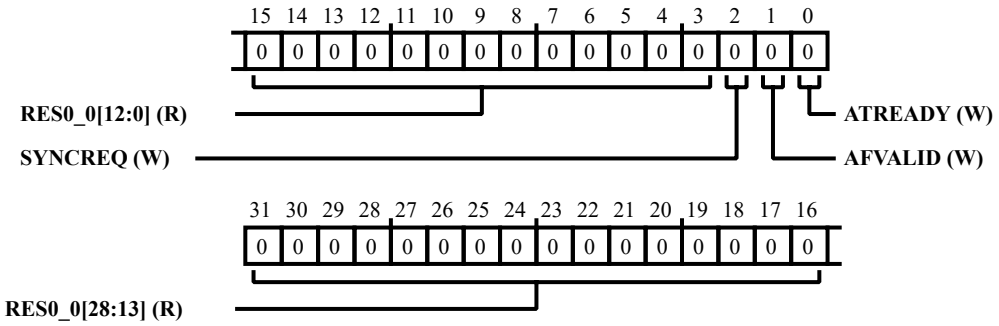

Figure 48-494: TRACE_ITATBCTR2 Register Diagram

Table 48-496: TRACE_ITATBCTR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:3 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
2 (RX/W)	SYNCREQ	. Sets the value of syncreq_rx in integration mode.
1 (RX/W)	AFVALID	. Sets the value of afvalid_rx in integration mode.
0 (RX/W)	ATREADY	. Sets the value of atready_rx in integration mode.

Integration Test ATB Data Register 0.

This register indicates the value of the atdata_rx input in integration mode. Only 5 bits are readable through this register, the MSB of each of the four data bytes and the LSB. Reads are allowed even in functional mode, but the register is disabled and does not get updated even if the inputs change. The reset value depends on the external source driving the inputs.

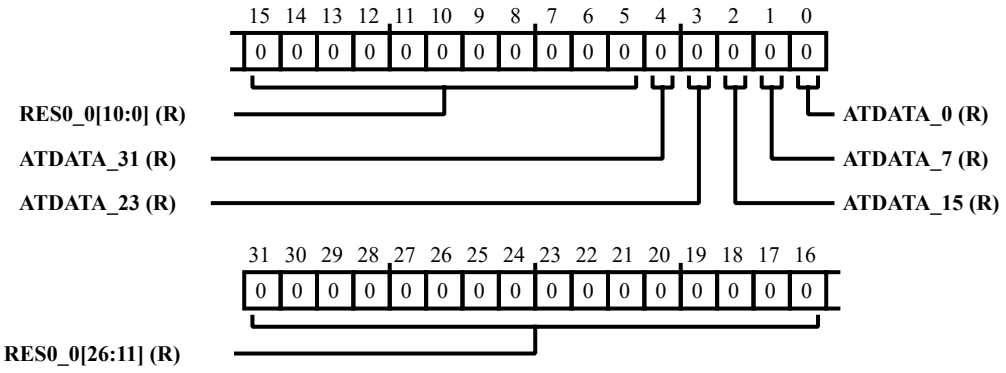

Figure 48-495: TRACE_ITATBDATA0 Register Diagram

Table 48-497: TRACE_ITATBDATA0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:5 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
4 (R/NW)	ATDATA_31	. Reads the value of atdata_rx[31] during integration mode.
3 (R/NW)	ATDATA_23	. Reads the value of atdata_rx[23] during integration mode.
2 (R/NW)	ATDATA_15	. Reads the value of atdata_rx[15] during integration mode.
1 (R/NW)	ATDATA_7	. Reads the value of atdata_rx[7] during integration mode.
0 (R/NW)	ATDATA_0	. Reads the value of atdata_rx[0] during integration mode.

Integration Mode Control Register.

The Integration Mode Control register is used to switch between functional mode and integration mode. After switching to integration mode and performing integration tests or topology detection, reset the system to ensure correct behavior of CoreSight and other connected system components.

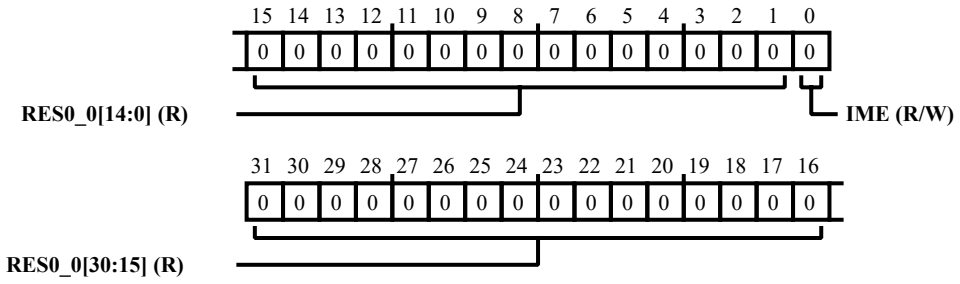

Figure 48-496: TRACE_ITCTRL Register Diagram

Table 48-498: TRACE_ITCTRL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:1 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
0 (R/W)	IME	. Integration Mode Enable.	
		0	The component must enter functional mode.
		1	The component must enter integration mode, and enable support for topology detection and integration testing.

Integration Test Output Control Register.

This register enables control of the flushcomp output in integration mode. Writes to this register are allowed in integration mode, as well as functional mode. However, the programmed value is driven to the output pin only in integration mode.

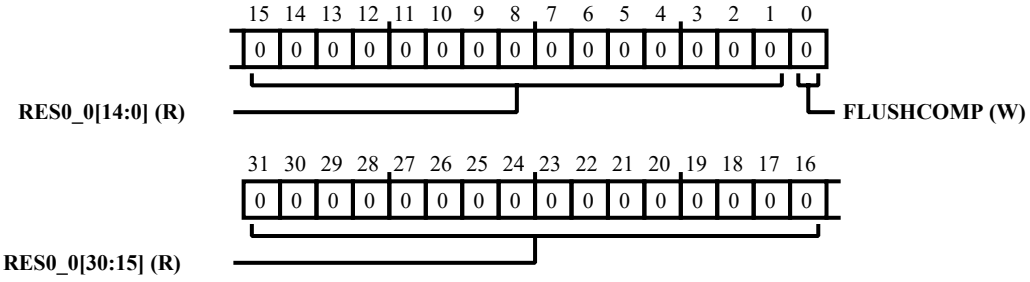

Figure 48-497: TRACE_ITOUTCTR Register Diagram

Table 48-499: TRACE_ITOUTCTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:1 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
0 (RX/W)	FLUSHCOMP	. Sets the value of flushcomp in integration mode.

Integration Test Trigger In and Flush In Register.

This register indicates the integration status of the flushin and trigin inputs in integration mode. Reads are allowed even in functional mode, but the register itself is disabled and does not get updated even if the inputs change. The reset value depends on the external source driving the inputs.

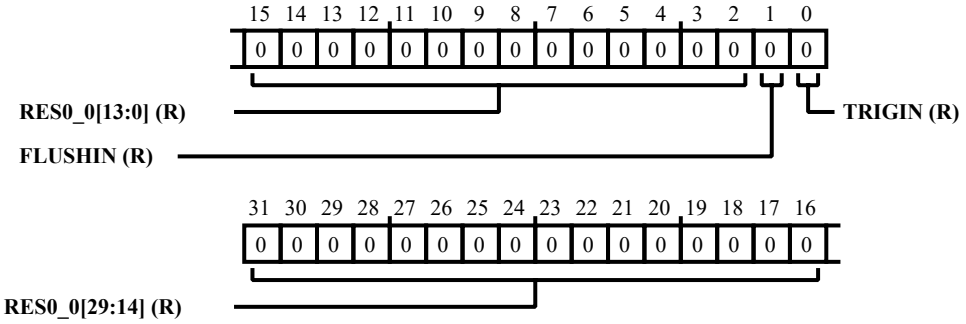

Figure 48-498: TRACE_ITTRFLIN Register Diagram

Table 48-500: TRACE_ITTRFLIN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:2 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
1 (R/NW)	FLUSHIN	. In integration mode, this bit latches to 1 on a rising edge of the flushin input. It is cleared when this register is read, or when integration mode is disabled.
0 (R/NW)	TRIGIN	. In integration mode, this bit latches to 1 on a rising edge of the trigin input. It is cleared when this register is read or when integration mode is disabled.

Peripheral Identification Register 0.

The PIDR0 register is part of the set of peripheral identification registers.

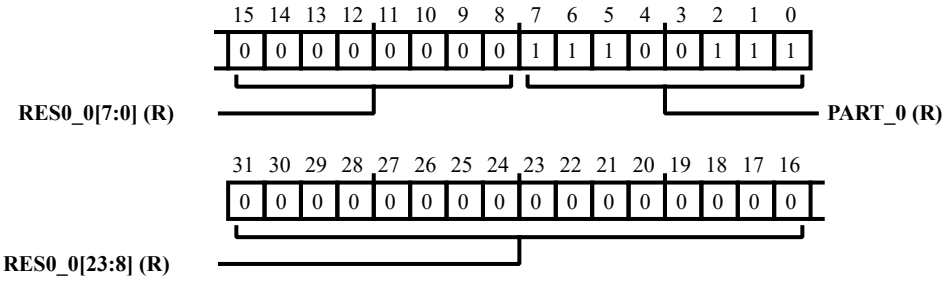

Figure 48-499: TRACE_PIDR0 Register Diagram

Table 48-501: TRACE_PIDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PART_0	. Part number, bits[7:0]. Taken together with PIDR1.PART_1 it indicates the component. The Part Number is selected by the designer of the component.

Peripheral Identification Register 1.

The PIDR1 register is part of the set of peripheral identification registers.

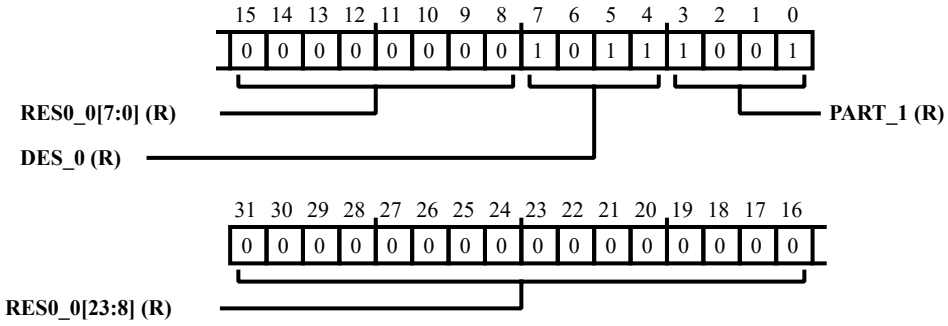

Figure 48-500: TRACE_PIDR1 Register Diagram

Table 48-502: TRACE_PIDR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:4 (R/NW)	DES_0	. JEP106 identification code, bits[3:0]. Together, with PIDR4.DES_2 and PIDR2.DES_1, they indicate the designer of the component and not the implementer, except where the two are the same.
3:0 (R/NW)	PART_1	. Part number, bits[11:8]. Taken together with PIDR0.PART_0 it indicates the component. The Part Number is selected by the designer of the component.

Peripheral Identification Register 2.

The PIDR2 register is part of the set of peripheral identification registers.

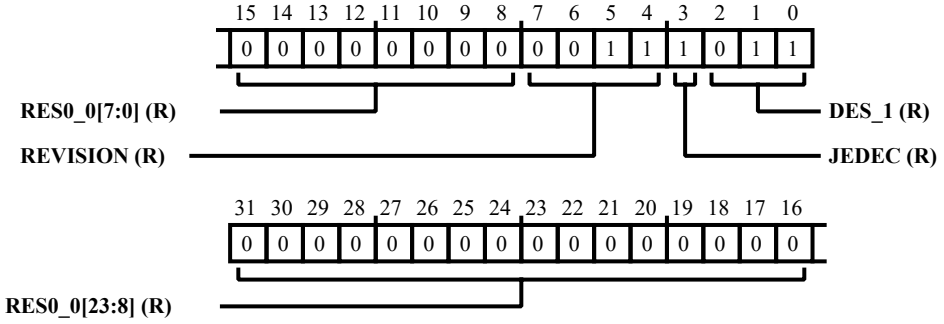

Figure 48-501: TRACE_PIDR2 Register Diagram

Table 48-503: TRACE_PIDR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:4 (R/NW)	REVISION	. Revision. It is an incremental value starting at 0x0 for the first design of a component. See the Component list in Chapter 1 for information on the RTL revision of the component.
3 (R/NW)	JEDEC	. 1 - Always set. Indicates that a JEDEC assigned value is used.
2:0 (R/NW)	DES_1	. JEP106 identification code, bits[6:4]. Together, with PIDR4.DES_2 and PIDR1.DES_0, they indicate the designer of the component and not the implementer, except where the two are the same.

Peripheral Identification Register 3.

The PIDR3 register is part of the set of peripheral identification registers.

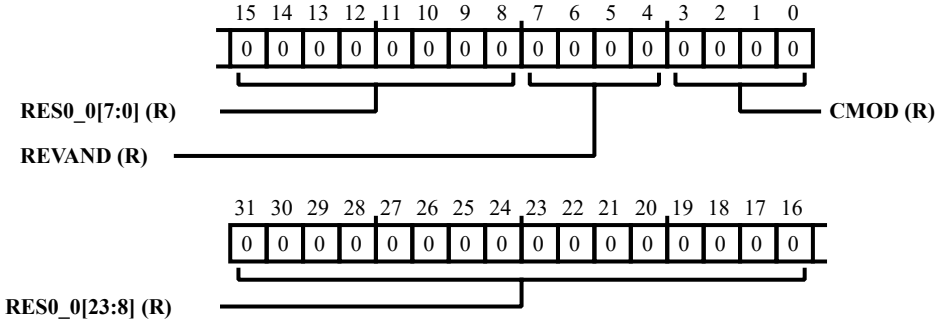

Figure 48-502: TRACE_PIDR3 Register Diagram

Table 48-504: TRACE_PIDR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:4 (R/NW)	REVAND	. This field indicates minor errata fixes specific to this design, for example metal fixes after implementation. In most cases this field is 0x0.
3:0 (R/NW)	CMOD	. Customer Modified. Where the component is reusable IP, this value indicates if the customer has modified the behavior of the component. In most cases this field is 0x0.

Peripheral Identification Register 4.

The PIDR4 register is part of the set of peripheral identification registers.

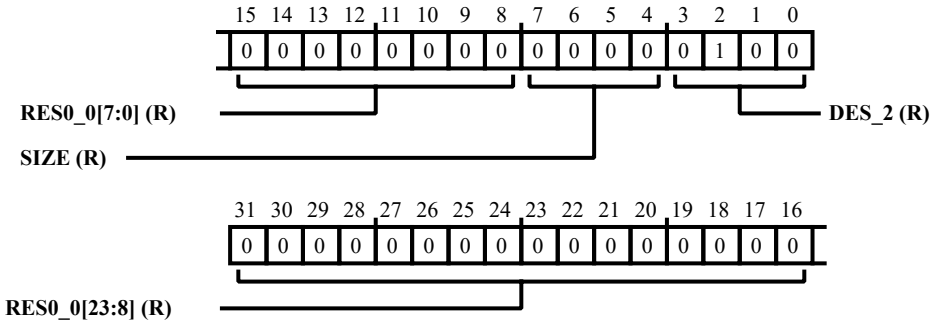

Figure 48-503: TRACE_PIDR4 Register Diagram

Table 48-505: TRACE_PIDR4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:4 (R/NW)	SIZE	. Indicates the memory size that is used by this component. Returns 0 indicating that the component uses an UNKNOWN number of 4KB blocks. Using the SIZE field to indicate the size of the component is deprecated.
3:0 (R/NW)	DES_2	. JEP106 continuation code. Together, with PIDR2.DES_1 and PIDR1.DES_0, they indicate the designer of the component and not the implementer, except where the two are the same.

Peripheral Identification Register 5.

The PIDR5 register is part of the set of peripheral identification registers.

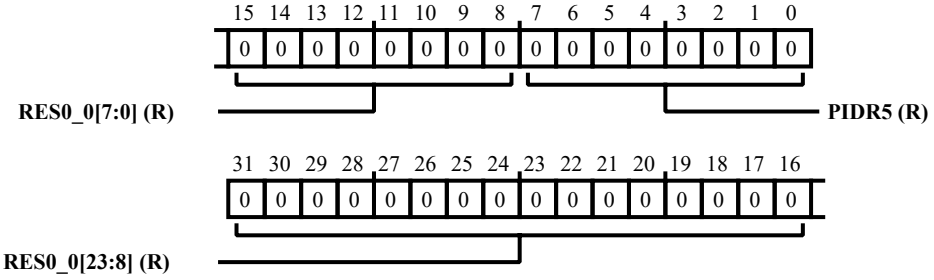

Figure 48-504: TRACE_PIDR5 Register Diagram

Table 48-506: TRACE_PIDR5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PIDR5	. Reserved.

Peripheral Identification Register 6.

The PIDR6 register is part of the set of peripheral identification registers.

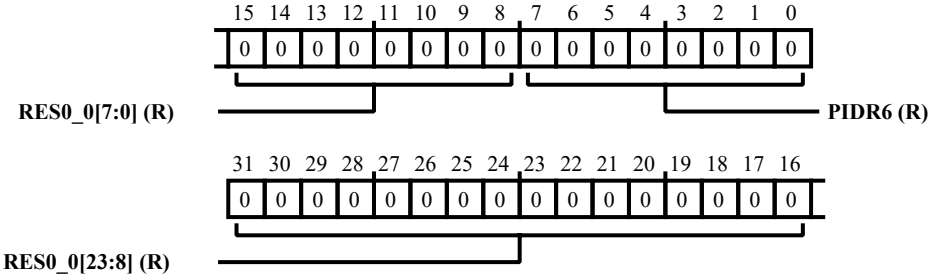

Figure 48-505: TRACE_PIDR6 Register Diagram

Table 48-507: TRACE_PIDR6 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PIDR6	. Reserved.

Peripheral Identification Register 7.

The PIDR7 register is part of the set of peripheral identification registers.

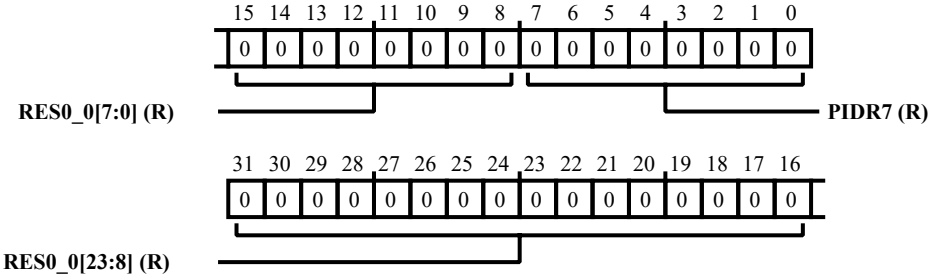

Figure 48-506: TRACE_PIDR7 Register Diagram

Table 48-508: TRACE_PIDR7 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PIDR7	. Reserved.

Supported Port Size Register.

The SSPSR register shows supported width configurations of the tracedata port. Each bit location represents a single port size that is supported, that is sizes 32 bits down to 1 bit, in bit locations [31:0]. If a bit is set, then that port size is supported. By default, the RTL is designed to support all port sizes. Port sizes, other than 1-bit, are configuration-dependent on the tie-off value of tp_maxdatasize. Bit[0] is always 1.

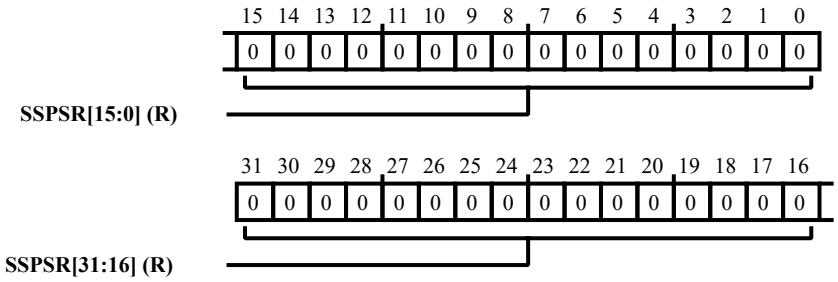

Figure 48-507: TRACE_SSPSR Register Diagram

Table 48-509: TRACE_SSPSR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	SSPSR	. Supported tracedata port sizes. Bit[0] is always 1.

Supported Trigger Modes Register.

The STMR register indicates the implemented Trigger Counter multipliers and other supported features of the trigger system.

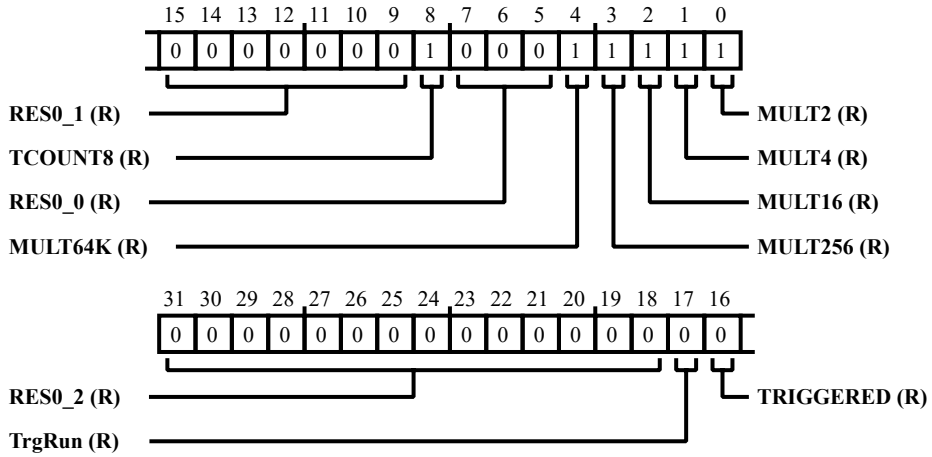

Figure 48-508: TRACE_STMR Register Diagram

Table 48-510: TRACE_STMR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:18 (R/NW)	RES0_2	. Reserved bit or field with SBZP behavior.	
17 (R/NW)	TRGRUN	. A trigger has occurred after a rising edge of trigin input, or a trigger packet (atid_rx = 0x7D) is received in the input trace:.	
		0	Either a trigger has not occurred or the counter is at 0.
		1	A trigger has occurred but the counter is not at 0.
16 (R/NW)	TRIGGERED	. A trigger has occurred after a rising edge of trigin input, or a trigger packet (atid_rx = 0x7D) is received in the input trace and the counter has reached 0. This bit is cleared when the TCVR or TCMR register is written.	
		0	Trigger has not occurred.
		1	Trigger has occurred.
15:9 (R/NW)	RES0_1	. Reserved bit or field with SBZP behavior.	
8 (R/NW)	TCOUNT8	. Returns 1 indicating that an 8-bit wide counter register is implemented for trigger insertion.	

Table 48-510: TRACE_STMR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
7:5 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
4 (R/NW)	MULT64K	. Returns 1, indicating that multiplying the trigger counter by 65536 is supported.
3 (R/NW)	MULT256	. Returns 1, indicating that multiplying the trigger counter by 256 is supported.
2 (R/NW)	MULT16	. Returns 1, indicating that multiplying the trigger counter by 16 is supported.
1 (R/NW)	MULT4	. Returns 1, indicating that multiplying the trigger counter by 4 is supported.
0 (R/NW)	MULT2	. Returns 1, indicating that multiplying the trigger counter by 2 is supported.

Supported Test Patterns/Modes Register.

The STPMR Register provides a set of known bit sequences or patterns that can be output over the trace port and can be detected by the TPA or TCD.

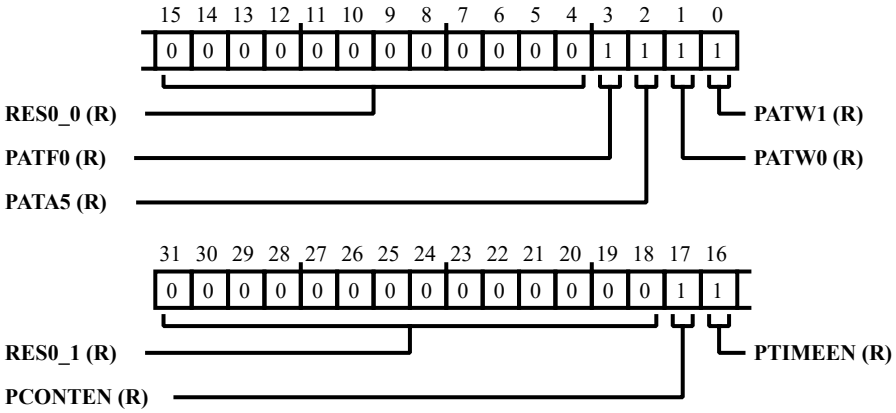

Figure 48-509: TRACE_STPMR Register Diagram

Table 48-511: TRACE_STPMR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:18 (R/NW)	RES0_1	. Reserved bit or field with SBZP behavior.
17 (R/NW)	PCONTEN	. Continuous Pattern Mode, returns 1 indicating that continuous pattern mode is supported.
16 (R/NW)	PTIMEEN	. Timed Pattern Mode, returns 1 indicating that timed pattern mode is supported.
15:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
3 (R/NW)	PATF0	. FF/00 Pattern, returns 1 indicating that the FF/00 pattern is supported over the trace port.
2 (R/NW)	PATA5	. 55/AA Pattern, returns 1 indicating that the 55/AA pattern is supported over the trace port.
1 (R/NW)	PATW0	. Walking 0 Pattern, returns 1 indicating that the walking 0s pattern is supported over the trace port.

Table 48-511: TRACE_STPMR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/NW)	PATW1	. Walking 1s Pattern, returns 1 indicating that the walking 1s pattern is supported over the trace port.

Trigger Counter Multiplier Register.

The TCMR register contains the selectors for the trigger counter multiplier. Several multipliers can be selected to create the required multiplier value between 1 (TCMR[4:0] = 0x0) and 2^31 (TCMR[4:0] = 0x1F). When more than one bit it set, the effective multiplier value is the product of selected multipliers. Writing to this register causes the trigger counter (the actual counter) to be reloaded and the state in the multipliers to be reset.

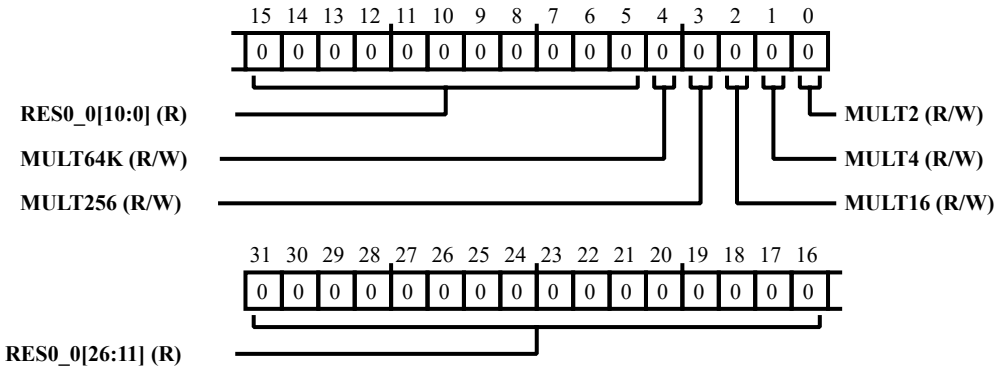

Figure 48-510: TRACE_TCMR Register Diagram

Table 48-512: TRACE_TCMR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:5 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
4 (R/W)	MULT64K	. Multiply the Trigger Counter by 65536:.	
		0	Multiplier disabled.
		1	Multiplier enabled.
3 (R/W)	MULT256	. Multiply the Trigger Counter by 256:.	
		0	Multiplier disabled.
		1	Multiplier enabled.
2 (R/W)	MULT16	. Multiply the Trigger Counter by 16:.	
		0	Multiplier disabled.
		1	Multiplier enabled.

Table 48-512: TRACE_TCMR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
1 (R/W)	MULT4	. Multiply the Trigger Counter by 4:.	
		0	Multiplier disabled.
		1	Multiplier enabled.
0 (R/W)	MULT2	. Multiply the Trigger Counter by 2:.	
		0	Multiplier disabled.
		1	Multiplier enabled.

Trigger Counter Value Register.

The TCVR register indicates the programmed trigger counter value. The TPIU implements a trigger counter that enables delaying the indication of triggers to any external connected trace capture devices. The counter is 8 bits wide and is intended only to be used with the counter multipliers within the Trigger Multiplier Register. When a trigger occurs (observed trigin=1 or atid_rx=0x7D), the TCVR.TrigCount value, with the TCMR, determines the number of words to be output from the formatter before the trigger is indicated on the Trace Port. When the trigger counter reaches zero, the value from the TCVR register is reloaded into the trigger counter. Writing to this register causes the trigger counter (the actual counter) to be reloaded. Reading this register returns the programmed count value and not the current count.

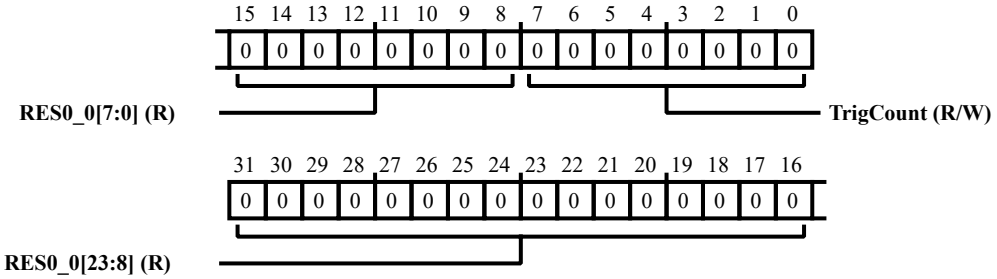

Figure 48-511: TRACE_TCVR Register Diagram

Table 48-513: TRACE_TCVR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/W)	TRIGCOUNT	. Programmed trigger counter value.

Test Pattern Repeat Counter Register.

This register indicates the number of times each test pattern is output on the Trace Port before switching to next pattern. For the register access to complete on APB clocking on traceclkin is needed.

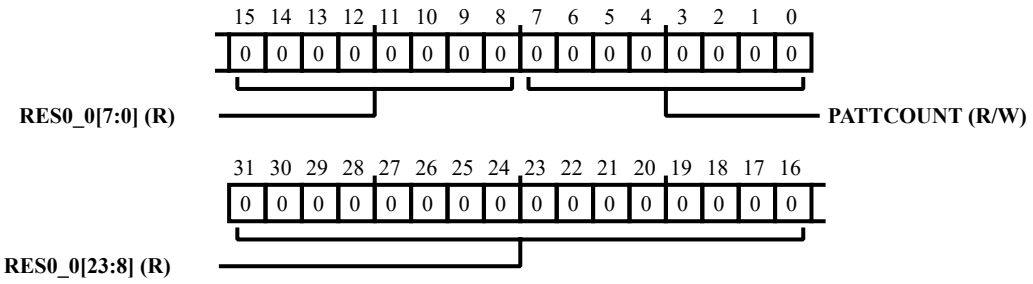

Figure 48-512: TRACE_TPRCR Register Diagram

Table 48-514: TRACE_TPRCR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/W)	PATTCOUNT	. An 8-bit counter value that indicates the number of traceclk cycles for which a pattern runs before it switches to the next enabled pattern. A write sets the initial counter value, and a read returns the programmed value. The pattern length is PATTCOUNT+1. The reset value is 0x0.

ADSP-2184x CSETF Register Descriptions

Your module description, here. (CSETF) contains the following registers.

Table 48-515: ADSP-2184x CSETF Register List

Name	Description
CSETF_AUTHSTATUS	Authentication Status Register.
CSETF_BUFWM	Buffer Level Water Mark.
CSETF_CBUFLEVEL	Current Buffer Fill Level.
CSETF_CIDR0	Component Identification Register 0.
CSETF_CIDR1	Component Identification Register 1.
CSETF_CIDR2	Component Identification Register 2.
CSETF_CIDR3	Component Identification Register 3.
CSETF_CLAIMCLR	Claim Tag Clear Register.

Table 48-515: ADSP-2184x CSETF Register List (Continued)

Name	Description
CSETF_CLAIMSET	Claim Tag Set Register.
CSETF_CTL	Control Register.
CSETF_DEVID	Device Configuration Register.
CSETF_DEVID1	Device Configuration Register 1.
CSETF_DEVTYPE	Device Type Identifier Register.
CSETF_FFCR	Formatter and Flush Control Register.
CSETF_FFSR	Formatter and Flush Status Register.
CSETF_ITATBCTR0	Integration Test ATB Control 0 Register.
CSETF_ITATBCTR1	Integration Test ATB Control 1 Register.
CSETF_ITATBCTR2	Integration Test ATB Control 2 Register.
CSETF_ITATBDATA0	Integration Test ATB Data 0 Register.
CSETF_ITATBMCTR0	Integration Test ATB Transmitter Control 0 register.
CSETF_ITATBMCTR1	Integration Test ATB Transmitter Control 1 register.
CSETF_ITATBMCTR2	Integration Test ATB Transmitter Control 2 register.
CSETF_ITATBMDATA0	Integration Test ATB Transmitter Data 0 register.
CSETF_ITCTRL	Integration Mode Control Register.
CSETF_ITEVTINTR	Integration Test Event and Interrupt Control Register.
CSETF_ITTRFLIN	Integration Test Trigger In and Flush In register.
CSETF_LBUFLEVEL	Latched Buffer Fill Level.
CSETF_MODE	Mode register.
CSETF_PIDR0	Peripheral Identification Register 0.
CSETF_PIDR1	Peripheral Identification Register 1.
CSETF_PIDR2	Peripheral Identification Register 2.
CSETF_PIDR3	Peripheral Identification Register 3.
CSETF_PIDR4	Peripheral Identification Register 4.
CSETF_PIDR5	Peripheral Identification Register 5.
CSETF_PIDR6	Peripheral Identification Register 6.
CSETF_PIDR7	Peripheral Identification Register 7.
CSETF_PSCR	Periodic Synchronization Counter Register.
CSETF_RRD	RAM Read Data register.
CSETF_RRP	RAM Read Pointer register.

Table 48-515: ADSP-2184x CSETF Register List (Continued)

Name	Description
CSETF_RSZ	RAM Size register.
CSETF_RWD	RAM Write Data register.
CSETF_RWP	RAM Write Pointer register.
CSETF_STS	Status register.
CSETF_TRG	Trigger Counter register.

Authentication Status Register.

Reports the current status of the authentication control signals.

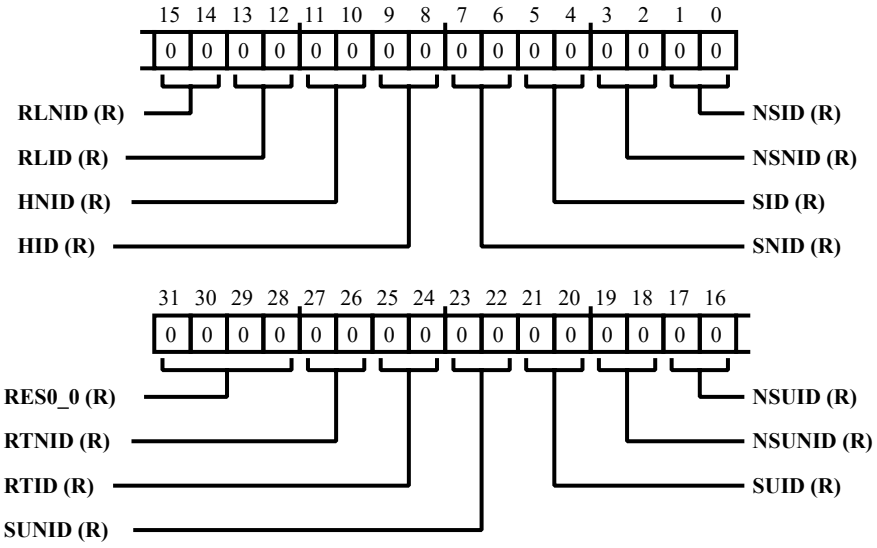

Figure 48-513: CSETF_AUTHSTATUS Register Diagram

Table 48-516: CSETF_AUTHSTATUS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:28 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
27:26 (R/NW)	RTNID	. Root non-invasive debug.	
		0	Separate Root non-invasive debug enable not implemented or Root state non-invasive debug features not implemented.
		1	Reserved.

1:0 (R/NW)	NSID	. Non-secure invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.

Buffer Level Water Mark.

The value that is programmed into the BUFWM register indicates the required threshold vacancy level in 32-bit words in the trace memory. When the available space in the FIFO is less than or equal to this value, that is, fill level >= (MEM_SIZE - BUFWM), the full output is asserted and the STS.Full bit is set. This register is used only in the FIFO modes, that is, SWF1, SWF2, and HWF modes. In CB mode, the same functionality is obtained by programming the RWP to the required vacancy trigger level, so that when the pointer wraps around, the full output gets asserted indicating that the vacancy level has fallen below the required level. Reading this register returns the programmed value. The maximum value that can be written into this register is MEM_SIZE - 1, in which case the full output is asserted after the first 32-bit word is written to trace memory. Writing to this register other than when in Disabled state results in UNPREDICTABLE behavior. Any software using it must program it with an initial value before setting the CTL.TraceCaptEn bit to 1.

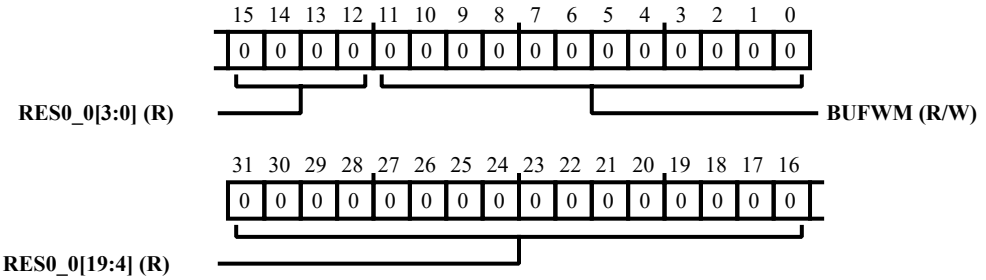

Figure 48-514: CSETF_BUFWM Register Diagram

Table 48-517: CSETF_BUFWM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:12 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
11:0 (R/W)	BUFWM	. Buffer Level Watermark. Indicates the desired threshold vacancy level in 32-bit words in the trace memory. The width of the register is log2(MEM_SIZE).

Current Buffer Fill Level.

The CBUFLEVEL register indicates the current fill level of the trace memory in units of 32-bit words. When the TMC leaves Disabled state, this register dynamically indicates the current fill level of trace memory. It retains its value on entering Disabled state. It is not affected by the reprogramming of pointer registers in Disabled state with the exception of RRD reads and RWD writes. Before leaving the Disabled state software must program RRP with the same value as RWP. Without doing this results in UNPREDICTABLE behavior.

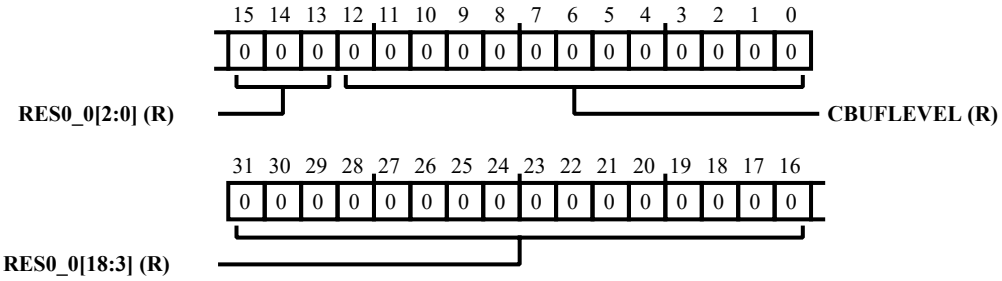

Figure 48-515: CSETF_CBUFLEVEL Register Diagram

Table 48-518: CSETF_CBUFLEVEL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:13 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
12:0 (R/NW)	CBUFLEVEL	. Current Buffer Fill Level. Indicates the current fill level of the trace memory in 32-bit words. The width of the register is 1 + log2(MEM_SIZE).

Component Identification Register 0.

The CIDR0 register is part of the set of component identification registers.

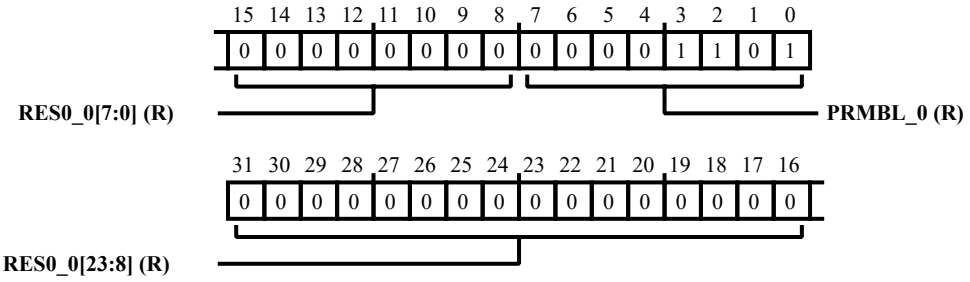

Figure 48-516: CSETF_CIDR0 Register Diagram

Table 48-519: CSETF_CIDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PRMBL_0	. Preamble. Returns 0x0D.

Component Identification Register 1.

The CIDR1 register is part of the set of component identification registers.

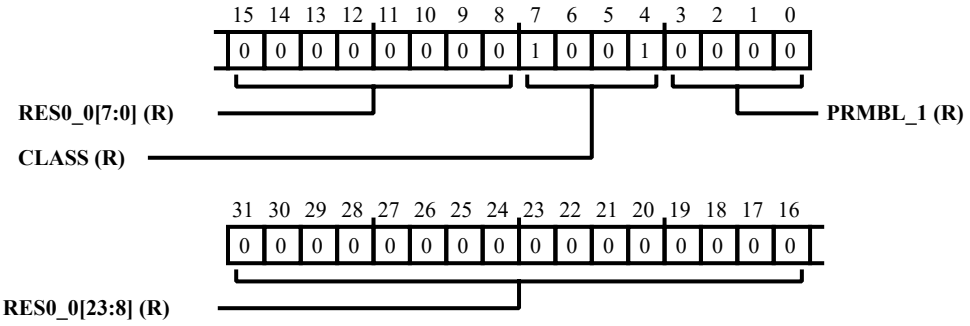

Figure 48-517: CSETF_CIDR1 Register Diagram

Table 48-520: CSETF_CIDR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
7:4 (R/NW)	CLASS	. Component class.	
		9	CoreSight component.
		15	CoreLink, PrimeCell, or system component.
3:0 (R/NW)	PRMBL_1	. Preamble. Returns 0x0.	

Component Identification Register 2.

The CIDR2 register is part of the set of component identification registers.

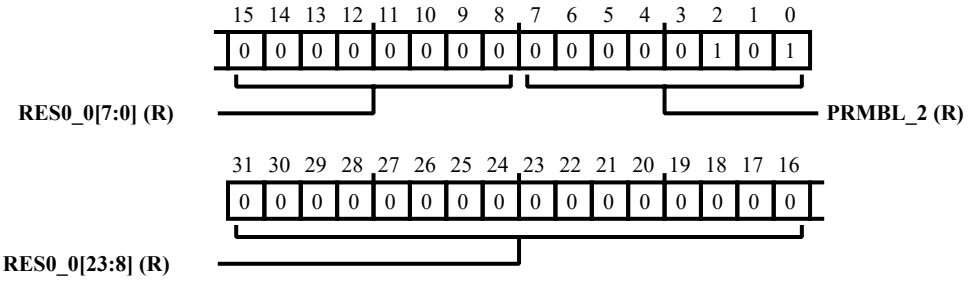

Figure 48-518: CSETF_CIDR2 Register Diagram

Table 48-521: CSETF_CIDR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PRMBL_2	. Preamble. Returns 0x05.

Component Identification Register 3.

The CIDR3 register is part of the set of component identification registers.

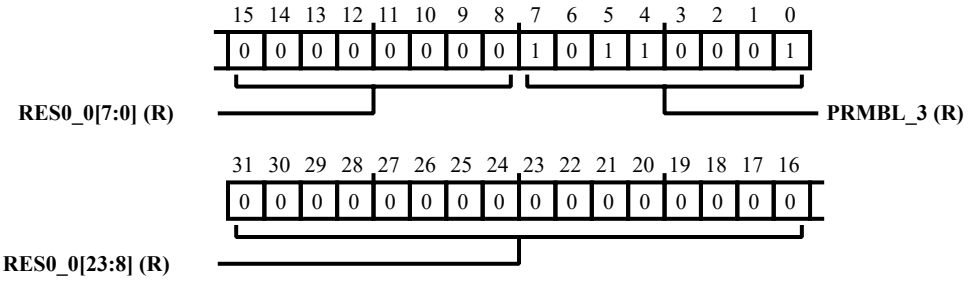

Figure 48-519: CSETF_CIDR3 Register Diagram

Table 48-522: CSETF_CIDR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PRMBL_3	. Preamble. Returns 0xB1.

Claim Tag Clear Register.

This register forms one half of the claim tag value. On writes, this location enables individual bits to be cleared. On reads, it returns the current claim tag value.

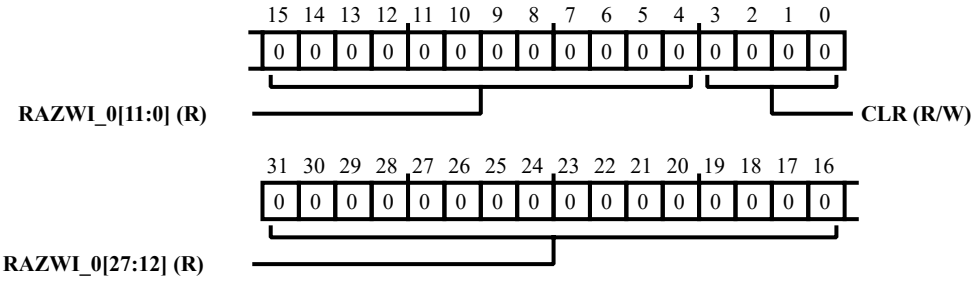

Figure 48-520: CSETF_CLAIMCLR Register Diagram

Table 48-523: CSETF_CLAIMCLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:4 (R/NW)	RAZWI_0	. RAZ/WI.
3:0 (R/W)	CLR	. A bit-programmable register bank that clears the claim tag value. It is zero at reset. It is used by software agents to signal to each other ownership of the hardware. It has no direct effect on the hardware itself.

Claim Tag Set Register.

This register forms one half of the claim tag value. On writes, this location enables individual bits to be set. On reads, it returns the number of bits that can be set.

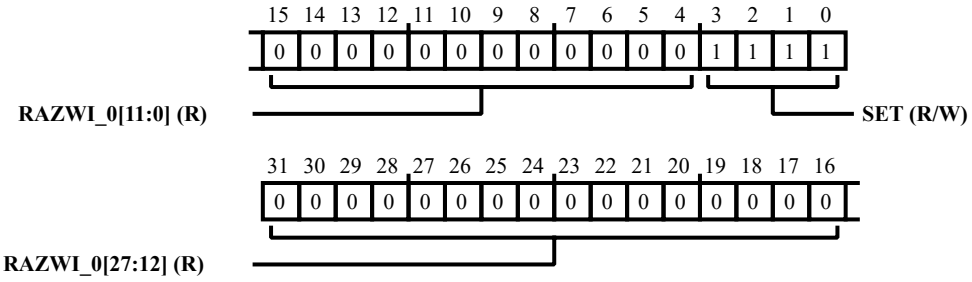

Figure 48-521: CSETF_CLAIMSET Register Diagram

Table 48-524: CSETF_CLAIMSET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:4 (R/NW)	RAZWI_0	. RAZ/WI.
3:0 (R/W)	SET	. A bit-programmable register bank that sets the claim tag value. A read returns a logic 1 for all implemented locations.

Control Register.

The CTL register controls trace stream capture. Setting the CTL.TraceCaptEn bit to 1 enables the TMC to capture the trace data. When trace capture is enabled, the formatter behavior is controlled by the FFCR register.

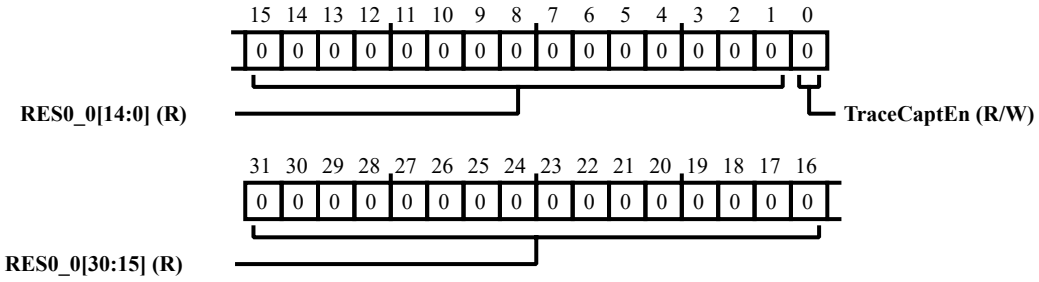

Figure 48-522: CSETF_CTL Register Diagram

Table 48-525: CSETF_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:1 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
0 (R/W)	TRACECAPTEN	. Trace capture enable:.	
		0	Disable trace capture.
		1	Enable trace capture.

Device Configuration Register.

This register is IMPLEMENTATION DEFINED for each Part Number and Designer. The register indicates the capabilities of the component.

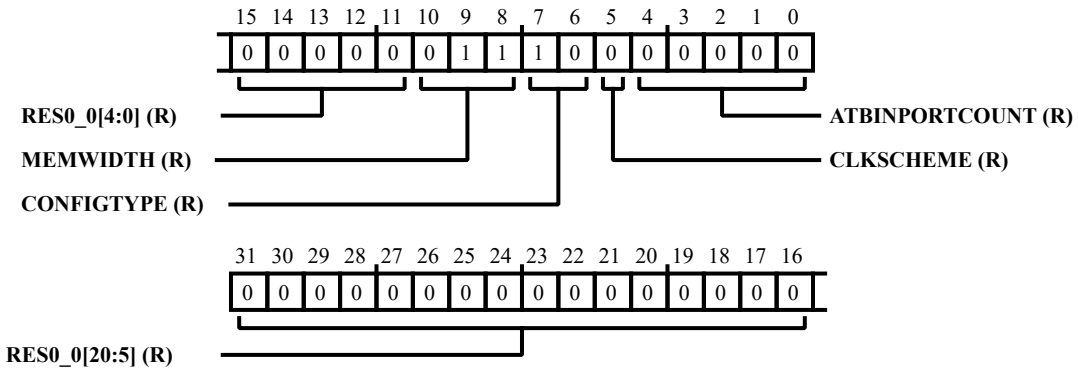

Figure 48-523: CSETF_DEVID Register Diagram

Table 48-526: CSETF_DEVID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:11 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
10:8 (R/NW)	MEMWIDTH	. Indicates the width of the internal memory data bus. For the ETF this value is twice ATB_DATA_WIDTH.	
		3	Memory interface databus is 64 bits wide. (ATB_DATA_WIDTH = 32bit).
		4	Memory interface databus is 128 bits wide. (ATB_DATA_WIDTH = 64bit).
		5	Memory interface databus is 256 bits wide. (ATB_DATA_WIDTH = 128bit).
7:6 (R/NW)	CONFIGTYPE	. Indicates the TMC configuration.	
		0	ETB - Embedded Trace Buffer.
		1	ETR - Embedded Trace Router.
		2	ETF - Embedded Trace FIFO.
		3	ETS - Embedded Trace Streamer.

Table 48-526: CSETF_DEVID Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
5 (R/NW)	CLKSCHEME	. RAM Clocking Scheme. This value indicates the TMC RAM clocking scheme used, that is, whether the TMC RAM operates synchronously or asynchronously to the TMC clock. Fixed to 0 indicating that TMC RAM clock is synchronous to the clk input.
4:0 (R/NW)	ATBINPORTCOUNT	. Hidden Level of ATB input multiplexing. This value indicates the type/number of ATB multiplexing present on the input ATB. Fixed to 0x00 indicating that no multiplexing is present.

Device Configuration Register 1.

Contains an IMPLEMENTATION DEFINED value.

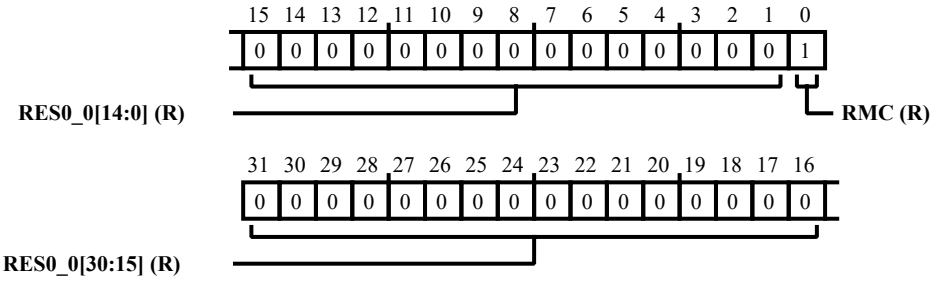

Figure 48-524: CSETF_DEVID1 Register Diagram

Table 48-527: CSETF_DEVID1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:1 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
0 (R/NW)	RMC	. Register management mode. TMC implements register management mode 1.

Device Type Identifier Register.

A debugger can use this register to get information about a component that has an unrecognized Part number.

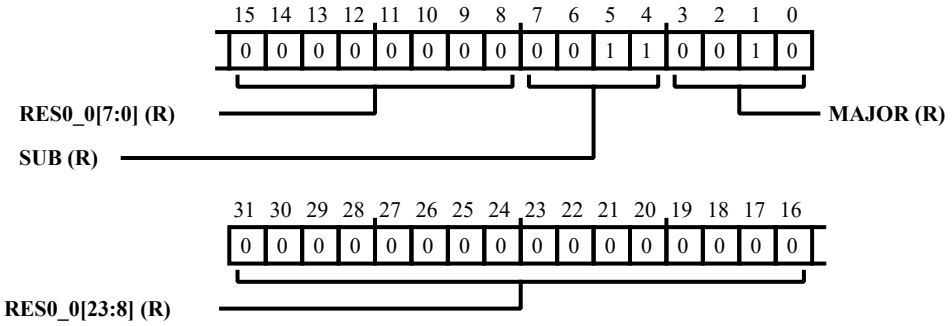

Figure 48-525: CSETF_DEVTYPE Register Diagram

Table 48-528: CSETF_DEVTYPE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:4 (R/NW)	SUB	. Minor classification. Returns 0x3, indicating this component is a FIFO.
3:0 (R/NW)	MAJOR	. Major classification. Returns 0x2, indicating this component is a Trace Link.

Formatter and Flush Control Register.

The FFCR controls the generation of stop, trigger and flush events. The insertion of a flush completion packet and the insertion of a trigger packet in the formatted trace is enabled here. Also one of the 2 formatter modes for bypass mode and normal mode can be changed here when the formatter has stopped.

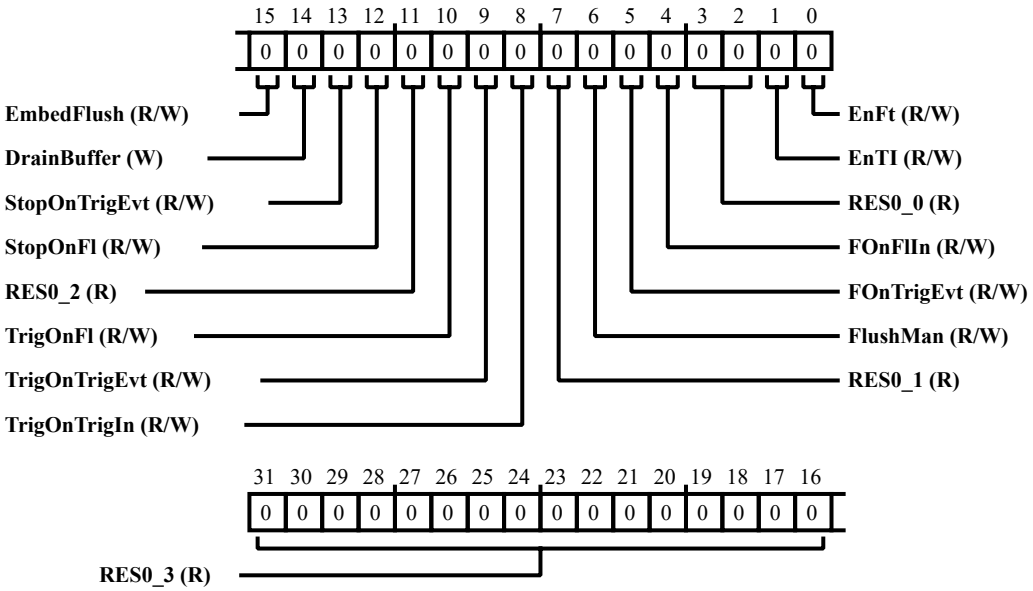

Figure 48-526: CSETF_FFCR Register Diagram

Table 48-529: CSETF_FFCR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:16 (R/NW)	RES0_3	. Reserved bit or field with SBZP behavior.	
15 (R/W)	EMBEDFLUSH	. Embed Flush ID (flush completion packet). Enables insertion of Flush ID 0x7B with a single byte of data payload = 0x00 in the output trace, immediately after the last flush data byte, when a flush completes on the ATB receiver interface. This bit is effective only in Normal formatting modes. In Bypass mode, the Flush ID insertion remains disabled and this bit is ignored.	
		0	Disable Flush ID insertion.
		1	Enable Flush ID insertion.

Table 48-529: CSETF_FFCR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
14 (RX/W)	DRAINBUFFER	. Drain Buffer. This bit is used to enable draining of the trace data through the ATB transmitter interface after the formatter has stopped. It is useful in CB mode to capture trace data into trace memory and then to drain the captured trace through the ATB transmitter interface. Writing a 1 to this bit when in Stopped state starts the drain of the contents of trace buffer. This bit always reads as 0. The STS.TMCReady bit goes LOW while the drain is in progress. This bit is functional only when the TMC is in CB mode and formatting is enabled, that is, FFCR.EnFt=1. Setting this bit when the TMC is in any other mode, or when not in Stopped state, results in UNPREDICTABLE behavior. When trace capture is complete in CB mode, all of the captured trace must be retrieved from the trace memory, either by reading all trace data out through RRD reads, or draining all trace data by setting the FFCR.DrainBuffer bit. Setting this bit after some of the captured trace has been read out through RRD results in UNPREDICTABLE behavior.
13 (R/W)	STOPONTRIGEVT	. Stop On Trigger Event. If this bit is set, the formatter is stopped when a Trigger Event has been observed. This bit must be used only in CB mode. If trace capture is enabled in SWF1, or HWF mode with this bit set, it results in UNPREDICTABLE behavior.
12 (R/W)	STOPONFL	. Stop On Flush. If this bit is set, the formatter is stopped on completion of a flush operation. The initiation of a flush operation is controlled by programming the register bits FFCR.FlushMan, FFCR.FOnTrigEvt, and FFCR.FOnFlIn. When a flush-initiation condition occurs, afvalid_rx is asserted, and when the flush completion is received, that is, afready_rx=1, trace capture is stopped. Any remaining data in the formatter is appended with a post-amble and written to trace memory. The flush operation is then complete. If a flush is initiated by the ATB Transmitter interface, its completion does not lead to a formatter stop regardless of the value that is programmed in this bit.
11 (R/NW)	RES0_2	. Reserved bit or field with SBZP behavior.
10 (R/W)	TRIGONFL	. Indicate on trace stream the completion of flush. If this bit is set, a trigger is indicated on the trace stream when afready_rx is received for a flush in progress. If this bit is clear, no triggers are embedded in the trace stream on flush completion. If Trigger Insertion is disabled, that is, FFCR.EnTI=0, then trigger indication on the trace stream is blocked regardless of the value that is programmed in this bit. If a flush is initiated by the ATB Transmitter interface, its completion does not lead to a trigger indication on the trace stream regardless of the value that is programmed in this bit.

Table 48-529: CSETF_FFCR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
9 (R/W)	TRIGONTRIGEVT	. Indicate on trace stream the occurrence of a Trigger Event. If this bit is set, a trigger is indicated on the output trace stream when a Trigger Event occurs. If Trigger Insertion is disabled, that is, FFCR.EnTI=0, then trigger indication on the trace stream is blocked regardless of the value that is programmed in this bit. This bit must be used only in CB mode. If trace capture is enabled in SWF1, or HWF mode with this bit set, it results in UNPREDICTABLE behavior.
8 (R/W)	TRIGONTRIGIN	. Indicate on trace stream the occurrence of a rising edge on trigin. If this bit is set, a trigger is indicated on the trace stream when a rising edge is detected on the trigin input. If Trigger Insertion is disabled, that is, FFCR.EnTI=0, then trigger indication on the trace stream is blocked regardless of the value that is programmed in this bit.
7 (R/NW)	RES0_1	. Reserved bit or field with SBZP behavior.
6 (R/W)	FLUSHMAN	. Manually generate a flush of the system. Writing 1 to this bit causes a flush to be generated. This bit is cleared automatically when, in formatter bypass mode, afready_rx was sampled high, or, in normal formatting mode, afready_rx was sampled high and all flush data was output to the trace memory. If CTL.TraceCaptEn=0, writes to this bit are ignored.
5 (R/W)	FONTRIGEVT	. Flush on Trigger Event. If FFCR.StopOnTrigEvt is set, this bit is ignored. Setting this bit generates a flush when a Trigger Event occurs. If FFCR.StopOnTrigEvt is set, this bit is ignored. This bit must be used only in CB mode. If trace capture is enabled in SWF1, or HWF mode with this bit set, it results in UNPREDICTABLE behavior.
4 (R/W)	FONFLIN	. Setting this bit enables the detection of transitions on the flushin input by the TMC. If this bit is set and the formatter has not already stopped, a rising edge on flushin initiates a flush request.
3:2 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
1 (R/W)	ENTI	. Enable Trigger Insertion. Setting this bit enables the insertion of triggers in the formatted trace stream. A trigger is indicated by inserting one byte of data 0x00 with atid_rx=0x7D in the trace stream. Trigger indication on the trace stream is also controlled by the register bits FFCR.TrigOnFl, FFCR.TrigOnTrigEvt, and FFCR.TrigOnTrigIn. This bit can only be changed when the TMC is in Disabled state. If FFCR.EnTI bit is set formatting is enabled.

Table 48-529: CSETF_FFCR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
0 (R/W)	ENFT	. Enable Formatter. If this bit is set, formatting is enabled. When EnTi is set, formatting is enabled. When CB mode is not used, formatting is also enabled. For backwards-compatibility with earlier versions of the ETB disabling of formatting is supported only in CB mode. This bit can only be changed when TMC is in Disabled state.

Formatter and Flush Status Register.

This register indicates the status of the Formatter, and the status of Flush request.

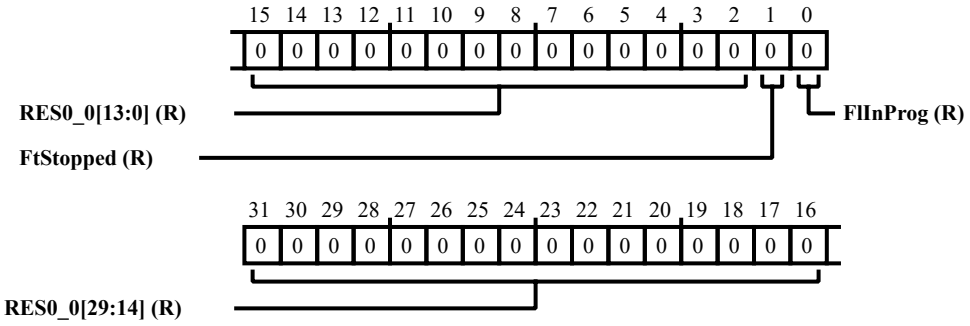

Figure 48-527: CSETF_FFSR Register Diagram

Table 48-530: CSETF_FFSR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:2 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
1 (R/NW)	FTSTOPPED	. Formatter Stopped. This bit behaves the same way as STS.FtEmpty.	
0 (R/NW)	FLINPROG	. Flush In Progress. This bit indicates whether the TMC is currently processing a flush request. The flush initiation is controlled by the flush control bits in the FFCR register. The flush request could additionally be from the ATB transmitter port. This bit is cleared to 0 when leaving the Disabled state and retains its value when entering the Disabled state. When in Disabled state, this bit is not updated.	
		0	No flush activity in progress.
		1	Flush in progress on the ATB receiver interface or the TMC internal pipeline.

Integration Test ATB Control 0 Register.

This register captures the values of ATB receiver inputs atvalid_rx, afready_rx, atwakeup_rx, and atbytes_rx in integration mode. In functional mode, this register behaves as RAZ/WI. In integration mode, writes to this register are ignored and the reads return the value of corresponding input pins. The width of this register is given by: 8+log2(ATB DATA WIDTH/8).

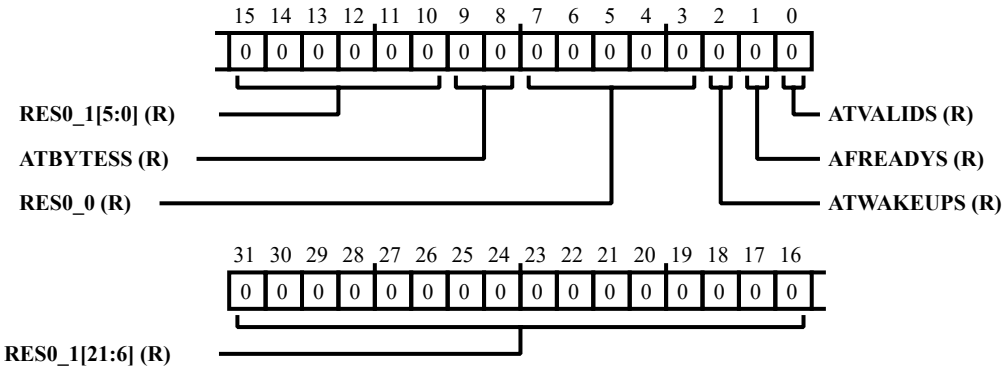

Figure 48-528: CSETF_ITATBCTR0 Register Diagram

Table 48-531: CSETF_ITATBCTR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:10 (R/NW)	RES0_1	. Reserved bit or field with SBZP behavior.
9:8 (R/NW)	ATBYTESS	. Returns the value of atbytes_rx input in integration mode. N=8+log2(ATB DATA WIDTH/8).
7:3 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
2 (R/NW)	ATWAKEUPS	. Returns the value of atwakeup_rx input in integration mode.
1 (R/NW)	AFREADYS	. Returns the value of afready_rx input in integration mode.
0 (R/NW)	ATVALIDS	. Returns the value of atvalid_rx input in integration mode.

Integration Test ATB Control 1 Register.

This register captures the value of the atid_rx[6:0] input in integration mode. In functional mode, this register behaves as RAZ/WI. In integration mode, writes to this register are ignored and the reads return the value of atid_rx input.

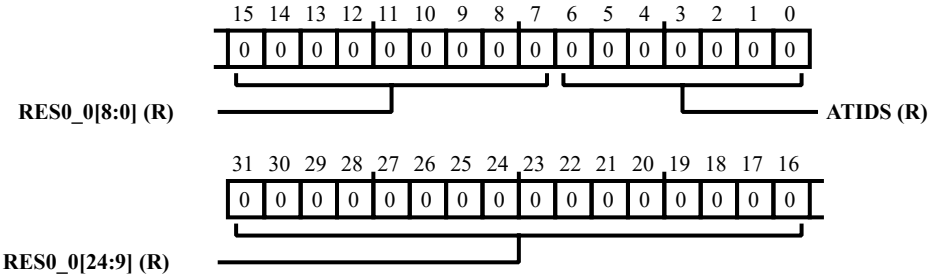

Figure 48-529: CSETF_ITATBCTR1 Register Diagram

Table 48-532: CSETF_ITATBCTR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:7 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
6:0 (R/NW)	ATIDS	. Returns the value of atid_rx[6:0] input in integration mode.

Integration Test ATB Control 2 Register.

This register enables control of ATB receiver outputs atready_rx, afvalid_rx, and syncreq_rx in integration mode. In functional mode, this register behaves as RAZ/WI. In integration mode, the value that is written to any bit of this register is driven on the output pin that is controlled by that bit and the reads return 0x0.

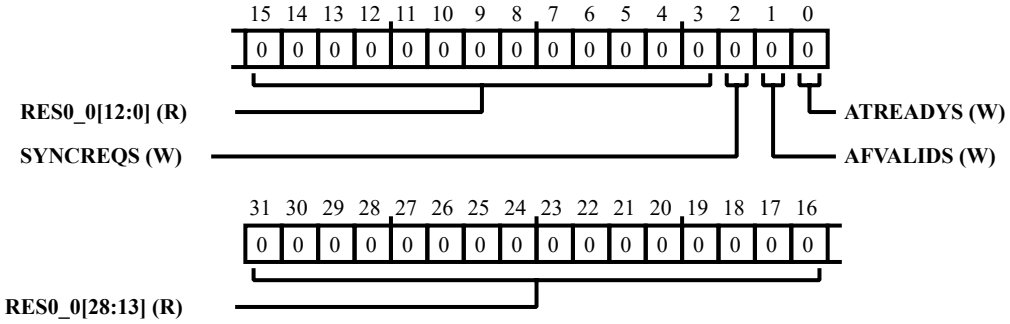

Figure 48-530: CSETF_ITATBCTR2 Register Diagram

Table 48-533: CSETF_ITATBCTR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:3 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
2 (RX/W)	SYNCREQS	. Controls the value of syncreq_rx output in integration mode.
1 (RX/W)	AFVALIDS	. Controls the value of afvalid_rx output in integration mode.
0 (RX/W)	ATREADYS	. Controls the value of atready_rx output in integration mode.

Integration Test ATB Data 0 Register.

This register captures the value of atdata_rx input in integration mode. In functional mode, this register behaves as RAZ/WI. In integration mode, writes to this register are ignored and the reads return the value of corresponding atdata_rx bits. The width of this register is given by: 1+(ATB DATA WIDTH)/8.

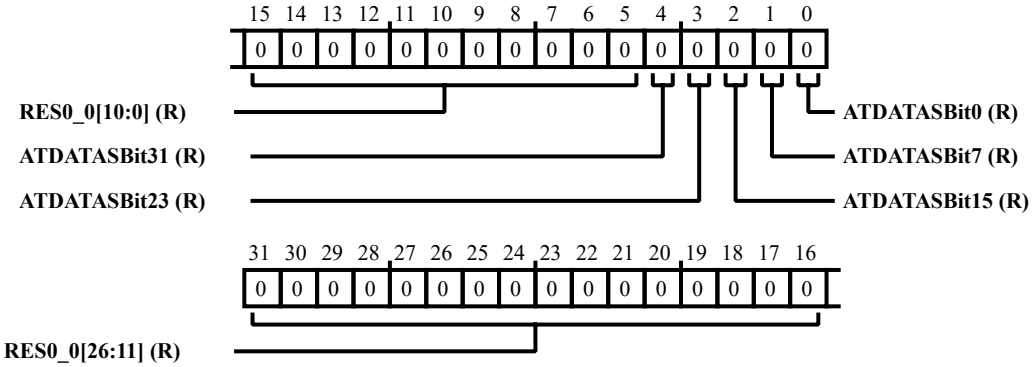

Figure 48-531: CSETF_ITATBDATA0 Register Diagram

Table 48-534: CSETF_ITATBDATA0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:5 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
4 (R/NW)	ATDATASBIT31	. Returns the value of atdata_rx[31] input in integration mode.
3 (R/NW)	ATDATASBIT23	. Returns the value of atdata_rx[23] input in integration mode.
2 (R/NW)	ATDATASBIT15	. Returns the value of atdata_rx[15] input in integration mode.
1 (R/NW)	ATDATASBIT7	. Returns the value of atdata_rx[7] input in integration mode.
0 (R/NW)	ATDATASBIT0	. Returns the value of atdata_rx[0] input in integration mode.

Integration Test ATB Transmitter Control 0 register.

This register enables control of the ATB transmitter outputs atbytes_tx, atwakeup_tx, afready_tx, and atvalid_tx in integration mode. In functional mode, this register behaves as RAZ/WI. In integration mode, the value that is written to any bit of this register is driven on the output pin that is controlled by that bit, and the reads return 0x0.

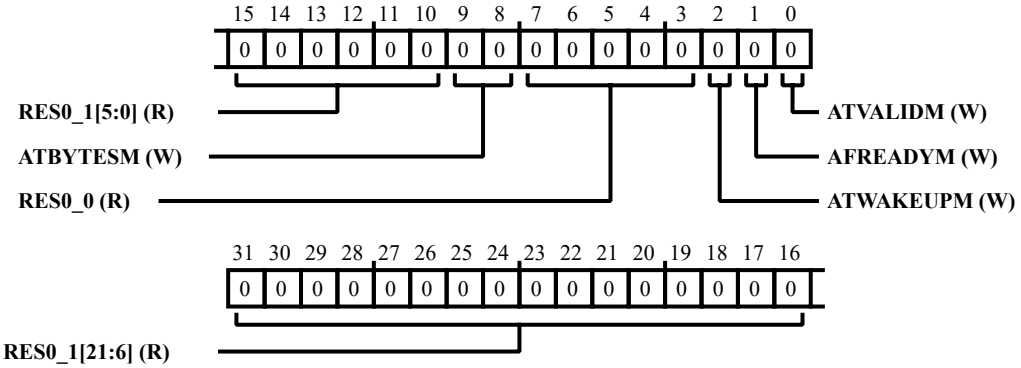

Figure 48-532: CSETF_ITATBMCTR0 Register Diagram

Table 48-535: CSETF_ITATBMCTR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:10 (R/NW)	RES0_1	. Reserved bit or field with SBZP behavior.
9:8 (RX/W)	ATBYTESM	. Controls the value of atbytes_tx output in integration mode. This width of this field is log2(ATB DATA WIDTH/8).
7:3 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
2 (RX/W)	ATWAKEUPM	. Controls the value of atwakeup_tx output in integration mode.
1 (RX/W)	AFREADYM	. Controls the value of afready_tx output in integration mode.
0 (RX/W)	ATVALIDM	. Controls the value of atvalid_tx output in integration mode.

Integration Test ATB Transmitter Control 1 register.

This register enables control of the atid_tx output in integration mode. In functional mode, this register behaves as RAZ/WI. In integration mode, the value that is written to this register is driven on the atid_tx output and the reads return 0x0.

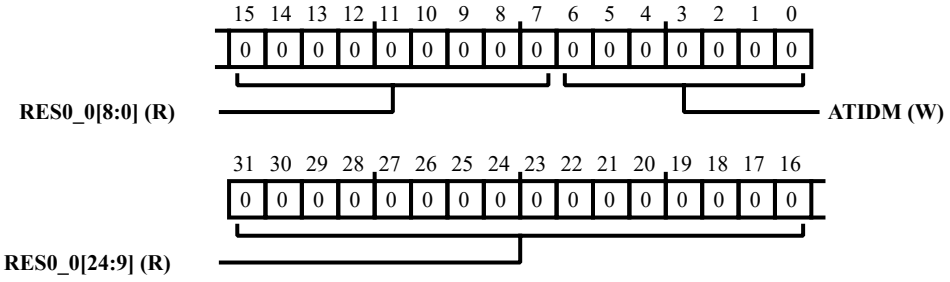

Figure 48-533: CSETF_ITATBMCTR1 Register Diagram

Table 48-536: CSETF_ITATBMCTR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:7 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
6:0 (RX/W)	ATIDM	. Controls the value of the atid_tx[6:0] output in integration mode.

Integration Test ATB Transmitter Control 2 register.

This register captures the values of ATB transmitter inputs atready_tx, afvalid_tx, and syncreq_tx in integration mode. In functional mode, this register behaves as RAZ/WI.

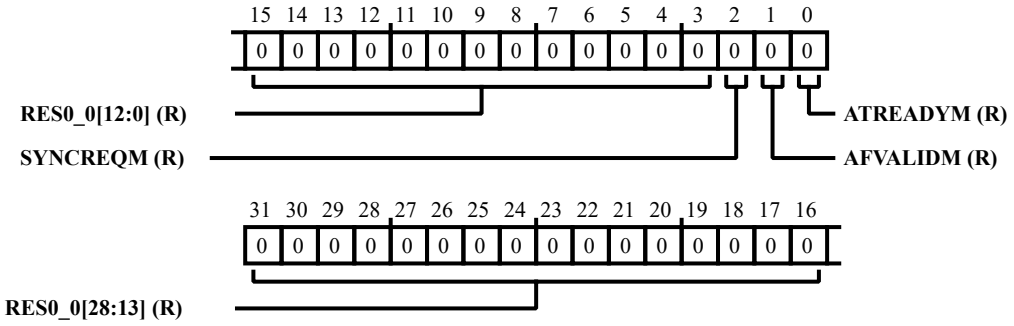

Figure 48-534: CSETF_ITATBMCTR2 Register Diagram

Table 48-537: CSETF_ITATBMCTR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:3 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
2 (R/NW)	SYNCREQM	. Integration status of syncreq_tx input. In integration mode, this bit latches to 1 on a rising edge of syncreq_tx input, which is cleared when this register is read or when integration mode is disabled.
1 (R/NW)	AFVALIDM	. Integration status of afvalid_tx input. In integration mode, writes are ignored and reads return the value of afvalid_tx input.
0 (R/NW)	ATREADYM	. Integration status of atready_tx input. In integration mode, writes are ignored and reads return the value of the atready_tx input.

Integration Test ATB Transmitter Data 0 register.

This register enables control of the atdata_tx output in integration mode. In functional mode, this register behaves as RAZ/WI. In integration mode, the value that is written to any given bit is driven on the output pin that is controlled by that bit and the reads return 0x0. The width of this register is given by 1+(ATB DATA WIDTH)/8.

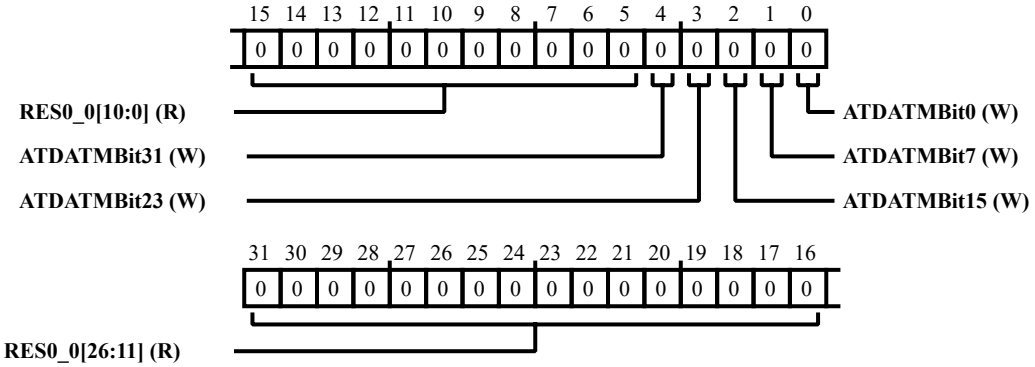

Figure 48-535: CSETF_ITATBMDATA0 Register Diagram

Table 48-538: CSETF_ITATBMDATA0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:5 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
4 (RX/W)	ATDATMBIT31	. Controls the value of atdata_tx[31] output in integration mode.
3 (RX/W)	ATDATMBIT23	. Controls the value of atdata_tx[23] output in integration mode.
2 (RX/W)	ATDATMBIT15	. Controls the value of atdata_tx[15] output in integration mode.
1 (RX/W)	ATDATMBIT7	. Controls the value of atdata_tx[7] output in integration mode.
0 (RX/W)	ATDATMBIT0	. Controls the value of atdata_tx[0] output in integration mode.

Integration Mode Control Register.

The Integration Mode Control register is used to switch between functional mode and integration mode. After switching to integration mode and performing integration tests or topology detection, reset the system to ensure correct behavior of CoreSight and other connected system components.

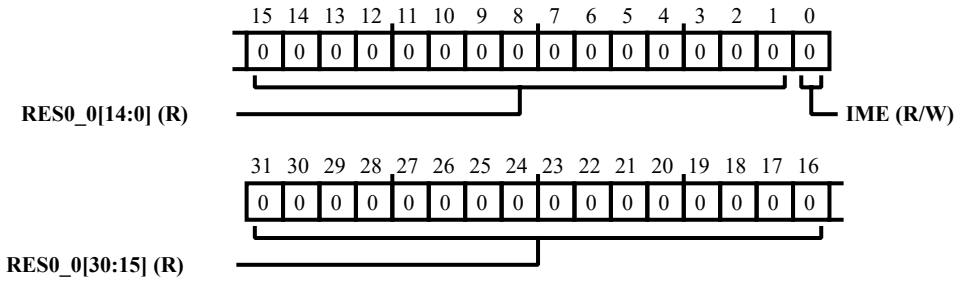

Figure 48-536: CSETF_ITCTRL Register Diagram

Table 48-539: CSETF_ITCTRL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:1 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
0 (R/W)	IME	. Integration Mode Enable.	
		0	The component must enter functional mode.
		1	The component must enter integration mode, and enable support for topology detection and integration testing.

Integration Test Event and Interrupt Control Register.

This register controls the values of event and interrupt outputs in integration mode. In functional mode, this register behaves as RAZ/WI. In integration mode, the value that is written to any bit of this register is driven on the output pin that is controlled by that bit and the reads return 0x0.

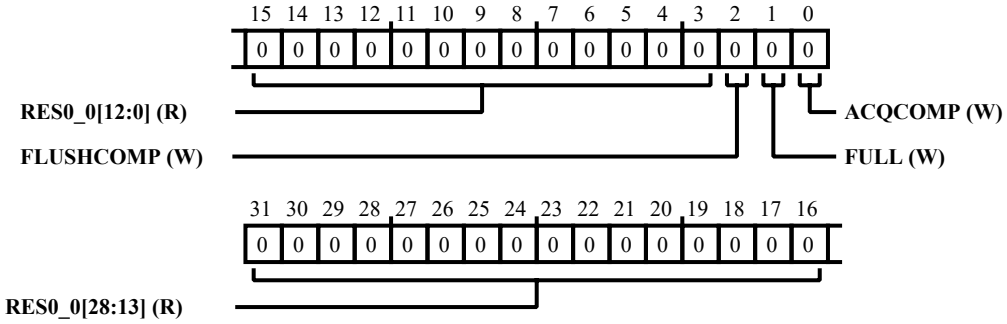

Figure 48-537: CSETF_ITEVTINTR Register Diagram

Table 48-540: CSETF_ITEVTINTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:3 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
2 (RX/W)	FLUSHCOMP	. Controls the value of flushcomp output in integration mode.
1 (RX/W)	FULL	. Controls the value of full output in integration mode.
0 (RX/W)	ACQCOMP	. Controls the value of acqcomp output in integration mode.

Integration Test Trigger In and Flush In register.

This register captures the values of the flushin and trigin inputs in integration mode. In functional mode, this register behaves as RAZ/WI.

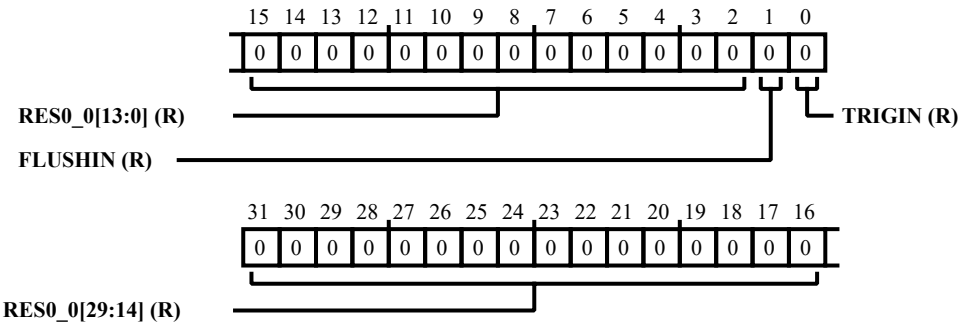

Figure 48-538: CSETF_ITTRFLIN Register Diagram

Table 48-541: CSETF_ITTRFLIN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:2 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
1 (R/NW)	FLUSHIN	. Integration status of flushin input. In integration mode, this bit latches to 1 on a rising edge of the flushin input. It is cleared when the register is read or when integration mode is disabled.
0 (R/NW)	TRIGIN	. Integration status of trigin input. In integration mode, this bit latches to 1 on a rising edge of the trigin input. It is cleared when the register is read or when integration mode is disabled.

Latched Buffer Fill Level.

Reading the LBUFLEVEL register returns the maximum fill level of the trace memory in 32-bit words since this register was last read. Reading this register also results in its contents being updated to the current fill level. When entering Disabled state, it retains its last value. While in Disabled state, reads from this register do not affect its value. When exiting Disabled state, the LBUFLEVEL register is updated to the current fill level.

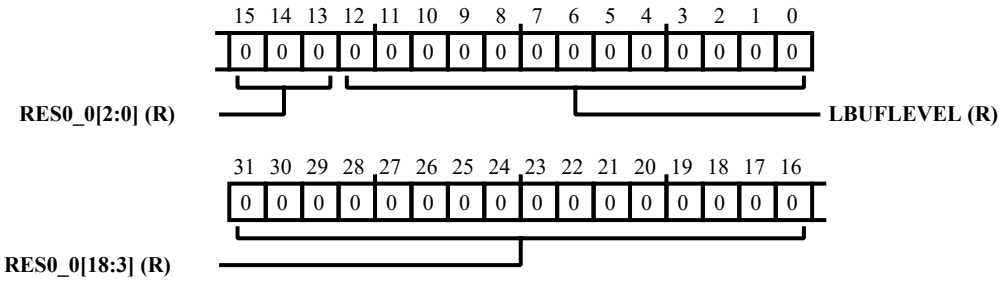

Figure 48-539: CSETF_LBUFLEVEL Register Diagram

Table 48-542: CSETF_LBUFLEVEL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:13 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
12:0 (R/NW)	LBUFLEVEL	. Latched Buffer Fill Level. Indicates the maximum fill level of the trace memory in 32-bit words since this register was last read. The width of the register is 1 + log2(MEM_SIZE).

Mode register.

The MODE register controls the TMC operating mode. The operating mode can only be changed when the TMC is in Disabled state. Attempting to write to this register in any other state results in UNPREDICTABLE behavior. The operating mode is ignored when in Disabled state.

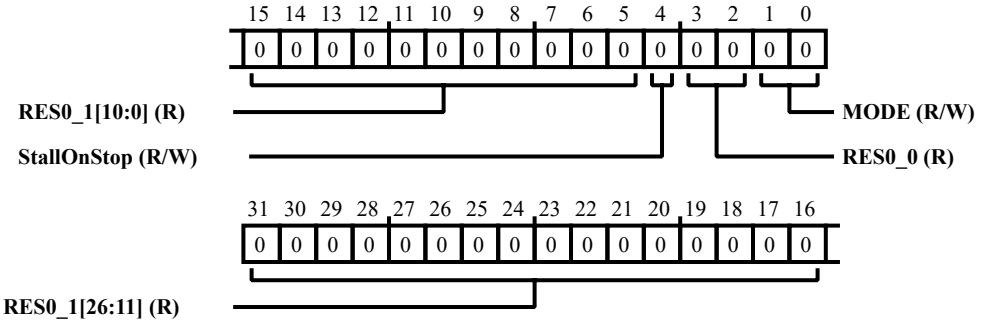

Figure 48-540: CSETF_MODE Register Diagram

Table 48-543: CSETF_MODE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:5 (R/NW)	RES0_1	. Reserved bit or field with SBZP behavior.	
4 (R/W)	STALLONSTOP	. Stall On Stop. If this bit is set and the formatter stops as a result of a stop event, the output atready_rx is de-asserted to stall the ATB interface and avoid loss of trace. If this bit is clear and the formatter stops as a result of a stop event, signal atready_rx remains asserted but the TMC discards further incoming trace.	
3:2 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
1:0 (R/W)	MODE	. Selects the operating mode. If a reserved MODE value is programmed and trace capture is enabled, the TMC starts to operate in SWF1 mode. However, reading the MODE.MODE field returns the programmed value.	
		0	CB, Circular Buffer mode.
		1	SWF1, Software Read FIFO mode 1.
		2	HWF, Hardware Read FIFO mode.
		3	Reserved. (SWF1).

Peripheral Identification Register 0.

The PIDR0 register is part of the set of peripheral identification registers.

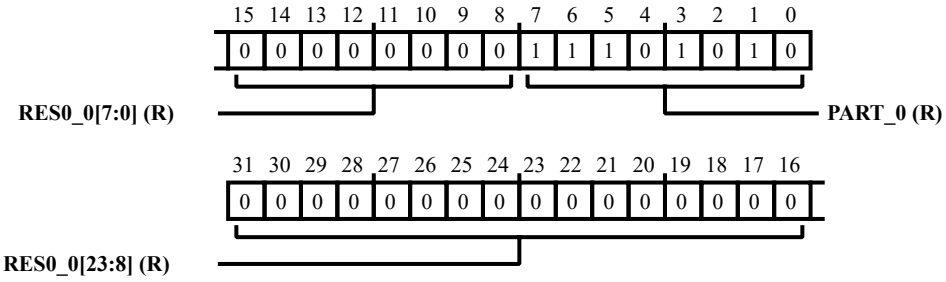

Figure 48-541: CSETF_PIDR0 Register Diagram

Table 48-544: CSETF_PIDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
7:0 (R/NW)	PART_0	. Part number (lower 8 bits).	
		232	ETR or ETS - Embedded Trace Router or Streamer.
		233	ETB - Embedded Trace Buffer.
		234	ETF - Embedded Trace FIFO.

Peripheral Identification Register 1.

The PIDR1 register is part of the set of peripheral identification registers.

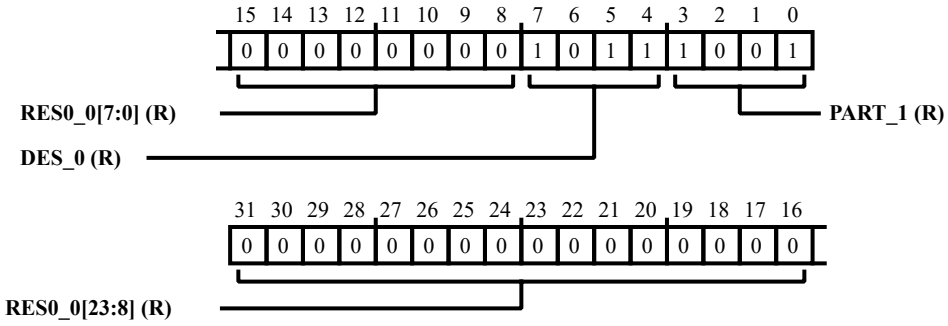

Figure 48-542: CSETF_PIDR1 Register Diagram

Table 48-545: CSETF_PIDR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:4 (R/NW)	DES_0	. JEP106 identification code, bits[3:0]. Together, with PIDR4.DES_2 and PIDR2.DES_1, they indicate the designer of the component and not the implementer, except where the two are the same.
3:0 (R/NW)	PART_1	. Part number, bits[11:8]. Taken together with PIDR0.PART_0 it indicates the component. The Part Number is selected by the designer of the component.

Peripheral Identification Register 2.

The PIDR2 register is part of the set of peripheral identification registers.

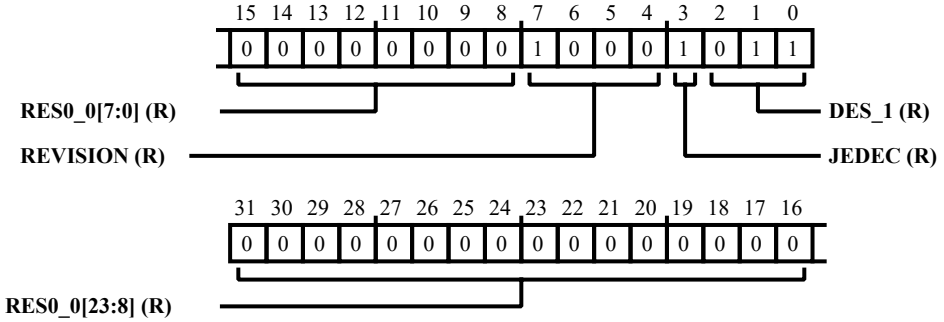

Figure 48-543: CSETF_PIDR2 Register Diagram

Table 48-546: CSETF_PIDR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:4 (R/NW)	REVISION	. Revision. It is an incremental value starting at 0x0 for the first design of a component. See the Component list in Chapter 1 for information on the RTL revision of the component.
3 (R/NW)	JEDEC	. 1 - Always set. Indicates that a JEDEC assigned value is used.
2:0 (R/NW)	DES_1	. JEP106 identification code, bits[6:4]. Together, with PIDR4.DES_2 and PIDR1.DES_0, they indicate the designer of the component and not the implementer, except where the two are the same.

Peripheral Identification Register 3.

The PIDR3 register is part of the set of peripheral identification registers.

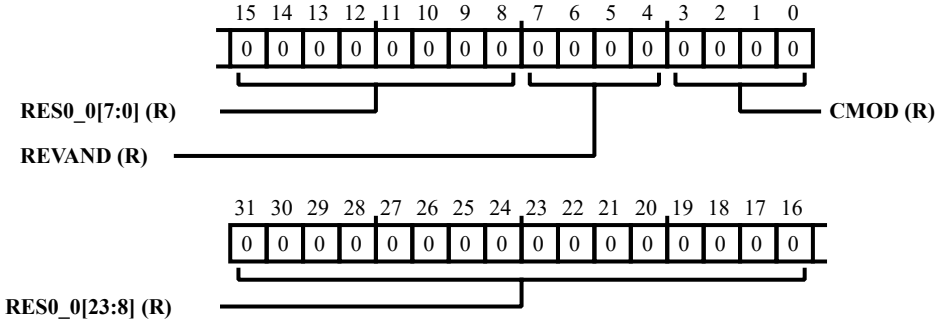

Figure 48-544: CSETF_PIDR3 Register Diagram

Table 48-547: CSETF_PIDR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:4 (R/NW)	REVAND	. This field indicates minor errata fixes specific to this design, for example metal fixes after implementation. In most cases this field is 0x0.
3:0 (R/NW)	CMOD	. Customer Modified. Where the component is reusable IP, this value indicates if the customer has modified the behavior of the component. In most cases this field is 0x0.

Peripheral Identification Register 4.

The PIDR4 register is part of the set of peripheral identification registers.

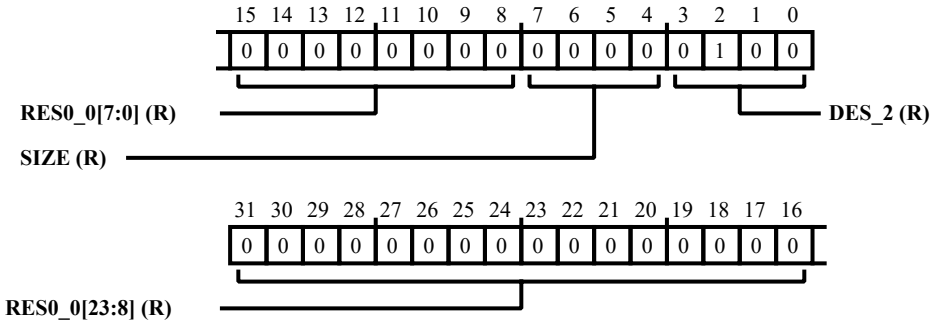

Figure 48-545: CSETF_PIDR4 Register Diagram

Table 48-548: CSETF_PIDR4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:4 (R/NW)	SIZE	. Indicates the memory size that is used by this component. Returns 0 indicating that the component uses an UNKNOWN number of 4KB blocks. Using the SIZE field to indicate the size of the component is deprecated.
3:0 (R/NW)	DES_2	. JEP106 continuation code. Together, with PIDR2.DES_1 and PIDR1.DES_0, they indicate the designer of the component and not the implementer, except where the two are the same.

Peripheral Identification Register 5.

The PIDR5 register is part of the set of peripheral identification registers.

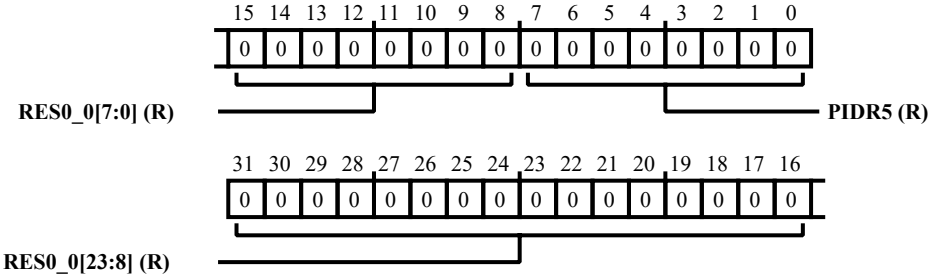

Figure 48-546: CSETF_PIDR5 Register Diagram

Table 48-549: CSETF_PIDR5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PIDR5	. Reserved.

Peripheral Identification Register 6.

The PIDR6 register is part of the set of peripheral identification registers.

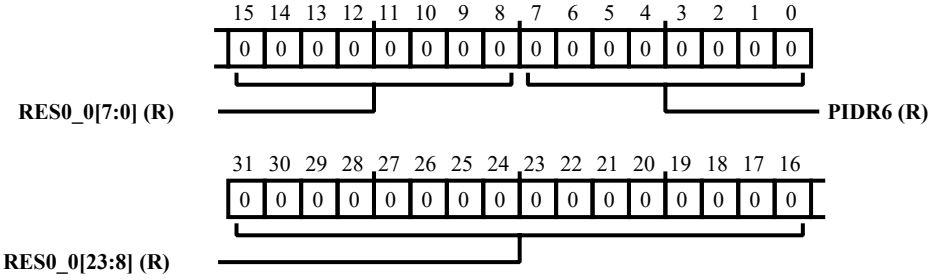

Figure 48-547: CSETF_PIDR6 Register Diagram

Table 48-550: CSETF_PIDR6 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PIDR6	. Reserved.

Peripheral Identification Register 7.

The PIDR7 register is part of the set of peripheral identification registers.

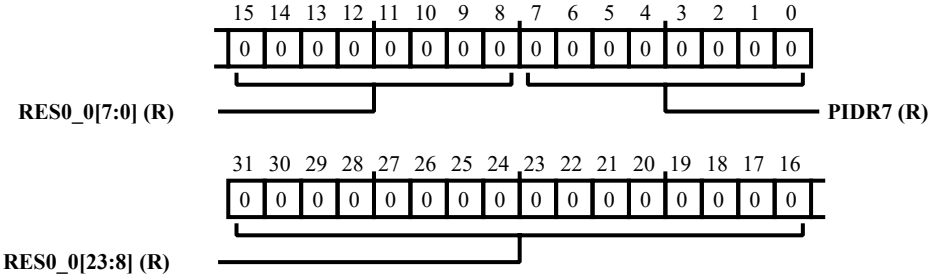

Figure 48-548: CSETF_PIDR7 Register Diagram

Table 48-551: CSETF_PIDR7 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PIDR7	. Reserved.

Periodic Synchronization Counter Register.

This register determines the reload value of the Periodic Synchronization Counter. This counter enables the frequency of sync packets to be optimized to the trace capture buffer size. The default behavior of the counter is to generate periodic synchronization requests, syncreq_rx, on the ATB receiver interface.

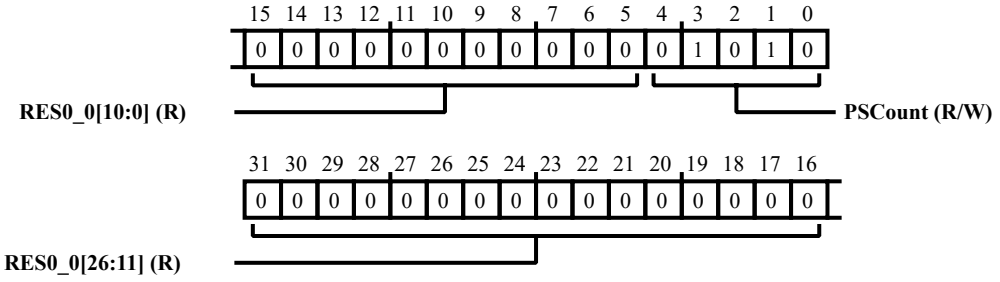

Figure 48-549: CSETF_PSCR Register Diagram

Table 48-552: CSETF_PSCR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:5 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
4:0 (R/W)	PSCOUNT	. Periodic Synchronization Count. Determines the reload value of the Synchronization Counter. The reload value takes effect the next time the counter reaches zero. When trace capture is enabled, the Synchronization Counter counts the number of bytes of trace data that is stored into the trace memory, regardless of whether the trace data has been formatted by the TMC or not, since the occurrence of the last sync request on the ATB receiver interface. When the counter reaches 0, a sync request is sent on the ATB receiver interface. Reads from this register return the reload value that is programmed in this register. This field resets to 0x0A, that is, the default sync period is 2^10 bytes. If a reserved value is programmed in this register field, the value 0x1B is used instead, and subsequent reads from this register also return 0x1B. The following constraints apply to the values written to the PSCount field: 0x0 - synchronization is disabled, 0x1-0x6 - reserved, 0x7-0x1B - synchronization period is 2^PSCount bytes. The smallest value 0x7 gives a sync period of 128 bytes. The maximum allowed value 0x1B gives a sync period of 2^27 bytes, 0x1C-0x1F - reserved.

RAM Read Data register.

Reading this register allows data to be read from the trace memory at the location pointed to by the RRP register when either in the Disabled state or operating in CB or SWF1 mode. When ATB_DATA_WIDTH is 32, 64 or 128 bit wide the memory width is twice as wide and a memory word holds 8, 16 or 32 bytes. Multiple RRD reads must be performed to read a full memory word. When a full memory width of data has been read via the RRD register, the RRP register is incremented to the next memory word. When the TMC left the Disabled state and the trace memory is empty, this register returns 0xFFFFFFFF. When the TMC left the Disabled state and the trace memory is empty, this register returns 0xFFFFFFFF. When operating in CB mode and the TMC left the Disabled state, this register returns 0xFFFFFFFF in all other states except the Stopped state. When operating in HWF mode, this register also returns 0xFFFFFFFF.

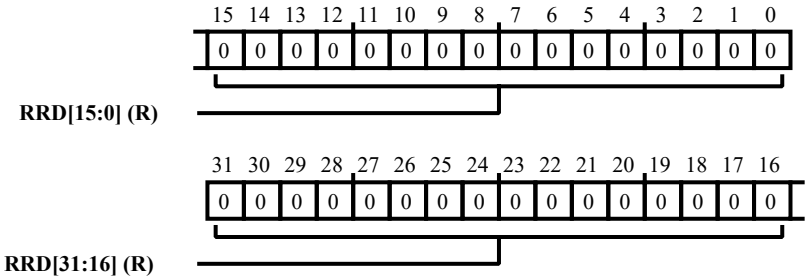

Figure 48-550: CSETF_RRD Register Diagram

Table 48-553: CSETF_RRD Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RRD	. Returns the data read from trace memory.

RAM Read Pointer register.

The RRP register contains the value of the read pointer that is used to read entries from trace memory over the APB interface. Software must program it with the same value as RWP before enabling trace capture.

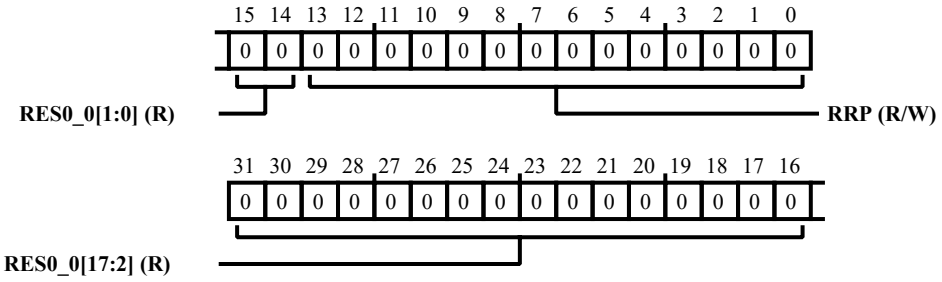

Figure 48-551: CSETF_RRP Register Diagram

Table 48-554: CSETF_RRP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:14 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
13:0 (R/W)	RRP	. The RRP width depends on the size of trace memory and is given by log2(MEM_SIZE x 4). The remaining MSBs of the 32-bit register are of type RAZ/WI. When ATB_DATA_WIDTH is 32, 64 or 128 bit wide the memory width is twice as wide and a memory word holds 8, 16 or 32 bytes. When a full memory width of data has been read via the RRD register, the RRP register is incremented to the next memory word. The lowest 4 bits have access type RAZ/WI when ATB_DATA_WIDTH is 32 or 64 bits. The lowest 5 bits have access type RAZ/WI when ATB_DATA_WIDTH is 128 bits.

RAM Size register.

The RSZ register defines the size of trace memory in units of 32-bit words.

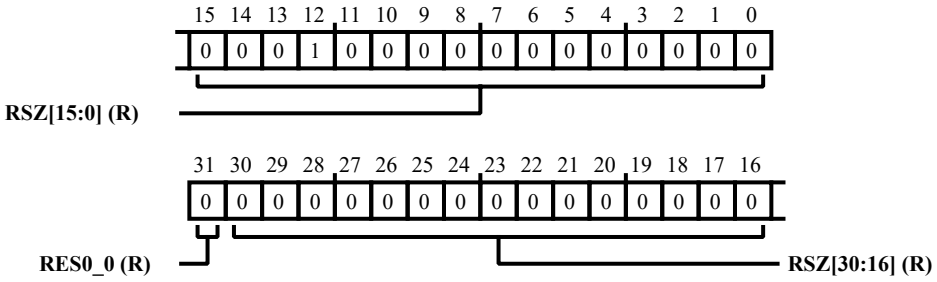

Figure 48-552: CSETF_RSZ Register Diagram

Table 48-555: CSETF_RSZ Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
30:0 (R/NW)	RSZ	. RAM size. Indicates the size of the RAM in 32-bit words. For example: Returns 0x00000100 if trace memory size is 1KB, 0x40000000 if trace memory size is 4GB. This field has the same value as the MEM_SIZE parameter.

RAM Write Data register.

The RWD register enables testing of trace memory connectivity to the TMC. Writing this register allows data to be written to the trace memory at the location pointed to by the RWP register when in the Disabled state. When ATB_DATA_WIDTH is 32, 64 or 128 bit wide the memory width is twice as wide and a memory word holds 8, 16 or 32 bytes. Multiple RWD writes must be performed to write a full memory word. When a full memory width of data has been written via the RWD register, the data is written to the trace memory and the RWP register is incremented to the next memory word.

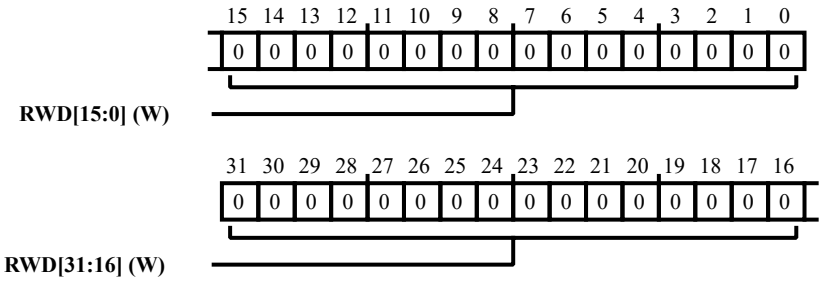

Figure 48-553: CSETF_RWD Register Diagram

Table 48-556: CSETF_RWD Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (RX/W)	RWD	. Data written to this register is placed in the trace memory.

RAM Write Pointer register.

The RWP register sets the write pointer that writes entries into the trace memory. Software must program it before enabling trace capture.

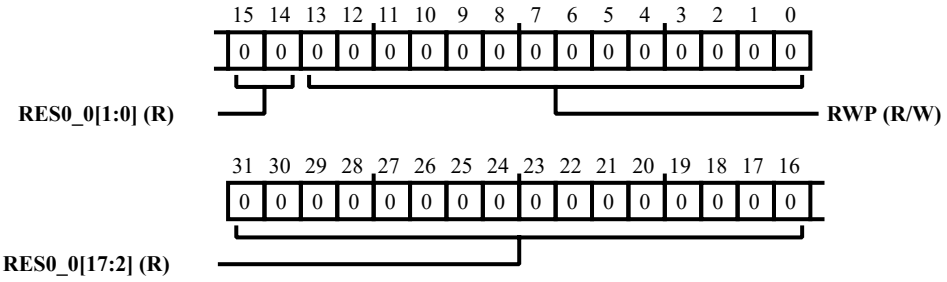

Figure 48-554: CSETF_RWP Register Diagram

Table 48-557: CSETF_RWP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:14 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
13:0 (R/W)	RWP	. The RWP width depends on the size of trace memory and is given by log2(MEM_SIZE x 4). The remaining MSBs of the 32-bit register are of type RAZ/WI. When ATB_DATA_WIDTH is 32, 64 or 128 bit wide the memory width is twice as wide and a memory word holds 8, 16 or 32 bytes. When a full memory width of data has been written to the RWD register, the RWP register is incremented to the next memory word. The lowest 4 bits have access type RAZ/WI when ATB_DATA_WIDTH is 32 or 64 bits. The lowest 5 bits have access type RAZ/WI when ATB_DATA_WIDTH is 128 bits.

Status register.

The STS register indicates the status of the Trace Memory Controller. After a reset, software must ignore all the fields of this register except STS.TMCReady. The other fields only have meaning when the TMC has left the Disabled state. Writes to all RO fields of this register are ignored.

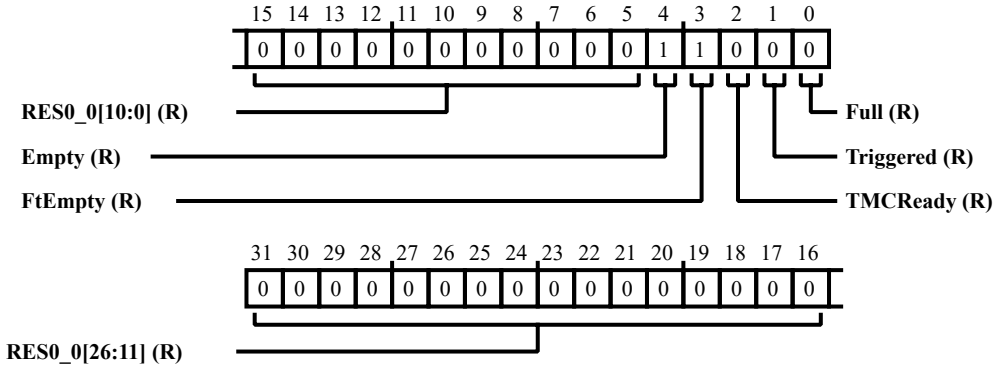

Figure 48-555: CSETF_STS Register Diagram

Table 48-558: CSETF_STS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:5 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
4 (R/NW)	EMPTY	. Trace buffer empty. If set, this bit indicates that the trace memory does not contain any valid trace data. The reset value of this bit is 1. On leaving Disabled state, this bit dynamically indicates the empty status of trace memory, CBUFLEVEL == 0. However, this does not mean that the pipeline stages within the TMC are empty. To determine whether the internal pipeline stages are empty, the software must read the STS.TMCReady bit. In Circular Buffer mode the Empty bit and the Full bit in this register can be 1 at the same time. This happens because the Full bit in this mode, when set, does not clear until TraceCaptEn is set.
3 (R/NW)	FTEMPTY	. Trace capture has been completed and all captured trace data has been written to the trace memory, set in Stopped or Disabled state. Otherwise, it is cleared. The reset value is 1.
2 (R/NW)	TMCREADY	. Trace capture has been completed, all captured trace data has been written to the trace memory, and reading from trace memory completed as a result of FFCR.DrainBuffer bit being set.

Table 48-558: CSETF_STS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
1 (R/NW)	TRIGGERED	. TMC triggered. This bit is set when trace capture is in progress and the TMC has detected a trigger event. This bit is cleared to 0 when leaving the Disabled state and retains its value when entering the Disabled state. A trigger event is when the TMC has written a set number of data words, as programmed in the TRG register, into the trace memory after a rising edge of trigin input, or a trigger packet (atid_rx = 0x7D) is received in the input trace.
0 (R/NW)	FULL	. Trace memory full. This bit helps determine the amount of valid data present in the trace memory. It is not affected by the reprogramming of pointer registers in Disabled state. It is cleared when the TMC leaves Disabled state. In Circular Buffer mode, this flag is set when the RAM write pointer wraps around the top of the buffer. It remains set until the TraceCaptEn bit is cleared and set. In Software FIFO and Hardware FIFO mode, this flag indicates that the current space in the trace memory is less than or equal to the value programmed in the BUFWM Register, that is, Fill level >= MEM_SIZE - BUFWM. The FULL output from the TMC reflects the value of this register bit, except when the Integration Mode bit in the ITCTRL Register, 0xF00, is set.

Trigger Counter register.

The TRG register, in Circular Buffer mode, specifies the number of 32-bit words to capture in the trace memory, after detecting either a rising edge on the trigin input or a trigger packet in the incoming trace stream, that is, where atid_rx = 0x7D. The value programmed must be aligned to the frame length of 128 bits. Software must program this register before leaving Disabled state.

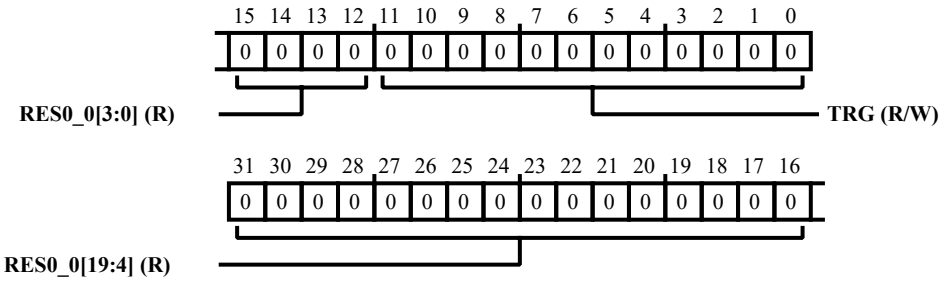

Figure 48-556: CSETF_TRG Register Diagram

Table 48-559: CSETF_TRG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:12 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
11:0 (R/W)	TRG	. Trigger count. This count represents the number of 32-bit words of trace that are captured between a trigger packet and a trigger event. The lowest two bits have access type RAZ/WI.

ADSP-2184x CSETR Register Descriptions

Your module description, here. (CSETR) contains the following registers.

Table 48-560: ADSP-2184x CSETR Register List

Name	Description
CSETR_AUTHSTATUS	Authentication Status Register.
CSETR_AXICTL	AXI Control Register.
CSETR_AXICTL1	AXI Control Register 1.
CSETR_BUFWM	Buffer Level Water Mark.
CSETR_CBUFLEVEL	Current Buffer Fill Level.
CSETR_CIDR0	Component Identification Register 0.
CSETR_CIDR1	Component Identification Register 1.

Table 48-560: ADSP-2184x CSETR Register List (Continued)

Name	Description
CSETR_CIDR2	Component Identification Register 2.
CSETR_CIDR3	Component Identification Register 3.
CSETR_CLAIMCLR	Claim Tag Clear Register.
CSETR_CLAIMSET	Claim Tag Set Register.
CSETR_CTL	Control Register.
CSETR_DBAHI	Data Buffer Address HIGH register.
CSETR_DBALO	Data Buffer Address Low register.
CSETR_DEVID	Device Configuration Register.
CSETR_DEVID1	Device Configuration Register 1.
CSETR_DEVTYPE	Device Type Identifier Register.
CSETR_FFCR	Formatter and Flush Control Register.
CSETR_FFSR	Formatter and Flush Status Register.
CSETR_ITATBCTR0	Integration Test ATB Control 0 Register.
CSETR_ITATBCTR1	Integration Test ATB Control 1 Register.
CSETR_ITATBCTR2	Integration Test ATB Control 2 Register.
CSETR_ITATBDATA0	Integration Test ATB Data 0 Register.
CSETR_ITCTRL	Integration Mode Control Register.
CSETR_ITEVTINTR	Integration Test Event and Interrupt Control Register.
CSETR_ITTRFLIN	Integration Test Trigger In and Flush In register.
CSETR_LBUFLEVEL	Latched Buffer Fill Level.
CSETR_MODE	Mode register.
CSETR_PIDR0	Peripheral Identification Register 0.
CSETR_PIDR1	Peripheral Identification Register 1.
CSETR_PIDR2	Peripheral Identification Register 2.
CSETR_PIDR3	Peripheral Identification Register 3.
CSETR_PIDR4	Peripheral Identification Register 4.
CSETR_PIDR5	Peripheral Identification Register 5.
CSETR_PIDR6	Peripheral Identification Register 6.
CSETR_PIDR7	Peripheral Identification Register 7.
CSETR_PSCR	Periodic Synchronization Counter Register.
CSETR_RRD	RAM Read Data register.

Table 48-560: ADSP-2184x CSETR Register List (Continued)

Name	Description
CSETR_RRP	RAM Read Pointer register.
CSETR_RRPHI	RAM Read Pointer High register.
CSETR_RSZ	RAM Size register.
CSETR_RURP	RAM Update Read Pointer register.
CSETR_RWD	RAM Write Data register.
CSETR_RWP	RAM Write Pointer register.
CSETR_RWPHI	RAM Write Pointer High register.
CSETR_STS	Status register.
CSETR_TRG	Trigger Counter register.

Authentication Status Register.

Reports the current status of the authentication control signals.

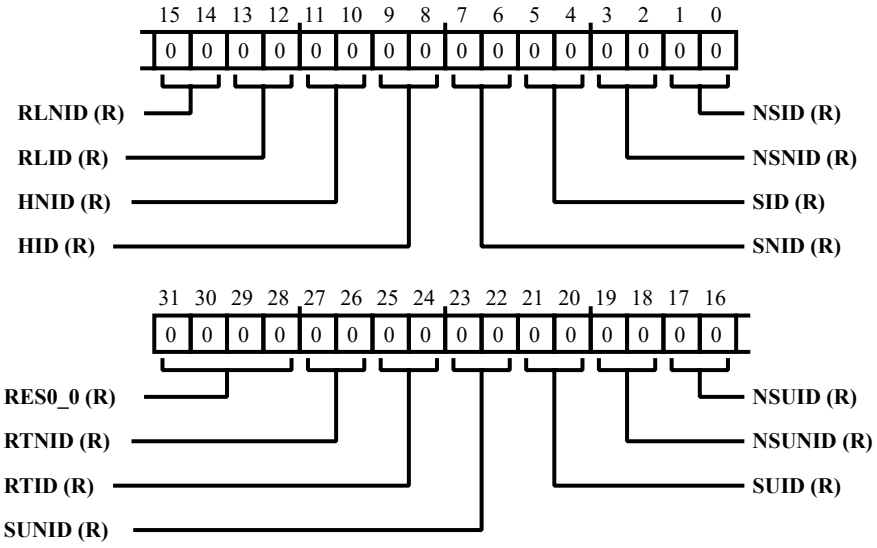

Figure 48-557: CSETR_AUTHSTATUS Register Diagram

Table 48-561: CSETR_AUTHSTATUS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:28 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
27:26 (R/NW)	RTNID	. Root non-invasive debug.	
		0	Separate Root non-invasive debug enable not implemented or Root state non-invasive debug features not implemented.
		1	Reserved.
		2	Implemented and disabled.
		3	Implemented and enabled.

Table 48-561: CSETR_AUTHSTATUS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
25:24 (R/NW)	RTID	. Root invasive debug.	
		0	Separate Root invasive debug enable not implemented or Root state invasive debug features not implemented.
		1	Reserved.
		2	Implemented and disabled.
		3	Implemented and enabled.
23:22 (R/NW)	SUNID	. Secure unprivileged non-invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.
21:20 (R/NW)	SUID	. Secure unprivileged invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.
19:18 (R/NW)	NSUNID	. Non-secure unprivileged non-invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.
17:16 (R/NW)	NSUID	. Non-secure unprivileged invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.

Table 48-561: CSETR_AUTHSTATUS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15:14 (R/NW)	RLNID	. Realm non-invasive debug.	
		0	Separate Realm non-invasive debug enable not implemented or Realm state non-invasive debug features not implemented.
		1	Reserved.
		2	Implemented and disabled.
		3	Implemented and enabled.
13:12 (R/NW)	RLID	. Realm invasive debug.	
		0	Separate Realm invasive debug enable not implemented or Realm state invasive debug features not implemented.
		1	Reserved.
		2	Implemented and disabled.
		3	Implemented and enabled.
11:10 (R/NW)	HNID	. Hypervisor non-invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.
9:8 (R/NW)	HID	. Hypervisor invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.

Table 48-561: CSETR_AUTHSTATUS Register Fields (Continued)

7:6 (R/NW)	SNID	. Secure non-invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.
5:4 (R/NW)	SID	. Secure invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.
3:2 (R/NW)	NSNID	. Non-secure non-invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.
1:0 (R/NW)	NSID	. Non-secure invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.

AXI Control Register.

This register controls TMC accesses to system memory through the AXI interface. The TMC only performs data accesses, so the arprot_m[2] and awprot_m[2] outputs are LOW for all AXI transfers.

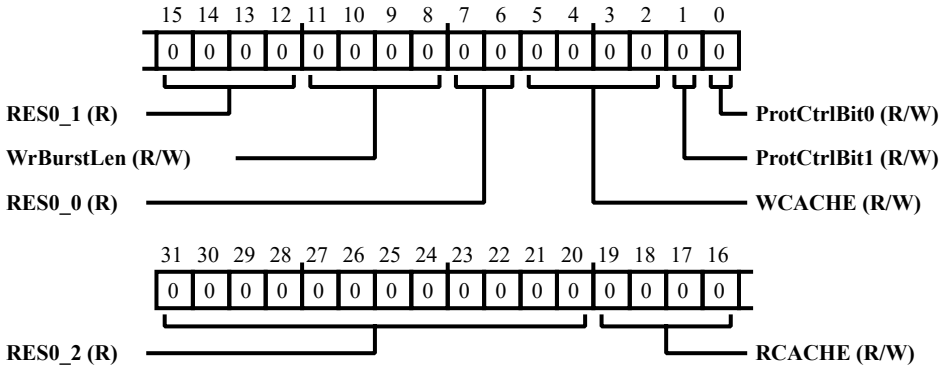

Figure 48-558: CSETR_AXICTL Register Diagram

Table 48-562: CSETR_AXICTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:20 (R/NW)	RES0_2	. Reserved bit or field with SBZP behavior.
19:16 (R/W)	RCACHE	. This field controls the AXI cache encoding for read transfers, that is, the value to be driven on the arcache_m[3:0] bus. Software must only program a valid AXI cache encoding value in this field. These values are defined in the AMBA AXI Protocol Specification. If software attempts to program an invalid value, 0x0 is written to this field instead.
15:12 (R/NW)	RES0_1	. Reserved bit or field with SBZP behavior.
11:8 (R/W)	WRBURSTLEN	. Write Burst Length. This field indicates the maximum number of data transfers that can occur within each burst that is initiated by the TMC on the AXI interface. The write burst that is initiated on the AXI can be shorter than the programmed value in a case when the formatter has stopped due to a stop condition having occurred.
7:6 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.

Table 48-562: CSETR_AXICTL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
5:2 (R/W)	WCACHE	. This field controls the AXI cache encoding for write transfers, that is, the value to be driven on the awcache_m[3:0] bus. Software must only program a valid AXI cache encoding value in this field. These values are defined in the AMBA AXI Protocol Specification. If software attempts to program an invalid value, 0x0 is written to this field instead.
1 (R/W)	PROTCTRLBIT1	. Secure Access (AXI definition). This bit controls the value that is driven on arprot_m[1] or awprot_m[1] on the AXI manager interface when performing AXI transfers.
0 (R/W)	PROTCTRLBIT0	. Privileged Access (AXI definition). This bit controls the value that is driven on arprot_m[0] or awprot_m[0] on the AXI manager interface when performing AXI transfers.

AXI Control Register 1.

This register controls address translation stashing requests made to a system MMU through the AXI interface.When the ETR is integrated with stash_disable == 1, this register behaves as RAZ/WI.

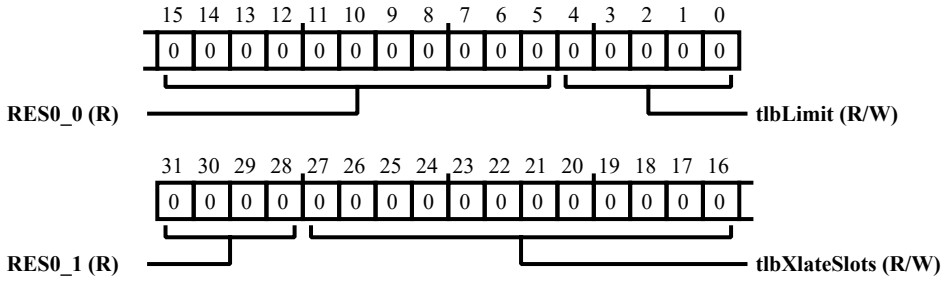

Figure 48-559: CSETR_AXICTL1 Register Diagram

Table 48-563: CSETR_AXICTL1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:28 (R/NW)	RES0_1	. Reserved bit or field with SBZP behavior.
27:16 (R/W)	TLBXLATESLOTS	. Writes: are ignored when stash_disabled tie-off is high. Otherwise, in Disabled state, stores APB write data [27:16] (The reset default is 0x0). Otherwise, in all other states, writing this field is disabled. Reads: Returns 0x0 when stash_disable tie-off is high. Otherwise this field returns the result of the stash_xlate_limit tie-off value exored with the stored APB write data. However, results less than 0x2 are limited to 0x2. 0x02 - 0xFFF ETR issues a maximum of 2 - 4095 outstanding stash translation requests.
15:5 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
4:0 (R/W)	TLBLIMIT	. Writes: are ignored when stash_disabled tie-off is high. Otherwise, in Disabled state, stores APB write data [5:0] (The reset default is 0x0). Otherwise, in all other states, writing this field is disabled.Reads: Returns 0x0 when stash_disable tie-off is high. Otherwise this field returns the result of tlb_limit tie-off value exored with the stored APB write data. However, results larger than 0x10 are limited to 0x10. 0x00 : Translation stashing is disabled 0x01 - 0x10 : The ETR issues stash translation requests for up to 2^tlbLimit * 4k pages ahead of RWP page.

Buffer Level Water Mark.

The value that is programmed into the BUFWM register indicates the required threshold vacancy level in 32-bit words in the trace memory. When the available space in the FIFO is less than or equal to this value, that is, fill level >= (MEM_SIZE - BUFWM), the full output is asserted and the STS.Full bit is set. This register is used only in the FIFO modes, that is, SWF1, SWF2, and HWF modes. In CB mode, the same functionality is obtained by programming the RWP to the required vacancy trigger level, so that when the pointer wraps around, the full output gets asserted indicating that the vacancy level has fallen below the required level. Reading this register returns the programmed value. The maximum value that can be written into this register is MEM_SIZE - 1, in which case the full output is asserted after the first 32-bit word is written to trace memory. Writing to this register other than when in Disabled state results in UNPREDICTABLE behavior. Any software using it must program it with an initial value before setting the CTL.TraceCaptEn bit to 1.

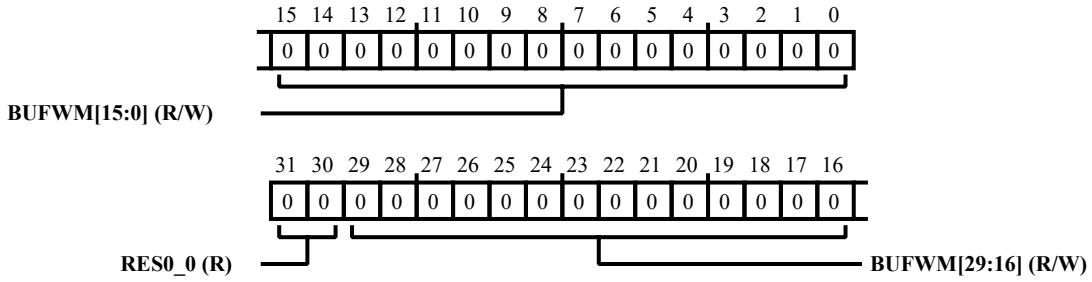

Figure 48-560: CSETR_BUFWM Register Diagram

Table 48-564: CSETR_BUFWM Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:30 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
29:0 (R/W)	BUFWM	. Buffer Level Watermark. Indicates the required threshold vacancy level in 32-bit words in the trace memory.

Current Buffer Fill Level.

The CBUFLEVEL register indicates the current fill level of the trace memory in units of 32-bit words. When the TMC leaves Disabled state, this register dynamically indicates the current fill level of trace memory. It retains its value on entering Disabled state. It is not affected by the reprogramming of pointer registers in Disabled state with the exception of RRD reads and RWD writes.

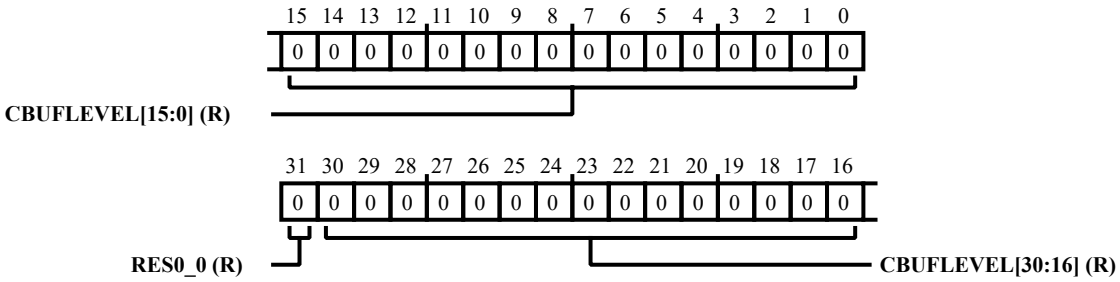

Figure 48-561: CSETR_CBUFLEVEL Register Diagram

Table 48-565: CSETR_CBUFLEVEL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
30:0 (R/NW)	CBUFLEVEL	. Current Buffer Fill Level. Indicates the current fill level of the trace memory in 32-bit words.

Component Identification Register 0.

The CIDR0 register is part of the set of component identification registers.

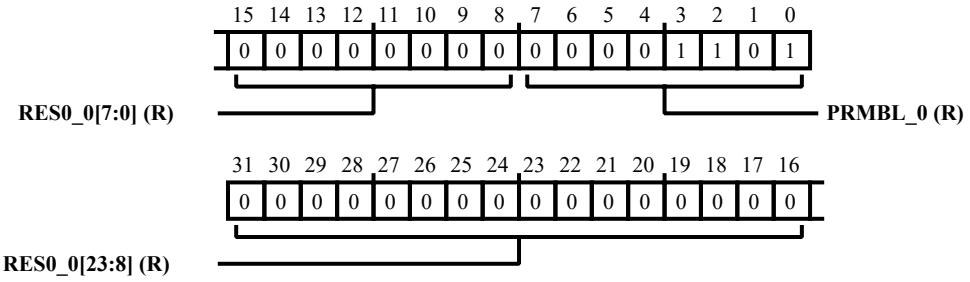

Figure 48-562: CSETR_CIDR0 Register Diagram

Table 48-566: CSETR_CIDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PRMBL_0	. Preamble. Returns 0x0D.

Component Identification Register 1.

The CIDR1 register is part of the set of component identification registers.

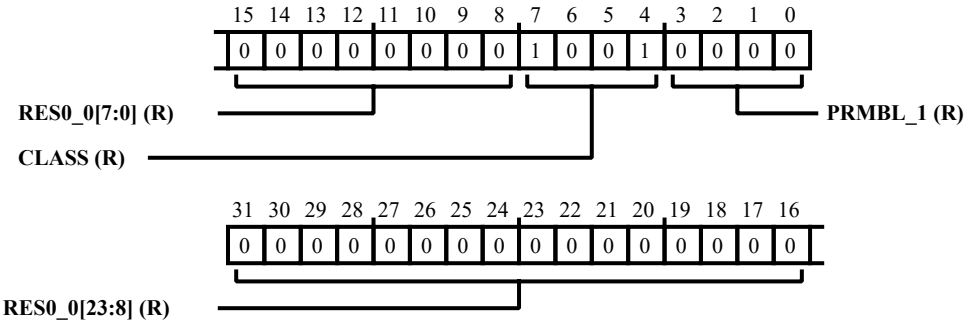

Figure 48-563: CSETR_CIDR1 Register Diagram

Table 48-567: CSETR_CIDR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
7:4 (R/NW)	CLASS	. Component class.	
		9	CoreSight component.
		15	CoreLink, PrimeCell, or system component.
3:0 (R/NW)	PRMBL_1	. Preamble. Returns 0x0.	

Component Identification Register 2.

The CIDR2 register is part of the set of component identification registers.

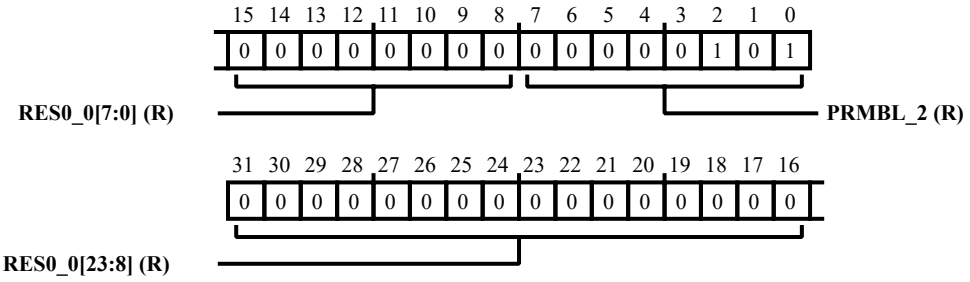

Figure 48-564: CSETR_CIDR2 Register Diagram

Table 48-568: CSETR_CIDR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PRMBL_2	. Preamble. Returns 0x05.

Component Identification Register 3.

The CIDR3 register is part of the set of component identification registers.

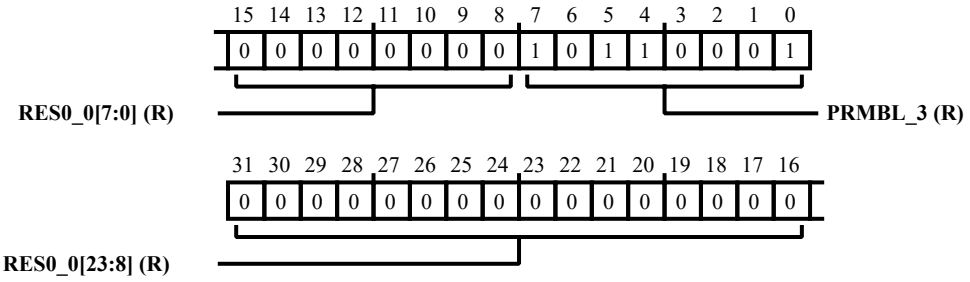

Figure 48-565: CSETR_CIDR3 Register Diagram

Table 48-569: CSETR_CIDR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PRMBL_3	. Preamble. Returns 0xB1.

Claim Tag Clear Register.

This register forms one half of the claim tag value. On writes, this location enables individual bits to be cleared. On reads, it returns the current claim tag value.

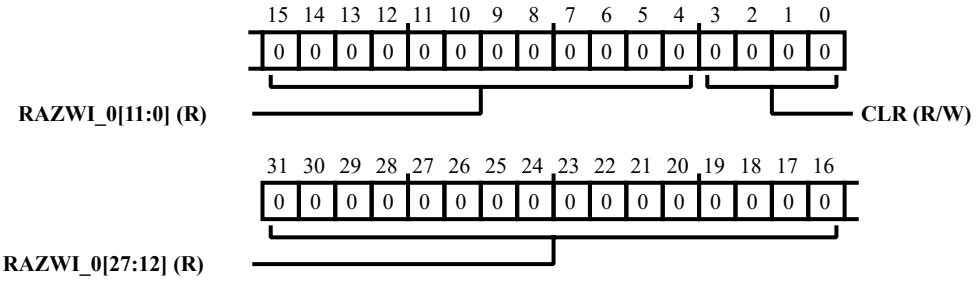

Figure 48-566: CSETR_CLAIMCLR Register Diagram

Table 48-570: CSETR_CLAIMCLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:4 (R/NW)	RAZWI_0	. RAZ/WI.
3:0 (R/W)	CLR	. A bit-programmable register bank that clears the claim tag value. It is zero at reset. It is used by software agents to signal to each other ownership of the hardware. It has no direct effect on the hardware itself.

Claim Tag Set Register.

This register forms one half of the claim tag value. On writes, this location enables individual bits to be set. On reads, it returns the number of bits that can be set.

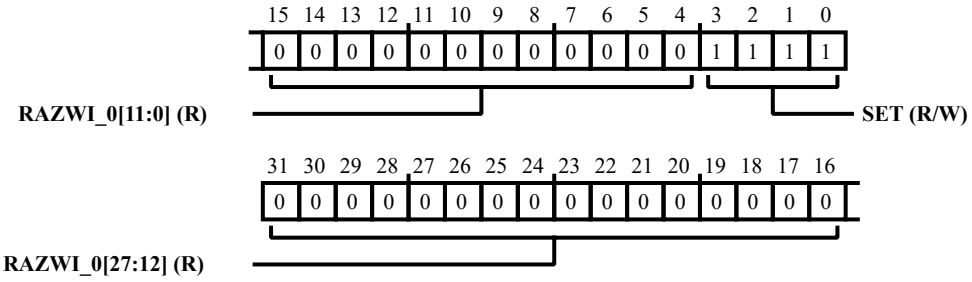

Figure 48-567: CSETR_CLAIMSET Register Diagram

Table 48-571: CSETR_CLAIMSET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:4 (R/NW)	RAZWI_0	. RAZ/WI.
3:0 (R/W)	SET	. A bit-programmable register bank that sets the claim tag value. A read returns a logic 1 for all implemented locations.

Control Register.

The CTL register controls trace stream capture. Setting the CTL.TraceCaptEn bit to 1 enables the TMC to capture the trace data. When trace capture is enabled, the formatter behavior is controlled by the FFCR register.

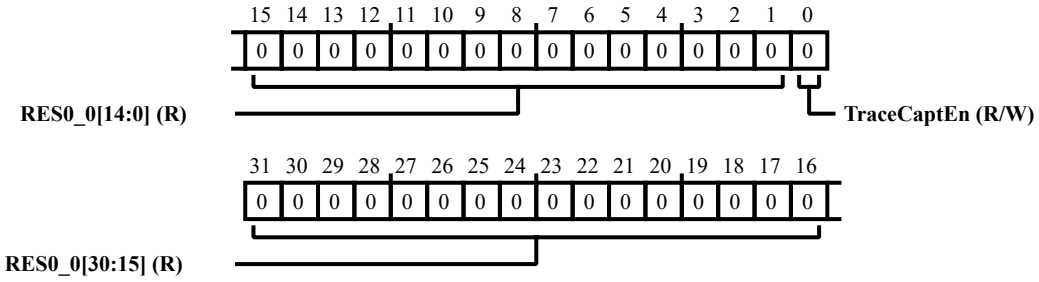

Figure 48-568: CSETR_CTL Register Diagram

Table 48-572: CSETR_CTL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:1 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
0 (R/W)	TRACECAPTEN	. Trace capture enable:.	
		0	Disable trace capture.
		1	Enable trace capture.

Data Buffer Address HIGH register.

This register, together with the DBALO register, enables the TMC to locate the trace buffer in system memory. It contains bits >= bit[32] of the start address of the trace buffer in system memory. The width of this register is given by: (AXI_ADDR_WIDTH - 32), however, if AXI_ADDR_WIDTH is <= 32 bits, this register is reserved and access type is RAZ/WI. Modifying this register, other than when in Disabled state, results in UNPREDICTABLE behavior. Software must program it with an initial value before setting CTL.TraceCaptEn bit to 1.

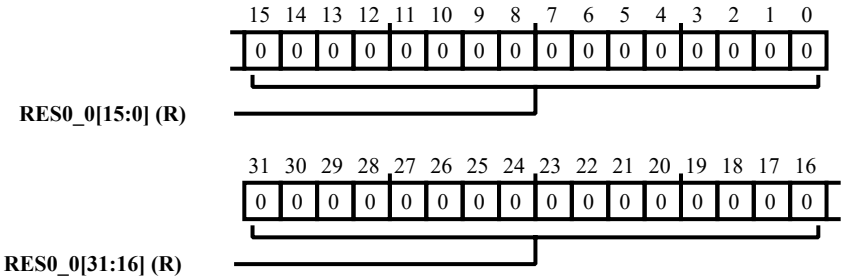

Figure 48-569: CSETR_DBAHI Register Diagram

Table 48-573: CSETR_DBAHI Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.

Data Buffer Address Low register.

This register, together with the DBAHI register, enables the TMC to locate the trace buffer in system memory. This register contains bits [31:0] of the start address of the trace buffer in system memory. This register is 32 bits wide if AXI_ADDR_WIDTH is >= 32 bits. Software must program it before enabling trace capture, and the programmed value must be aligned to the Trace Memory Data Width and the Frame Width. Programming an unaligned value results in UNPREDICTABLE behavior. Modifying this register other than when in Disabled state results in UNPREDICTABLE behavior.

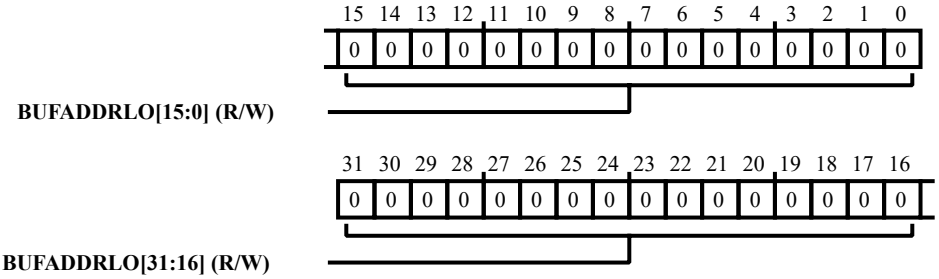

Figure 48-570: CSETR_DBALO Register Diagram

Table 48-574: CSETR_DBALO Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	BUFADDRLO	. Data Buffer Low Address. Holds the lower 32 bits of the AXI address that is used to locate the trace buffer in system memory.The lowest four bits have access type RAZ/WI.

Device Configuration Register.

This register is IMPLEMENTATION DEFINED for each Part Number and Designer. The register indicates the capabilities of the component.

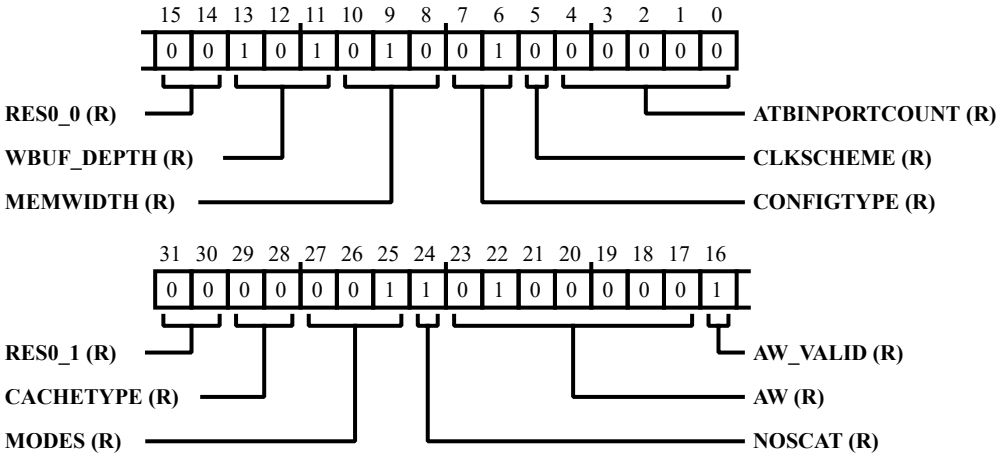

Figure 48-571: CSETR_DEVID Register Diagram

Table 48-575: CSETR_DEVID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:30 (R/NW)	RES0_1	. Reserved bit or field with SBZP behavior.	
29:28 (R/NW)	CACHETYPE	. Indicates the format of BUSCTL register bus control fields. Reads as 2'b00 indicating that AXICTL bus attribute bits [19:16] and [5:2] follow an implementation-defined non-generic format. See AXICTL register description.	
27:25 (R/NW)	MODES	. Indicates the supported modes of operation. Reads as 3'b001 indicating that ETR supports CB, SWF1, and SWF2 modes.	
24 (R/NW)	NOSCAT	. Indicates whether the scatter-gather mode is implemented. Fixed at 1 indicating that scatter-gather mode is not implemented.	
23:17 (R/NW)	AW	. This field indicates the width of AXI address bus in ETR configuration. This field is valid only when DEVID.AW_VALID is set. Possible values are:.	
		32	32-bit AXI address bus.
		40	40-bit AXI address bus.
		44	44-bit AXI address bus.

Table 48-575: CSETR_DEVID Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		48	48-bit AXI address bus.
		52	52-bit AXI address bus.
		64	64-bit AXI address bus.
16 (R/NW)	AW_VALID	. Indicates whether field DEVID.AW is valid. The value of this field is fixed at 1.	
15:14 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
13:11 (R/NW)	WBUF_DEPTH	. Log2 of the number of write buffer entries. This value is set by the parameter WBUFFER_DEPTH. Each entry is of size ATB_DATA_WIDTH.	
		2	Depth of Write buffer is 4 entries.
		3	Depth of Write buffer is 8 entries.
		4	Depth of Write buffer is 16 entries.
		5	Depth of Write buffer is 32 entries.
		6	Depth of Write buffer is 64 entries.
		7	Depth of Write buffer is 128 entries.
10:8 (R/NW)	MEMWIDTH	. Indicates the width of the internal memory data bus. For the ETR this value is equal to ATB_DATA_WIDTH.	
		2	Memory interface databus is 32 bits wide. (ATB_DATA_WIDTH = 32bit).
		3	Memory interface databus is 64 bits wide. (ATB_DATA_WIDTH = 64bit).
		4	Memory interface databus is 128 bits wide. (ATB_DATA_WIDTH = 128bit).
7:6 (R/NW)	CONFIGTYPE	. Indicates the TMC configuration.	
		0	ETB - Embedded Trace Buffer.
		1	ETR - Embedded Trace Router.
		2	ETF - Embedded Trace FIFO.
		3	ETS - Embedded Trace Streamer.

Table 48-575: CSETR_DEVID Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
5 (R/NW)	CLKSCHEME	. RAM Clocking Scheme. This value indicates the TMC RAM clocking scheme used, that is, whether the TMC RAM operates synchronously or asynchronously to the TMC clock. Fixed to 0 indicating that TMC RAM clock is synchronous to the clk input.
4:0 (R/NW)	ATBINPORTCOUNT	. Hidden Level of ATB input multiplexing. This value indicates the type/number of ATB multiplexing present on the input ATB. Fixed to 0x00 indicating that no multiplexing is present.

Device Configuration Register 1.

Contains an IMPLEMENTATION DEFINED value.

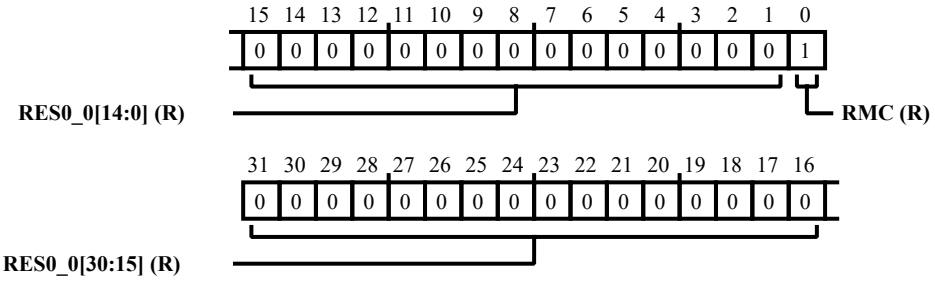

Figure 48-572: CSETR_DEVID1 Register Diagram

Table 48-576: CSETR_DEVID1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:1 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
0 (R/NW)	RMC	. Register management mode. TMC implements register management mode 1.

Device Type Identifier Register.

A debugger can use this register to get information about a component that has an unrecognized Part number.

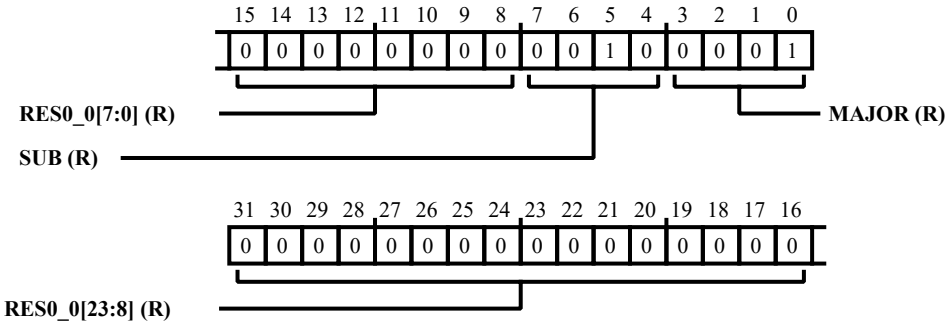

Figure 48-573: CSETR_DEVTYPE Register Diagram

Table 48-577: CSETR_DEVTYPE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:4 (R/NW)	SUB	. Minor classification. Returns 0x2, indicating this component is a Buffer.
3:0 (R/NW)	MAJOR	. Major classification. Returns 0x1, indicating this component is a Trace Sink.

Formatter and Flush Control Register.

The FFCR controls the generation of stop, trigger and flush events. The insertion of a flush completion packet and the insertion of a trigger packet in the formatted trace is enabled here. Also one of the 2 formatter modes for bypass mode and normal mode can be changed here when the formatter has stopped.

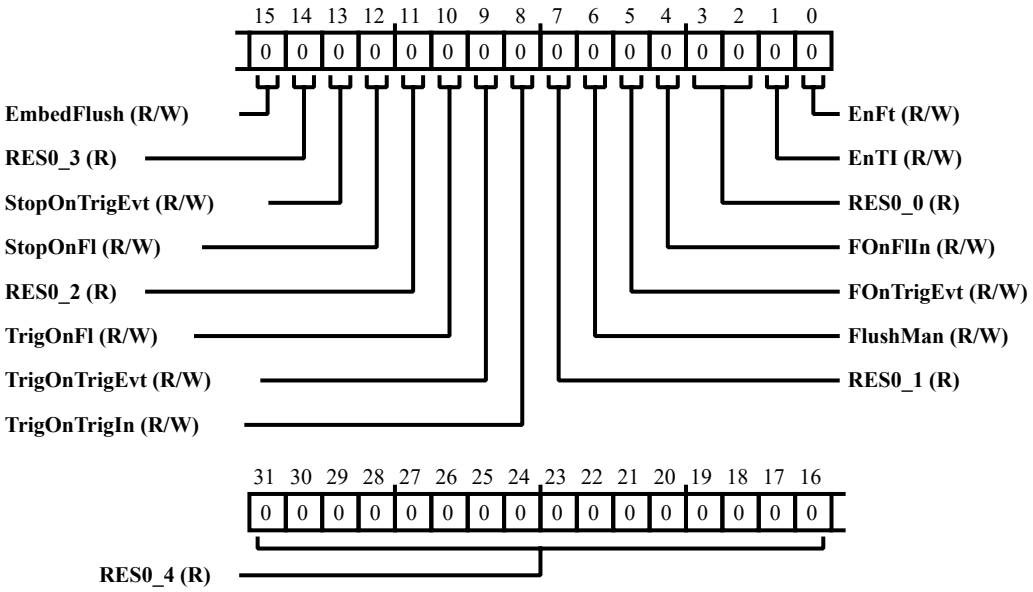

Figure 48-574: CSETR_FFCR Register Diagram

Table 48-578: CSETR_FFCR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:16 (R/NW)	RES0_4	. Reserved bit or field with SBZP behavior.	
15 (R/W)	EMBEDFLUSH	. Embed Flush ID (flush completion packet). Enables insertion of Flush ID 0x7B with a single byte of data payload = 0x00 in the output trace, immediately after the last flush data byte, when a flush completes on the ATB receiver interface. This bit is effective only in Normal formatting modes. In Bypass mode, the Flush ID insertion remains disabled and this bit is ignored.	
		0	Disable Flush ID insertion.
		1	Enable Flush ID insertion.
14 (R/NW)	RES0_3	. Reserved bit or field with SBZP behavior.	

Table 48-578: CSETR_FFCR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
13 (R/W)	STOPONTRIGEVT	. Stop On Trigger Event. If this bit is set, the formatter is stopped when a Trigger Event has been observed. This bit must be used only in CB mode. If trace capture is enabled in SWF1, or SWF2 mode with this bit set, it results in UNPREDICTABLE behavior.
12 (R/W)	STOPONFL	. Stop On Flush. If this bit is set, the formatter is stopped on completion of a flush operation. The initiation of a flush operation is controlled by programming the register bits FFCR.FlushMan, FFCR.FOnTrigEvt, and FFCR.FOnFlIn. When a flush-initiation condition occurs, afvalid_rx is asserted, and when the flush completion is received, that is, afready_rx=1, trace capture is stopped. Any remaining data in the formatter is appended with a post-amble and written to trace memory. The flush operation is then complete.
11 (R/NW)	RES0_2	. Reserved bit or field with SBZP behavior.
10 (R/W)	TRIGONFL	. Indicate on trace stream the completion of flush. If this bit is set, a trigger is indicated on the trace stream when afready_rx is received for a flush in progress. If this bit is clear, no triggers are embedded in the trace stream on flush completion. If Trigger Insertion is disabled, that is, FFCR.EnTI=0, then trigger indication on the trace stream is blocked regardless of the value that is programmed in this bit.
9 (R/W)	TRIGONTRIGEVT	. Indicate on trace stream the occurrence of a Trigger Event. If this bit is set, a trigger is indicated on the output trace stream when a Trigger Event occurs. If Trigger Insertion is disabled, that is, FFCR.EnTI=0, then trigger indication on the trace stream is blocked regardless of the value that is programmed in this bit. This bit must be used only in CB mode. If trace capture is enabled in SWF1, or SWF2 mode with this bit set, it results in UNPREDICTABLE behavior.
8 (R/W)	TRIGONTRIGIN	. Indicate on trace stream the occurrence of a rising edge on trigin. If this bit is set, a trigger is indicated on the trace stream when a rising edge is detected on the trigin input. If Trigger Insertion is disabled, that is, FFCR.EnTI=0, then trigger indication on the trace stream is blocked regardless of the value that is programmed in this bit.
7 (R/NW)	RES0_1	. Reserved bit or field with SBZP behavior.

Table 48-578: CSETR_FFCR Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
6 (R/W)	FLUSHMAN	. Manually generate a flush of the system. Writing 1 to this bit causes a flush to be generated. This bit is cleared automatically when, in formatter bypass mode, afready_rx was sampled high, or, in normal formatting mode, afready_rx was sampled high and all flush data was output to the trace memory. If CTL.TraceCaptEn=0, writes to this bit are ignored.
5 (R/W)	FONTRIGEVT	. Flush on Trigger Event. If FFCR.StopOnTrigEvt is set, this bit is ignored. Setting this bit generates a flush when a Trigger Event occurs. If FFCR.StopOnTrigEvt is set, this bit is ignored. This bit must be used only in CB mode. If trace capture is enabled in SWF1, or SWF2 mode with this bit set, it results in UNPREDICTABLE behavior.
4 (R/W)	FONFLIN	. Setting this bit enables the detection of transitions on the flushin input by the TMC. If this bit is set and the formatter has not already stopped, a rising edge on flushin initiates a flush request.
3:2 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
1 (R/W)	ENTI	. Enable Trigger Insertion. Setting this bit enables the insertion of triggers in the formatted trace stream. A trigger is indicated by inserting one byte of data 0x00 with atid_rx=0x7D in the trace stream. Trigger indication on the trace stream is also controlled by the register bits FFCR.TrigOnFl, FFCR.TrigOnTrigEvt, and FFCR.TrigOnTrigIn. This bit can only be changed when the TMC is in Disabled state. If FFCR.EnTI bit is set formatting is enabled.
0 (R/W)	ENFT	. Enable Formatter. If this bit is set, formatting is enabled. When EnTi is set, formatting is enabled. When CB mode is not used, formatting is also enabled. For backwards-compatibility with earlier versions of the ETB disabling of formatting is supported only in CB mode. This bit can only be changed when TMC is in Disabled state.

Formatter and Flush Status Register.

This register indicates the status of the Formatter, and the status of Flush request.

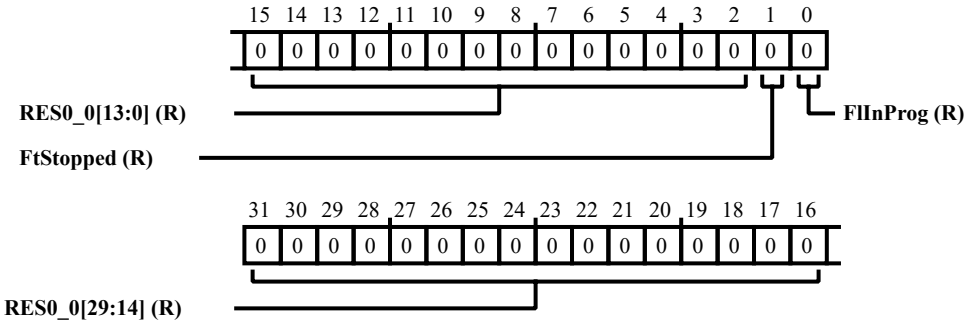

Figure 48-575: CSETR_FFSR Register Diagram

Table 48-579: CSETR_FFSR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:2 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
1 (R/NW)	FTSTOPPED	. Formatter Stopped. This bit behaves the same way as STS.FtEmpty.	
0 (R/NW)	FLINPROG	. Flush In Progress. This bit indicates whether the TMC is currently processing a flush request. The flush initiation is controlled by the flush control bits in the FFCR register. This bit is cleared to 0 when leaving the Disabled state and retains its value when entering the Disabled state. When in Disabled state, this bit is not updated.	
		0	No flush activity in progress.
		1	Flush in progress on the ATB receiver interface or the TMC internal pipeline.

Integration Test ATB Control 0 Register.

This register captures the values of ATB receiver inputs atvalid_rx, afready_rx, atwakeup_rx, and atbytes_rx in integration mode. In functional mode, this register behaves as RAZ/WI. In integration mode, writes to this register are ignored and the reads return the value of corresponding input pins. The width of this register is given by: 8+log2(ATB DATA WIDTH/8).

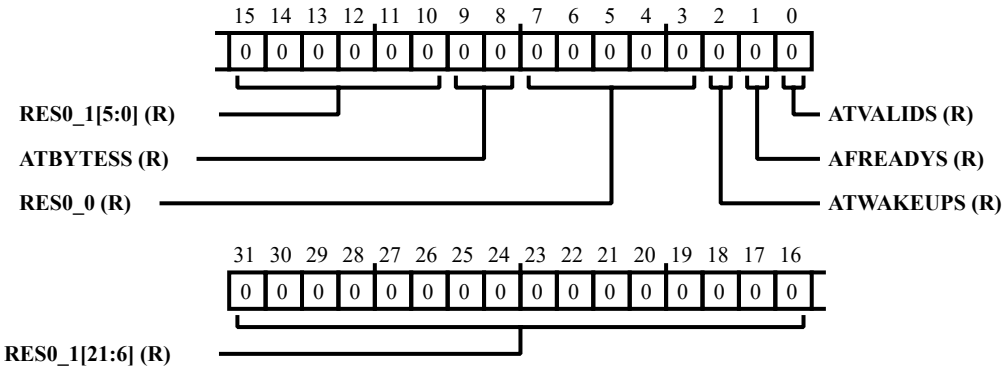

Figure 48-576: CSETR_ITATBCTR0 Register Diagram

Table 48-580: CSETR_ITATBCTR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:10 (R/NW)	RES0_1	. Reserved bit or field with SBZP behavior.
9:8 (R/NW)	ATBYTESS	. Returns the value of atbytes_rx input in integration mode. N=8+log2(ATB DATA WIDTH/8).
7:3 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
2 (R/NW)	ATWAKEUPS	. Returns the value of atwakeup_rx input in integration mode.
1 (R/NW)	AFREADYS	. Returns the value of afready_rx input in integration mode.
0 (R/NW)	ATVALIDS	. Returns the value of atvalid_rx input in integration mode.

Integration Test ATB Control 1 Register.

This register captures the value of the atid_rx[6:0] input in integration mode. In functional mode, this register behaves as RAZ/WI. In integration mode, writes to this register are ignored and the reads return the value of atid_rx input.

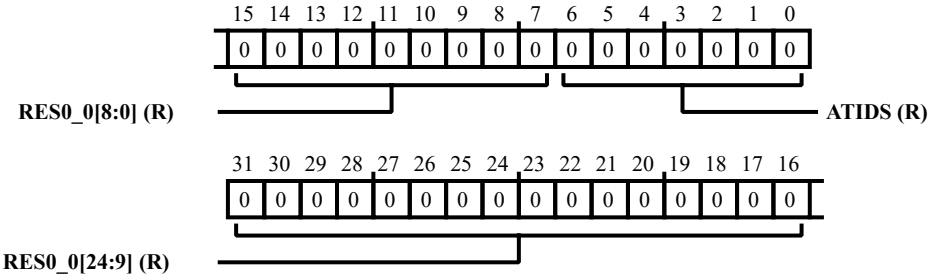

Figure 48-577: CSETR_ITATBCTR1 Register Diagram

Table 48-581: CSETR_ITATBCTR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:7 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
6:0 (R/NW)	ATIDS	. Returns the value of atid_rx[6:0] input in integration mode.

Integration Test ATB Control 2 Register.

This register enables control of ATB receiver outputs atready_rx, afvalid_rx, and syncreq_rx in integration mode. In functional mode, this register behaves as RAZ/WI. In integration mode, the value that is written to any bit of this register is driven on the output pin that is controlled by that bit and the reads return 0x0.

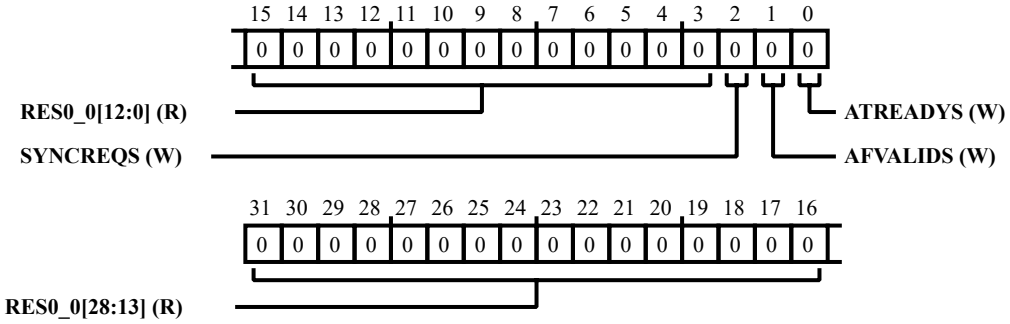

Figure 48-578: CSETR_ITATBCTR2 Register Diagram

Table 48-582: CSETR_ITATBCTR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:3 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
2 (RX/W)	SYNCREQS	. Controls the value of syncreq_rx output in integration mode.
1 (RX/W)	AFVALIDS	. Controls the value of afvalid_rx output in integration mode.
0 (RX/W)	ATREADYS	. Controls the value of atready_rx output in integration mode.

Integration Test ATB Data 0 Register.

This register captures the value of atdata_rx input in integration mode. In functional mode, this register behaves as RAZ/WI. In integration mode, writes to this register are ignored and the reads return the value of corresponding atdata_rx bits. The width of this register is given by: 1+(ATB DATA WIDTH)/8.

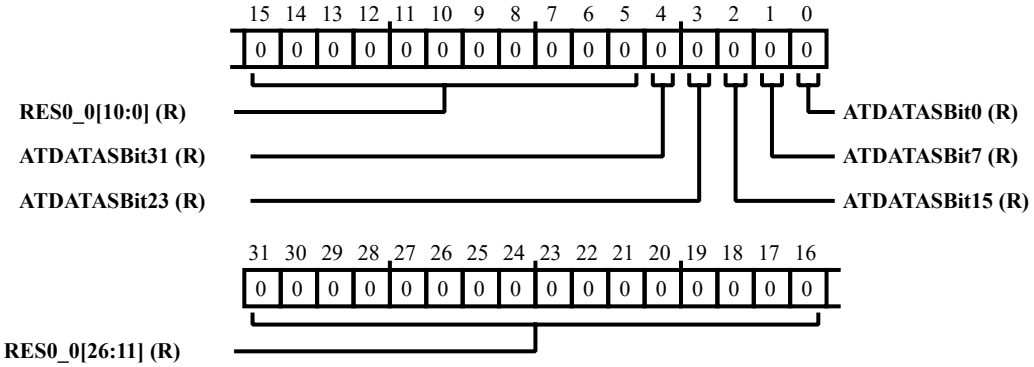

Figure 48-579: CSETR_ITATBDATA0 Register Diagram

Table 48-583: CSETR_ITATBDATA0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:5 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
4 (R/NW)	ATDATASBIT31	. Returns the value of atdata_rx[31] input in integration mode.
3 (R/NW)	ATDATASBIT23	. Returns the value of atdata_rx[23] input in integration mode.
2 (R/NW)	ATDATASBIT15	. Returns the value of atdata_rx[15] input in integration mode.
1 (R/NW)	ATDATASBIT7	. Returns the value of atdata_rx[7] input in integration mode.
0 (R/NW)	ATDATASBIT0	. Returns the value of atdata_rx[0] input in integration mode.

Integration Mode Control Register.

The Integration Mode Control register is used to switch between functional mode and integration mode. After switching to integration mode and performing integration tests or topology detection, reset the system to ensure correct behavior of CoreSight and other connected system components.

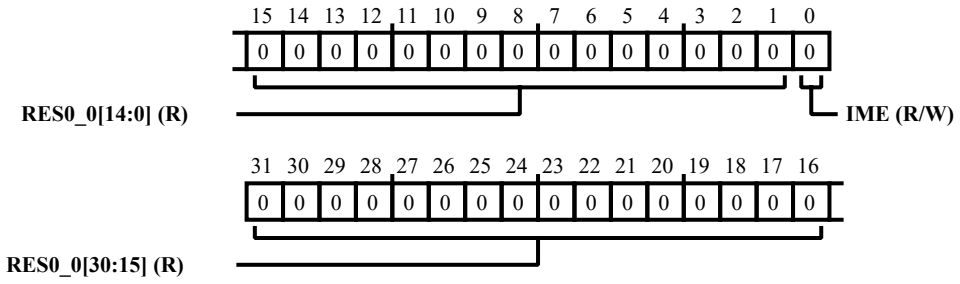

Figure 48-580: CSETR_ITCTRL Register Diagram

Table 48-584: CSETR_ITCTRL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:1 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
0 (R/W)	IME	. Integration Mode Enable.	
		0	The component must enter functional mode.
		1	The component must enter integration mode, and enable support for topology detection and integration testing.

Integration Test Event and Interrupt Control Register.

This register controls the values of event and interrupt outputs in integration mode. In functional mode, this register behaves as RAZ/WI. In integration mode, the value that is written to any bit of this register is driven on the output pin that is controlled by that bit and the reads return 0x0.

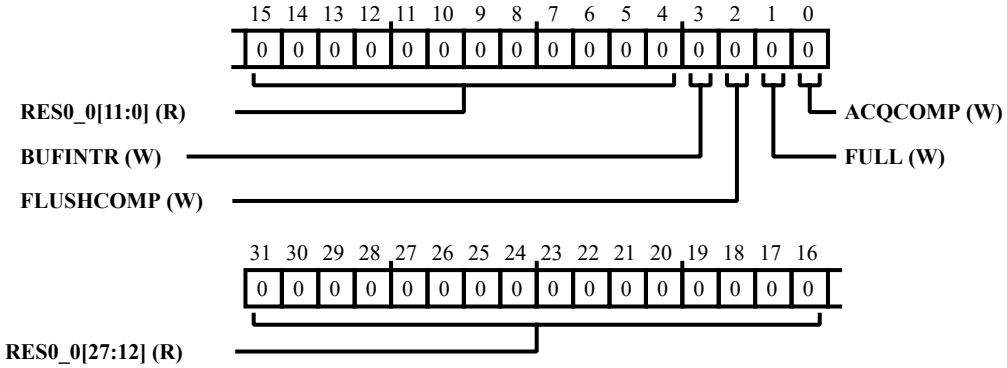

Figure 48-581: CSETR_ITEVTINTR Register Diagram

Table 48-585: CSETR_ITEVTINTR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:4 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
3 (RX/W)	BUFINTR	. Controls the value of bufintr output in integration mode.
2 (RX/W)	FLUSHCOMP	. Controls the value of flushcomp output in integration mode.
1 (RX/W)	FULL	. Controls the value of full output in integration mode.
0 (RX/W)	ACQCOMP	. Controls the value of acqcomp output in integration mode.

Integration Test Trigger In and Flush In register.

This register captures the values of the flushin and trigin inputs in integration mode. In functional mode, this register behaves as RAZ/WI.

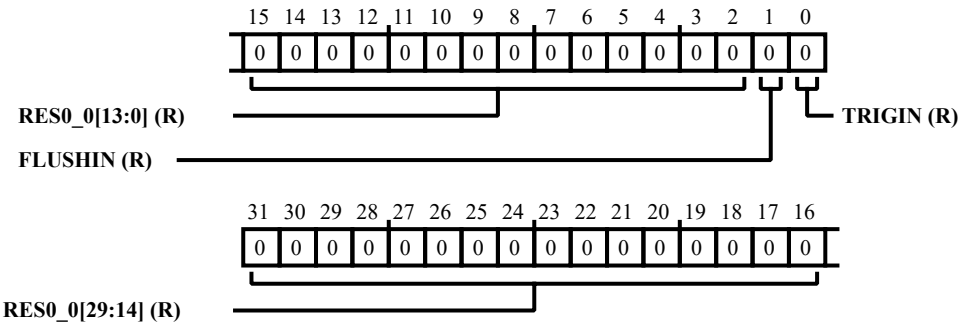

Figure 48-582: CSETR_ITTRFLIN Register Diagram

Table 48-586: CSETR_ITTRFLIN Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:2 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
1 (R/NW)	FLUSHIN	. Integration status of flushin input. In integration mode, this bit latches to 1 on a rising edge of the flushin input. It is cleared when the register is read or when integration mode is disabled.
0 (R/NW)	TRIGIN	. Integration status of trigin input. In integration mode, this bit latches to 1 on a rising edge of the trigin input. It is cleared when the register is read or when integration mode is disabled.

Latched Buffer Fill Level.

Reading the LBUFLEVEL register returns the maximum fill level of the trace memory in 32-bit words since this register was last read. Reading this register also results in its contents being updated to the current fill level. When entering Disabled state, it retains its last value. While in Disabled state, reads from this register do not affect its value. When exiting Disabled state, the LBUFLEVEL register is updated to the current fill level.

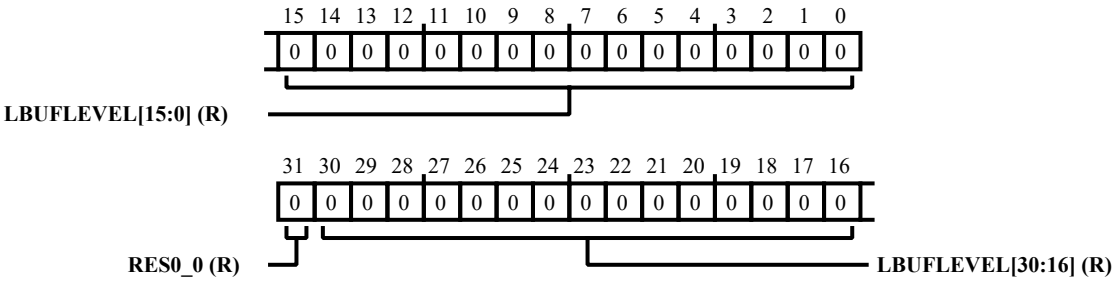

Figure 48-583: CSETR_LBUFLEVEL Register Diagram

Table 48-587: CSETR_LBUFLEVEL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
30:0 (R/NW)	LBUFLEVEL	. Latched Buffer Fill Level. Indicates the maximum fill level of the trace memory in 32-bit words since this register was last read.

Mode register.

The MODE register controls the TMC operating mode. The operating mode can only be changed when the TMC is in Disabled state. Attempting to write to this register in any other state results in UNPREDICTABLE behavior. The operating mode is ignored when in Disabled state.

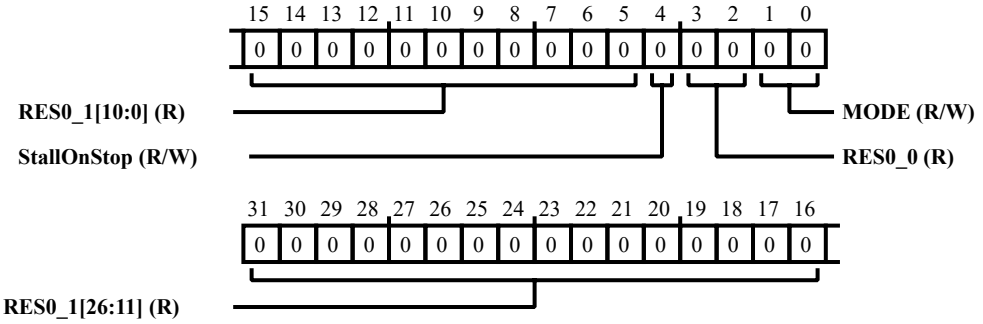

Figure 48-584: CSETR_MODE Register Diagram

Table 48-588: CSETR_MODE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:5 (R/NW)	RES0_1	. Reserved bit or field with SBZP behavior.	
4 (R/W)	STALLONSTOP	. Stall On Stop. If this bit is set and the formatter stops as a result of a stop event, the output atready_rx is de-asserted to stall the ATB interface and avoid loss of trace. If this bit is clear and the formatter stops as a result of a stop event, signal atready_rx remains asserted but the TMC discards further incoming trace.	
3:2 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
1:0 (R/W)	MODE	. Selects the operating mode. If a reserved MODE value is programmed and trace capture is enabled, the TMC starts to operate in SWF1 mode. However, reading the MODE.MODE field returns the programmed value.	
		0	CB, Circular Buffer mode.
		1	SWF1, Software Read FIFO mode 1.
		2	Reserved. (SWF1).
		3	SWF2, Software Read FIFO mode 2.

Peripheral Identification Register 0.

The PIDR0 register is part of the set of peripheral identification registers.

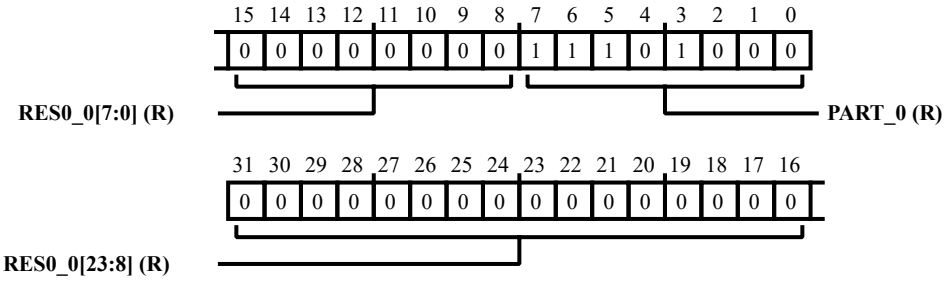

Figure 48-585: CSETR_PIDR0 Register Diagram

Table 48-589: CSETR_PIDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
7:0 (R/NW)	PART_0	. Part number (lower 8 bits).	
		232	ETR or ETS - Embedded Trace Router or Streamer.
		233	ETB - Embedded Trace Buffer.
		234	ETF - Embedded Trace FIFO.

Peripheral Identification Register 1.

The PIDR1 register is part of the set of peripheral identification registers.

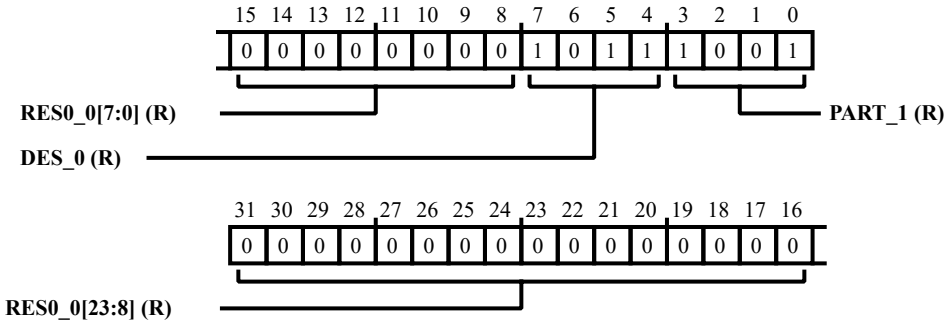

Figure 48-586: CSETR_PIDR1 Register Diagram

Table 48-590: CSETR_PIDR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:4 (R/NW)	DES_0	. JEP106 identification code, bits[3:0]. Together, with PIDR4.DES_2 and PIDR2.DES_1, they indicate the designer of the component and not the implementer, except where the two are the same.
3:0 (R/NW)	PART_1	. Part number, bits[11:8]. Taken together with PIDR0.PART_0 it indicates the component. The Part Number is selected by the designer of the component.

Peripheral Identification Register 2.

The PIDR2 register is part of the set of peripheral identification registers.

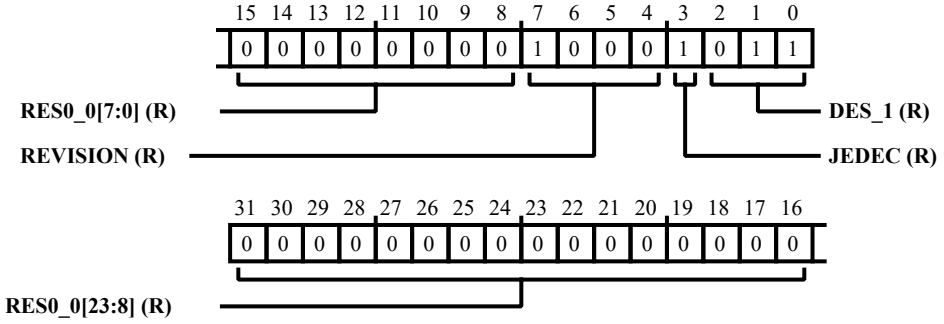

Figure 48-587: CSETR_PIDR2 Register Diagram

Table 48-591: CSETR_PIDR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:4 (R/NW)	REVISION	. Revision. It is an incremental value starting at 0x0 for the first design of a component. See the Component list in Chapter 1 for information on the RTL revision of the component.
3 (R/NW)	JEDEC	. 1 - Always set. Indicates that a JEDEC assigned value is used.
2:0 (R/NW)	DES_1	. JEP106 identification code, bits[6:4]. Together, with PIDR4.DES_2 and PIDR1.DES_0, they indicate the designer of the component and not the implementer, except where the two are the same.

Peripheral Identification Register 3.

The PIDR3 register is part of the set of peripheral identification registers.

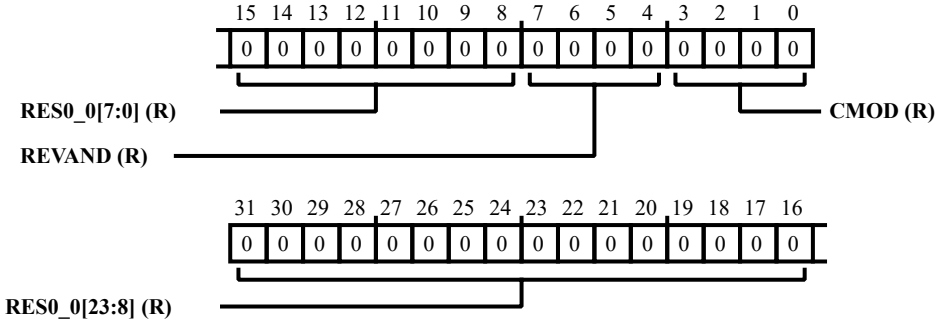

Figure 48-588: CSETR_PIDR3 Register Diagram

Table 48-592: CSETR_PIDR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:4 (R/NW)	REVAND	. This field indicates minor errata fixes specific to this design, for example metal fixes after implementation. In most cases this field is 0x0.
3:0 (R/NW)	CMOD	. Customer Modified. Where the component is reusable IP, this value indicates if the customer has modified the behavior of the component. In most cases this field is 0x0.

Peripheral Identification Register 4.

The PIDR4 register is part of the set of peripheral identification registers.

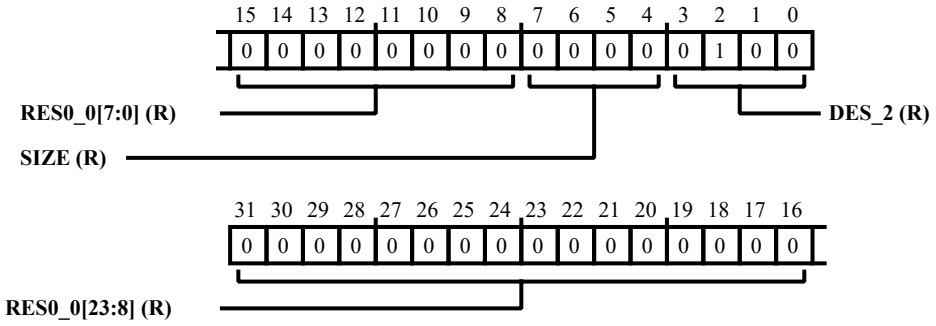

Figure 48-589: CSETR_PIDR4 Register Diagram

Table 48-593: CSETR_PIDR4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:4 (R/NW)	SIZE	. Indicates the memory size that is used by this component. Returns 0 indicating that the component uses an UNKNOWN number of 4KB blocks. Using the SIZE field to indicate the size of the component is deprecated.
3:0 (R/NW)	DES_2	. JEP106 continuation code. Together, with PIDR2.DES_1 and PIDR1.DES_0, they indicate the designer of the component and not the implementer, except where the two are the same.

Peripheral Identification Register 5.

The PIDR5 register is part of the set of peripheral identification registers.

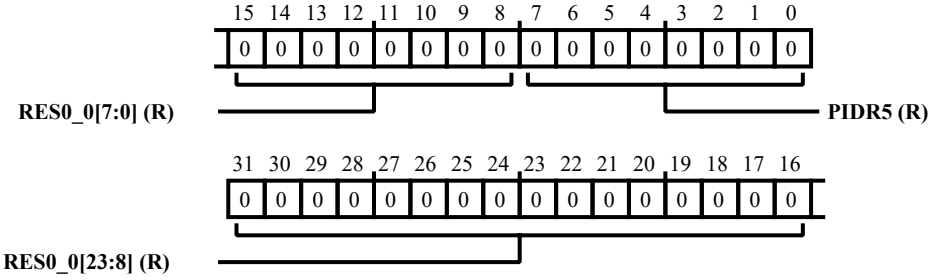

Figure 48-590: CSETR_PIDR5 Register Diagram

Table 48-594: CSETR_PIDR5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PIDR5	. Reserved.

Peripheral Identification Register 6.

The PIDR6 register is part of the set of peripheral identification registers.

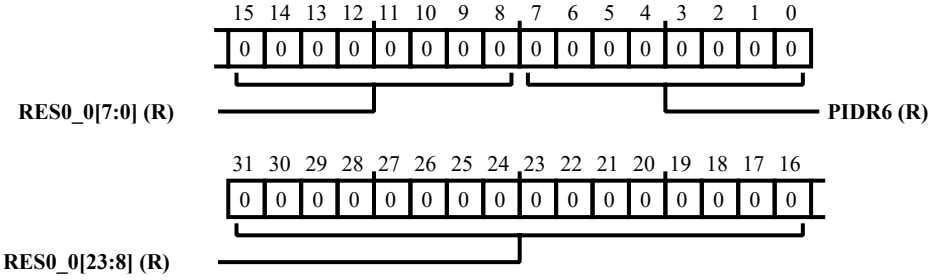

Figure 48-591: CSETR_PIDR6 Register Diagram

Table 48-595: CSETR_PIDR6 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PIDR6	. Reserved.

Peripheral Identification Register 7.

The PIDR7 register is part of the set of peripheral identification registers.

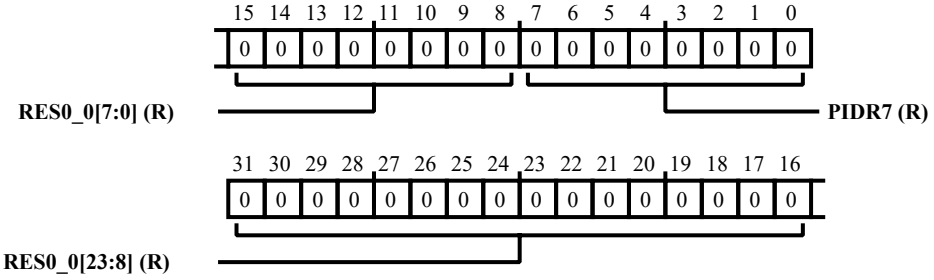

Figure 48-592: CSETR_PIDR7 Register Diagram

Table 48-596: CSETR_PIDR7 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PIDR7	. Reserved.

Periodic Synchronization Counter Register.

This register determines the reload value of the Periodic Synchronization Counter. This counter enables the frequency of sync packets to be optimized to the trace capture buffer size. The default behavior of the counter is to generate periodic synchronization requests, syncreq_rx, on the ATB receiver interface.

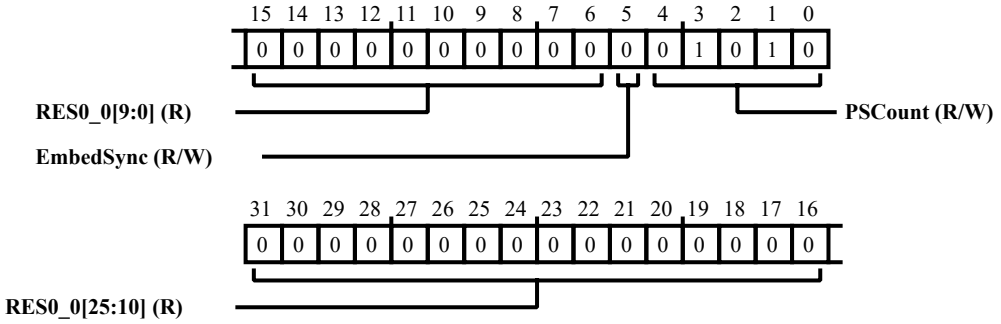

Figure 48-593: CSETR_PSCR Register Diagram

Table 48-597: CSETR_PSCR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:6 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
5 (R/W)	EMBEDSYNC	. Embed Frame Sync Packet in the trace stream. Setting this bit to 1 enables the formatter to insert frame sync packets in the trace stream at periodic intervals. If this bit is set and the Synchronization Counter is enabled, the formatter inserts a 32-bit frame sync packet in the trace stream when the counter reaches 0. This bit is effective only when formatting is enabled, that is when FFCR.EnTI=1 or FFCR.EnFt=1, and it is ignored when the formatter is in bypass mode.
4:0 (R/W)	PSCOUNT	. Periodic Synchronization Count. Determines the reload value of the Synchronization Counter. The reload value takes effect the next time the counter reaches zero. When trace capture is enabled, the Synchronization Counter counts the number of bytes of trace data that is stored into the trace memory, regardless of whether the trace data has been formatted by the TMC or not, since the occurrence of the last sync request on the ATB receiver interface. When the counter reaches 0, a sync request is sent on the ATB receiver interface. Reads from this register return the reload value that is programmed in this register. This field resets to 0x0A, that is, the default sync period is 2^10 bytes. If a reserved value is programmed in this register field, the value 0x1B is used instead, and subsequent reads from this register also return 0x1B. The following constraints apply to the values written to the PSCount field: 0x0 - synchronization is disabled, 0x1-0x6 - reserved, 0x7-0x1B - synchronization period is 2^PSCount bytes. The smallest value 0x7 gives a sync period of 128 bytes. The maximum allowed value 0x1B gives a sync period of 2^27 bytes, 0x1C-0x1F - reserved.

RAM Read Data register.

Reading this register allows data to be read from the trace memory at the location pointed to by the RRP/RRPHI registers when either in the Disabled state or operating in CB or SWF1 mode. When ATB_DATA_WIDTH is 32, 64 or 128 bit wide the AXI data width is the same and a memory word holds 4, 8, or 16 bytes. When ATB_DATA_WIDTH is 64 or 128 bit wide multiple RRD reads must be performed to read a full memory word. When a full memory width of data has been read via the RRD register, the RRP register is incremented to the next memory word. When the TMC left the Disabled state and the trace memory is empty, this register returns 0xFFFFFFFF. When the TMC left the Disabled state and the trace memory is empty, this register returns 0xFFFFFFFF. When operating in CB mode and the TMC left the Disabled state, this register returns 0xFFFFFFFF in all other states except the Stopped state. When operating in SWF2 mode, this register also returns 0xFFFFFFFF. When the MemErr bit in the STS Register is set, reading this register returns an error response on the APB completer interface.

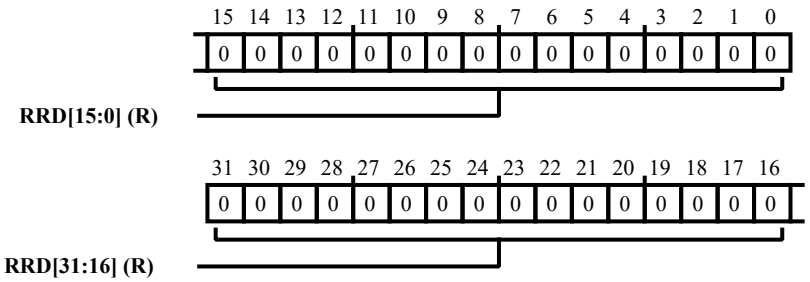

Figure 48-594: CSETR_RRD Register Diagram

Table 48-598: CSETR_RRD Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	RRD	. Returns the data read from trace memory.

RAM Read Pointer register.

The RRP register contains the value of the read pointer that is used to read entries from trace memory over the APB interface. Software must program it before enabling trace capture.

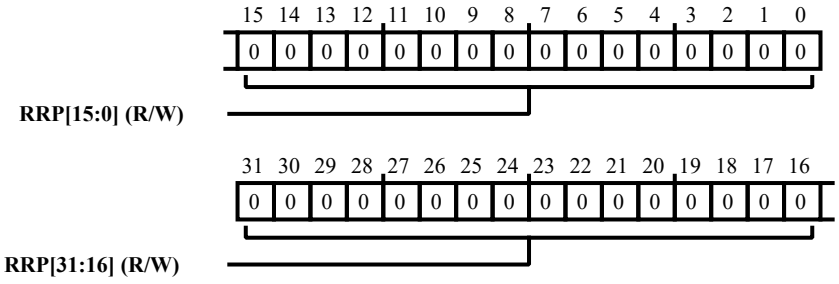

Figure 48-595: CSETR_RRP Register Diagram

Table 48-599: CSETR_RRP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	RRP	. This register represents the lower 32 bits of the AXI address that is used to access the trace memory with RRD read acesses. When ATB_DATA_WIDTH is 32, 64 or 128 bit wide the AXI data width is the same and a memory word holds 4, 8, or 16 bytes. When a full memory width of data has been read via the RRD register, the RRP register is incremented to the next memory word. The lowest 2 bits have access type RAZ/WI when ATB_DATA_WIDTH is 32 bits. The lowest 3 bits have access type RAZ/WI when ATB_DATA_WIDTH is 64 bits. The lowest 4 bits have access type RAZ/WI when ATB_DATA_WIDTH is 128 bits.

RAM Read Pointer High register.

The RAM Read Pointer High register contains address bits >= bit[32] of the read pointer that is used to read entries from trace memory over the APB interface. Software must program it before enabling trace capture.

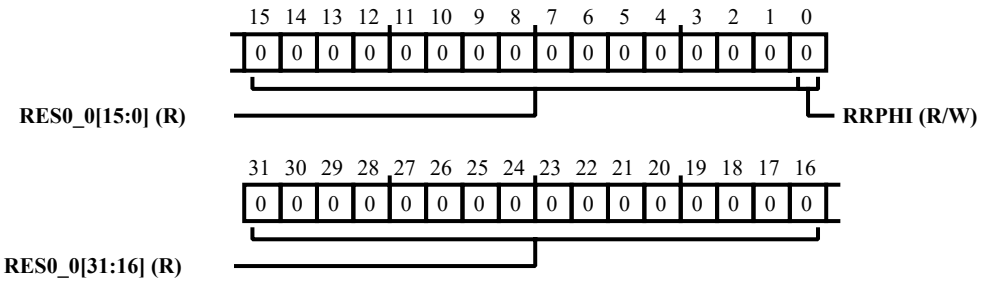

Figure 48-596: CSETR_RRPHI Register Diagram

Table 48-600: CSETR_RRPHI Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
-1:0 (R/W)	RRPHI	. RAM Read Pointer High. Bits [32] and above of the RAM read pointer.
31:0 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.

RAM Size register.

The RSZ register defines the size of trace memory in units of 32-bit words.

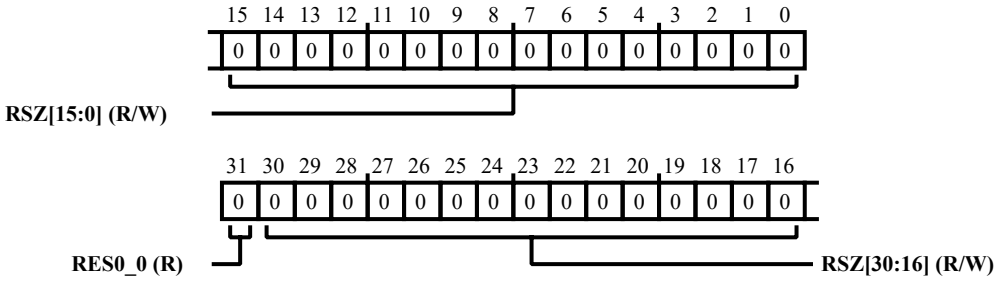

Figure 48-597: CSETR_RSZ Register Diagram

Table 48-601: CSETR_RSZ Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
30:0 (R/W)	RSZ	. RAM size. Indicates the size of trace memory in 32-bit words. The size of the trace buffer must be a multiple of the AXI data width. This can be found by looking at the MEMWIDTH field in the DEVID Register. The maximum trace buffer size permitted is 4GB. The minimum trace buffer size enabled in Software FIFO mode and Hardware FIFO mode is 512 bytes. The minimum trace buffer size enabled in Circular Buffer mode is one AXI dataword. Returns the programmed value on reading. The burst length programmed in the AXICTL Register, WrBurstLen, must be compatible with the trace buffer size and the AXI data width so that the total number of bytes of data transferred in a burst is not greater than the trace buffer size. Programming an incompatible burst length results in UNPREDICTABLE behavior. Modifying this register when the TMCReady bit, STS Register, 0x00C is clear, or the TraceCaptEn bit, CTL Register, 0x020 is set, results in UNPREDICTABLE behavior. Arm recommends that DBA+RSZ*4<2^AXI_ADDR_WIDTH.

RAM Update Read Pointer register.

The RURP register enables software to inform the TMC of the amount of trace data that is extracted directly from system memory in SWF2 mode. Writes to this register are ignored when the TMC is in Disabled state or when not in SWF2 mode.

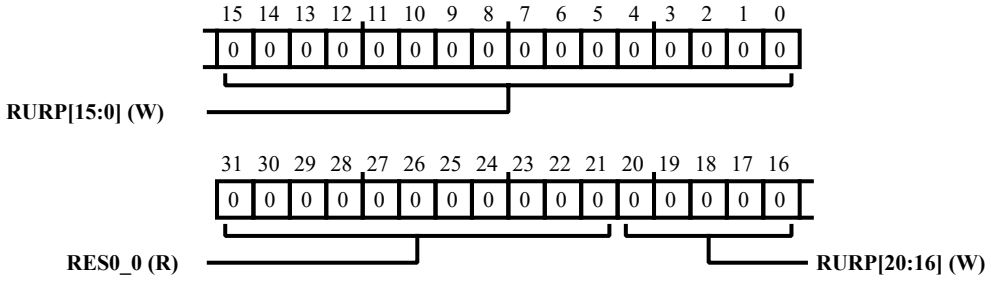

Figure 48-598: CSETR_RURP Register Diagram

Table 48-602: CSETR_RURP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:21 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
20:0 (RX/W)	RURP	. RAM Update Read Pointer. A write to the RURP register causes the TMC to update the RAM Read Pointer, both the RRP and RRPHI registers, based on the value that is written to it. RURP allows up to 1MB of data to be extracted in a single chunk. Reads always return 0x0. The following constraints apply to the write values: 0x000000 - no effect, 0x000010-0x100000 - increment RRP by this value, 0x100010-0x1FFFFF - reserved. The programmed value must also be aligned to the Trace Memory Data Width and the Frame Width. Programming an unaligned or reserved value results in UNPREDICTABLE behavior.

RAM Write Data register.

The RWD register enables testing of trace memory connectivity to the TMC. Writing this register allows data to be written to the trace memory at the location pointed to by the RWP/RWPHI registers when in the Disabled state. When ATB_DATA_WIDTH is 32, 64 or 128 bit wide the AXI data width is the same and a memory word holds 4, 8, or 16 bytes. When ATB_DATA_WIDTH is 64 or 128 bit wide multiple RWD writes must be performed to write a full memory word. When a full memory width of data has been written via the RWD register, the data is written to the trace memory and the RWP register is incremented to the next memory word. When the STS.MemErr bit is set, writing to this register returns an error response on the APB interface and the write data is discarded.

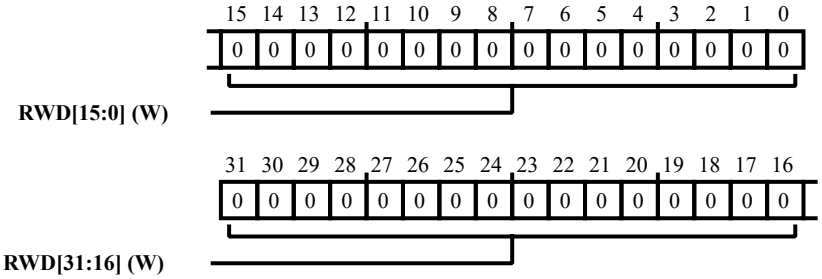

Figure 48-599: CSETR_RWD Register Diagram

Table 48-603: CSETR_RWD Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (RX/W)	RWD	. Data written to this register is placed in the trace memory.

RAM Write Pointer register.

The RWP register sets the write pointer that writes entries into the trace memory. Software must program it before enabling trace capture.

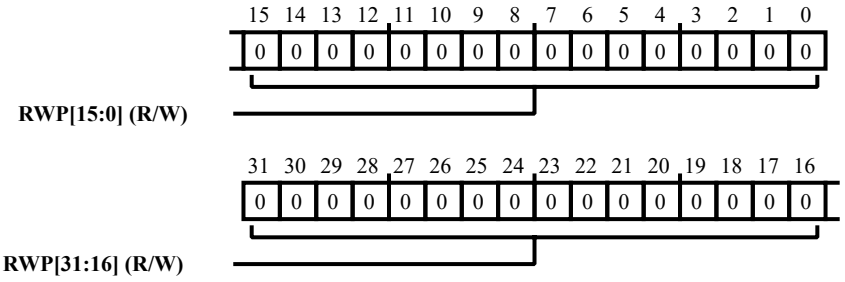

Figure 48-600: CSETR_RWP Register Diagram

Table 48-604: CSETR_RWP Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	RWP	. This register represents the lower 32 bits of the AXI address that is used to access the trace memory with RRD read acesses. When ATB_DATA_WIDTH is 32, 64 or 128 bit wide the AXI data width is the same and a memory word holds 4, 8, or 16 bytes. When a full memory width of data has been written via the RWD register, the RWP register is incremented to the next memory word. The lowest 2 bits have access type RAZ/WI when ATB_DATA_WIDTH is 32 bits. The lowest 3 bits have access type RAZ/WI when ATB_DATA_WIDTH is 64 bits. The lowest 4 bits have access type RAZ/WI when ATB_DATA_WIDTH is 128 bits. When leaving the Disabled state and RWP does not point inside the buffer space (starting with DBA and ending before DBA+RSZ*4) then STS.MemErr is set.

RAM Write Pointer High register.

The RAM Write Pointer High register sets bits >= bit[32] of the write pointer that is used to write entries into the trace memory. Software must program it before enabling trace capture.

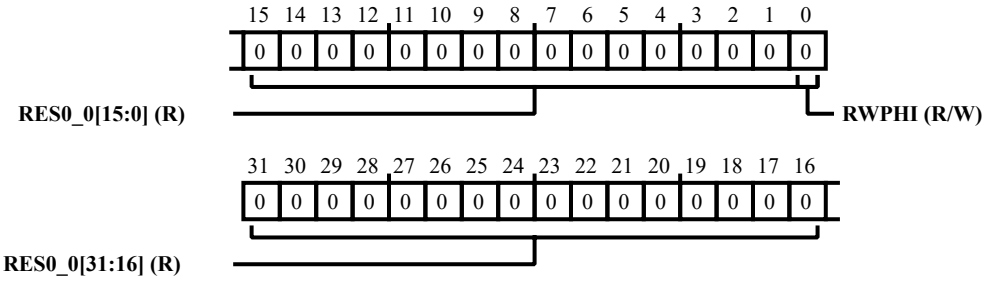

Figure 48-601: CSETR_RWPHI Register Diagram

Table 48-605: CSETR_RWPHI Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
-1:0 (R/W)	RWPHI	. RAM Write Pointer High. Bits [32] and above of the RAM write pointer.
31:0 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.

Status register.

The STS register indicates the status of the Trace Memory Controller. After a reset, software must ignore all the fields of this register except STS.TMCReady. The other fields only have meaning when the TMC has left the Disabled state. Writes to all RO fields of this register are ignored.

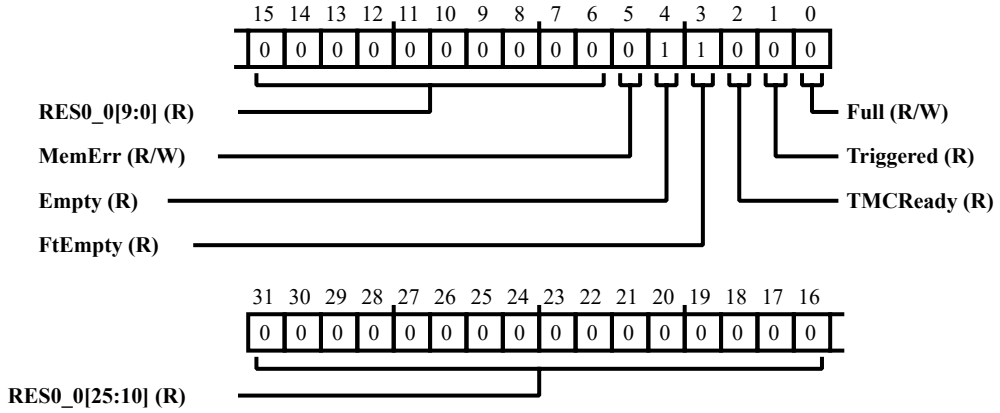

Figure 48-602: CSETR_STS Register Diagram

Table 48-606: CSETR_STS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:6 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
5 (R/W)	MEMERR	. Memory error status. This bit is set when an error has occurred on the AXI manager interface. The error can be caused by either an error response received from the connected AXI subordinate or attempted AXI transfers without proper authentication and Leaving the Disbled state and RWP does not point inside the buffer space (starting with DBA and ending before DBA+RSZ*4). Writes to this bit are allowed in Disabled or Stopped state. Writing 0 has no affect. Writing 1 clears this bit.
4 (R/NW)	EMPTY	. Trace buffer empty. If set, this bit indicates that the trace memory does not contain any valid trace data. The reset value of this bit is 1. On leaving Disabled state, this bit dynamically indicates the empty status of trace memory, CBUFLEVEL == 0. However, this does not mean that the pipeline stages within the TMC are empty. To determine whether the internal pipeline stages are empty, the software must read the STS.TMCReady bit. In Circular Buffer mode the Empty bit and the Full bit in this register can be 1 at the same time. This happens because the Full bit in this mode, when set, does not clear until TraceCaptEn is set.

Table 48-606: CSETR_STS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration
3 (R/NW)	FTEMPTY	. Trace capture has been completed and all captured trace data has been written to the trace memory, set in Stopped, Disabled or Draining state. Otherwise, it is cleared. The reset value is 1.
2 (R/NW)	TMCREADY	. Trace capture has been completed, all captured trace data has been written to the trace memory, and reading from trace memory completed as a result of final AXI write completing.
1 (R/NW)	TRIGGERED	. TMC triggered. This bit is set when trace capture is in progress and the TMC has detected a trigger event. This bit is cleared to 0 when leaving the Disabled state and retains its value when entering the Disabled state. A trigger event is when the TMC has written a set number of data words, as programmed in the TRG register, into the trace memory after a rising edge of trigin input, or a trigger packet (atid_rx = 0x7D) is received in the input trace.
0 (R/W)	FULL	. Trace memory full. This bit helps determine the amount of valid data present in the trace memory. In Circular Buffer mode writes to this bit are allowed in Disabled state, for example for clearing this bit. However, it is not affected by the reprogramming of pointer registers in this state. In Circular Buffer mode, this flag is set when the RAM write pointer wraps around the top of the buffer. It remains set until this bit is written 0 in Disabled state. In Software FIFO mode, this flag indicates that the current space in the trace memory is less than or equal to the value programmed in the BUFWM Register, that is, Fill level >= MEM_SIZE - BUFWM. The FULL output from the TMC reflects the value of this register bit, except when the Integration Mode bit in the ITCTRL Register, 0xF00, is set.

Trigger Counter register.

The TRG register, in Circular Buffer mode, specifies the number of 32-bit words to capture in the trace memory, after detecting either a rising edge on the trigin input or a trigger packet in the incoming trace stream, that is, where atid_rx = 0x7D. The value programmed must be aligned to the frame length of 128 bits. Software must program this register before leaving Disabled state.

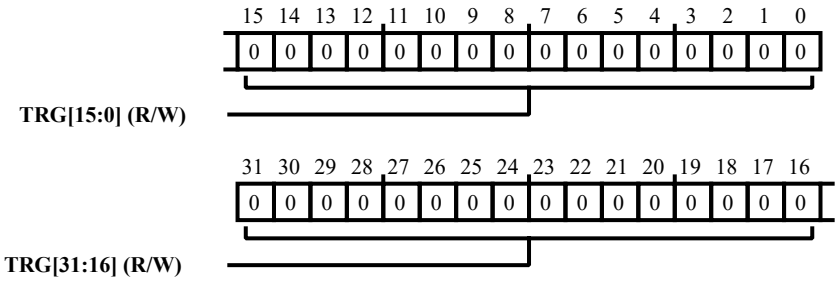

Figure 48-603: CSETR_TRG Register Diagram

Table 48-607: CSETR_TRG Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/W)	TRG	. Trigger count. This count represents the number of 32-bit words of trace that are captured between a trigger packet and a trigger event. The lowest two bits have access type RAZ/WI.

ADSP-2184x CSTF Register Descriptions

Your module description, here. (CSTF) contains the following registers.

Table 48-608: ADSP-2184x CSTF Register List

Name	Description
CSTF_AUTHSTATUS	Authentication Status Register.
CSTF_CIDR0	Component Identification Register 0.
CSTF_CIDR1	Component Identification Register 1.
CSTF_CIDR2	Component Identification Register 2.
CSTF_CIDR3	Component Identification Register 3.
CSTF_CLAIMCLR	Claim Tag Clear Register.
CSTF_CLAIMSET	Claim Tag Set Register.
CSTF_DEVAFF0	Device Affinity register 0.
CSTF_DEVAFF1	Device Affinity register 1.

Table 48-608: ADSP-2184x CSTF Register List (Continued)

Name	Description
CSTF_DEVARCH	Device Architecture Register.
CSTF_DEVID	Device Configuration Register.
CSTF_DEVID1	Device Configuration Register 1.
CSTF_DEVID2	Device Configuration Register 2.
CSTF_DEVTYPE	Device Type Identifier Register.
CSTF_FUNNELCONTROL	Funnel Control register.
CSTF_ITATBCTR0	Integration test control register 0.
CSTF_ITATBCTR1	Integration test control register 1.
CSTF_ITATBCTR2	Integration test control register 2.
CSTF_ITATBCTR3	Integration test control register 3.
CSTF_ITATBDATA0	Integration test data register.
CSTF_ITCTRL	Integration Mode Control Register.
CSTF_PIDR0	Peripheral Identification Register 0.
CSTF_PIDR1	Peripheral Identification Register 1.
CSTF_PIDR2	Peripheral Identification Register 2.
CSTF_PIDR3	Peripheral Identification Register 3.
CSTF_PIDR4	Peripheral Identification Register 4.
CSTF_PIDR5	Peripheral Identification Register 5.
CSTF_PIDR6	Peripheral Identification Register 6.
CSTF_PIDR7	Peripheral Identification Register 7.
CSTF_PRIORITYCONTROL	Priority Control register.

Authentication Status Register.

Reports the current status of the authentication control signals.

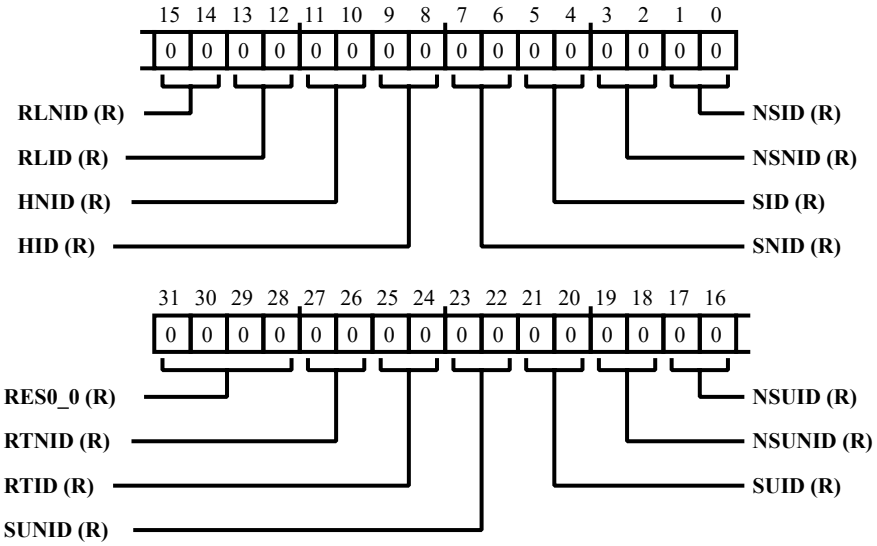

Figure 48-604: CSTF_AUTHSTATUS Register Diagram

Table 48-609: CSTF_AUTHSTATUS Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:28 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
27:26 (R/NW)	RTNID	. Root non-invasive debug.	
		0	Separate Root non-invasive debug enable not implemented or Root state non-invasive debug features not implemented.
		1	Reserved.
		2	Implemented and disabled.
		3	Implemented and enabled.

Table 48-609: CSTF_AUTHSTATUS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
25:24 (R/NW)	RTID	. Root invasive debug.	
		0	Separate Root invasive debug enable not implemented or Root state invasive debug features not implemented.
		1	Reserved.
		2	Implemented and disabled.
		3	Implemented and enabled.
23:22 (R/NW)	SUNID	. Secure unprivileged non-invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.
21:20 (R/NW)	SUID	. Secure unprivileged invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.
19:18 (R/NW)	NSUNID	. Non-secure unprivileged non-invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.
17:16 (R/NW)	NSUID	. Non-secure unprivileged invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.

Table 48-609: CSTF_AUTHSTATUS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
15:14 (R/NW)	RLNID	. Realm non-invasive debug.	
		0	Separate Realm non-invasive debug enable not implemented or Realm state non-invasive debug features not implemented.
		1	Reserved.
		2	Implemented and disabled.
		3	Implemented and enabled.
13:12 (R/NW)	RLID	. Realm invasive debug.	
		0	Separate Realm invasive debug enable not implemented or Realm state invasive debug features not implemented.
		1	Reserved.
		2	Implemented and disabled.
		3	Implemented and enabled.
11:10 (R/NW)	HNID	. Hypervisor non-invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.
9:8 (R/NW)	HID	. Hypervisor invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.

Table 48-609: CSTF_AUTHSTATUS Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
7:6 (R/NW)	SNID	. Secure non-invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.
5:4 (R/NW)	SID	. Secure invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.
3:2 (R/NW)	NSNID	. Non-secure non-invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.
1:0 (R/NW)	NSID	. Non-secure invasive debug.	
		0	Debug level is not supported.
		1	Reserved.
		2	Supported and disabled.
		3	Supported and enabled.

Component Identification Register 0.

The CIDR0 register is part of the set of component identification registers.

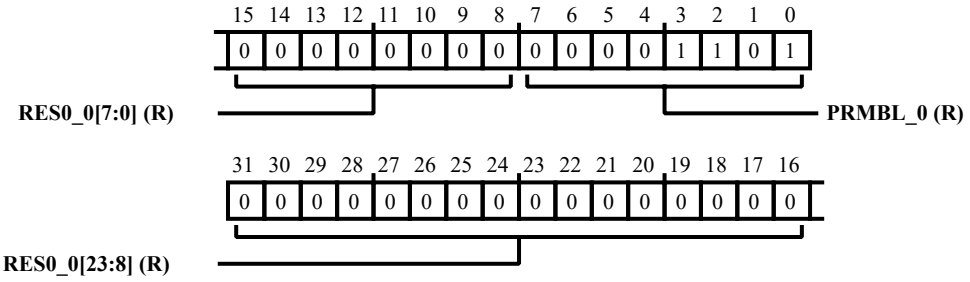

Figure 48-605: CSTF_CIDR0 Register Diagram

Table 48-610: CSTF_CIDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PRMBL_0	. Preamble. Returns 0x0D.

Component Identification Register 1.

The CIDR1 register is part of the set of component identification registers.

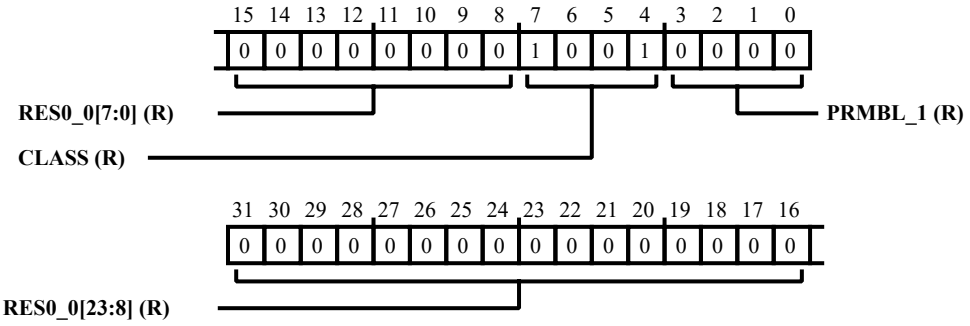

Figure 48-606: CSTF_CIDR1 Register Diagram

Table 48-611: CSTF_CIDR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
7:4 (R/NW)	CLASS	. Component class.	
		9	CoreSight component.
		15	CoreLink, PrimeCell, or system component.
3:0 (R/NW)	PRMBL_1	. Preamble. Returns 0x0.	

Component Identification Register 2.

The CIDR2 register is part of the set of component identification registers.

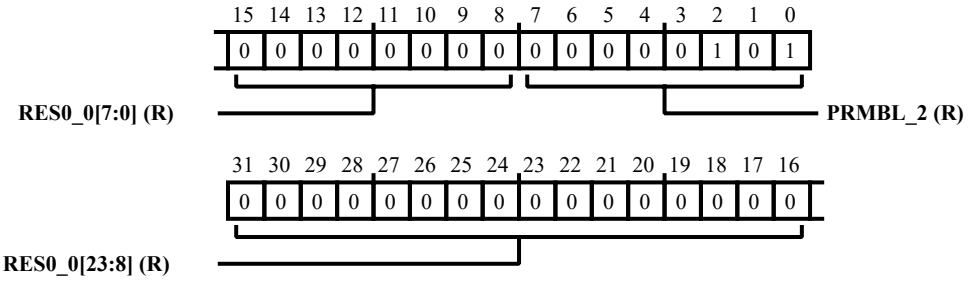

Figure 48-607: CSTF_CIDR2 Register Diagram

Table 48-612: CSTF_CIDR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PRMBL_2	. Preamble. Returns 0x05.

Component Identification Register 3.

The CIDR3 register is part of the set of component identification registers.

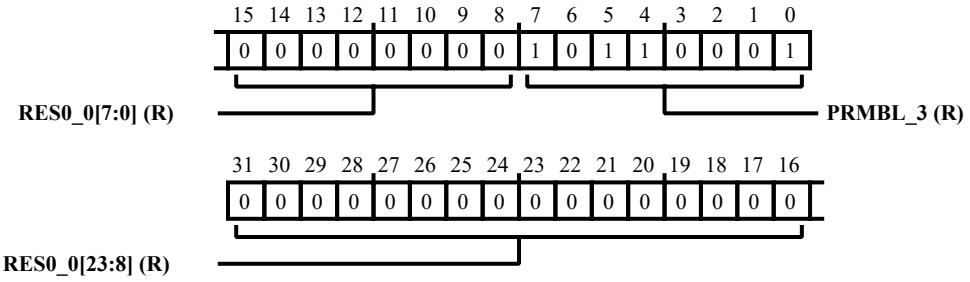

Figure 48-608: CSTF_CIDR3 Register Diagram

Table 48-613: CSTF_CIDR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PRMBL_3	. Preamble. Returns 0xB1.

Claim Tag Clear Register.

This register forms one half of the claim tag value. On writes, this location enables individual bits to be cleared. On reads, it returns the current claim tag value.

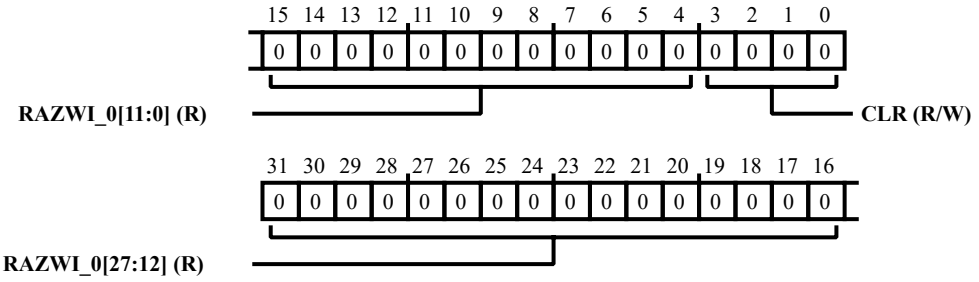

Figure 48-609: CSTF_CLAIMCLR Register Diagram

Table 48-614: CSTF_CLAIMCLR Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:4 (R/NW)	RAZWI_0	. RAZ/WI.
3:0 (R/W)	CLR	. A bit-programmable register bank that clears the claim tag value. It is zero at reset. It is used by software agents to signal to each other ownership of the hardware. It has no direct effect on the hardware itself.

Claim Tag Set Register.

This register forms one half of the claim tag value. On writes, this location enables individual bits to be set. On reads, it returns the number of bits that can be set.

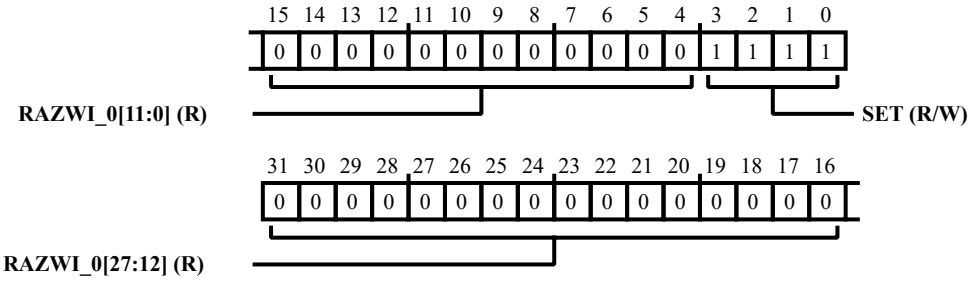

Figure 48-610: CSTF_CLAIMSET Register Diagram

Table 48-615: CSTF_CLAIMSET Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:4 (R/NW)	RAZWI_0	. RAZ/WI.
3:0 (R/W)	SET	. A bit-programmable register bank that sets the claim tag value. A read returns a logic 1 for all implemented locations.

Device Affinity register 0.

Enables a debugger to determine if two components have an affinity with each other.

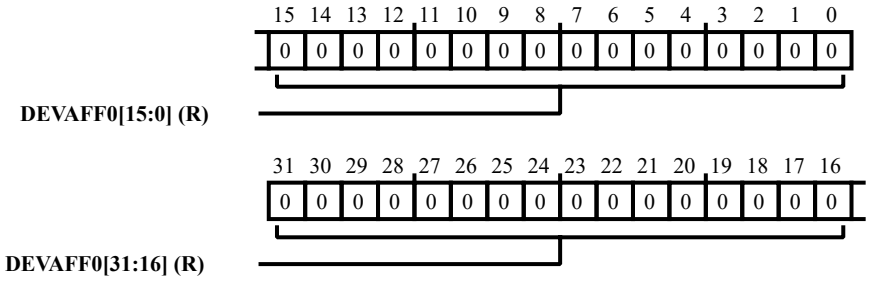

Figure 48-611: CSTF_DEVAFF0 Register Diagram

Table 48-616: CSTF_DEVAFF0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	DEVAFF0	. This field is RAZ.

Device Affinity register 1.

Enables a debugger to determine if two components have an affinity with each other.

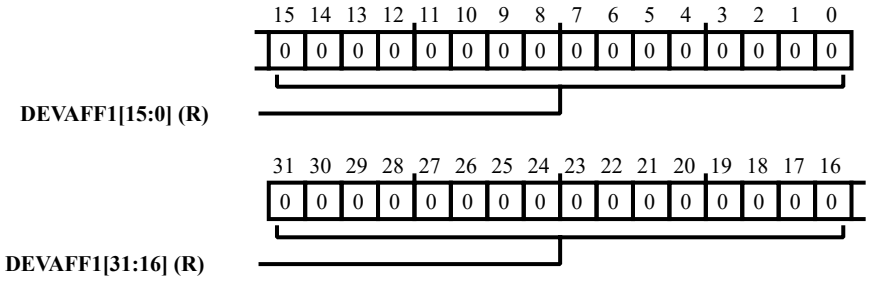

Figure 48-612: CSTF_DEVAFF1 Register Diagram

Table 48-617: CSTF_DEVAFF1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	DEVAFF1	. This field is RAZ.

Device Architecture Register.

Identifies the architect and architecture of a CoreSight component. The architect might differ from the designer of a component, for example Arm defines the architecture but another company designs and implements the component.

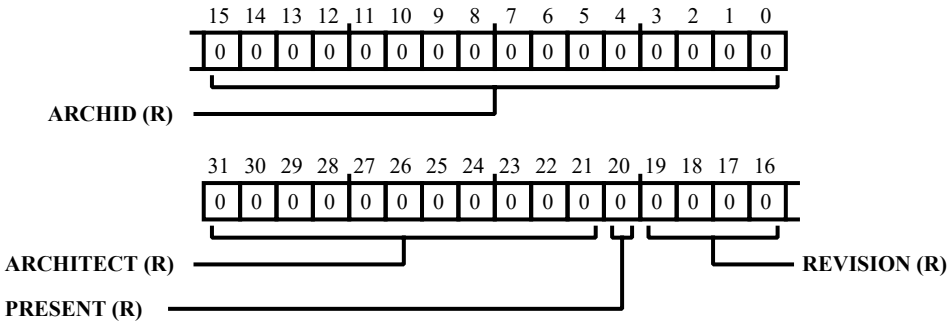

Figure 48-613: CSTF_DEVARCH Register Diagram

Table 48-618: CSTF_DEVARCH Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:21 (R/NW)	ARCHITECT	. Defines the architect of the component.	
		571	Arm.
20 (R/NW)	PRESENT	. Indicates the presence of this register.	
		0	DEVARCH is not present.
		1	DEVARCH is present.
19:16 (R/NW)	REVISION	. Architecture revision. Returns the revision of the architecture that the ARCHID field specifies.	
15:0 (R/NW)	ARCHID	. Architecture ID. Returns a value that identifies the architecture of the component.	
		2583	Memory Access Port v2 architecture.
		2599	JTAG Access Port v2 architecture.
		2631	Unknown Access Port v2 architecture.
		2807	CoreSight ROM architecture.
		6676	CTI architecture.

Device Configuration Register.

This register is IMPLEMENTATION DEFINED for each Part Number and Designer. The register indicates the capabilities of the component.

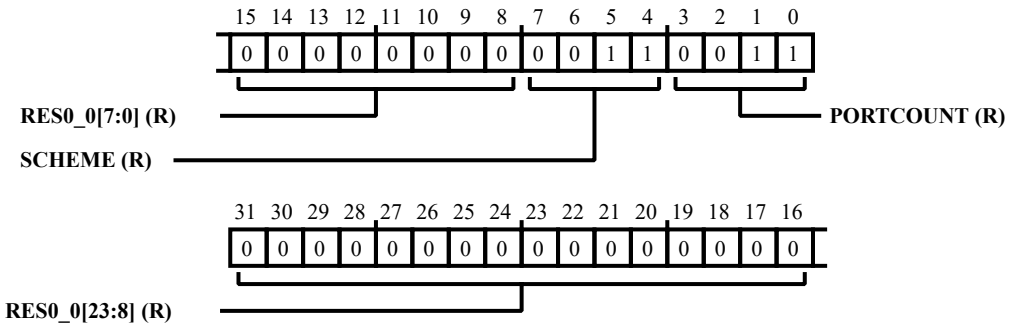

Figure 48-614: CSTF_DEVID Register Diagram

Table 48-619: CSTF_DEVID Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:4 (R/NW)	SCHEME	. Indicates priority scheme implemented. Input priority is controlled by the PRIORITYCONTROL register.
3:0 (R/NW)	PORTCOUNT	. Indicates the number of input ports connected.

Device Configuration Register 1.

Contains an IMPLEMENTATION DEFINED value.

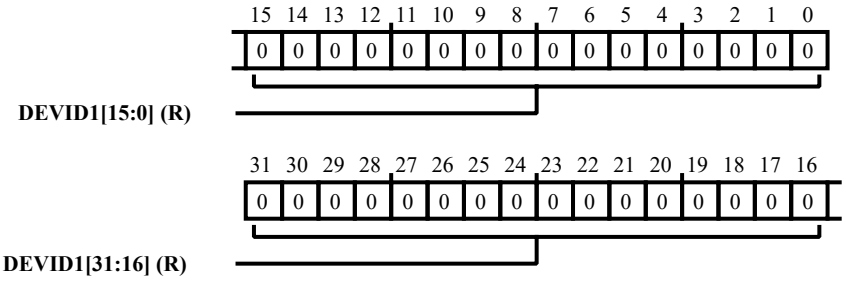

Figure 48-615: CSTF_DEVID1 Register Diagram

Table 48-620: CSTF_DEVID1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	DEVID1	. This field is RAZ.

Device Configuration Register 2.

Contains an IMPLEMENTATION DEFINED value.

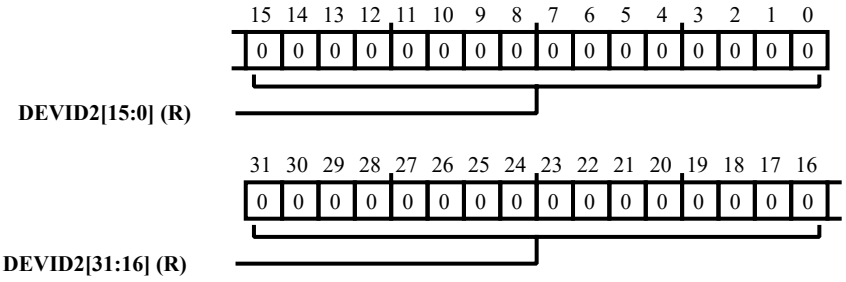

Figure 48-616: CSTF_DEVID2 Register Diagram

Table 48-621: CSTF_DEVID2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	DEVID2	. This field is RAZ.

Device Type Identifier Register.

A debugger can use this register to get information about a component that has an unrecognized Part number.

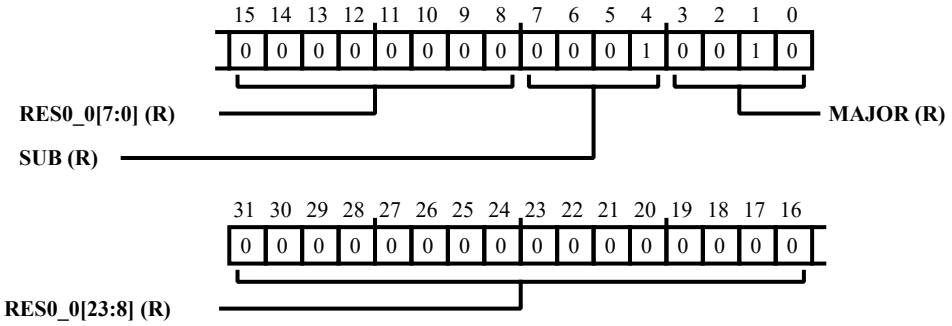

Figure 48-617: CSTF_DEVTYPE Register Diagram

Table 48-622: CSTF_DEVTYPE Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:4 (R/NW)	SUB	. Minor classification. Returns 0x1, indicating this component is a Funnel/Router.
3:0 (R/NW)	MAJOR	. Major classification. Returns 0x2, indicating this component is a Trace Link.

Funnel Control register.

The FUNNELCONTROL register enables each of the trace sources and controls the hold time for switching between them.

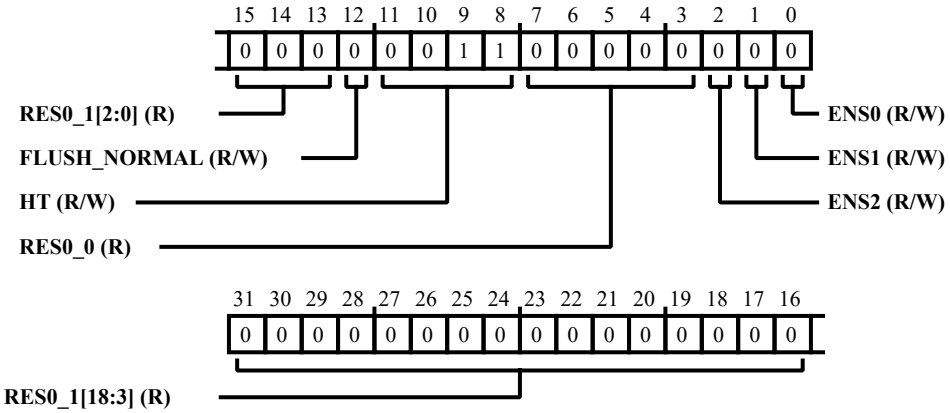

Figure 48-618: CSTF_FUNNELCONTROL Register Diagram

Table 48-623: CSTF_FUNNELCONTROL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:13 (R/NW)	RES0_1	. Reserved bit or field with SBZP behavior.	
12 (R/W)	FLUSH_NORMAL	. This bit, when clear, allows receiver ports that are already flushed to receive further data even if there are other ports that have not completed flush. If set, a port that has completed flush is not be allowed to receive further data until all ports have completed flush.	
11:8 (R/W)	HT	. Hold time. Value sets the minimum hold time before switching trace sources (funnel inputs) based on the ID. Value used is programmed value + 1.	
		0	1 transaction hold time.
		1	2 transactions hold time.
		2	3 transactions hold time.
		3	4 transactions hold time.
		4	5 transactions hold time.
		5	6 transactions hold time.
		6	7 transactions hold time.
		7	8 transactions hold time.

Table 48-623: CSTF_FUNNELCONTROL Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		8	9 transactions hold time.
		9	10 transactions hold time.
		10	11 transactions hold time.
		11	12 transactions hold time.
		12	13 transactions hold time.
		13	14 transactions hold time.
		14	15 transactions hold time.
		15	Reserved.
7:3 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
2 (R/W)	ENS2	. Enable receiver interface 2. Field is RES0 if receiver interface 2 is not implemented.	
		0	Receiver interface disabled.
		1	Receiver interface enabled.
1 (R/W)	ENS1	. Enable receiver interface 1.	
		0	Receiver interface disabled.
		1	Receiver interface enabled.
0 (R/W)	ENS0	. Enable receiver interface 0.	
		0	Receiver interface disabled.
		1	Receiver interface enabled.

Integration test control register 0.

The ITATBCTR0 register enables you to observabe and control the ATBYTES buses, and the AFREADY and ATVALID signals into and out of the funnel. For receiver signals coming into the funnel, the register views the ports that are selected through the FUNNELCONTROL register. Only one port must be selected for integration test.

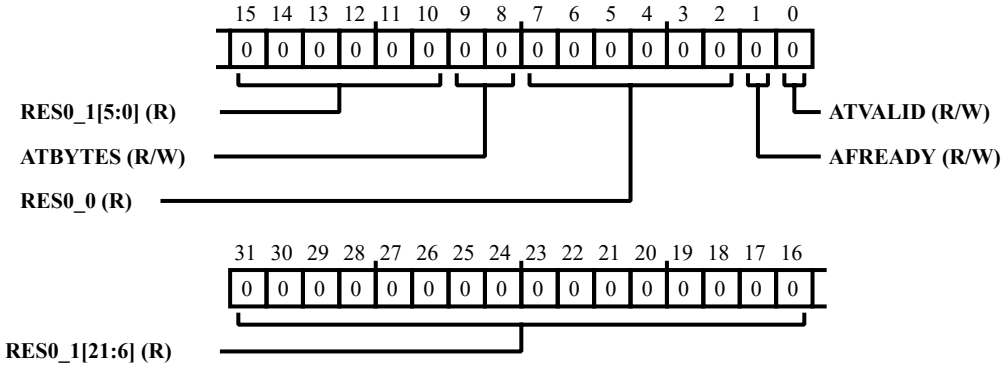

Figure 48-619: CSTF_ITATBCTR0 Register Diagram

Table 48-624: CSTF_ITATBCTR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:10 (R/NW)	RES0_1	. Reserved bit or field with SBZP behavior.	
9:8 (R/W)	ATBYTES	. Reads the value on atbytes_rx[1:0] and writes the values on atbytes_tx[1:0].	
7:2 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
1 (R/W)	AFREADY	. Reads and controls the afready signals into, and out of, the funnel:.	
		0	On reads: afready_rx is LOW. On writes: sets afready_tx LOW.
		1	On reads: afready_rx is HIGH. On writes: sets afready_tx HIGH.
0 (R/W)	ATVALID	. Reads and controls the atvalid signals into, and out of, the funnel:.	
		0	On reads: atvalid_rx is LOW. On writes: sets atvalid_tx LOW.
		1	On reads: atvalid_rx is HIGH. On writes: sets atvalid_tx HIGH.

Integration test control register 1.

The ITATBCTR1 register enables you to observe and control the ATID buses into and out of the funnel. For receiver signals coming into the funnel, the register views the ports that are selected through the FUNNELCONTROL register. Only one port must be selected for integration test.

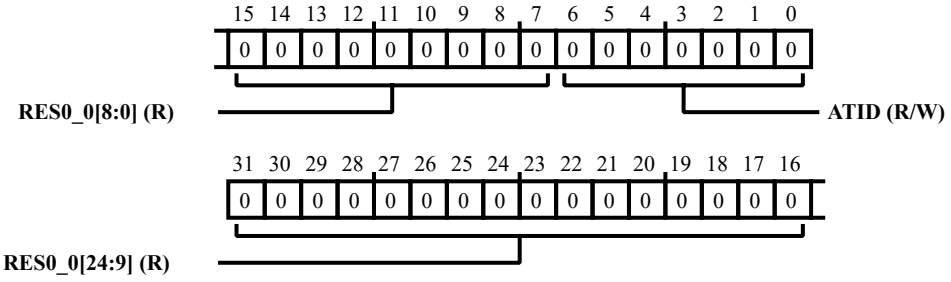

Figure 48-620: CSTF_ITATBCTR1 Register Diagram

Table 48-625: CSTF_ITATBCTR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:7 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
6:0 (R/W)	ATID	. When read returns the value on atid_rx, when written drives the value on atid_tx.

Integration test control register 2.

The ITATBCTR2 register enables you to observe and control the afvalid and atready signals into and out of the funnel. For receiver signals coming into the funnel, the register views the ports that are selected through the FUNNELCONTROL register. Only one port must be selected for integration test.

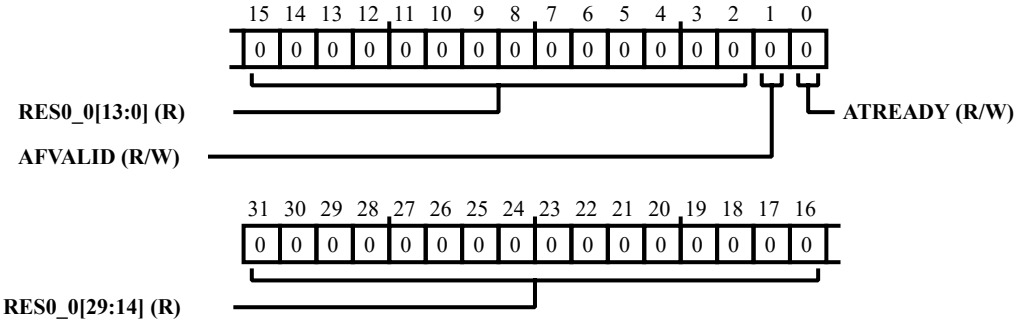

Figure 48-621: CSTF_ITATBCTR2 Register Diagram

Table 48-626: CSTF_ITATBCTR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:2 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
1 (R/W)	AFVALID	. Reads and controls the afvalid signals into, and out of, the funnel:.	
		0	On reads: afvalid_tx is LOW. On writes: sets afvalid_rx LOW.
		1	On reads: afvalid_tx is HIGH. On writes: sets afvalid_rx HIGH.
0 (R/W)	ATREADY	. Reads and controls the atready signal into, and out of, the funnel:.	
		0	On reads: atready_tx is LOW. On writes: sets atready_rx LOW.
		1	On reads: atready_tx is HIGH. On writes: sets atready_rx HIGH.

Integration test control register 3.

The ITATBCTR3 register enables you to observe and control the SYNCREQ signals into and out of the funnel. Only one receiver interface must be selected for integration test. The syncreq receiver on the transmitter interface has a latching function to capture a pulse arriving on that input. The arrival of a pulse sets the latch so that the value can be read. Reading the register clears the latch. Reading a 1 indicates that a syncreq_tx pulse arrived since the last read. Reading a 0 indicates that no syncreq_tx pulse has arrived. Writing a 1 to the register causes a syncreq_rx pulse to be generated to the upstream component.

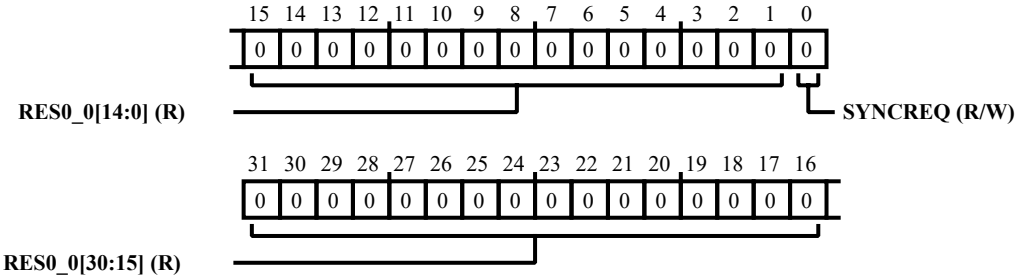

Figure 48-622: CSTF_ITATBCTR3 Register Diagram

Table 48-627: CSTF_ITATBCTR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:1 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
0 (R/W)	SYNCREQ	. Reads and controls the SYNCREQ signals into, and out of, the funnel. Reading clears the latch.	
		0	On reads: no syncreq_tx pulse has arrived. On writes: no effect.
		1	On reads: a syncreq_tx pulse arrived since the last read. On writes: generates a syncreq_rx pulse to the upstream component.

Integration test data register.

The ITATBDATA0 register allows observability and controllability of the ATDATA buses into and out of the funnel. For receiver signals coming into the funnel, the register views the ports that are selected through the funnel control register. Only one port must be selected for integration test.

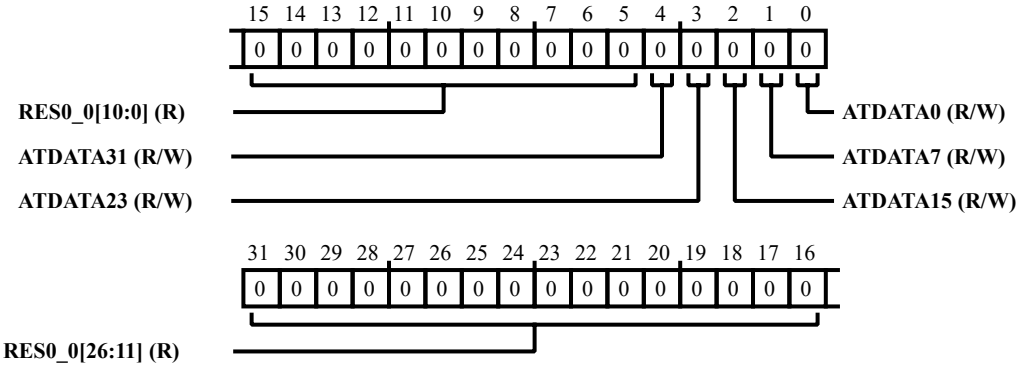

Figure 48-623: CSTF_ITATBDATA0 Register Diagram

Table 48-628: CSTF_ITATBDATA0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:5 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
4 (R/W)	ATDATA31	. Reads atdata_rx[31] and writes atdata_tx[31]. RES0 if ATB_DATA_WIDTH < 32.	
		0	On reads, the value of atdata_rx[31] is 0. On writes, sets atdata_tx[31] to 0.
		1	On reads, the value of atdata_rx[31] is 1. On writes, sets atdata_tx[31] to 1.
3 (R/W)	ATDATA23	. Reads atdata_rx[23] and writes atdata_tx[23]. RES0 if ATB_DATA_WIDTH < 32.	
		0	On reads, the value of atdata_rx[23] is 0. On writes, sets atdata_tx[23] to 0.
		1	On reads, the value of atdata_rx[23] is 1. On writes, sets atdata_tx[23] to 1.

Table 48-628: CSTF_ITATBDATA0 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
2 (R/W)	ATDATA15	. Reads atdata_rx[15] and writes atdata_tx[15]. RES0 if ATB_DATA_WIDTH < 16.	
		0	On reads, the value of atdata_rx[15] is 0. On writes, sets atdata_tx[15] to 0.
		1	On reads, the value of atdata_rx[15] is 1. On writes, sets atdata_tx[15] to 1.
1 (R/W)	ATDATA7	. Reads atdata_rx[7] and writes atdata_tx[7].	
		0	On reads, the value of atdata_rx[7] is 0. On writes, sets atdata_tx[7] to 0.
		1	On reads, the value of atdata_rx[7] is 1. On writes, sets atdata_tx[7] to 1.
0 (R/W)	ATDATA0	. Reads atdata_rx[0] and writes atdata_tx[0].	
		0	On reads, the value of atdata_rx[0] is 0. On writes, sets atdata_tx[0] to 0.
		1	On reads, the value of atdata_rx[0] is 1. On writes, sets atdata_tx[0] to 1.

Integration Mode Control Register.

The Integration Mode Control register is used to switch between functional mode and integration mode. After switching to integration mode and performing integration tests or topology detection, reset the system to ensure correct behavior of CoreSight and other connected system components.

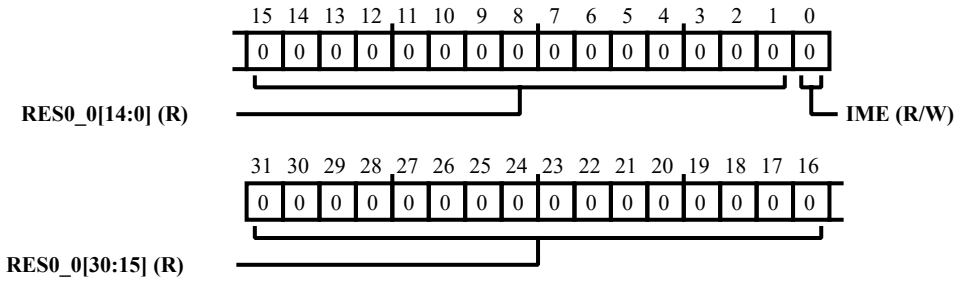

Figure 48-624: CSTF_ITCTRL Register Diagram

Table 48-629: CSTF_ITCTRL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:1 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
0 (R/W)	IME	. Integration Mode Enable.	
		0	The component must enter functional mode.
		1	The component must enter integration mode, and enable support for topology detection and integration testing.

Peripheral Identification Register 0.

The PIDR0 register is part of the set of peripheral identification registers.

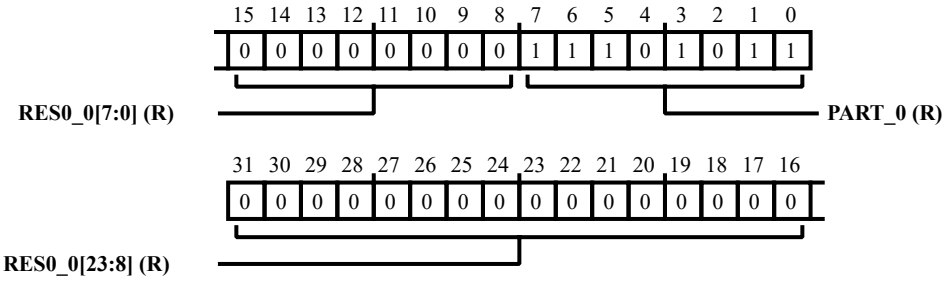

Figure 48-625: CSTF_PIDR0 Register Diagram

Table 48-630: CSTF_PIDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PART_0	. Part number, bits[7:0]. Taken together with PIDR1.PART_1 it indicates the component. The Part Number is selected by the designer of the component.

Peripheral Identification Register 1.

The PIDR1 register is part of the set of peripheral identification registers.

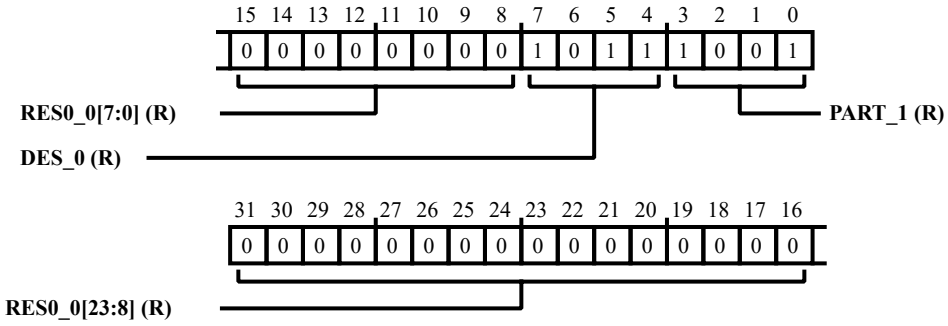

Figure 48-626: CSTF_PIDR1 Register Diagram

Table 48-631: CSTF_PIDR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:4 (R/NW)	DES_0	. JEP106 identification code, bits[3:0]. Together, with PIDR4.DES_2 and PIDR2.DES_1, they indicate the designer of the component and not the implementer, except where the two are the same.
3:0 (R/NW)	PART_1	. Part number, bits[11:8]. Taken together with PIDR0.PART_0 it indicates the component. The Part Number is selected by the designer of the component.

Peripheral Identification Register 2.

The PIDR2 register is part of the set of peripheral identification registers.

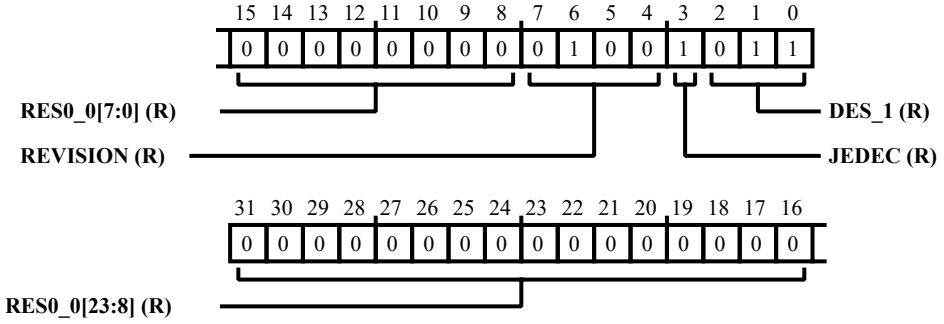

Figure 48-627: CSTF_PIDR2 Register Diagram

Table 48-632: CSTF_PIDR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:4 (R/NW)	REVISION	. Revision. It is an incremental value starting at 0x0 for the first design of a component. See the Component list in Chapter 1 for information on the RTL revision of the component.
3 (R/NW)	JEDEC	. 1 - Always set. Indicates that a JEDEC assigned value is used.
2:0 (R/NW)	DES_1	. JEP106 identification code, bits[6:4]. Together, with PIDR4.DES_2 and PIDR1.DES_0, they indicate the designer of the component and not the implementer, except where the two are the same.

Peripheral Identification Register 3.

The PIDR3 register is part of the set of peripheral identification registers.

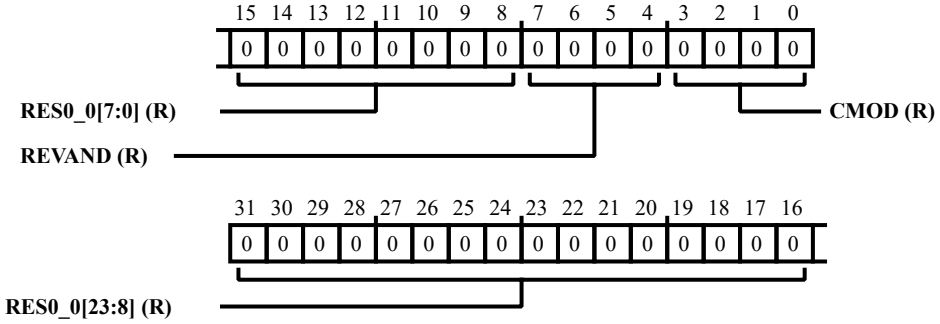

Figure 48-628: CSTF_PIDR3 Register Diagram

Table 48-633: CSTF_PIDR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:4 (R/NW)	REVAND	. This field indicates minor errata fixes specific to this design, for example metal fixes after implementation. In most cases this field is 0x0.
3:0 (R/NW)	CMOD	. Customer Modified. Where the component is reusable IP, this value indicates if the customer has modified the behavior of the component. In most cases this field is 0x0.

Peripheral Identification Register 4.

The PIDR4 register is part of the set of peripheral identification registers.

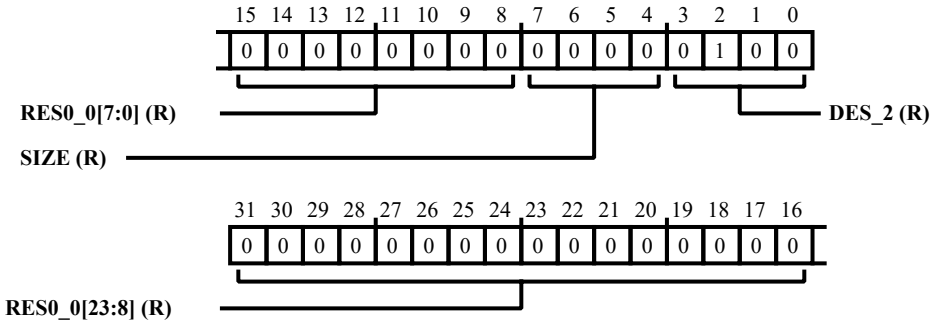

Figure 48-629: CSTF_PIDR4 Register Diagram

Table 48-634: CSTF_PIDR4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:4 (R/NW)	SIZE	. Indicates the memory size that is used by this component. Returns 0 indicating that the component uses an UNKNOWN number of 4KB blocks. Using the SIZE field to indicate the size of the component is deprecated.
3:0 (R/NW)	DES_2	. JEP106 continuation code. Together, with PIDR2.DES_1 and PIDR1.DES_0, they indicate the designer of the component and not the implementer, except where the two are the same.

Peripheral Identification Register 5.

The PIDR5 register is part of the set of peripheral identification registers.

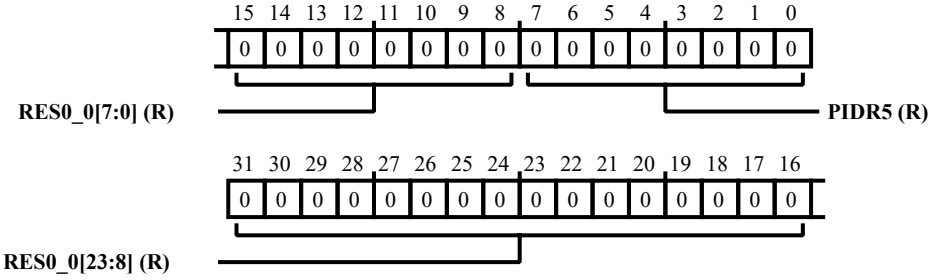

Figure 48-630: CSTF_PIDR5 Register Diagram

Table 48-635: CSTF_PIDR5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PIDR5	. Reserved.

Peripheral Identification Register 6.

The PIDR6 register is part of the set of peripheral identification registers.

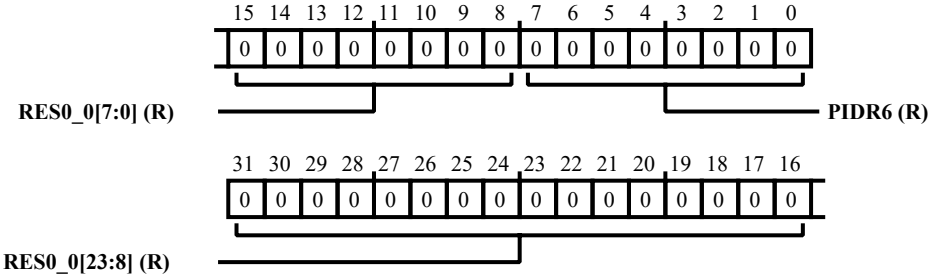

Figure 48-631: CSTF_PIDR6 Register Diagram

Table 48-636: CSTF_PIDR6 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PIDR6	. Reserved.

Peripheral Identification Register 7.

The PIDR7 register is part of the set of peripheral identification registers.

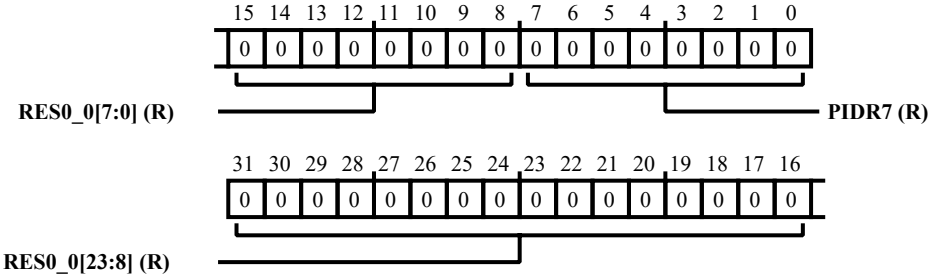

Figure 48-632: CSTF_PIDR7 Register Diagram

Table 48-637: CSTF_PIDR7 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PIDR7	. Reserved.

Priority Control register.

The PRIORITYCONTROL register sets the priority of each port (receiver interface) of the funnel. The programming software requires that the ports are all disabled before the priority control register contents are changed. Changing the port priorities in real time is not supported. If the priority control register is written when one or more of the ports are enabled, then the write is silently rejected and the value in the priority control register remains unchanged. The lower the priority value, the higher is its priority when selecting the next port to be serviced. If two or more ports have the same priority value, then the lowest numbered port is serviced first.

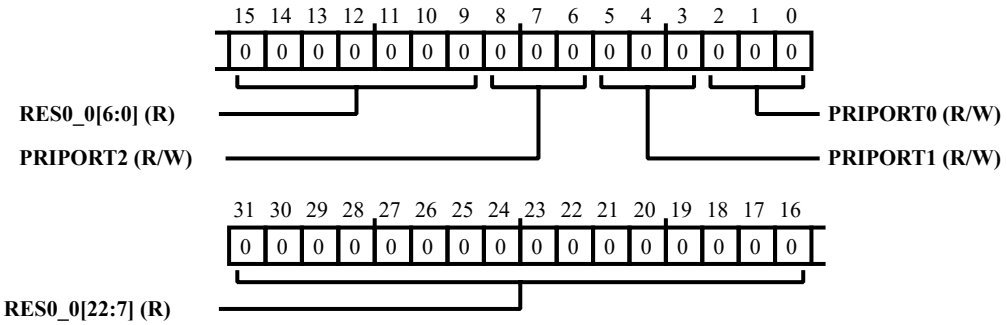

Figure 48-633: CSTF_PRIORITYCONTROL Register Diagram

Table 48-638: CSTF_PRIORITYCONTROL Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:9 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
8:6 (R/W)	PRIPORT2	. Priority value for port 2. Field is RES0 if port 2 is not implemented.
5:3 (R/W)	PRIPORT1	. Priority value for port 1.
2:0 (R/W)	PRIPORT0	. Priority value for port 0.

ADSP-2184x A55_SYSTMRRD Register Descriptions

Your module description, here. (A55_SYSTMRRD) contains the following registers.

Table 48-639: ADSP-2184x A55_SYSTMRRD Register List

Name	Description
A55_SYSTMRRD_CIDR0	Component Identification Register 0.
A55_SYSTMRRD_CIDR1	Component Identification Register 1.

Table 48-639: ADSP-2184x A55_SYSTMRRD Register List (Continued)

Name	Description
A55_SYSTMRRD_CIDR2	Component Identification Register 2.
A55_SYSTMRRD_CIDR3	Component Identification Register 3.
A55_SYSTMRRD_CNTCVLREAD	Current value of Counter[31:0].
A55_SYSTMRRD_CNTCVUREAD	Current value of Counter[63:32].
A55_SYSTMRRD_PIDR0	Peripheral Identification Register 0.
A55_SYSTMRRD_PIDR1	Peripheral Identification Register 1.
A55_SYSTMRRD_PIDR2	Peripheral Identification Register 2.
A55_SYSTMRRD_PIDR3	Peripheral Identification Register 3.
A55_SYSTMRRD_PIDR4	Peripheral Identification Register 4.
A55_SYSTMRRD_PIDR5	Peripheral Identification Register 5.
A55_SYSTMRRD_PIDR6	Peripheral Identification Register 6.
A55_SYSTMRRD_PIDR7	Peripheral Identification Register 7.

Component Identification Register 0.

The CIDR0 register is part of the set of component identification registers.

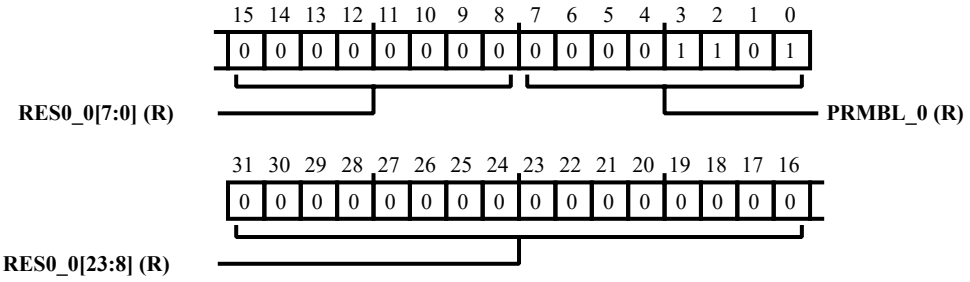

Figure 48-634: A55_SYSTMRRD_CIDR0 Register Diagram

Table 48-640: A55_SYSTMRRD_CIDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PRMBL_0	. Preamble. Returns 0x0D.

Component Identification Register 1.

The CIDR1 register is part of the set of component identification registers.

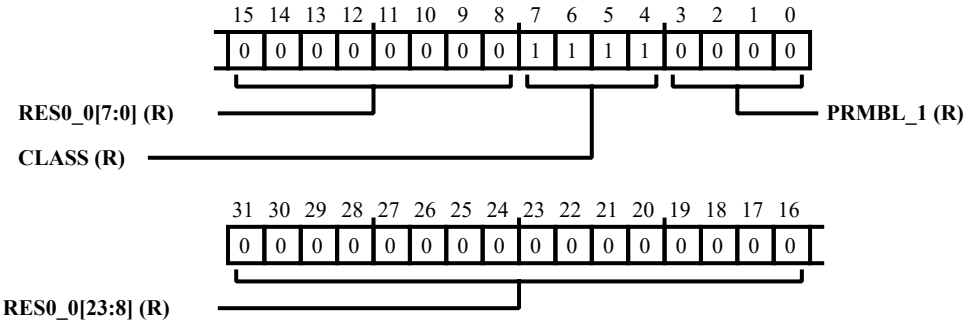

Figure 48-635: A55_SYSTMRRD_CIDR1 Register Diagram

Table 48-641: A55_SYSTMRRD_CIDR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration	
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.	
7:4 (R/NW)	CLASS	. Component class.	
		9	CoreSight component.
		15	CoreLink, PrimeCell, or system component.
3:0 (R/NW)	PRMBL_1	. Preamble. Returns 0x0.	

Component Identification Register 2.

The CIDR2 register is part of the set of component identification registers.

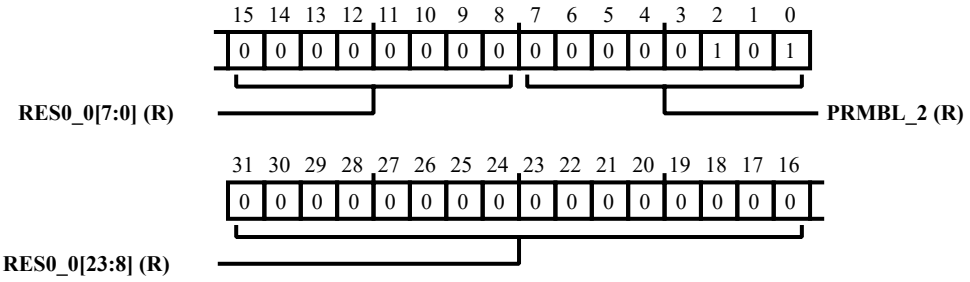

Figure 48-636: A55_SYSTMRRD_CIDR2 Register Diagram

Table 48-642: A55_SYSTMRRD_CIDR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PRMBL_2	. Preamble. Returns 0x05.

Component Identification Register 3.

The CIDR3 register is part of the set of component identification registers.

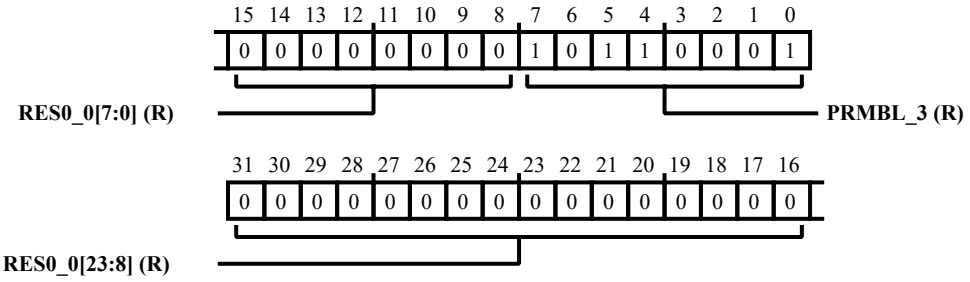

Figure 48-637: A55_SYSTMRRD_CIDR3 Register Diagram

Table 48-643: A55_SYSTMRRD_CIDR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PRMBL_3	. Preamble. Returns 0xB1.

Current value of Counter[31:0].

The CNTCVLREAD register reads the lower 32 bits of the current counter value.

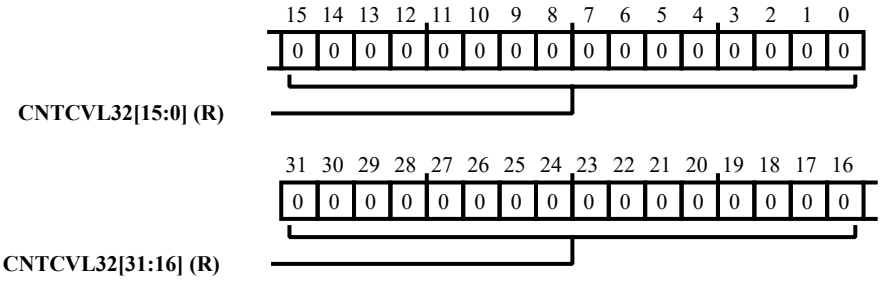

Figure 48-638: A55_SYSTMRRD_CNTCVLREAD Register Diagram

Table 48-644: A55_SYSTMRRD_CNTCVLREAD Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNTCVL32	. The lower 32 bits of the current timestamp counter value.

Current value of Counter[63:32].

The CNTCVUREAD register reads the upper 32 bits of the current counter value.

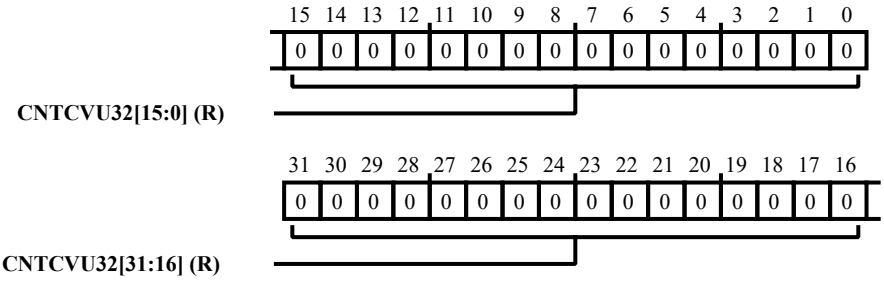

Figure 48-639: A55_SYSTMRRD_CNTCVUREAD Register Diagram

Table 48-645: A55_SYSTMRRD_CNTCVUREAD Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:0 (R/NW)	CNTCVU32	. The upper 32 bits of the current timestamp counter value.

Peripheral Identification Register 0.

The PIDR0 register is part of the set of peripheral identification registers.

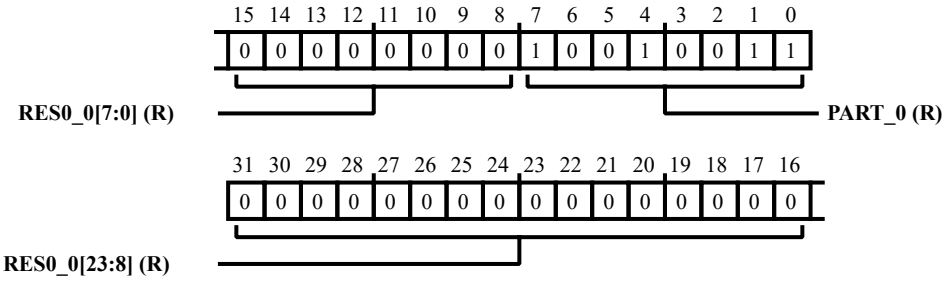

Figure 48-640: A55_SYSTMRRD_PIDR0 Register Diagram

Table 48-646: A55_SYSTMRRD_PIDR0 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PART_0	. Part number, bits[7:0]. Taken together with PIDR1.PART_1 it indicates the component. The Part Number is selected by the designer of the component.

Peripheral Identification Register 1.

The PIDR1 register is part of the set of peripheral identification registers.

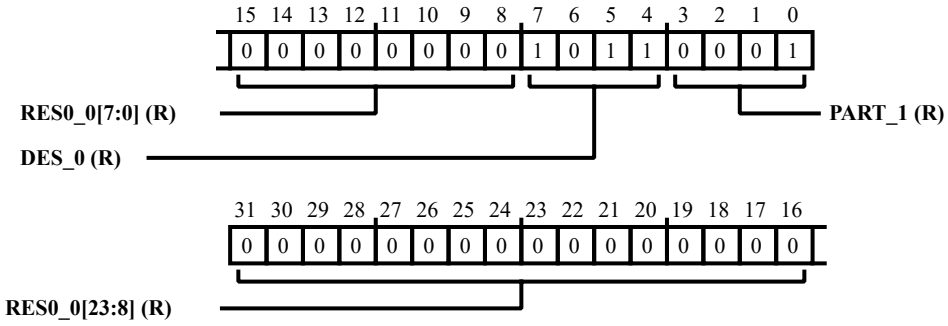

Figure 48-641: A55_SYSTMRRD_PIDR1 Register Diagram

Table 48-647: A55_SYSTMRRD_PIDR1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:4 (R/NW)	DES_0	. JEP106 identification code, bits[3:0]. Together, with PIDR4.DES_2 and PIDR2.DES_1, they indicate the designer of the component and not the implementer, except where the two are the same.
3:0 (R/NW)	PART_1	. Part number, bits[11:8]. Taken together with PIDR0.PART_0 it indicates the component. The Part Number is selected by the designer of the component.

Peripheral Identification Register 2.

The PIDR2 register is part of the set of peripheral identification registers.

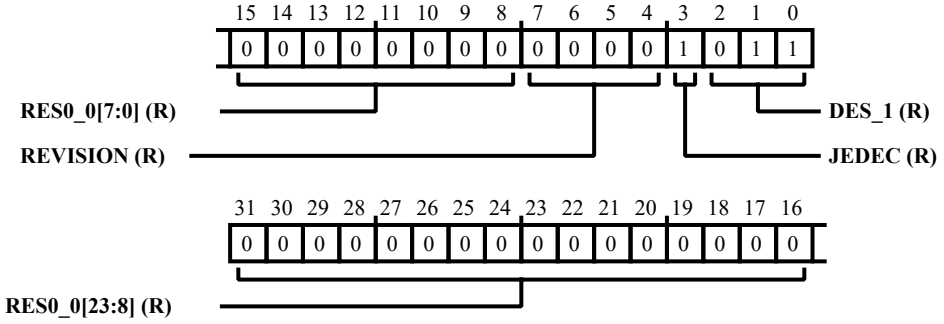

Figure 48-642: A55_SYSTMRRD_PIDR2 Register Diagram

Table 48-648: A55_SYSTMRRD_PIDR2 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:4 (R/NW)	REVISION	. Revision. It is an incremental value starting at 0x0 for the first design of a component. See the Component list in Chapter 1 for information on the RTL revision of the component.
3 (R/NW)	JEDEC	. 1 - Always set. Indicates that a JEDEC assigned value is used.
2:0 (R/NW)	DES_1	. JEP106 identification code, bits[6:4]. Together, with PIDR4.DES_2 and PIDR1.DES_0, they indicate the designer of the component and not the implementer, except where the two are the same.

Peripheral Identification Register 3.

The PIDR3 register is part of the set of peripheral identification registers.

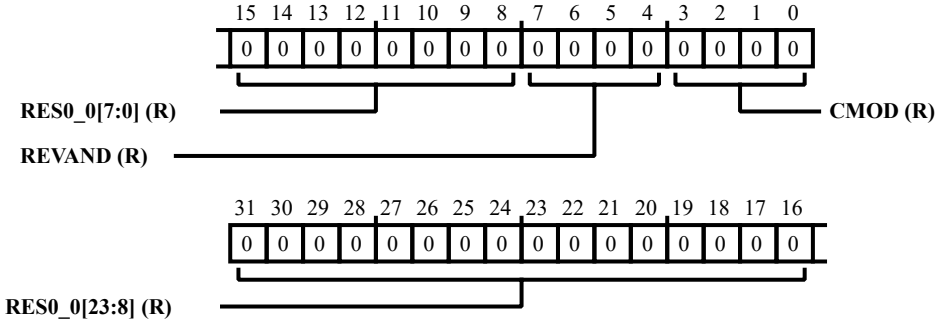

Figure 48-643: A55_SYSTMRRD_PIDR3 Register Diagram

Table 48-649: A55_SYSTMRRD_PIDR3 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:4 (R/NW)	REVAND	. This field indicates minor errata fixes specific to this design, for example metal fixes after implementation. In most cases this field is 0x0.
3:0 (R/NW)	CMOD	. Customer Modified. Where the component is reusable IP, this value indicates if the customer has modified the behavior of the component. In most cases this field is 0x0.

Peripheral Identification Register 4.

The PIDR4 register is part of the set of peripheral identification registers.

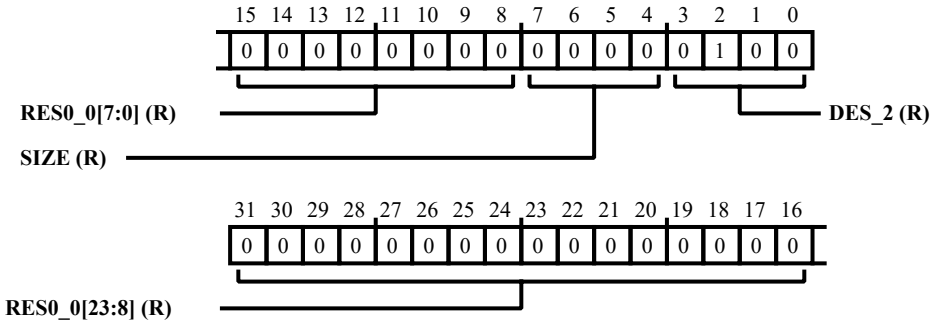

Figure 48-644: A55_SYSTMRRD_PIDR4 Register Diagram

Table 48-650: A55_SYSTMRRD_PIDR4 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:4 (R/NW)	SIZE	. Indicates the memory size that is used by this component. Returns 0 indicating that the component uses an UNKNOWN number of 4KB blocks. Using the SIZE field to indicate the size of the component is deprecated.
3:0 (R/NW)	DES_2	. JEP106 continuation code. Together, with PIDR2.DES_1 and PIDR1.DES_0, they indicate the designer of the component and not the implementer, except where the two are the same.

Peripheral Identification Register 5.

The PIDR5 register is part of the set of peripheral identification registers.

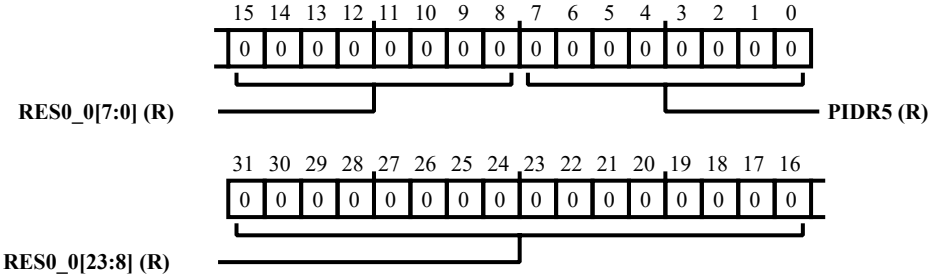

Figure 48-645: A55_SYSTMRRD_PIDR5 Register Diagram

Table 48-651: A55_SYSTMRRD_PIDR5 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PIDR5	. Reserved.

Peripheral Identification Register 6.

The PIDR6 register is part of the set of peripheral identification registers.

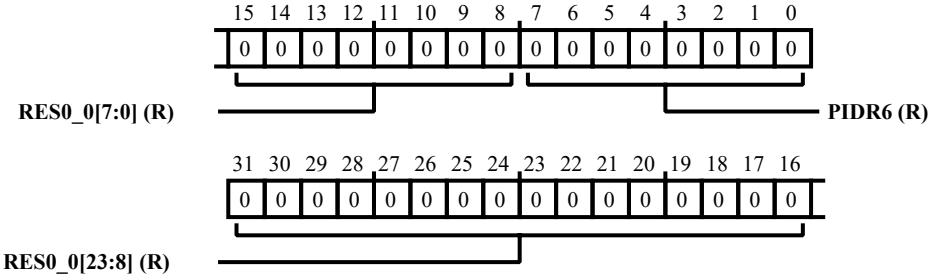

Figure 48-646: A55_SYSTMRRD_PIDR6 Register Diagram

Table 48-652: A55_SYSTMRRD_PIDR6 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PIDR6	. Reserved.

Peripheral Identification Register 7.

The PIDR7 register is part of the set of peripheral identification registers.

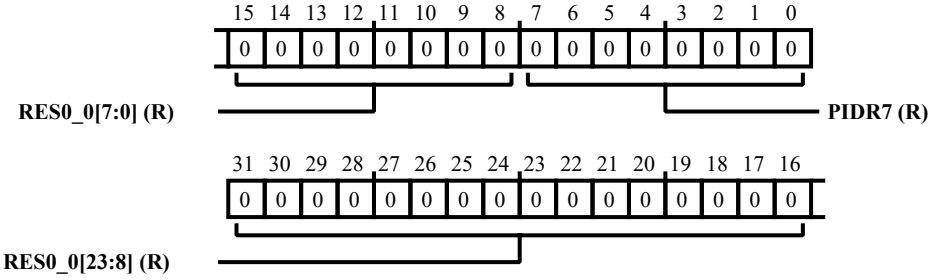

Figure 48-647: A55_SYSTMRRD_PIDR7 Register Diagram

Table 48-653: A55_SYSTMRRD_PIDR7 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:8 (R/NW)	RES0_0	. Reserved bit or field with SBZP behavior.
7:0 (R/NW)	PIDR7	. Reserved.

ADSP-2184x A55_C0 Register Descriptions

Your module description, here. (A55_C0) contains the following registers.

Table 48-654: ADSP-2184x A55_C0 Register List

Name	Description
A55_C0_DBGBCR0_EL1	Debug Breakpoint Control Registers.
A55_C0_DBGBCR1_EL1	Debug Breakpoint Control Registers.
A55_C0_DBGBCR2_EL1	Debug Breakpoint Control Registers.
A55_C0_DBGBCR3_EL1	Debug Breakpoint Control Registers.
A55_C0_DBGBCR4_EL1	Debug Breakpoint Control Registers.
A55_C0_DBGBCR5_EL1	Debug Breakpoint Control Registers.
A55_C0_DBGCLAIMCLR_EL1	Debug Claim Tag Clear register.
A55_C0_DBGCLAIMSET_EL1	Debug Claim Tag Set register.
A55_C0_DBGDTRRX_EL0	Debug Data Transfer Register, Receive.
A55_C0_DBGDTRTX_EL0	Debug Data Transfer Register, Transmit.

Table 48-654: ADSP-2184x A55_C0 Register List (Continued)

Name	Description
A55_C0_DBGWCR0_EL1	Debug Watchpoint Control Registers.
A55_C0_DBGWCR1_EL1	Debug Watchpoint Control Registers.
A55_C0_DBGWCR2_EL1	Debug Watchpoint Control Registers.
A55_C0_DBGWCR3_EL1	Debug Watchpoint Control Registers.
A55_C0_DBGWVR0_EL1_31_0	Debug Watchpoint Value Registers.
A55_C0_DBGWVR0_EL1_63_32	Debug Watchpoint Value Registers.
A55_C0_DBGWVR1_EL1_31_0	Debug Watchpoint Value Registers.
A55_C0_DBGWVR1_EL1_63_32	Debug Watchpoint Value Registers.
A55_C0_DBGWVR2_EL1_31_0	Debug Watchpoint Value Registers.
A55_C0_DBGWVR2_EL1_63_32	Debug Watchpoint Value Registers.
A55_C0_DBGWVR3_EL1_31_0	Debug Watchpoint Value Registers.
A55_C0_DBGWVR3_EL1_63_32	Debug Watchpoint Value Registers.
A55_C0_EDCIDSR	External Debug Context ID Sample Register.
A55_C0_EDECCR	External Debug Exception Catch Control Register.
A55_C0_EDESR	External Debug Event Status Register.
A55_C0_EDITCTRL	External Debug Integration mode Control register.
A55_C0_EDITR	External Debug Instruction Transfer Register.
A55_C0_EDPRCR	External Debug Power/Reset Control Register.
A55_C0_EDPRSR	External Debug Processor Status Register.
A55_C0_EDRCR	External Debug Reserve Control Register.
A55_C0_EDSCR	External Debug Status and Control Register.
A55_C0_EDWAR_31_0	External Debug Watchpoint Address Register.
A55_C0_EDWAR_63_32	External Debug Watchpoint Address Register.
A55_C0_OSLAR_EL1	OS Lock Access Register.
A55_C0_TRCACATR0_31_0	Trace Address Comparator Access Type Registers.
A55_C0_TRCACATR0_63_32	Trace Address Comparator Access Type Registers.
A55_C0_TRCACATR1_31_0	Trace Address Comparator Access Type Registers.
A55_C0_TRCACATR1_63_32	Trace Address Comparator Access Type Registers.
A55_C0_TRCACATR2_31_0	Trace Address Comparator Access Type Registers.
A55_C0_TRCACATR2_63_32	Trace Address Comparator Access Type Registers.
A55_C0_TRCACATR3_31_0	Trace Address Comparator Access Type Registers.

Table 48-654: ADSP-2184x A55_C0 Register List (Continued)

Name	Description
A55_C0_TRCACATR3_63_32	Trace Address Comparator Access Type Registers.
A55_C0_TRCACATR4_31_0	Trace Address Comparator Access Type Registers.
A55_C0_TRCACATR4_63_32	Trace Address Comparator Access Type Registers.
A55_C0_TRCACATR5_31_0	Trace Address Comparator Access Type Registers.
A55_C0_TRCACATR5_63_32	Trace Address Comparator Access Type Registers.
A55_C0_TRCACATR6_31_0	Trace Address Comparator Access Type Registers.
A55_C0_TRCACATR6_63_32	Trace Address Comparator Access Type Registers.
A55_C0_TRCACATR7_31_0	Trace Address Comparator Access Type Registers.
A55_C0_TRCACATR7_63_32	Trace Address Comparator Access Type Registers.
A55_C0_TRCACVR0_31_0	Trace Address Comparator Value Registers.
A55_C0_TRCACVR0_63_32	Trace Address Comparator Value Registers.
A55_C0_TRCACVR1_31_0	Trace Address Comparator Value Registers.
A55_C0_TRCACVR1_63_32	Trace Address Comparator Value Registers.
A55_C0_TRCACVR2_31_0	Trace Address Comparator Value Registers.
A55_C0_TRCACVR2_63_32	Trace Address Comparator Value Registers.
A55_C0_TRCACVR3_31_0	Trace Address Comparator Value Registers.
A55_C0_TRCACVR3_63_32	Trace Address Comparator Value Registers.
A55_C0_TRCACVR4_31_0	Trace Address Comparator Value Registers.
A55_C0_TRCACVR4_63_32	Trace Address Comparator Value Registers.
A55_C0_TRCACVR5_31_0	Trace Address Comparator Value Registers.
A55_C0_TRCACVR5_63_32	Trace Address Comparator Value Registers.
A55_C0_TRCACVR6_31_0	Trace Address Comparator Value Registers.
A55_C0_TRCACVR6_63_32	Trace Address Comparator Value Registers.
A55_C0_TRCACVR7_31_0	Trace Address Comparator Value Registers.
A55_C0_TRCACVR7_63_32	Trace Address Comparator Value Registers.
A55_C0_TRCAUXCTLR	Trace Auxiliary Control Register.
A55_C0_TRCBBCTLR	Trace Branch Broadcast Control Register.
A55_C0_TRCCCCTLR	Trace Cycle Count Control Register.
A55_C0_TRCCIDCCTLR0	Trace Context ID Comparator Control Register 0.
A55_C0_TRCCIDCVR0_31_0	Trace Context ID Comparator Value Registers.
A55_C0_TRCCIDCVR0_63_32	Trace Context ID Comparator Value Registers.

Table 48-654: ADSP-2184x A55_C0 Register List (Continued)

Name	Description
A55_C0_TRCCLAIMCLR	Trace Claim Tag Clear Register.
A55_C0_TRCCLAIMSET	Trace Claim Tag Set Register.
A55_C0_TRCCNTCTLR0	Trace Counter Control Registers.
A55_C0_TRCCNTCTLR1	Trace Counter Control Registers.
A55_C0_TRCCNTRLDVR0	Trace Counter Reload Value Registers.
A55_C0_TRCCNTRLDVR1	Trace Counter Reload Value Registers.
A55_C0_TRCCNTVR0	Trace Counter Value Registers.
A55_C0_TRCCNTVR1	Trace Counter Value Registers.
A55_C0_TRCCONFIGR	Trace Configuration Register.
A55_C0_TRCEVENTCTL0R	Trace Event Control 0 Register.
A55_C0_TRCEVENTCTL1R	Trace Event Control 1 Register.
A55_C0_TRCEXTINSELR	Trace External Input Select Register.
A55_C0_TRCIDR0	Trace ID Register 0.
A55_C0_TRCIDR1	Trace ID Register 1.
A55_C0_TRCIDR2	Trace ID Register 2.
A55_C0_TRCIDR3	Trace ID Register 3.
A55_C0_TRCIDR4	Trace ID Register 4.
A55_C0_TRCIDR5	Trace ID Register 5.
A55_C0_TRCIMSPEC0	Trace IMPLEMENTATION DEFINED Register 0.
A55_C0_TRCITATBIDR	Integration ATB Identification Register.
A55_C0_TRCITCTRL	Trace Integration Mode Control Register.
A55_C0_TRCITIATBINR	Integration Instruction ATB In Register.
A55_C0_TRCITIATBOUTR	Integration Instruction ATB Out Register.
A55_C0_TRCITIDATAR	Integration Instruction ATB Data Register.
A55_C0_TRCOSLAR	Trace OS Lock Access Register.
A55_C0_TRCOSLSR	Trace OS Lock Status Register.
A55_C0_TRCPDSR	Trace PowerDown Status Register.
A55_C0_TRCPRGCTLR	Trace Programming Control Register.
A55_C0_TRCRSCTLR10	Trace Resource Selection Control Registers.
A55_C0_TRCRSCTLR11	Trace Resource Selection Control Registers.
A55_C0_TRCRSCTLR12	Trace Resource Selection Control Registers.

Table 48-654: ADSP-2184x A55_C0 Register List (Continued)

Name	Description
A55_C0_TRCRSCTLR13	Trace Resource Selection Control Registers.
A55_C0_TRCRSCTLR14	Trace Resource Selection Control Registers.
A55_C0_TRCRSCTLR15	Trace Resource Selection Control Registers.
A55_C0_TRCRSCTLR2	Trace Resource Selection Control Registers.
A55_C0_TRCRSCTLR3	Trace Resource Selection Control Registers.
A55_C0_TRCRSCTLR4	Trace Resource Selection Control Registers.
A55_C0_TRCRSCTLR5	Trace Resource Selection Control Registers.
A55_C0_TRCRSCTLR6	Trace Resource Selection Control Registers.
A55_C0_TRCRSCTLR7	Trace Resource Selection Control Registers.
A55_C0_TRCRSCTLR8	Trace Resource Selection Control Registers.
A55_C0_TRCRSCTLR9	Trace Resource Selection Control Registers.
A55_C0_TRCSEQEVR0	Trace Sequencer State Transition Control Registers.
A55_C0_TRCSEQEVR1	Trace Sequencer State Transition Control Registers.
A55_C0_TRCSEQEVR2	Trace Sequencer State Transition Control Registers.
A55_C0_TRCSEQRSTEVR	Trace Sequencer Reset Control Register.
A55_C0_TRCSEQSTR	Trace Sequencer State Register.
A55_C0_TRCSSCCR0	Trace Single-Shot Comparator Control Registers.
A55_C0_TRCSSCSR0	Trace Single-Shot Comparator Status Registers.
A55_C0_TRCSTALLCTLR	Trace Stall Control Register.
A55_C0_TRCSTATR	Trace Status Register.
A55_C0_TRCSYNCPR	Trace Synchronization Period Register.
A55_C0_TRCTRACEIDR	Trace Trace ID Register.
A55_C0_TRCTSCTLR	Trace Global Timestamp Control Register.
A55_C0_TRCVICTLR	Trace ViewInst Main Control Register.
A55_C0_TRCVIIECTLR	Trace ViewInst Include/Exclude Control Register.
A55_C0_TRCVISSCTLR	Trace ViewInst Start/Stop Control Register.
A55_C0_TRCVMIDCVR0_31_0	Trace VMID Comparator Value Registers.
A55_C0_TRCVMIDCVR0_63_32	Trace VMID Comparator Value Registers.
A55_C0_PMCCFILTR_EL0	Performance Monitors Cycle Counter Filter Register.
A55_C0_PMCCNTR_EL0_31_0	Performance Monitors Cycle Counter.
A55_C0_PMCCNTR_EL0_63_32	Performance Monitors Cycle Counter.

Table 48-654: ADSP-2184x A55_C0 Register List (Continued)

Name	Description
A55_C0_PMCEID0	Performance Monitors Common Event Identification register 0.
A55_C0_PMCEID1	Performance Monitors Common Event Identification register 1.
A55_C0_PMCEID2	Performance Monitors Common Event Identification register 2.
A55_C0_PMCEID3	Performance Monitors Common Event Identification register 3.
A55_C0_PMCFGR	Performance Monitors Configuration Register.
A55_C0_PMCNTENCLR_EL0	Performance Monitors Count Enable Clear register.
A55_C0_PMCNTENSET_EL0	Performance Monitors Count Enable Set register.
A55_C0_PMCR_EL0	Performance Monitors Control Register.
A55_C0_PMEVCNTR0_EL0	Performance Monitors Event Count Registers.
A55_C0_PMEVCNTR1_EL0	Performance Monitors Event Count Registers.
A55_C0_PMEVCNTR2_EL0	Performance Monitors Event Count Registers.
A55_C0_PMEVCNTR3_EL0	Performance Monitors Event Count Registers.
A55_C0_PMEVCNTR4_EL0	Performance Monitors Event Count Registers.
A55_C0_PMEVCNTR5_EL0	Performance Monitors Event Count Registers.
A55_C0_PMEVTYPER0_EL0	Performance Monitors Event Type Registers.
A55_C0_PMEVTYPER1_EL0	Performance Monitors Event Type Registers.
A55_C0_PMEVTYPER2_EL0	Performance Monitors Event Type Registers.
A55_C0_PMEVTYPER3_EL0	Performance Monitors Event Type Registers.
A55_C0_PMEVTYPER4_EL0	Performance Monitors Event Type Registers.
A55_C0_PMEVTYPER5_EL0	Performance Monitors Event Type Registers.
A55_C0_PMINTENCLR_EL1	Performance Monitors Interrupt Enable Clear register.
A55_C0_PMINTENSET_EL1	Performance Monitors Interrupt Enable Set register.
A55_C0_PMITCTRL	Performance Monitors Integration mode Control register.
A55_C0_PMOVSCLR_EL0	Performance Monitors Overflow Flag Status Clear register.
A55_C0_PMOVSSET_EL0	Performance Monitors Overflow Flag Status Set register.
A55_C0_PMSWINC_EL0	Performance Monitors Software Increment register.

Debug Breakpoint Control Registers.

Holds control information for a breakpoint. Forms breakpoint n together with value register DBGBVR0_EL1.

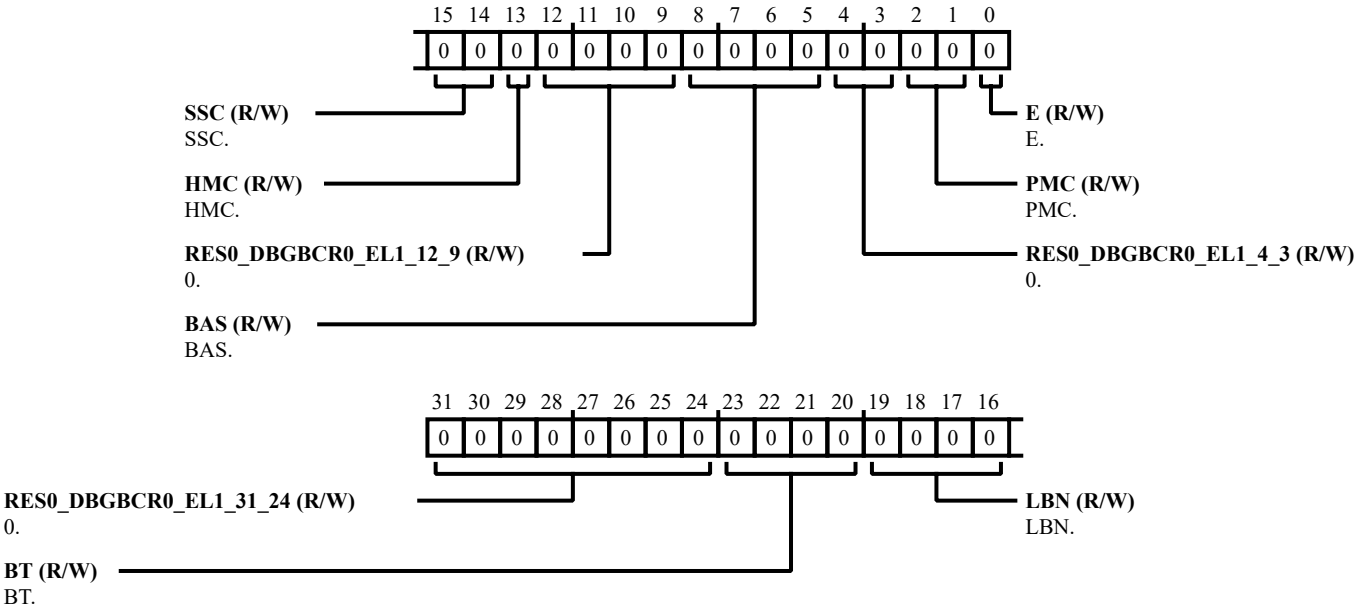

Figure 48-648: A55_C0_DBGBCR0_EL1 Register Diagram

Table 48-655: A55_C0_DBGBCR0_EL1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	RES0_DBGBCR0_EL1_31_24	0.. Reserved, RES0.

Table 48-655: A55_C0_DBGBCR0_EL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
23:20 (R/W)	BT	BT.. Breakpoint Type. Possible values are: 0000 Unlinked address match. 0001 Linked address match. 0010 Unlinked Context ID match. 0011 Linked Context ID match. 0100 Unlinked instruction address mismatch. 0101 Linked instruction address mismatch. 0110 Unlinked CONTEXTIDR_EL1 match (ARMv8.1). 0111 Linked CONTEXTIDR_EL1 match (ARMv8.1). 1000 Unlinked VMID match. 1001 Linked VMID match. 1010 Unlinked VMID and Context ID match. 1011 Linked VMID and Context ID match. 1100 Unlinked CONTEXTIDR_EL2 match (ARMv8.1). 1101 Linked CONTEXTIDR_EL2 match (ARMv8.1). 1110 Unlinked Full Context ID match (ARMv8.1). 1111 Linked Full Context ID match (ARMv8.1). The field breaks down as follows: BT[3:1]: Base type.000Match address. DBGBVR<n>_EL1 is the address of an instruction.001Match Context ID. DBGBVR<n>_EL1.ContextID is a Context ID compared against CONTEXTIDR_EL1 in ARMv8.0, and in ARMv8.1 when not in a Host OS or a Host Application. In ARMv8.1, when in a Host OS or Host Application, the Context ID is compared against CONTEXTIDR_EL1.010Mismatch address. DBGBVR<n>_EL1 is the address of an instruction to be stepped.011Match CONTEXTIDR_EL1. DBGBVR<n>_EL1.ContextID is a Context ID compared against CONTEXTIDR_EL1.100Match VMID. DBGBVR<n>_EL1.VMID is a VMID compared against VTTBR_EL2.VMID.101Match VMID and Context ID. DBGBVR<n>_EL1.ContextID is a Context ID compared against CONTEXTIDR_EL1, and DBGBVR<n>_EL1.VMID is a VMID compared against VTTBR_EL2.VMID.110Match CONTEXTIDR_EL2. DBGBVR<n>_EL1.ContextID2 is a Context ID compared against CONTEXTIDR_EL2.111Match Full Context ID. DBGBVR<n>_EL1.ContextID is compared against CONTEXTIDR_EL1, and DBGBVR<n>_EL1.ContextID2 is compared against CONTEXTIDR_EL2. BT[0]: Enable linking. All other values are reserved. Constraints on breakpoint programming mean other values are reserved under some conditions. For more information, including the effect of programming this field to a reserved value, see .	
		0	Unlinked address match.
		1	Linked address match.
		2	Unlinked Context ID match.
		3	Linked Context ID match.
		4	Unlinked instruction address mismatch.
		5	Linked instruction address mismatch.
		6	Unlinked CONTEXTIDR_EL1 match (ARMv8.1).
		7	Linked CONTEXTIDR_EL1 match (ARMv8.1).
		8	Unlinked VMID match.
		9	Linked VMID match.

Table 48-655: A55_C0_DBGBCR0_EL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
		10	Unlinked VMID and Context ID match.
		11	Linked VMID and Context ID match.
		12	Unlinked CONTEXTIDR_EL2 match (ARMv8.1).
		13	Linked CONTEXTIDR_EL2 match (ARMv8.1).
		14	Unlinked Full Context ID match (ARMv8.1).
		15	Linked Full Context ID match (ARMv8.1).
19:16 (R/W)	LBN	LBN.. Linked breakpoint number. For Linked address matching breakpoints, this specifies the index of the Context-matching breakpoint linked to. For all other breakpoint types this field is ignored and reads of the register return an UNKNOWN value. This field is ignored when the value of DBGBCR<n>_EL1.E is 0.	
15:14 (R/W)	SSC	SSC.. Security state control. Determines the Security states under which a Breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the HMC and PMC fields, and there are constraints on the permitted values of the {HMC, SSC, PMC} fields. For more information, including the effect of programming the fields to a reserved set of values, see .	
13 (R/W)	HMC	HMC.. Higher mode control. Determines the debug perspective for deciding when a Breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the SSC and PMC fields, and there are constraints on the permitted values of the {HMC, SSC, PMC} fields. For more information see DBGBCR<n>_EL1.SSC description.	
12:9 (R/W)	RES0_DBGBCR0_EL1_12_9	0.. Reserved, RES0.	

Table 48-655: A55_C0_DBGBCR0_EL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
8:5 (R/W)	BAS	BAS.. Byte address select. Defines which half-words an address-matching breakpoint matches, regardless of the instruction set and Execution state. In an AArch64-only implementation, this field is reserved, RES1. The permitted values depend on the breakpoint type. For Address match breakpoints in either AArch32 or AArch64 state, the permitted values are: BAS Match instruction at Constraint for debuggers 0011 DBGBVR<n>_EL1 Use for T32 instructions. 1100 DBGBVR<n>_EL1+2 Use for T32 instructions. 1111 DBGBVR<n>_EL1 Use for A64 and A32 instructions. All other values are reserved. For more information, see . For Address mismatch breakpoints in an AArch32 stage 1 translation regime, the permitted values are: BAS Step instruction at Constraint for debuggers 0000 - Use for a match anywhere breakpoint. 0011 DBGBVR<n>_EL1 Use for stepping T32 instructions. 1100 DBGBVR<n>_EL1+2 Use for stepping T32 instructions. 1111 DBGBVR<n>_EL1 Use for stepping A64 and A32 instructions. For more information, see . For Context matching breakpoints, this field is RES1 and ignored.	
4:3 (R/W)	RES0_DBGBCR0_EL1_4_3	0.. Reserved, RES0.	
2:1 (R/W)	PMC	PMC.. Privilege mode control. Determines the Exception level or levels at which a Breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the SSC and HMC fields, and there are constraints on the permitted values of the {HMC, SSC, PMC} fields. For more information see the DBGBCR<n>_EL1.SSC description.	
0 (R/W)	E	E.. Enable breakpoint DBGBVR<n>_EL1. Possible values are: 0 Breakpoint disabled. 1 Breakpoint enabled.	
		0	Breakpoint disabled.
		1	Breakpoint enabled.

Debug Breakpoint Control Registers.

Holds control information for a breakpoint. Forms breakpoint n together with value register DBGBVR1_EL1.

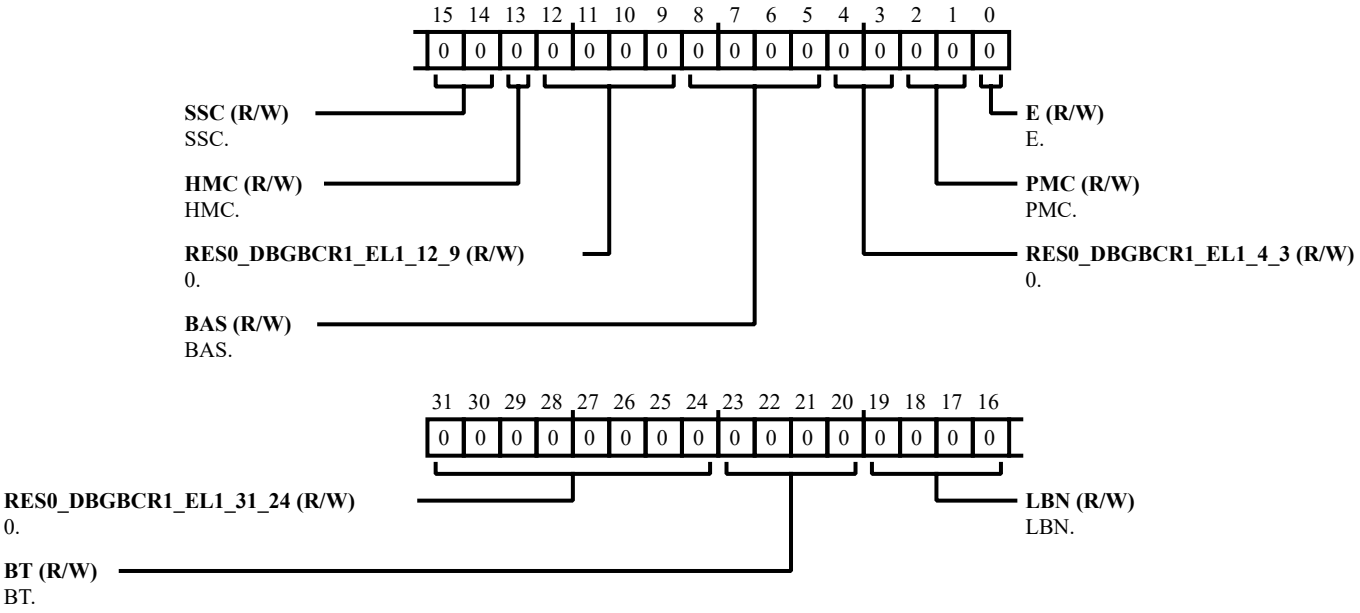

Figure 48-649: A55_C0_DBGBCR1_EL1 Register Diagram

Table 48-656: A55_C0_DBGBCR1_EL1 Register Fields

Bit No. (Access)	Bit Name	Description/Enumeration
31:24 (R/W)	RES0_DBGBCR1_EL1_31_24	0.. Reserved, RES0.

Table 48-656: A55_C0_DBGBCR1_EL1 Register Fields (Continued)

Bit No. (Access)	Bit Name	Description/Enumeration	
23:20 (R/W)	BT	BT.. Breakpoint Type. Possible values are: 0000 Unlinked address match. 0001 Linked address match. 0010 Unlinked Context ID match. 0011 Linked Context ID match. 0100 Unlinked instruction address mismatch. 0101 Linked instruction address mismatch. 0110 Unlinked CONTEXTIDR_EL1 match (ARMv8.1). 0111 Linked CONTEXTIDR_EL1 match (ARMv8.1). 1000 Unlinked VMID match. 1001 Linked VMID match. 1010 Unlinked VMID and Context ID match. 1011 Linked VMID and Context ID match. 1100 Unlinked CONTEXTIDR_EL2 match (ARMv8.1). 1101 Linked CONTEXTIDR_EL2 match (ARMv8.1). 1110 Unlinked Full Context ID match (ARMv8.1). 1111 Linked Full Context ID match (ARMv8.1). The field breaks down as follows: BT[3:1]: Base type.000Match address. DBGBVR<n>_EL1 is the address of an instruction.001Match Context ID. DBGBVR<n>_EL1.ContextID is a Context ID compared against CONTEXTIDR_EL1 in ARMv8.0, and in ARMv8.1 when not in a Host OS or a Host Application. In ARMv8.1, when in a Host OS or Host Application, the Context ID is compared against CONTEXTIDR_EL1.010Mismatch address. DBGBVR<n>_EL1 is the address of an instruction to be stepped.011Match CONTEXTIDR_EL1. DBGBVR<n>_EL1.ContextID is a Context ID compared against CONTEXTIDR_EL1.100Match VMID. DBGBVR<n>_EL1.VMID is a VMID compared against VTTBR_EL2.VMID.101Match VMID and Context ID. DBGBVR<n>_EL1.ContextID is a Context ID compared against CONTEXTIDR_EL1, and DBGBVR<n>_EL1.VMID is a VMID compared against VTTBR_EL2.VMID.110Match CONTEXTIDR_EL2. DBGBVR<n>_EL1.ContextID2 is a Context ID compared against CONTEXTIDR_EL2.111Match Full Context ID. DBGBVR<n>_EL1.ContextID is compared against CONTEXTIDR_EL1, and DBGBVR<n>_EL1.ContextID2 is compared against CONTEXTIDR_EL2. BT[0]: Enable linking. All other values are reserved. Constraints on breakpoint programming mean other values are reserved under some conditions. For more information, including the effect of programming this field to a reserved value, see .	
		0	Unlinked address match.
