**FEATURES**

- Low Output Noise: 90μVRMS (100kHz BW)
- Fixed Output Voltage: 5V
- Input Voltage Range: 2.7V to 4.4V
- No Inductors Required
- Uses Small Ceramic Capacitors
- Output Current Up to 30mA
- 550kHz Switching Frequency
- Low Operating Current: 190μA
- Low Shutdown Current: 4μA
- Internal Thermal Shutdown and Current Limiting
- Low Profile (1mm) ThinSOT™ Package

**APPLICATIONS**

- VCO Power Supplies for Cellular Phones
- 2-Way Pagers
- Wireless PCMCIA Cards
- Portable Medical Instruments
- Low Power Data Acquisition
- Remote Transmitters
- White LED Drivers
- GaAs Switches

**DESCRIPTION**

The **LTC®1928-5** is a doubler charge pump with an internal low noise, low dropout (LDO) linear regulator. The part is designed to provide a low noise boosted supply voltage for powering noise sensitive devices such as high frequency VCOs in wireless applications.

An internal charge pump converts a 2.7V to 4.4V input to a boosted output, while the internal LDO regulator converts the boosted voltage to a low noise regulated output. The regulator is capable of supplying up to 30mA of output current. Shutdown reduces the supply current to <8μA, removes the load from VIN by disabling the regulator and discharges VOUT to ground through a 200Ω switch.

The LTC1928-5 LDO regulator is stable with only 2μF on the output. Small ceramic capacitors can be used, reducing PC board area.

The LTC1928-5 is short-circuit and overtemperature protected. The part is available in a 6-pin low profile (1mm) ThinSOT package.

**APPLICATIONS**

- VCO Power Supplies for Cellular Phones
- 2-Way Pagers
- Wireless PCMCIA Cards
- Portable Medical Instruments
- Low Power Data Acquisition
- Remote Transmitters
- White LED Drivers
- GaAs Switches

| CN/SHDN Input Current   | $\text{CN/SHDN} = 0\text{V}$ (Note 5)         | ●  | –1   | –3   | –6   | $\mu\text{A}$ |

**Note 1:** Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

**Note 2:** The LTC1928ES6-5 is guaranteed to meet performance specifications from $0^\circ\text{C}$ to $70^\circ\text{C}$. Specifications over the $–40^\circ\text{C}$ to $85^\circ\text{C}$ operating temperature range are assured by design, characterization and correlation with statistical process controls.

**Note 3:** Dropout voltage is the minimum input/output voltage required to maintain regulation at the specified output current. In dropout the output voltage will be equal to: $V_{CPO} – V_{\text{DROPOUT}}$ (see Figure 2).

**PIN FUNCTIONS**

**VIN (Pin 1):** Input Voltage, 2.7V to 4.4V. VIN should be bypassed with a ≥2µF low ESR capacitor as close to the pin as possible for best performance. A minimum capacitance value of 0.1µF is required.

**GND (Pin 2):** System Ground.

**VOUT (Pin 3):** Low Noise Regulated Output Voltage. VOUT should be bypassed with a ≥2µF low ESR capacitor as close to the pin as possible for best performance. The VOUT voltage is internally set to 5V.

**CPO (Pin 4):** Boosted Unregulated Voltage. Approximately 1.95VIN at low loads. Bypass with a ≥2µF low ESR capacitor.

**CP (Pin 5):** Flying Capacitor Positive Input.

**CN/SHDN (Pin 6):** Flying Capacitor Negative Input and SHDN. When this pin is pulled to ground through a 100Ω resistor, the part will go into shutdown within approximately 30µs.
APPLICATIONS INFORMATION

Operation

The LTC1928-5 uses a switched-capacitor charge pump to generate a CPO voltage of approximately 2VIN. CPO powers an internal low dropout linear regulator that supplies a regulated output at VOUT. Internal comparators are used to sense CPO and VIN voltages for power-up conditioning. The output current is sensed to determine the charge pump operating mode. A trimmed internal bandgap is used as the voltage reference and a trimmed internal oscillator is used to control the charge pump switches.

The charge pump is a doubler configuration that uses one external flying capacitor. When enabled, a 2-phase nonoverlapping clock controls the charge pump switches. At start-up, the LDO is disabled and the load is removed from CPO. When CPO reaches 1.75VIN the LDO is enabled. If CPO falls below 1.45VIN the LDO will be disabled. Generally, the charge pump runs open loop with continuous clocking for low noise. If CPO is greater than 1.95VIN and IOUT is less than 200µA, the charge pump will operate in Burst Mode operation for increased efficiency but slightly higher output noise. In Burst Mode operation, the clock is disabled when CPO reaches 1.95VIN and enabled when CPO droops by about 150mV. The switching frequency is precisely controlled to ensure that the frequency is above 455kHz and at the optimum rate to ensure maximum efficiency. The switch edge rates are also controlled to minimize noise. The effective output resistance at CPO is dependent on the voltage at VIN, CPO, the flying capacitor value CFLY and the junction temperature. A low ESR capacitor of ≥2µF should be used at CPO for minimum noise.

The LDO is used to filter the ripple on CPO and to set an output voltage independent of CPO. VOUT is set by an in-
APPLICATIONS INFORMATION

ternal reference and resistor divider. The LDO requires a capacitor on \( V_{\text{OUT}} \) for stability and improved load transient response. A low ESR capacitor of \( \geq 2\mu F \) should be used.

Maximum \( I_{\text{OUT}} \) Calculations

The maximum available current can be calculated based on the open circuit CPO voltage, the dropout voltage of the LDO and the effective output resistance of the charge pump. The open circuit CPO voltage is approximately \( 2V_{\text{IN}} \) (see Figure 2).

Example:

\[
\begin{align*}
V_{\text{IN}} &= 3V \\
V_{\text{OUT}} &= 5V \\
R_{\text{CPO}} &= 30\Omega \\
\text{Maximum unloaded CPO voltage} &= 2V_{\text{IN}} = 6V \\
V_{\text{DROPOUT(MAX)}} &= 100mV \\
I_{\text{OUT(MAX)}} &= \frac{(2V_{\text{IN}} - V_{\text{DROPOUT(MAX)}} - V_{\text{OUT}})/R_{\text{CPO}}}{6V - 0.1V - 5V/30\Omega = 30mA} \\
V_{\text{CPO}} &= 6V - (30mA \cdot 30\Omega) = 5.1V \\
\end{align*}
\]

For minimum noise applications the LDO must be kept out of dropout to prevent CPO noise from coupling into \( V_{\text{OUT}} \).

External CPO Loading

The CPO output can drive an external load (for example, an LDO). The current required by this additional load will reduce the available current from \( V_{\text{OUT}} \). If the external load requires 1mA, the available current at \( V_{\text{OUT}} \) will be reduced by 1mA.

Short-Circuit and Thermal Protection

\( V_{\text{OUT}} \) can be shorted to ground indefinitely. Internal circuitry will limit the output current. If the junction temperature exceeds 150°C the part will shut down. Excessive power dissipation due to heavy loads will also cause the part to shut down when the junction temperature exceeds 150°C. The part will become enabled when the junction temperature drops below 140°C. If the fault conditions remain in place, the part will cycle between the shutdown and enabled states.

Capacitor Selection

For best performance it is recommended that low ESR ceramic capacitors be used to reduce noise and ripple. \( C_{\text{OUT}} \) must be \( \geq 2\mu F \) and \( C_{\text{CPO}} \) must be equal to or greater than \( C_{\text{OUT}} \). \( C_{\text{IN}} \) is dependent on the input power supply source impedance. The charge pump demands large instantaneous currents which may induce ripple onto a common voltage rail. \( C_{\text{IN}} \) should be \( \geq 2\mu F \) and a spike reducing resistor of 2.2Ω may be required between \( V_{\text{IN}} \) and the supply.

A low ESR ceramic capacitor is recommended for the flying capacitor \( C_{\text{FLY}} \) with a value of 0.47μF. At low load or high \( V_{\text{IN}} \) a smaller capacitor could be used to reduce ripple on CPO which would reflect as lower ripple on \( V_{\text{OUT}} \).

If a minimum enable time is required, the CPO output filter capacitor should be at least 2x the \( V_{\text{OUT}} \) filter capacitor. When the LDO is first enabled, the CPO capacitor will dump a large amount of charge into the \( V_{\text{OUT}} \) capacitor. If the drop in the CPO voltage falls below 1.45\( V_{\text{IN}} \) the LDO will be disabled and the CPO voltage will be required to charge up to 1.75\( V_{\text{IN}} \) to enable the LDO. The resulting cycling extends the enable time.

Output Ripple

The output ripple on CPO includes a spike component from the charge pump switches and a droop component which is dependent on the load current and the value of \( C_{3} \). The charge pump has been carefully designed to minimize the spike component, however, low ESR capacitors are essential to reduce the remaining spike energy effect on the CPO voltage. \( C_{\text{CPO}} \) should be increased for high load currents to minimize the droop component. Ripple components on CPO are greatly reduced at \( V_{\text{OUT}} \) by the LDO, however, \( C_{\text{OUT}} \) should also be a low ESR capacitor to improve filtering of the CPO noise.
APPLICATIONS INFORMATION

Shutdown

When CN/SHDN = 0V, the part will be in shutdown, the supply current will be <8µA and VOUT will be shorted to ground through a 160Ω switch. In addition, CPO will be high impedance and disconnected from VIN and CN/SHDN.

Shutdown is achieved by internally sampling the CN/SHDN pin for a low voltage. Time between shutdown samples is about 30µs. During the sample time the charge pump switches are disabled and CN/SHDN must be pulled to ground within 400ns. A resistor value between 100Ω and 1k is recommended. Parasitic lead capacitance should be minimized on the CN/SHDN pin.

Power-On Reset

Upon initial power-up, a power-on reset circuit ensures that the internal functions are correctly initialized. Once VIN reaches about 1V, the power-on reset circuit will enable the part as long as the CN/SHDN pin is not pulled low.

Thermal Considerations

The power handling capability of the device will be limited by the maximum rated junction temperature (125°C). The device dissipation PD = IOUT(2VIN – VOUT) + VIN(2mA). The device dissipates the majority of its heat through its pins, especially GND (Pin 2). Thermal resistance to ambient can be optimized by connecting GND to a large copper region on the PCB, which serves as a heat sink. Applications that operate the LTC1928-5 near maximum power levels should maximize the copper area at all pins except CP and CN/SHDN and ensure that there is some airflow over the part to carry away excess heat.

General Layout Considerations

Due to the high switching frequency and high transient currents produced by the device, careful board layout is a must. A clean board layout using a ground plane and short connections to all capacitors will improve noise performance and ensure proper regulation.

Measuring Output Noise

Measuring the LTC1928 low noise levels requires care. Figure 3 shows a test setup for taking the measurement. Good connection and signal handling technique should yield about 800µVP-P over a 2.5MHz bandwidth. The noise measurement involves AC-coupling the LTC1928 output into the test setup’s input and terminating this connection with 50Ω. Coaxial connections must be maintained to preserve measurement integrity.
