Low Voltage, High Efficiency
Step-Down DC/DC Converter

**FEATURES**

- Wide Input Supply Voltage Range: 2.5V to 6V
- High Efficiency: Up to 95%
- Low \( R_{DS(ON)} \) Internal Switch: 0.32\( \Omega \) (\( V_{IN} = 4.5V \))
- Current Mode Operation for Excellent Line and Load Transient Response
- Short-Circuit Protected
- Low Dropout Operation: 100% Duty Cycle
- Built-In Low-Battery Detector
- Low Quiescent Current at Light Loads: \( I_Q = 165\mu A \)
- Ultralow Shutdown Current: \( I_Q = 0.5\mu A \)
- Peak Inductor Current Independent of Inductor Value
- Available in 14-Pin SO Package

**APPLICATIONS**

- Single Cell Li-Ion Step-Down Converters
- 3- or 4-Cell NiMH Step-Down Converters
- Cellular Telephones
- 5V to 3.3V Conversion
- 3.3V to 2.5V Conversion
- Inverting Converters
- Portable Instruments

**DESCRIPTION**

The LTC®-1626 is a monolithic, low voltage, step-down current mode DC/DC converter featuring Burst Mode™ operation at low output current.

The input supply voltage range of 2.5V to 6V makes the LTC1626 ideal for single cell Li-Ion and 3- or 4-cell NiCd/ NiMH applications. A built-in 0.32\( \Omega \) switch (\( V_{IN} = 4.5V \)) allows up to 0.6A of output current.

The LTC1626 incorporates automatic power saving Burst Mode operation to reduce gate charge losses when the load current drops below the level required for continuous operation. With no load, the converter draws only 165\( \mu A \). In shutdown, it draws a mere 0.5\( \mu A \)—making it ideal for current sensitive applications.

The inductor current is user-programmable via an external current sense resistor. In dropout, the internal P-channel MOSFET switch is turned on continuously, maximizing battery life.

The ● denotes specifications that apply over the specified operating temperature range.

**Note 1:** $T_J$ is calculated from the ambient temperature $T_A$ and power dissipation according to the following formula:

$$T_J = T_A + (P_D \cdot 110°C/W)$$

**Note 2:** Dynamic supply current is higher due to the gate charge being delivered at the switching frequency.

**Note 3:** In applications where $R_{SENSE}$ is placed at ground potential, the off-time increases by approximately 40%.

**Note 4:** C grade device specifications are guaranteed over the 0°C to 70°C temperature range. In addition, C grade device specifications are assured over the –40°C to 85°C temperature range by design or correlation, but are not production tested.

FIGURE 1 CIRCUIT

Supply Current in Shutdown Low Voltage Behavior
PIN FUNCTIONS

**PWR VIN (Pins 1, 13):** Supply for the Power MOSFET and Its Driver. Decouple this pin properly to ground.

**VIN (Pin 2):** Main Supply for All the Control Circuitry in the LTC1626.

**LBO (Pin 3):** Open-Drain Output of the Low-Battery Comparator. This pin will sink current when Pin 4 (LBI) goes below 1.25V. During shutdown, this pin is high impedance.

**LBI (Pin 4):** The (–) Input of the Low-Battery Comparator. The (+) input is connected to a reference voltage of 1.25V. If not used, connect to VIN.

**C_T (Pin 5):** External capacitor C_T from Pin 5 to ground sets the switch off-time. The operating frequency is dependent on the input voltage and C_T.

**I_{TH} (Pin 6):** Feedback Amplifier Decoupling Point. The current comparator threshold is proportional to Pin 6 voltage.

**SENSE– (Pin 7):** Connects to the (–) Input of the Current Comparator.

**SENSE+ (Pin 8):** The (+) Input to the Current Comparator. A built-in offset between Pins 7 and 8 in conjunction with R_{SENSE} sets the current trip threshold.

**V_FB (Pin 9):** This pin serves as the feedback pin from an external resistive divider used to set the output voltage.

**SHDN (Pin 10):** Shutdown Pin. Pulling this pin to VIN keeps the internal switch off and puts the LTC1626 in micropower shutdown. If not used, connect to SGND.

**SGND (Pin 11):** Small-Signal Ground. Must be routed separately from other grounds to the (–) terminal of C_OUT.

**PWR GND (Pin 12):** Switch Driver Ground. Connects to the (–) terminal of C_IN.

**SW (Pin 14):** Drain of the P-Channel MOSFET Switch. Cathode of the Schottky diode must be connected closely to this pin.

BLOCK DIAGRAM
OPERATION

The nominal off-time of the LTC1626 is set by an external timing capacitor connected between the CT pin and ground. The operating frequency is then determined by the off-time and the difference between VIN and VOUT.

The output voltage is set by an external divider returned to the VFB pin. A voltage comparator V and a gain block G compare the divided output voltage with a reference voltage of 1.25V.

To optimize efficiency, the LTC1626 automatically switches between continuous and Burst Mode operation. The voltage comparator is the primary control element when the device is in Burst Mode operation, while the gain block controls the output voltage in continuous mode.

When the load is heavy, the LTC1626 is in continuous operation. During the switch “ON” time, current comparator C monitors the voltage between the SENSE+ and SENSE– pins connected across an external shunt in series with the inductor. When the voltage across the shunt reaches the comparator’s threshold value, its output signal changes state, resetting the flip-flop and turning the internal P-channel MOSFET off. The timing capacitor connected to the CT pin is now allowed to discharge at a rate determined by the off-time controller.

When the voltage on the timing capacitor has discharged past VTH1, comparator T trips, sets the flip-flop and causes the switch to turn on. Also, the timing capacitor is recharged. The inductor current will again ramp up until the current comparator C trips. The cycle then repeats. When the load current increases, the output voltage decreases slightly. This causes the output of the gain stage (Pin 6) to increase the current comparator threshold, thus tracking the load current.

When the load is relatively light, the LTC1626 automatically switches to Burst Mode operation. The current loop is interrupted when the output voltage reaches the desired regulated value. The hysteretic voltage comparator V trips when VOUT is above the desired output voltage, turning off the switch and causing the timing capacitor to discharge. This capacitor discharges past VTH1 until its voltage drops below VTH2. Comparator S then trips and a sleep signal is generated. The circuit now enters into sleep mode with the power MOSFET turned off. In sleep mode, the LTC1626 is in standby and the load current is supplied by the output capacitor. All unused circuitry is shut off, reducing quiescent current from 1.9mA to 165μA. When the output capacitor discharges by the amount of the hysteresis of the comparator V, the P-channel switch turns on again and the process repeats itself. During Burst Mode operation, the peak inductor’s current is set at 25mV/RSENSE.

To avoid the operation of the current loop interfering with Burst Mode operation, a built-in offset VOS is incorporated in the gain stage. This prevents the current from increasing until the output voltage has dropped below a minimum threshold.

In dropout, the P-channel MOSFET is turned on continuously (100% duty cycle) providing low dropout operation with VOUT = VIN.

APPLICATIONS INFORMATION

The basic LTC1626 application circuit is shown in Figure 1. External component selection is driven by the load requirement and begins with the selection of RSENSE. Once RSENSE is known, CT and L can be chosen. Next, the Schottky diode D1 is selected followed by CIN and COUT.

RSENSE Selection for Output Current

RSENSE is chosen based on the required output current. With the current comparator monitoring the voltage developed across RSENSE, the threshold of the comparator determines the peak inductor current. Depending upon the load current condition, the threshold of the comparator lies between 25mV/RSENSE and 150mV/RSENSE. The maximum output current of the LTC1626 is:

\[
I_{OUT(MAX)} = 150mV/RSENSE - I_{RIPPLE}/2 \quad (A)
\]

Where IRIPPLE is the peak-to-peak inductor ripple current. At a relatively light load, the LTC1626 is in Burst Mode operation. In this mode, the peak current is set at 25mV/RSENSE. To fully benefit from Burst Mode operation, the
inductor current should be continuous during burst periods. Hence, the peak-to-peak inductor ripple current must not exceed 25mV/RSENSE.

To account for light load conditions, the $I_{\text{OUT(MAX)}}$ is then given by:

$$I_{\text{OUT(MAX)}} = \frac{150\text{mV}}{R_{\text{SENSE}}} - \frac{25\text{mV}}{2R_{\text{SENSE}}} \quad (A)$$

Solving for $R_{\text{SENSE}}$ and allowing a margin of variations in the LTC1626 and external component values yields:

$$R_{\text{SENSE}} = \frac{100\text{mV}}{I_{\text{OUT(MAX)}}} \quad (\Omega)$$

The LTC1626 switch is capable of supplying a maximum of 1.2A of output current. Therefore, the minimum value of $R_{\text{SENSE}}$ that can be used is 0.083Ω. A graph for selecting $R_{\text{SENSE}}$ versus maximum output current is given in Figure 2.

**Operating Frequency Considerations**

For most applications, the LTC1626 should be operated in the 100kHz to 300kHz range. This range can be extended, however, up to 600kHz, to accommodate smaller size/valued inductors, such as low profile types, with a slight decrease in efficiency due to gate charge losses. Some experimentation may be required to determine the optimum operating frequency for a particular set of external components and operating conditions.

**$C_T$ and $L$ Selection**

The value of $C_T$ is calculated from the desired continuous mode operating frequency:

$$C_T = \frac{(V_{\text{IN}} - V_{\text{OUT}})}{(V_{\text{IN}} + V_D)(3300)(V_{\text{IN}} - V_{\text{BE}})(f_0)} \quad (F)$$

where $V_D$ is the drop across the Schottky diode D1 and $V_{BE}$ is a base-emitter voltage drop (0.6V).

The complete expression for operating frequency is given by:

$$f_0 = \left( \frac{1}{t_{\text{OFF}}} \right) \left( \frac{V_{\text{IN}} - V_{\text{OUT}}}{V_{\text{IN}} + V_D} \right) \quad (Hz)$$

where:

$$t_{\text{OFF}} = (3300)(C_T)(V_{\text{IN}} - V_{\text{BE}}) \quad (sec)$$

Figure 3 is a graph of operating frequency versus power supply voltage for the 2.5V regulator circuit shown in Figure 1 ($C_T = 270\text{pF}$). Note that the frequency is relatively constant with supply voltage but drops as the supply voltage approaches the regulated output voltage.

To maintain continuous inductor current at light load, the inductor must be chosen to provide no more than 25mV/RSENSE of peak-to-peak ripple current. This results in the following expression for $L$:

$$L \geq (5.2)(10^5)(R_{\text{SENSE}})(C_T)(V_{\text{REG}}) \quad (H)$$

Using an inductance smaller than the above value will result in inductor current being discontinuous. As a con-
sequence, the LTC1626 will delay entering Burst Mode operation and efficiency will be degraded at low currents.

![Figure 1. Operating Frequency vs Supply Voltage for Circuit Shown in Figure 1](image)

**Inductor Core Selection**

With the value of L selected, the type of inductor must be chosen. Basically, there are two kinds of losses in an inductor—core and copper losses.

Core losses are dependent on the peak-to-peak ripple current and core material. However, they are independent of the physical size of the core. By increasing inductance, the peak-to-peak inductor ripple current will decrease, therefore reducing core loss. Utilizing low core loss material, such as molypermalloy or Kool Mu® will allow the user to concentrate on reducing copper loss and preventing saturation.

Although higher inductance reduces core loss, it increases copper loss as it requires more windings. When space is not a premium, larger wire can be used to reduce the wire resistance. This also prevents excessive heat dissipation in the inductor.

**Catch Diode Selection**

Losses in the catch diode depend on forward drop and switching times. Therefore, Schottky diodes are a good choice for low drop and fast switching times.

The catch diode carries the load current during the off-time. The average diode current is therefore dependent on the P-channel switch duty cycle. At high input voltages, the diode conducts most of the time. As VIN approaches VOUT, the diode conducts only a small fraction of the time. The most stressful condition for the diode is when the regulator output is shorted to ground.

Under short-circuit conditions, the diode must safely handle ISC(PK) at close to 100% duty cycle. Most LTC1626 circuits will be well served by either an MBRM5819 or an MBRS130LT3. An MBR0520LT1 is a good choice for IOUT(MAX) ≤ 500mA.

**Input Capacitor (CIN) Selection**

In continuous mode, the input current of the converter is a square wave of duty cycle VOUT/VIN. To prevent large voltage transients, a low effective series resistance (ESR) input capacitor must be used. In addition, the capacitor must handle a high RMS current. The CIN RMS current is given by:

$$I_{RMS} \approx \frac{I_{OUT}[V_{IN} - V_{OUT}]}{V_{IN}}^{1/2}$$

This formula has a maximum at V_IN = 2V_OUT, where I_{RMS} = I_{OUT}/2. This simple worst case is commonly used to design because even significant deviations do not offer much relief. Note that capacitor manufacturer’s ripple current ratings are often based on only 2000 hours lifetime. This make it advisable to further derate the capacitor, or choose a capacitor rated at a higher temperature than required. Do not underspecify this component. An additional 0.1μF ceramic capacitor is also required on PWR VIN for high frequency decoupling.

**Output Capacitor (COUT) Selection**

The selection of COUT is driven by the ESR for proper operation of the LTC1626. The required ESR of COUT is:

$$ESR_{COUT} < 50mV/I_{RIPPLE}$$

where I_{RIPPLE} is the ripple current of the inductor. For the case where the I_{RIPPLE} is 25mV/RSENSE, the required ESR of COUT is:

Kool Mu® is a registered trademark of Magnetics, Inc.
APPLICATIONS INFORMATION

ESR_{COUT} < 2R_{SENSE}

To avoid overheating, the output capacitor must be sized to handle the ripple current generated by the inductor. The worst-case RMS ripple current in the output capacitor is given by:

\[ I_{RMS} < \frac{150\text{mV}}{2R_{SENSE}} \text{(ARMS)} \]

Generally, once the ESR requirements for C_{OUT} have been met, the RMS current rating far exceeds the \( I_{ripp}\) requirement.

In some surface mount applications, multiple capacitors may have to be paralleled to meet the capacitance, ESR or RMS current handling requirement of the application. Aluminum electrolyte and dry tantalum capacitors are both available in surface mount configurations. In the case of tantalum, it is critical that the capacitors are surge tested for use in switching power supplies. An excellent choice is the AVX TPS series of surface mount tantalums, available in case heights ranging from 2mm to 4mm. Other capacitor types include Sanyo OS-CON, Nichicon PL series and Sprague 595D series. Consult the manufacturer for other specific recommendations.

When the capacitance of C_{OUT} is made too small, the output ripple at low frequencies will be large enough to trip the voltage comparator. This causes Burst Mode operation to be activated when the LTC1626 would normally be in continuous mode operation. The effect will be most pronounced with low R_{SENSE} values and can be improved at higher frequencies.

Low-Battery Detection

The low-battery detector senses the input voltage through an external resistive divider. This divided voltage connects to the (–) input of a voltage comparator (LBI) and is compared to an internal 1.25V reference voltage. Neglecting LBI input bias current, the following expression is used for setting the trip voltage threshold:

\[ V_{\text{LB}_{\text{TRIP}}} = 1.25 \left( 1 + \frac{R_4}{R_3} \right) \]

The LBO is an N-channel open drain that goes low when the battery voltage drops below the threshold voltage. In shutdown, the comparator is disabled and LBO is in the high impedance state. Figure 4 is a schematic diagram detailing the low-battery comparator connection and operation.

Setting the Output Voltage

The LTC1626 develops a 1.25V reference voltage between the feedback pin \( V_{FB} \) and the signal ground as shown in Figure 5. By selecting resistor R1, a constant current is caused to flow through R1 and R2 which sets the desired output voltage. The regulated output voltage is determined by:

\[ V_{OUT} = 1.25 \left( 1 + \frac{R_2}{R_1} \right) \]

\( R_1 \) should be \( \leq 10k \) to ensure that sufficient current flows through the divider to maintain accuracy and to provide a minimum load for the regulator output at elevated temperatures. (See Switch Leakage Current curve in Typical Performance Characteristics section.)

To prevent stray pickup, a 100pF capacitor is suggested across R1, located close to the LTC1626.
**Thermal Considerations**

In a majority of applications, the LTC1626 does not dissipate much heat due to its high efficiency. However, in applications where the switching regulator is running at high duty cycles or the part is in dropout with the switch turned on continuously (DC), some thermal analysis is required. The goal of the thermal analysis is to determine whether the power dissipated by the regulator exceeds the maximum junction temperature. The temperature rise is given by:

\[ T_{\text{RISE}} = P_D \cdot \theta_{JA} \]

where \( P_D \) is the power dissipated by the regulator and \( \theta_{JA} \) is the thermal resistance from the junction of the die to the ambient temperature.

The junction temperature is given by:

\[ T_J = T_{\text{RISE}} + T_{\text{AMBIENT}} \]

As an example, consider the case when the LTC1626 is in dropout at an input voltage of 3V with a load current of 0.5A. From the Typical Performance Characteristics graph of Switch Resistance, the ON resistance of the P-channel switch is 0.45\( \Omega \). Therefore, power dissipated by the part is:

\[ P_D = I^2 \cdot R_{DS(ON)} = 113\text{mW} \]

The SO package junction-to-ambient thermal resistance \( \theta_{JA} \) is 110\( ^\circ \text{C/W} \). Therefore, the junction temperature of the regulator when it is operating in a 25\( ^\circ \text{C} \) ambient temperature is:

\[ T_J = (0.113 \cdot 110) + 25 = 38^\circ \text{C} \]

Remembering that the above junction temperature is obtained from an \( R_{DS(ON)} \) at 25\( ^\circ \text{C} \), we might recalculate the junction temperature based on a higher \( R_{DS(ON)} \) since it increases with temperature. However, we can safely assume that the actual junction temperature will not exceed the absolute maximum junction temperature of 125\( ^\circ \text{C} \).

**Board Layout Considerations**

When laying out the printed circuit board, the following checklist should be used to ensure proper operation of the LTC1626. These items are also illustrated graphically in the layout diagram of Figure 6. Check the following in your layout:

1. Are the signal and power grounds separated? The LTC1626 signal ground (Pin 11) must return to the (–) plate of \( C_{OUT} \). The power ground (Pin 12) returns to the anode of the Schottky diode and the (–) plate of \( C_{IN} \).

2. Does the (+) plate of \( C_{IN} \) connect to the power \( V_{IN} \) (Pins 1, 13) as close as possible? This capacitor provides the AC current to the internal P-channel MOSFET and its driver.

---

**Figure 6. LTC1626 Layout Diagram (See Board Layout Checklist)**
3. Is the input decoupling capacitor (0.1\,\mu F) connected closely between power \(V_{\text{IN}}\) (Pins 1, 13) and power ground (Pin 12)? This capacitor carries the high-frequency peak currents.

4. Is the Schottky diode closely connected between the power ground (Pin 12) and switch output (Pin 14)?

5. Does the LTC1626 SENSE– (Pin 7) connect to a point close to \(R_{\text{SENSE}}\) and the (+) plate of \(C_{\text{OUT}}\)? The resistor divider \(R_{1}-R_{2}\) must be connected between the (+) plate of \(C_{\text{OUT}}\) and the signal ground.

6. Are the SENSE– and SENSE+ leads routed together with minimum PC trace spacing? The 1000\,\mu F capacitor between Pin 7 and Pin 8 should be as close as possible to the LTC1626.

7. Is SHDN (Pin 10) actively pulled to ground during normal operation? The shutdown pin is high impedance and must not be allowed to float.

---

**TYPICAL APPLICATIONS**

**Single Cell Li-Ion to 2.5V Converter**

\((V_{\text{IN}} = 2.7\,\text{V to 4.5\,V})\)

---

**3- to 4-Cell NiCd/NiMH to 2.5V Converter**

\((V_{\text{IN}} = 2.7\,\text{V to 6\,V})\)
