

New Low Cost Differential Input Video Amplifiers Simplify Designs and Improve Performance – Design Note 55

John Wright

The LT[®]1190 is a family of high speed amplifiers optimized for video performance on $\pm 5V$ or single $+5V$ supplies. The family includes three voltage feedback op amps and two video difference amplifiers. All amplifiers slew at $450V/\mu s$, and deliver $\pm 50mA$ output current for driving cables. The LT1193 video difference amplifier features uncommitted high input impedance (+) and (-) inputs, and can be used in differential or single-ended configurations. In addition, the LT1193 has an adjustable gain of two or greater, with a $-3dB$ bandwidth of $80MHz$.

Wideband Voltage Controlled Amplifier

The LT1193 video difference amplifier combined with an MC1496 balanced modulator make a low cost $50MHz$ Voltage Controlled Amplifier (VCA), shown in Figure 1. The input signal of the MC1496 at pin 1 is multiplied by the Control Voltage on Pin 10, and appears as a differential output current at Pins 6 and 12. The LT1193 acts to level shift the differential signal and convert it to a single-ended output. Resistor R_B is used to set the bias current in the MC1496 to $1mA$ in each $200\Omega R_L$, while R_{CM} is used to shift the differential output into the common mode range of the LT1193. Resistors R_1

through R_4 bias the MC1496 inputs so that the Control Voltage V_C can be referenced to $0V$. Positive V_C causes positive gain; negative V_C gives a phase inversion ($-A_V$), while $0V$ on V_C gives maximum attenuation (within the V_{OS} of the MC1496 control inputs). The value of R_e is chosen by knowing the maximum input signal:

$$R_e = (V_{IN \text{ max}})/1mA$$

For the example shown the maximum input signal is $100mV$ peak, therefore, $R_e = 100\Omega$. At this maximum input signal there is significant distortion from the re modulation of the input pair. Linearity can be improved by increasing R_e at the expense of gain. The maximum voltage gain of the VCA is:

$$\frac{V_o}{V_i} = (A_V \text{ of LT1193}) \left(\frac{2R_L}{R_e + 2r_e} \right)$$

$$V_o/V_{IN} = 2(2 \times 200)/(100 + 52) = 5.26 = 14.42dB$$

Figures 2 and 3, show the frequency response and harmonic distortion of the VCA.

Figure 3. VCA Output Spectrum

The voltage gain of the VCA can be increased at the expense of bandwidth by changing the value of load resistors R_L . Shorting RCM and increasing R_L to 2k will increase the maximum gain by 20dB and the -3dB bandwidth will drop to approximately 10MHz.

The LT1193 has a shutdown feature that reduces its power dissipation to only 15mW and forces a three-state output. The three-state output occurs when Pin 5 is taken to V^- . The high Z state, dominated by the impedance of the feedback network, is useful for multiplexing several amplifiers on the same cable. The impedance of the feedback resistors should not be raised above 1k Ω because stray capacitance on the (-) input can cause instability.

Extending the Input Range on the LT1193

Figure 4 shows a simplified schematic of the LT1193. In normal operation the REF pin 1 is grounded or taken to a DC offset control voltage, while differential signals are applied between Pins 2 and 3. The LT1193 has been optimized for gains of 2 or greater, and this means the input stage must handle fairly large input signals. The maximum input signal occurs when the input differential

amplifier is tilted over hard in one direction, and 1.2mA flows through the 1k Ω R_e . The maximum input swing is therefore 1.2Vp or 2.4Vp-p. The second differential pair is running at slightly larger current so that when the first input stage limits, the second stage remains biased to maintain the feedback.

Occasionally it is necessary to handle signals larger than 2.4Vp-p at the input. The LT1193 input stage can be tricked to handle up to 4.8Vp-p. To do this, it is necessary to ground Pin 3 and apply the differential input signal between Pin 1 and 2. The input signal is now applied across two 1k resistors in series. Since the input signal is applied to both input pairs, the first pair will run out of bias current before the second pair, causing the amplifier to go open loop. This effect is shown in Figure 5 for the amplifier operating in a closed loop gain of 1. The LT1193 has a unity gain phase margin of only 40 degrees, so when operating at unity gain, care must be taken to avoid instability.
