The LT® 3062 is a micropower, low dropout (LDO) linear regulator that operates over a 1.6V to 45V supply range and is available in a series of fixed output and adjustable versions. The device supplies 200mA of output current with a typical dropout voltage of 300mV. A single external capacitor provides programmable low noise reference performance and output soft-start functionality. The LT3062’s quiescent current is merely 45μA and provides fast transient response with a minimum 3.3μF output capacitor. In shutdown, quiescent current is less than 1μA and the reference soft start capacitor is reset.

The LT3062 optimizes stability and transient response with low ESR, ceramic output capacitors. The LT3062 does not require the addition of ESR as is common with other regulators.

Internal protection circuitry includes reverse-battery protection, reverse-output protection, reverse-current protection, current limit foldback and thermal limit protection.

The LT3062 is available in fixed output voltages of 3.3V and 5V, and as an adjustable device with an output voltage range from the 600mV reference up to 40V. The LT3062 is offered in the thermally enhanced 8-lead 2mm × 3mm DFN and MSOP packages.

</tbody>
</table>

**Note 1:** Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

**Note 2:** Absolute maximum input to output differential voltage is not achievable with all combinations of rated IN pin and OUT pin voltages. With the IN pin at 50V, the OUT pin may not be pulled below 0V. The total measured voltage from IN to OUT must not exceed ±50V. If OUT is above ground, do not pull IN more than 40V below OUT.

**Note 3:** The LT3062 is tested and specified under pulse load conditions such that $T_J = T_A$. The LT3062E regulators are 100% tested at $T_A = 25^\circ C$ and performance is guaranteed from 0°C to 125°C. Performance at –40°C to 125°C is assured by design, characterization and correlation with statistical process controls. The LT3062I regulators are guaranteed over the full –40°C to 125°C operating junction temperature range. The LT3062MP regulators are 100% tested over the –55°C to 150°C operating junction temperature range. The LT3062H regulators are 100% tested at the 150°C operating junction temperature. High junction temperatures degrade operating lifetimes. Operating lifetime is derated at junction temperature greater than 125°C.

**Note 4:** The ADJ pin bias current flows out of the ADJ pin.

**Note 5:** Maximum junction temperature limits operating conditions. The regulated output voltage specification does not apply for all possible combinations of input voltage and output current. Limit the output current range if operating at the maximum input voltage. Limit the input-to-output voltage differential if operating at maximum output current. Current limit foldback limits the maximum output current as a function of input-to-output voltage. See Current Limit $V_{IN} – V_{OUT}$ in the Typical Performance Characteristics section.

**Note 6:** To satisfy minimum input voltage requirements, the LT3062 adjustable version is tested and specified for these conditions with an external resistor divider (bottom 60k, top 230k) for an output voltage of 2.9V. The external resistor divider adds 10µA of DC load on the output. The external current is not factored into GND pin current.

**Note 7:** Dropout voltage is the minimum input-to-output voltage differential needed to maintain regulation at a specified output current. In dropout, the output voltage equals: $(V_{IN} – V_{DROPOUT})$.

**Note 8:** GND pin current is tested with $V_{IN} = V_{OUT(NOMINAL)} + 0.6V$ and a current source load. GND pin current will increase in dropout. See GND pin current curves in the Typical Performance Characteristics section. For fixed voltage options, an internal resistor divider will add 5µA to the GND pin current. See the GND Pin Current curves in the Typical Performance Characteristics section.

**Note 9:** ADJ pin bias current flows out of the ADJ pin.

**Note 10:** SHDN pin current flows into the SHDN pin.

**Note 11:** To satisfy requirements for minimum input voltage, current limit is tested at $V_{IN} = V_{OUT(NOMINAL)} + 1V$ or $V_{IN} = 2.1V$, whichever is greater.

**Note 12:** This IC includes thermal limit which protects the device during momentary overload conditions. Junction temperature exceeds 125°C (E-Grade and I-Grade) or 150°C (MP-Grade and H-Grade) when thermal limit is active. Continuous operation above the specified maximum junction temperature may impair device reliability.

**Note 13:** Reverse output current is tested with the IN pin grounded and the OUT pin forced to the specified voltage. This current flows into the OUT pin and out of the GND pin.

PIN FUNCTIONS

REF/BYP (Pin 1): Reference/ Bypass. Connecting a single capacitor from this pin to GND bypasses the LT3062’s reference noise and soft-starts the reference. A 10nF bypass capacitor typically reduces output voltage noise to 30μV RMS in a 10Hz to 100kHz bandwidth. Soft-start time is directly proportional to the REF/BYP capacitor value. If the LT3062 is placed in shutdown, REF/BYP is actively pulled low by an internal device to reset soft-start. If low noise or soft-start performance is not required, this pin must be left floating (unconnected). Do not drive this pin with any active circuitry.

ADJ (Pin 2): Adjust. This pin is the error amplifier’s inverting terminal. Its typical bias current of 15nA flows out of the pin (see curve of ADJ Pin Bias Current vs Temperature in the Typical performance Characteristics section). The ADJ pin voltage is 600mV referenced to GND.

OUT (Pins 3, 4): Output. These pins supply power to the load. A minimum output capacitor of 3.3μF is required to prevent oscillations. Large load transient applications require larger output capacitors to limit peak voltage transients. See the Applications Information section for more information on transient response and reverse output characteristics. The output voltage range is 600mV to 40V.

IN (Pins 5, 6): Input. These pins supply power to the device. The LT3062 requires a bypass capacitor at IN if the device is located more than six inches from the main input filter capacitor. In general, the output impedance of a battery rises with frequency, so it is advisable to include a bypass capacitor in battery-powered circuits. A bypass capacitor in the range of 1μF to 10μF suffices. See Input Capacitance and Stability in the Application Information section for more information.

The LT3062 withstands reverse voltages on the IN pin with respect to the GND and OUT pins. In a reversed input situation, such as the battery plugged in backwards, the LT3062 behaves as if a large value resistor is in series with its input. Limited reverse current flows into the LT3062 and no reverse voltage appears at the load. The device protects itself and the load.

SHDN (Pin 7): Shutdown. Pulling the SHDN pin low puts the LT3062 into a low power state and turns the output off. Drive the SHDN pin with either logic or an open collector/drain with a pull-up resistor. The resistor supplies the pull-up current to the open collector/drain logic, normally several microamperes, and the SHDN pin current, typically less than 3μA. If unused, connect the SHDN pin to V IN. The LT3062 does not function if the SHDN pin is not connected. The SHDN pin cannot be driven below GND unless tied to the IN pin. If the SHDN pin is driven below GND while IN is powered, the output will turn on. SHDN pin logic cannot be referenced to a negative rail.

GND (Pin 8, Exposed Pad Pin 9): Ground. Connect the bottom of the external resistor divider that sets the output voltage directly to GND for optimum regulation. Tie the exposed pad Pin 9 directly to Pin 8 and the PCB ground. This exposed pad provides enhanced thermal performance with its connection to the PCB ground. See the Applications Information section for thermal considerations and calculating junction temperature.

For more information www.linear.com/LT3062
The LT3062 is a 200mA low dropout regulator with shutdown that is available in fixed output and adjustable versions. The device is capable of supplying 200mA at a typical dropout voltage of 300mV and operates over a 1.6V to 45V input range.

A single external capacitor provides programmable low noise reference performance and output soft-start functionality. For example, connecting a 10nF capacitor from the REF/BYP pin to GND lowers output noise to 30µV RMS over a 10Hz to 100kHz bandwidth. This capacitor also soft-starts the reference and prevents output voltage overshoot at turn-on.

The LT3062’s quiescent current is merely 45µA, while providing fast transient response with a 3.3µF minimum low ESR ceramic output capacitor. In shutdown, quiescent current is less than 1µA and the reference soft-start capacitor and output are reset.

The LT3062 optimizes stability and transient response with low ESR, ceramic output capacitors. The LT3062 does not require the addition of ESR as is common with other regulators. The LT3062 has an adjustable output and typically provides 0.1% line regulation and 0.1% load regulation. A curve of load regulation appears in the Typical Performance Characteristics section.

Internal protection circuitry includes reverse-battery protection, reverse-current protection, current limit with foldback and thermal shutdown.

Adjustable Operation

The adjustable LT3062 has an output voltage range of 0.6V to 40V. Output voltage is set by the ratio of two external resistors, as shown in Figure 1. The device regulates the output to maintain the ADJ pin voltage at 0.6V referenced to ground. The current in R1 equals 0.6V/R1, and R2’s current is R1’s current minus the ADJ pin bias current.

The ADJ pin bias current, 15nA at 25°C, flows from the ADJ pin through R1 to GND. Calculate the output voltage using the formula in Figure 1. R1’s value should not be greater than 124k to provide a minimum ~5µA load current so that output voltage errors, caused by the ADJ pin bias current, are minimized. Note that in shutdown, the output is turned off and the divider current is zero. Curves of ADJ Pin Voltage vs Temperature and ADJ Pin Bias Current vs Temperature appear in the Typical Performance Characteristics section.

The LT3062 is tested and specified with the ADJ pin tied to the OUT pin for an output voltage of 0.6V. Specifications for output voltages greater than 0.6V are proportional to the ratio of the desired output voltage to 0.6V: \( \frac{V_{\text{OUT}}}{0.6V} \). For example, load regulation for an output current change of 1mA to 200mA is –0.3mV typical at \( V_{\text{OUT}} = 0.6V \). At \( V_{\text{OUT}} = 12V \), load regulation is:

\[
\frac{12V}{0.6V} \cdot (-0.3mV) = -6mV
\]

Table 1 shows 1% resistor divider values for some common output voltages with a resistor divider current of 5µA.

Bypass Capacitance, Output Voltage Noise and Transient Response

The LT3062 regulator provides low output voltage noise over the 10Hz to 100kHz bandwidth while operating at full load with the addition of a bypass capacitor (CREF/BYP) from the REF/BYP pin to GND. A good quality low-leakage capacitor is recommended. This capacitor bypasses the reference of the regulator, providing a low frequency noise pole for the internal reference. With the use of 10nF for CREF/BYP, the output voltage noise decreases to as low as 30µVRMS when the output voltage is set for 0.6V. For higher output voltages (generated by using a resistor divider), the output voltage noise gains up accordingly when using CREF/BYP by itself.

To lower the output voltage noise for higher output voltages, include a feedforward capacitor (CFF) from VOUT to the ADJ pin. A good quality, low leakage capacitor is recommended. This capacitor bypasses the error amplifier of the regulator, providing a low frequency noise pole. With the use of 10nF for both CFF and CREF/BYP, output voltage noise decreases to 30µVRMS when the output voltage is set to 5V by a 5µA feedback resistor divider. If the current in the feedback resistor divider is doubled, CFF must also be doubled to achieve equivalent noise performance.

Higher values of output voltage noise may be measured if care is not exercised with regard to circuit layout and testing. Crosstalk from nearby traces can induce unwanted noise onto the LT3062's output. Power supply ripple rejection must also be considered. The LT3062 regulator does not have unlimited power supply rejection and will pass a small portion of the input noise through to the output.

Using a feedforward capacitor (CFF) from VOUT to the ADJ pin has the added benefit of improving transient response for output voltages greater than 0.6V. With no feedforward capacitor, the settling time will increase as the output voltage is raised above 0.6V. Use the equation in Figure 2 to determine the minimum value of CFF to achieve a transient response that is similar to 0.6V output voltage performance regardless of the chosen output voltage (see Figure 3 and Transient Response in the Typical Performance Characteristics section).

Feedforward capacitance can also be used in fixed-voltage parts; the feedforward capacitor is connected from OUT to ADJ in the same manner. In this case, the current in the internal feedback resistor divider is 5µA.
APPLICATIONS INFORMATION

During start-up, the internal reference soft-starts if a reference bypass capacitor is present. Regulator startup time is directly proportional to the size of the bypass capacitor, slowing to 6ms with a 10nF bypass capacitor (See SHDN Transient Response vs REF/BYP Capacitor in the Typical Performance Characteristics section). The reference bypass capacitor is actively pulled low during shutdown to reset the internal reference.

Start-up time is also affected by the use of a feedforward capacitor. Start-up time is directly proportional to the size of the feedforward capacitor and output voltage, and is inversely proportional to the feedback resistor divider current, slowing to 15ms with a 4.7nF feedforward capacitor and a 10µF output capacitor for an output voltage set to 5V by a 5µA feedback resistor divider.

Output Capacitance

The LT3062 regulator is stable with a wide range of output capacitors. The ESR of the output capacitor affects stability, most notably with small capacitors. Use a minimum output capacitor of 3.3µF with an ESR of 3Ω or less to prevent oscillations. If a feedforward capacitor is used with output voltages set for greater than 24V, use a minimum output capacitor of 10µF. The LT3062 is a micropower device and output load transient response is a function of output capacitance. Larger values of output capacitance decrease the peak deviations and provide improved transient response for larger load current changes. Bypass capacitors, used to decouple individual components powered by the LT3062, will increase the effective output capacitor value. For applications with large load current transients, a low ESR ceramic capacitor in parallel with a bulk tantalum capacitor often provides an optimally damped response.

Give extra consideration to the use of ceramic capacitors. Manufacturers make ceramic capacitors with a variety of dielectrics, each with different behavior across temperature and applied voltage. The most common dielectrics are specified with EIA temperature characteristic codes of Z5U, Y5V, X5R and X7R. The Z5U and Y5V dielectrics provide high C-V products in a small package at low cost, but exhibit strong voltage and temperature coefficients as shown in Figures 4 and 5. When used with a 5V regulator, a 16V 10µF Y5V capacitor can exhibit an effective value as low as 1µF to 2µF for the DC bias voltage applied and over the operating temperature range. The X5R and X7R dielectrics yield much more stable characteristics and are more suitable for use as the output capacitor. The X7R type works over a wider temperature range and has better temperature stability, while the X5R is less expensive and is available in higher values. Care still must be exercised when using X5R and X7R capacitors; the X5R and X7R codes only specify operating temperature range and maximum capacitance change over temperature. Capacitance change due to DC bias with X5R and X7R capacitors is better than Y5V and Z5U capacitors, but can still be significant enough to drop capacitor values below appropriate levels. Capacitor DC bias characteristics tend to improve as component case size increases, but expected capacitance at operating voltage should be verified.

Voltage and temperature coefficients are not the only sources of problems. Some ceramic capacitors have a piezoelectric response. A piezoelectric device generates voltage across its terminals due to mechanical stress, similar to the way a piezoelectric accelerometer or microphone works. For a ceramic capacitor, the stress can be induced by vibrations in the system or thermal transients.
The resulting voltages produced can cause appreciable amounts of noise. A ceramic capacitor produced the trace in Figure 6 in response to light tapping from a pencil. Similar vibration induced behavior can masquerade as increased output voltage noise.

**Figure 4. Ceramic Capacitor DC Bias Characteristics**

**Figure 5. Ceramic Capacitor Temperature Characteristics**

**Figure 6. Noise Resulting from Tapping on a Ceramic Capacitor**

### Input Capacitance and Stability

Low ESR, ceramic input bypass capacitors are acceptable for applications without long input leads. However, applications connecting a power supply to an LT3062 circuit’s IN and GND pins with long input wires combined with a low ESR, ceramic input capacitor are prone to voltage spikes, reliability concerns and application-specific board oscillations.

The input wire inductance found in many battery-powered applications, combined with the low ESR ceramic input capacitor, forms a high Q LC resonant tank circuit. In some instances this resonant frequency beats against the output current dependent LDO bandwidth and interferes with proper operation. Simple circuit modifications/solutions are then required. This behavior is not indicative of LT3062 instability, but is a common ceramic input bypass capacitor application issue.

The self-inductance, or isolated inductance, of a wire is directly proportional to its length. Wire diameter is not a major factor on its self-inductance. For example, the self-inductance of a 2-AWG isolated wire (diameter = 0.26") is about half the self-inductance of a 30-AWG wire (diameter = 0.01"). One foot of 30-AWG wire has approximately 465nH of self-inductance.
APPLICATIONS INFORMATION

Two methods can reduce wire self-inductance. One method divides the current flowing towards the LT3062 between two parallel conductors. In this case, the farther apart the wires are from each other, the more the self-inductance is reduced; up to a 50% reduction when placed a few inches apart. Splitting the wires connects two equal inductors in parallel, but placing them in close proximity creates mutual inductance adding to the self-inductance. The second and most effective way to reduce overall inductance is to place both forward and return current conductors (the input and GND wires) in very close proximity. Two 30-AWG wires separated by only 0.02", used as forward and return current conductors, reduce the overall self-inductance to approximately one-fifth that of a single isolated wire.

If a battery, mounted in close proximity, powers the LT3062, a 1µF input capacitor suffices for stability. However, if a distant supply powers the LT3062, use a larger value input capacitor. Use a rough guideline of 1µF (in addition to the 1µF minimum) per 8 inches of wire length. The minimum input capacitance needed to stabilize the application also varies with power supply output impedance variations. Placing additional capacitance on the LT3062’s output also helps. However, this requires an order of magnitude more capacitance in comparison with additional LT3062 input bypassing. Series resistance between the supply and the LT3062 input also helps stabilize the application; as little as 0.1Ω to 0.5Ω suffices. This impedance dampens the LC tank circuit at the expense of dropout voltage. A better alternative is to use higher ESR tantalum or electrolytic capacitors at the LT3062 input in place of ceramic capacitors.

Overload Recovery

Like many IC power regulators, the LT3062 has safe operating area protection. The safe area protection decreases current limit as input-to-output voltage increases and keeps the power transistor inside a safe operating region for all values of input-to-output voltage. The protective design provides some output current at all values of input-to-output voltage up to the device breakdown.

When power is first applied, as input voltage rises, the output follows the input, allowing the regulator to start up into very heavy loads. During start-up, as the input voltage is rising, the input-to-output voltage differential is small, allowing the regulator to supply large output currents. With a high input voltage, a problem can occur wherein removal of an output short will not allow the output to recover.

The problem occurs with a heavy output load when the input voltage is high and the output voltage is low. Common situations include immediately after the removal of a short-circuit or if the shutdown pin is pulled high after the input voltage has already been turned on. The load line for such a load may intersect the output current curve at two points. If this happens, there are two stable output operating points for the regulator. With this double intersection, the input power supply may need to be cycled down to zero and brought up again to make the output recover.
Thermal Considerations

The power handling capability of the device will be limited by the maximum rated junction temperature (125°C for LT3062E, LT3062I or 150°C for LT3062MP, LT3062H). Two components comprise the power dissipated by the device:

1. Output current multiplied by the input/output voltage differential: \( I_{\text{OUT}} \times (V_{\text{IN}} - V_{\text{OUT}}) \), and
2. GND pin current multiplied by the input voltage: \( I_{\text{GND}} \times V_{\text{IN}} \)

GND pin current is determined using the GND Pin Current curves in the Typical Performance Characteristics section. Power dissipation will be equal to the sum of the two components listed above.

The LT3062 regulator has internal thermal limiting that protects the device during overload conditions. For continuous normal conditions, the maximum junction temperature of 125°C (E-grade, I-grade) or 150°C (MP-grade, H-grade) must not be exceeded. Carefully consider all sources of thermal resistance from junction to ambient including other heat sources mounted in proximity to the LT3062.

The undersides of the LT3062 packages have exposed metal from the lead frame to the die attachment. The package allows heat to directly transfer from the die junction to the printed circuit board metal to control maximum operating junction temperature. The dual-in-line pin arrangement allows metal to extend beyond the ends of the package on the topside (component side) of a PCB. Connect this metal to GND on the PCB. The multiple IN and OUT pins of the LT3062 also assist in spreading heat to the PCB.

For surface mount devices, heat sinking is accomplished by using the heat spreading capabilities of the PC board and its copper traces. Copper board stiffeners and plated through-holes can also be used to spread the heat generated by power devices.

The following tables list thermal resistance for several different board sizes and copper areas. All measurements were taken in still air on a 4 layer FR-4 board with 1oz solid internal planes and 2oz top/bottom external trace planes with a total board thickness of 1.6mm. The four layers were electrically isolated with no thermal vias present. PCB layers, copper weight, board layout and thermal vias will affect the resultant thermal resistance. For more information on thermal resistance and high thermal conductivity test boards, refer to JEDEC standard JESD51, notably JESD51-12 and JESD51-7. Achieving low thermal resistance necessitates attention to detail and careful PCB layout.

Calculating Junction Temperature

Example: Given an output voltage of 2.5V, an input voltage range of 12V ±5%, an output current range of 0mA to 50mA and a maximum ambient temperature of 85°C, what will the maximum junction temperature be?

The power dissipated by the device equals:

\[ P = I_{\text{OUT(MAX)}} \cdot (V_{\text{IN(MAX)}} - V_{\text{OUT}}) + I_{\text{GND}} \cdot V_{\text{IN(MAX)}} \]

where,

\[ I_{\text{OUT(MAX)}} = 50mA \]
\[ V_{\text{IN(MAX)}} = 12.6V \]
\[ I_{\text{GND}} \text{ at } (I_{\text{OUT}} = 50mA, V_{\text{IN}} = 12V) = 1mA \]

So,

\[ P = 50mA \cdot (12.6V - 2.5V) + 1mA \cdot 12.6V = 0.518W \]

Using a DFN package, the thermal resistance will be in the range of 38°C/W to 45°C/W depending on the copper area. So the junction temperature rise above ambient will be approximately equal to:

\[ 0.518W \cdot 45°C/W = 23.3°C \]

The maximum junction temperature equals the maximum ambient temperature plus the maximum junction temperature rise above ambient or:

\[ T_{\text{J MAX}} = 85°C + 23.3°C = 108.3°C \]

Protection Features

The LT3062 incorporates several protection features that make it ideal for use in battery-powered circuits. In addition to the normal protection features associated with monolithic regulators, such as current limiting and thermal limiting, the device also protects against reverse-input voltages, reverse-output voltages and reverse output-to-input voltages.

Current limit protection and thermal overload protection protect the device against current overload conditions at the output of the device. The typical thermal limit temperature is 165°C. For normal operation, do not exceed a junction temperature of 125°C (LT3062E, LT3062I) or 150°C (LT3062MP, LT3062H).

The LT3062 IN pin withstands reverse voltages of 50V. The device limits current flow to less than 1mA (typically less than 250µA) and no negative voltage appears at OUT. The device protects both itself and the load against batteries that are plugged in backwards.

The SHDN pin cannot be driven below GND unless tied to the IN pin. If the SHDN pin is driven below GND while IN is powered, the output will turn on. SHDN pin logic cannot be referenced to a negative rail.

The LT3062 incurs no damage if its output is pulled below ground. If the input is left open-circuit or grounded, the output can be pulled below ground by 50V. No current flows through the pass transistor from the output. However, current flows in (but is limited by) the resistor divider that sets the output voltage. Current flows from the bottom resistor in the divider and from the ADJ pin's internal clamp through the top resistor in the divider to the external circuitry pulling OUT below ground. If the input is powered by a voltage source, the output sources current equal to its current limit capability and the LT3062 protects itself by thermal limiting. In this case, grounding the SHDN pin turns off the device and stops the output from sourcing current.
The LT3062 incurs no damage if the ADJ pin is pulled above or below ground by 50V. If the input is left open circuit or grounded, the ADJ pin performs like a large resistor (typically 30k) in series with a diode when pulled above or below ground.

In circuits where a backup battery is required, several different input/output conditions can occur. The output voltage may be held up temporarily or otherwise while the input is pulled to ground, pulled to some intermediate voltage or left open-circuit. Current flow back into the OUT and ADJ pins follows the curve shown in Figure 7. If the LT3062’s IN pin is forced below the OUT pin or the OUT pin is pulled above the IN pin, regardless of the state of the SHDN pin, input current typically drops to less than 1µA.

<td>LT3061</td>
<td>45V VIN, Micropower, Low Noise, 100mA Low Dropout Linear Regulator with Active Output Discharge</td>
<td>Active Output Discharge, Input Voltage Range: 1.6V to 45V, Quiescent Current: 45µA, Dropout Voltage: 250mV, Low Noise: 30µVRMS (10Hz to 100kHz), Adjustable Output: 600mV to 19V, 8-Lead MSOP and 2mm x 3mm DFN.</td>
</tr>
<tr>
<td>LT3063</td>
<td>45V VIN, Micropower, Low Noise, 200mA Low Dropout Linear Regulator with Active Output Discharge</td>
<td>Active Output Discharge, Input Voltage Range: 1.6V to 45V, Quiescent Current: 45µA, Dropout Voltage: 300mV, Low Noise: 30µVRMS (10Hz to 100kHz), Adjustable Output: 600mV to 19V, 8-Lead MSOP and 2mm x 3mm DFN.</td>
</tr>
<tr>
<td>LT3082</td>
<td>200mA, Parallelable, Single Resistor Low Dropout Linear Regulator</td>
<td>Outputs May Be Paralleled for Higher Output, Current or Heat Spreading, Wide Input Voltage Range: 1.2V to 40V Low Value Input/Output Capacitors Required: 0.22µF, Single Resistor Sets Output Voltage Initial Set Pin Current Accuracy: 1%, Low Output Noise: 40µVRMS (10Hz to 100kHz) Reverse-Battery Protection, Reverse-Current Protection; 8-Lead SOT-23, 3-Lead SOT-223 and 8-Lead 3mm x 3mm DFN Packages.</td>
</tr>
<tr>
<td>LT3085</td>
<td>500mA, Parallelable, Low Noise, Low Dropout Linear Regulator</td>
<td>275mV Dropout Voltage (2-Supply Operation), Low Noise: 40µVRMS, VIN: 1.2V to 36V, VOUT: 0V to 35.7V, Current-Based Reference with 1-Resistor VOUT Set, Directly Parallelable (No Op Amp Required), Stabe with Ceramic Capacitors; MS8 and 2mm x 3mm DFN-6 Packages</td>
</tr>
