**FEATURES**
- Monitors Temperature and Two Voltages
- Voltage Output Proportional to Temperature
- Adjustable Thresholds for Temperature and Voltage
- ±1°C Remote Temperature Accuracy
- ±2°C Internal Temperature Accuracy
- ±1.5% Voltage Threshold Accuracy
- 3.5ms Update Time
- 2.25V to 5.5V Supply Voltage
- Input Glitch Rejection
- Adjustable Reset Timeout
- 220μA Quiescent Current
- Open Drain Alert Outputs
- Available in 3mm × 3mm QFN Package

**APPLICATIONS**
- Network Servers
- Core, I/O Voltage Monitors
- Desktop and Notebook Computers
- Environmental Monitoring

**DESCRIPTION**

The LTC®2995 is a high accuracy temperature sensor and dual supply monitor. It converts the temperature of an external diode sensor and/or its own die temperature to an analog output voltage while rejecting errors due to noise and series resistance. Two supply voltages and the measured temperature are compared against upper and lower limits set with resistive dividers. If a threshold is exceeded, the device communicates an alert by pulling low the correspondent open drain logic output.

The LTC2995 gives ±1°C accurate temperature results using commonly available NPN or PNP transistors or temperature diodes built into modern digital devices. Voltages are monitored with 1.5% accuracy. A 1.8V reference output simplifies threshold programming and can be used as an ADC reference input.

The LTC2995 provides an accurate, low power solution for temperature and voltage monitoring in a compact 3mm × 3mm QFN package.

PIN FUNCTIONS

**D+:** Diode Sense Current Source. D+ sources the remote diode sensing current. Connect D+ to the anode of the remote sensor device. It is recommended to connect a 470pF bypass capacitor between D+ and D-. Larger capacitors may cause settling time errors (see Typical Performance Characteristics). If D+ is tied to VCC, the LTC2995 measures the internal sensor temperature. Tie D+ to VCC if unused.

**D-:** Diode Sense Current Sink. Connect D- to the cathode of the remote sensor device. Tie D- to GND for single wire remote temperature measurement (see Applications Information) or internal temperature sensing.

**DS:** Diode Select Input. Three state pin that selects temperature sensor location. Tie DS to VCC to monitor the temperature of the internal diode or to GND to monitor the temperature of the external diode. When DS is left unconnected, the LTC2995 monitors both sensors alternately. If D+ is tied to VCC, the LTC2995 measures the internal sensor temperature regardless of the state of DS.

**Exposed Pad:** Exposed pad may be left open or soldered to GND for better thermal coupling.

**GND:** Device Ground

**OV:** Overvoltage Logic Output. Open drain logic output that pulls to GND when either the voltage at VL1 or VL2 is above 0.5V. Held low for a programmable delay time set by the capacitor connected to pin TMR. OV has a weak 400kΩ pull-up to VCC and may be pulled above VCC using an external pull-up. Leave OV open if unused.

**PS:** Polarity Select Input. Selects the polarity of temperature thresholds VT1 and VT2. Connect PS to VCC to configure VT1 as undertemperature and VT2 as overtemperature threshold. Leave PS unconnected to configure both VT1 and VT2 as overtemperature thresholds. Connect PS to GND to configure both VT1 and VT2 as undertemperature thresholds. Tie to VCC if temperature thresholds are unused.

**TMR:** Reset Delay Timer. Attach an external capacitor (CTMR) to GND to set the delay time until alerts on T01, T02, UV and OV are reset. Leaving the pin open generates a minimum delay of 500μs. Capacitance on this pin adds an additional 8ms/nF reset delay time. Tie TMR to VCC to bypass the timer.

**TO1:** Temperature Logic Output 1. Open drain logic output that pulls to GND when VPTAT crosses the threshold voltage on pin VT1 with a polarity set by the PS pin (see Table 3 in Applications Information). When VPTAT crosses the threshold voltage on pin VT1 with opposite polarity, an additional hysteresis of 20mV is required to release TO1 high after a delay adjustable by the capacitor on TMR. TO1 has a weak 400kΩ pull-up to VCC and may be pulled above VCC using an external pull-up. Leave TO1 open if unused.

**TO2:** Temperature Logic Output 2. Open drain logic output that pulls to GND when VPTAT crosses the threshold voltage on pin VT2 with a polarity set by the PS pin (see Table 3 in Applications Information). When VPTAT crosses the threshold voltage on pin VT2 with opposite polarity, an additional hysteresis of 20mV is required to release TO2 high after a delay adjustable by the capacitor on TMR. TO2 has a weak 400kΩ pull-up to VCC and may be pulled above VCC using an external pull-up. Leave TO2 open if unused.

**UV:** Undervoltage Logic Output. Open drain logic output that pulls to GND when either the voltage at VH1 or VH2 is below 0.5V. Held low for an adjustable delay time set by the capacitor connected to pin TMR. UV has a weak 400kΩ pull-up to VCC and may be pulled above VCC using an external pull-up. Leave pin open if unused.

**VCC:** Supply Voltage. Bypass this pin to GND with a 0.1μF (or greater) capacitor. VCC operating range is 2.25V to 5.5V.

**VH1, VH2:** Voltage High Inputs 1 and 2. When the voltage on either pin is below 0.5V, an undervoltage condition is triggered. Tie pin to VCC if unused.

**VL1, VL2:** Voltage Low Inputs 1 and 2. When the voltage on either pin is above 0.5V, an overvoltage condition is triggered. Tie pin to GND if unused.

**VPTAT:** Proportional to Absolute Temperature Voltage Output. The voltage on this pin is proportional to the selected sensor’s absolute temperature. An internal or external sensor is chosen with the DS pin. VPTAT can drive up to ±200μA of load current and up to 1000pF of capacitive load. For larger load capacitances insert a 1k
LTC2995

PIN FUNCTIONS

resistor between V\textsubscript{PTAT} and the load to ensure stability. V\textsubscript{PTAT} is pulled low when the supply voltage goes below the under voltage lockout threshold.

V\textsubscript{REF}: Voltage Reference Output. V\textsubscript{REF} provides a 1.8V reference voltage. V\textsubscript{REF} can drive up to ±200μA of load current and up to 1000pF of capacitive load. For larger load capacitances insert 1kΩ between V\textsubscript{REF} and the load to ensure stability. Leave V\textsubscript{REF} open if unused.

VT1: Temperature Threshold 1. When V\textsubscript{PTAT} crosses the voltage on VT1 with a polarity set by the PS pin, \textbar TO1 \textbar is pulled low. Tie VT1 to GND if unused.

VT2: Temperature Threshold 2. When V\textsubscript{PTAT} crosses the voltage on VT2 with a polarity set by the PS pin, \textbar TO2 \textbar is pulled low. Tie VT2 to V\textsubscript{CC} if unused.

BLOCK DIAGRAM
OPERATION

Overview
The LTC2995 combines the functionality of a temperature measurement and monitor device with a dual voltage supervisor. It provides a buffered voltage proportional to the absolute temperature of either an internal or a remote diode (V_{PTAT}) and compares this voltage to thresholds that can be set by external resistor dividers from the on-board reference (V_{REF}).

The LTC2995 also provides four voltage threshold inputs that are continuously compared to an internal 0.5V reference allowing two systems voltages to be monitored for undervoltage and overvoltage conditions.

Diode Temperature Sensor
Temperature measurements are conducted by measuring the voltage of either an internal or an external diode with multiple test currents. The relationship between diode voltage V_D and diode current I_D can be solved for absolute Temperature in degrees Kelvin T:

\[
T = \frac{q \eta k}{\ln \left( \frac{I_D}{I_S} \right)} \left( V_D - V_{D1} \right)
\]

where I_S is a process dependent factor on the order of 10^{-13}A, \eta is the diode ideality factor, k is the Boltzmann constant and q is the electron charge. This equation shows a relationship between temperature and voltage dependent on the process depended variable I_S. Measuring the same diode (with the same value I_S) at two different currents (I_{D1} and I_{D2}) yields an expression independent of I_S:

\[
T = \frac{q \eta k}{\ln \left( \frac{I_D}{I_S} \right)} \left( V_{D2} - V_{D1} \right)
\]

Series Resistance Cancellation
Resistance in series with the remote diode causes a positive temperature error by increasing the measured voltage at each test current. The composite voltage equals:

\[
V_D + V_{ERROR} = \eta \frac{kT}{q} \left( \ln \left( \frac{I_D}{I_S} \right) + R_S \right)
\]

The LTC2995 removes this error term from the sensor signal by subtracting a cancellation voltage V_{CANCEL}. A resistance extraction circuit uses one additional current measurement to determine the series resistance in the measurement path. Once the correct value of the resistor is determined, V_{CANCEL} equals V_{ERROR}. Now the temperature to voltage converter input signal is free from errors due to series resistance.

LTC2995 can cancel series resistances up several hundred ohms (see Typical Performance Characteristics curves). Higher series resistances cause the cancelation voltage to saturate.
**APPLICATIONS INFORMATION**

**Temperature Measurements**

The LTC2995 continuously measures the sensor diode at different test currents and generates a voltage proportional to the absolute temperature of the sensor at the V\textsubscript{PTAT} pin. The voltage at V\textsubscript{PTAT} is updated every 3.5ms.

The gain of V\textsubscript{PTAT} is calibrated to 4mV/K for the measurement of the internal diode as well as for remote diodes with an ideality factor of 1.004.

\[
T_{\text{KELVIN}} = \frac{V_{\text{PTAT}}}{4\text{mV/K}} \quad (\eta = 1.004)
\]

If an external sensor with an ideality factor different from 1.004 is used, the gain of V\textsubscript{PTAT} will be scaled by the ratio of the actual ideality factor (\(\eta_{\text{ACT}}\)) to 1.004. In these cases, the temperature of the external sensor can be calculated from V\textsubscript{PTAT} by:

\[
T_{\text{KELVIN}} = \frac{V_{\text{PTAT}}}{4\text{mV/K}} \cdot \frac{1.004}{\eta_{\text{ACT}}}
\]

Temperature in degrees Celsius can be deduced from degrees Kelvin by:

\[
T_{\text{CELSIUS}} = T_{\text{KELVIN}} - 273.15
\]

The three-state diode select pin (DS) determines whether the temperature of the external or the internal diode is measured and displayed at V\textsubscript{PTAT} as described in Table 1.

<table>
<thead>
<tr>
<th>DIODE LOCATION</th>
<th>DS PIN</th>
</tr>
</thead>
<tbody>
<tr>
<td>Internal</td>
<td>V\textsubscript{CC}</td>
</tr>
<tr>
<td>External</td>
<td>GND</td>
</tr>
<tr>
<td>Both</td>
<td>Open</td>
</tr>
</tbody>
</table>

If the DS pin is left open, the LTC2995 measures both diodes alternately and V\textsubscript{PTAT} changes every 30ms from the voltage corresponding to the temperature of the internal sensor to the voltage corresponding to the temperature of the external sensor. If D\textsuperscript{+} is tied to V\textsubscript{CC}, the LTC2995 measures the internal diode regardless of the state of the DS pin.

**Choosing an External Sensor**

The LTC2995 is factory calibrated for an ideality factor of 1.004, which is typical of the popular MMBT3904 NPN transistor. Semiconductor purity and wafer level processing intrinsically limit device-to-device variation, making these devices interchangeable between manufacturers with a temperature error of typically less than 0.5°C. Some recommended sources are listed in Table 2:

Discrete two terminal diodes are not recommended as remote sensing devices as their ideality factor is typically much higher than 1.004. Also MOS transistors are not suitable as they don’t exhibit the required current to temperature relationship. Furthermore gold doped transistors (low beta), high frequency and high voltage transistors should be avoided as remote sensing devices.

**Connecting an External Sensor**

The change in sensor voltage per °C is hundreds of microvolts, so electrical noise must be kept to a minimum. Bypass D\textsuperscript{+} and D\textsuperscript{−} with a 470pF capacitor close to the LTC2995 to suppress external noise. Recommended shielding and PCB trace considerations for best noise immunity are illustrated in Figure 1.
**APPLICATIONS INFORMATION**

Leakage currents at D+ affect the precision of the remote temperature measurements. 100nA leakage current leads to an additional error of 2°C (see Typical Performance Characteristics).

Note that bypass capacitors greater than 1nF will cause settling time errors in the different measurement currents and therefore introduce an error in the temperature measurement (see Typical Performance Characteristics).

The LTC2995 compensates series resistance in the measurement path and thereby allows accurate remote temperature measurements even with several meters of distance between the sensor and the device. The cable length between the sensor and the LTC2995 is only limited by the mutual capacitance introduced between D+ and D− which degrades measurement accuracy (see Typical Performance Characteristics).

For example an AT6 cable with 50pF/m should be kept shorter than ~20m to keep the capacitance less than 1nF.

To save wiring, the cathode of the remote sensor can also be connected to remote GND and D− to local GND as shown below.

The temperature measurement of the LTC2995 relies only on differences between the diode voltage at multiple test circuits. Therefore DC offsets smaller than 300mV between remote and local GND do not impact the precision of the temperature measurement. The cathode of the sensor can accommodate modest ground shifts across a system which is beneficial in applications where a good thermal connectivity of the sensor to a device whose temperature is to be monitored (shunt resistor, coil, etc.) is required. Care must be taken if the potential difference between the cathode and D− does not only content DC but also AC components. Noise around odd multiples of 6kHz (±20%) is amplified by the measurement algorithm and converted at a DC offset in the temperature measurement (see Typical Performance Characteristics).

The LTC2995 can withstand up to ±4kV of electrostatic discharge (ESD, human body). ESD beyond this voltage can damage or degrade the device including lowering the remote sensor measurement accuracy due to increased leakage currents on D+ or D−.

To protect the sensing inputs against larger ESD strikes, external protection can be added using TVS diodes to ground (Figure 3). Care must be taken to choose diodes with low capacitance and low leakage currents in order not to degrade the external sensor measurement accuracy (see Typical Performance Characteristics curves).

To make the connection of the cable to the IC polarity insensitive during installation, two sensor transistors with opposite polarity at the end of a two wire cable can be used as shown on Figure 4.

Again, care must be taken that the leakage current of the second transistor does not degrade the measurement accuracy.
Output Noise Filtering

The $V_{PTAT}$ output typically exhibits 0.6mV RMS (0.25°C RMS) noise. For applications which require lower noise digital or analog averaging can be applied to the output. Choose the averaging time according to:

$$t_{AVG} = \left( \frac{0.01{\circ}C}{\sqrt{Hz}} \right)^2$$

where $t_{AVG}$ is the averaging time and $T_{NOISE}$ the desired temperature noise in °C RMS. For example, if the desired noise performance is 0.015°C RMS, set the averaging time to one second. See Typical Performance Characteristics.

Temperature Monitoring

The LTC2995 continuously compares the voltage at $V_{PTAT}$ to the voltages at the pins VT1 and VT2 to detect either an overtemperature (OT) or undertemperature (UT) condition. The VT1 comparator output drives the open-drain logic output pin $TO1$ and the VT2 comparator output drives the open-drain logic output pin $TO2$. The polarity of these comparisons is configured via the three-state polarity select pin (PS) (Table 3).

If pin PS is connected to $VCC$, the voltage on VT1 becomes an undertemperature threshold and the voltage on VT2 an overtemperature threshold. In this configuration $TO1$ is pulled low if the voltage $V_{PTAT}$ falls during five consecutive conversions below the undertemperature threshold VT1. Once pulled low, $TO1$ is released high again if $V_{PTAT}$ rises above VT1 plus an additional hysteresis of about 20mV. Accordingly, $TO2$ is pulled low if the voltage $V_{PTAT}$ rises above the overtemperature threshold VT2 and –once pulled low– $TO2$ is released high if $V_{PTAT}$ falls below VT2 minus an additional hysteresis of about 20mV. Leaving PS unconnected configures both VT1 and VT2 as overtemperature thresholds and connecting PS to GND configures them both as undertemperature thresholds. If the internal and external sensors are monitored alternately by leaving DS unconnected, VT1 becomes a dedicated threshold for the internal sensor and VT2 becomes a dedicated threshold for the external sensor.

Temperature Monitor Design Example

The LTC2995 can be configured to give an early warning if the temperature of the internal sensor rises above 60°C and an alarm if the temperature passes 90°C. Tie the DS pin to $VCC$ to select the internal sensor and leave the pin PS unconnected to configure both input voltages VT1 and VT2 as overtemperature thresholds. The voltages at VT1 and VT2 are set to:

$$VT1 = (60K + 273.15K) \cdot \frac{4\text{mV}}{K} = 1.332V$$

$$VT2 = (90K + 273.15K) \cdot \frac{4\text{mV}}{K} = 1.452V$$

When $V_{PTAT}$ reaches the threshold voltage on pin VT1, $TO1$ is pulled low indicating an overtemperature early warning. If the temperature reaches 90°C $TO2$ is also pulled low, indicating an overtemperature alarm.

Once the temperature drops below each threshold, the corresponding $TO$ pins will return high after a time-out-period ($t_{UOTO}$) set by the capacitor connected to TMR.
APPLICATIONS INFORMATION

Temperature Thresholds

The threshold voltages at VT1 and VT2 can be set with the 1.8V reference voltage (VREF) and a resistive divider as shown in Figure 5.

The following design procedure can be used to size the resistive divider.

1. Calculate Threshold Voltages:
   \[
   VT1 = T1 \cdot \frac{4 \text{mV}}{K} \cdot \eta_{ACT} \cdot 1.004
   \]
   \[
   VT2 = T2 \cdot \frac{4 \text{mV}}{K} \cdot \eta_{ACT} \cdot 1.004
   \]
   where \(\eta_{ACT}\) denotes the actual ideality factor if an external sensor is used and T1 and T2 are the desired threshold temperatures in degrees Kelvin.

2. Choose \(R_{TA}\) to obtain the desired VT1 threshold for a desired current through the resistive divider (IREF):
   \[
   R_{TA} = \frac{VT1}{IREF}
   \]

3. Choose \(R_{TB}\) to obtain the desired VT2 threshold:
   \[
   R_{TB} = \frac{VT2 - VT1}{IREF}
   \]
4. Finally \( R_{TC} \) is determined by:

\[
R_{TC} = \frac{1.8V - VT2}{I_{REF}}
\]

In the Temperature Monitor example discussed earlier with thresholds at \( VT1 = 60°C \) and \( VT2 = 90°C \) and a desired reference current of 10\( \mu \)A, the required values for \( R_{TA} \), \( R_{TB} \) and \( R_{TC} \) can be calculated as:

\[
\begin{align*}
R_{TA} &= \frac{1.332V}{10\mu A} = 133.2k \\
R_{TB} &= \frac{1.452V - 1.332V}{10\mu A} = 12k \\
R_{TC} &= \frac{1.8V - 1.452V}{10\mu A} = 34.8k
\end{align*}
\]

Voltage Monitoring

In addition to temperature measurement, the LTC2995 features a low power dual voltage monitoring circuit. Each voltage monitor has two inputs (\( VH1/VL1 \) and \( VH2/VL2 \)) for detecting undervoltage and overvoltage conditions. If either \( VH1 \) or \( VH2 \) falls below 0.5V (typical), the LTC2995 communicates an undervoltage condition by pulling \( UV \) low. Similarly, an overvoltage condition is flagged by pulling \( OV \) low if either \( VL1 \) or \( VL2 \) rises above 0.5V.

When configured to monitor a positive voltage \( V_n \) using the 3-resistor circuit configuration shown in Figure 5, \( VH_n \) will be connected to the high side tap of the resistive divider and \( VL_n \) will be connected to the low side tap of the resistive divider.

Voltage Monitor Design Procedure

The following 3-step design procedure selects appropriate resistances to obtain the desired UV and OV trip points for the voltage monitor circuit in Figure 7.

1. \( R_A \) is chosen to set the desired trip point for the overvoltage monitor:

\[
R_A = \left| \frac{0.5V \cdot V_n}{I_n \cdot V_{OV}} \right| 
\]

2. Once \( R_A \) is known, \( R_B \) is chosen to set the desired trip point for the undervoltage monitor:

\[
R_B = \left| \frac{0.5V \cdot V_n}{I_n \cdot V_{UV}} \right| - R_A
\]

3. Once, \( R_A \) and \( R_B \) are known, \( R_C \) is determined by:

\[
R_C = \left| \frac{V_n}{I_n} \right| - R_A - R_B
\]

Voltage Monitor Example

A typical voltage monitor application is shown in Figure 2. The monitored voltage is a 5V ±10% supply. Nominal current in the resistive divider is 10\( \mu \)A.

1. Find \( R_A \) to set the OV trip point of the monitor:

\[
R_A = \left| \frac{0.5V \cdot 5V}{10\mu A \cdot 5.5V} \right| = 45.3k
\]
## APPLICATIONS INFORMATION

2. Find $R_B$ to set the UV trip point of the monitor:

$$R_B = \frac{0.5V \cdot 0V}{10\mu A} - 453 \Omega = 10k$$

3. Determine $R_C$ to complete the design:

$$R_C = \frac{5V}{10\mu A} - 453\Omega - 100\Omega = 442k$$

### Power-Up and Undervoltage Lockout

As soon as $V_{CC}$ reaches approximately 1V during power-up, the OV as well as T01 and T02 weakly pull to $V_{CC}$ while the UV output asserts low indicating an undervoltage lockout condition. Above $V_{CC} = 2V$ (typical), the VH and VL inputs take control. Once both VH inputs and $V_{CC}$ are valid, an internal timer is started. After an adjustable delay time, UV weakly pulls high.

When $V_{CC}$ falls below 1.9V, the LTC2995 indicates again an undervoltage lockout (UVLO) condition by pulling low UV while OV is cleared.

### Threshold Accuracy

Reset threshold accuracy is important in a supply sensitive system. Ideally, such a system would only reset if supply voltages fell outside the exact threshold for a specified margin. All LTC2995 Vhn/VLn inputs have a relative threshold accuracy of ±1.5% over the full operating temperature range. For example, when the LTC2995 is configured to monitor a 5V input with a 10% tolerance, the desired UV trip point is 4.5V. Because of the ±1.5% relative accuracy of the LTC2995, the UV trip point can be anywhere between 4.433V and 4.567V which is 4.5V ±1.5%.

Likewise, the accuracy of the resistances chosen for $R_A$, $R_B$, and $R_C$ can affect the UV and OV trip points as well. Using the previous example, if the resistances used to set the UV trip point have 1% accuracy, the UV trip range can grow to between 4.354V and 4.650V. This is illustrated in the following calculations.

The UV trip point is given as:

$$V_{UV} = 0.5V \cdot \left(1 + \frac{R_C}{R_A + R_B}\right)$$

The two extreme conditions, with a relative accuracy of 1.5% and resistance accuracy of 1%, result in:

$$V_{UV\text{(MIN)}} = 0.5V \cdot 0.985 \cdot \left(1 + \frac{R_C \cdot 0.99}{(R_A + R_B) \cdot 1.01}\right)$$

and

$$V_{UV\text{(MAX)}} = 0.5V \cdot 1.015 \cdot \left(1 + \frac{R_C \cdot 1.01}{(R_A + R_B) \cdot 0.99}\right)$$

For a desired trip point of 4.5V, $\frac{R_C}{R_A + R_B} = 8$

Therefore,

$$V_{UV\text{(MIN)}} = 0.5V \cdot 0.985 \cdot \left(1 + \frac{8 \cdot 0.99}{1.01}\right) = 4.3545V$$

and

$$V_{UV\text{(MAX)}} = 0.5V \cdot 1.015 \cdot \left(1 + \frac{8 \cdot 1.01}{0.99}\right) = 4.650V$$

### Glitch Immunity

In any supervisory application, noise on the monitored DC voltage can cause spurious resets. To solve this problem without adding hysteresis to the VH/VL comparators, which would add error to the trip voltage, the LTC2995 lowpass filters the output of the comparator. This filter causes the output of the comparator to be integrated before asserting the UV or OV logic. Any transient at the input of the comparator must be of sufficient magnitude and duration before the comparator will trigger the output logic. The Typical Performance Characteristics section shows a graph of the Typical Transient Duration vs Comparator Overdrive.

In temperature monitoring, the voltage at $V_{PTAT}$ must exceed a threshold for five consecutive temperature update intervals before the respective TO pin is pulled low. Once the $V_{PTAT}$ voltage crosses back the threshold with an additional 20mV of hysteresis, the respective TO pin is released after a single update interval and an additional delay adjustable by the capacitor on TMR.
Applications Information

Timing of Alert Outputs

The LTC2995 has an adjustable timeout period ($t_{UOTO}$) that holds UV, OV, TO1 or TO2 asserted after any faults have cleared. This delay will minimize the effect of input noise with a frequency above $1/t_{UOTO}$.

A voltage monitoring example: When any VH drops below its threshold, the UV pin asserts low. When all VH inputs recover above their thresholds, the UV pin weakly pulls high. However, if any input falls below its threshold during this timeout period, the timer resets and restarts when all inputs are again above the thresholds.

A temperature monitoring example: Tying PS to VCC configures TO2 as overtemperature output. In case of an overtemperature condition pin TO2 asserts low. The output timer starts when the temperature crosses back below the threshold minus the temperature hysteresis. If the temperature remains below the threshold, the timer finishes and pin TO2 releases high.

Selecting the Timing Capacitor

The timeout period ($t_{UOTO}$) for the LTC2995 is adjustable in order to accommodate a variety of applications. Connecting a capacitor, $C_{TMR}$, between the TMR pin and ground sets the timeout period. The value of capacitor needed for a particular timeout period is:

$$C_{TMR} = \frac{t_{UOTO} - 0.5 \text{ms}}{8(\text{ms} / \text{nF})}$$

The Reset Timeout Period vs Capacitance graph found in the Typical Performance Characteristics section shows the desired delay time as a function of the value of the timer capacitor that should be used. Leaving the TMR pin open with no external capacitor generates a timeout period of approximately 500μs. For long timeout periods, the only limitation is the availability of a large value capacitor with low leakage. Capacitor leakage current must not exceed the minimum TMR charging current of 1.5μA.

Tying the TMR pin to VCC will bypass the timeout period and no delay will occur.

Digital Output Characteristics

The DC characteristics of the UV, OV, TO1 and TO2 pull-up and pull-down strength are shown in the Typical Performance Characteristics section. Each pin has a weak 400kΩ internal pull-up to VCC and a strong pull-down to ground and can be pulled above VCC.

This arrangement allows these pins to have open-drain behavior while possessing several other beneficial characteristics. The weak pull-up eliminates the need for an external pull-up resistor when the rise time on the pin is not critical. On the other hand, the open drain configuration allows for wired-OR connections and can be useful when more than one signal needs to pull-down on the output.

At $V_{CC} = 1$V, the weak pull-up current is barely turned on. Therefore, an external pull-up resistor of no more than 100k is recommended on the pin if the state and pull-up strength of the pin is crucial at very low $V_{CC}$.

Note however, by adding an external pull-up resistor, the pull-up strength on the pin is increased. Therefore, if it is connected in a wired-OR connection, the pull-down strength of any single device needs to accommodate this additional pull-up strength.

Output Rise and Fall Time Estimation

The UV, OV, TO1 and TO2 outputs have strong pull-down capability. The following formula estimates the output fall time (90% to 10%) for a particular external load capacitance ($C_{LOAD}$):

$$t_{\text{FALL}} \approx 2.2 \cdot R_{PD} \cdot C_{LOAD}$$

where $R_{PD}$ is the on-resistance of the internal pull-down transistor estimated to be typically 40Ω at $V_{DD} > 1$V and at room temperature (25°C), and $C_{LOAD}$ is the external load capacitance on the pin. Assuming a 150pF load capacitance, the fall time is about 13ns. The rise time on the UV, OV, TO1 and TO2 pins is limited by a 400k pull-up resistance to $V_{DD}$. A similar formula estimates the output rise time (10% to 90%):

$$t_{\text{RISE}} \approx 2.2 \cdot R_{PU} \cdot C_{LOAD}$$

where $R_{PU}$ is the pull-up resistance.
LTC2995

**TYPICAL APPLICATIONS**

±10% Voltage Monitor (1.8V and 2.5V) and Internal/Remote Overtemperature Monitor

*POWER SUPPLIES*

±20% Voltage Monitor (12V and 5V) and 0°C to 70°C Internal UT/OT Monitoring with Common Temperature and Powergood LED

*TEMPERATURE AND POWER GOOD LED*
TYPICAL APPLICATIONS

Celsius Thermometer and ±10% Voltage Monitor (1.8V and 2.5V)

±10% Voltage Monitor (12V and 5V) and –20°C to 70°C Internal UT/OT Monitor with Manual Undervoltage Reset Button
PACKAGE DESCRIPTION

Please refer to http://www.linear.com/designtools/packaging/ for the most recent package drawings.

UD Package
20-Lead Plastic QFN (3mm × 3mm)
(Reference LTC DWG # 05-08-1720 Rev A)

NOTE:
1. DRAWING IS NOT A JEDEC PACKAGE OUTLINE
2. DRAWING NOT TO SCALE
3. ALL DIMENSIONS ARE IN MILLIMETERS
4. DIMENSIONS OF EXPOSED PAD ON BOTTOM OF PACKAGE DO NOT INCLUDE MOLD FLASH. MOLD FLASH, IF PRESENT, SHALL NOT EXCEED 0.15mm ON ANY SIDE
5. EXPOSED PAD SHALL BE SOLDER PLATED
6. SHADED AREA IS ONLY A REFERENCE FOR PIN 1 LOCATION ON THE TOP AND BOTTOM OF PACKAGE

Information furnished by Linear Technology Corporation is believed to be accurate and reliable. However, no responsibility is assumed for its use. Linear Technology Corporation makes no representation that the interconnection of its circuits as described herein will not infringe on existing patent rights.
TYPICAL APPLICATION

Dual OV/UV ±10% Supply and 75°C/125°C OT/OT Remote Temperature Monitor
