The LTC®3256 is a wide input range switched capacitor step-down DC/DC converter that produces two regulated outputs: a 5V output via direct connection to the charge pump output, and a 3.3V output via a low dropout (LDO) linear post-regulator. The device provides up to 350mA of total output current. At 12V $V_{IN}$ and maximum load on both outputs, power dissipation is reduced by over 2W compared to a dual LDO regulator solution.

The LTC3256 maximizes efficiency by running the charge pump in 2:1 mode over as wide an operating range as possible, and automatically switches to 1:1 mode due to $V_{IN}$ and load conditions. Controlled input current and switching slew rates minimize conducted and radiated EMI. An integrated watchdog timer, independent power good outputs and reset input ensure reliable system operation and fault monitoring. A buffered 1.1V reference output enables system self-testing for safety critical applications.

The LTC3256 has numerous safety features including overcurrent fault protection, overtemperature protection and tolerance of 38V input transients. The LTC3256 is available in a thermally enhanced 16-lead MSOP plastic package with exposed pad (MSE16).

</table>

**Note 1:** Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

**Note 2:** All voltages are referenced to GND unless otherwise specified.

**Note 3:** The LTC3256E is guaranteed to meet performance specifications from 0°C to 85°C operating junction temperature. Specifications over the –40°C to 125°C operating junction temperature range are assured by design, characterization and correlation with statistical process controls. The LTC3256H is guaranteed over the –40°C to 125°C operating junction temperature range. The LTC3256MP is guaranteed and tested over the –55°C to 150°C operating junction temperature range. High junction temperatures degrade operating lifetimes; operating lifetime is derated for junction temperatures greater than 125°C. Note that the maximum ambient temperature consistent with these specifications is determined by specific operating conditions in conjunction with board layout, the rated package thermal resistance and other environmental factors.

The junction temperature \( (T_J, \text{in °C}) \) is calculated from the ambient temperature \( (T_A, \text{in °C}) \) and power dissipation \( (P_D, \text{in Watts}) \) according to the formula:

\[
T_J = T_A + (P_D \cdot \theta_{JA})
\]

where \( \theta_{JA} (\text{in °C/W}) \) is the package thermal impedance.

**Note 4:** This IC has overtemperature protection that is intended to protect the device during momentary overload conditions. Junction temperatures will exceed 150°C when overtemperature protection is active. Continuous operation above the specified maximum operating junction temperature may impair device reliability.

**Note 5:** The maximum operating junction temperature of 150°C must be followed. Certain combinations of input voltage and output current will cause the junction temperature to exceed 150°C and must be avoided. See Thermal Management section for information on calculating maximum operating conditions. Due to thermal limitations of production equipment, only no load regulation is checked at 38V.
TYPICAL PERFORMANCE CHARACTERISTICS  \( T_A = 25\,^\circ\text{C} \), unless otherwise noted.

**PIN FUNCTIONS**

**C– (Pin 1):** Charge Pump Flying Capacitor Negative Connection.

**C+ (Pin 2):** Charge Pump Flying Capacitor Positive Connection.

**OUTCP (Pin 3):** Charge Pump Output. The charge pump output should be bypassed with a 10µF or greater X7R ceramic capacitor. The charge pump output is enabled if either ENx pin is logic high. OUTCP is the input supply for the 3.3V LDO.

**OUT5 (Pin 4):** 5V Output Pin. Connects to the charge pump output, OUTCP, through an internal power switch controlled by the EN5 input when VIN > 10V (typical), and regulates to 5V with VIN as a power source when VIN < 10V (typical).

**REFOUT (Pin 5):** 1.1V Reference Output. Provides a buffered version of the LTC3256’s internal bandgap reference voltage with 2k output impedance (typical). To maximize supply rejection, REFOUT should be bypassed with a 0.1µF ceramic capacitor.

**OUT3 (Pin 6):** 3.3V Low-Dropout Linear Regulator (LDO) Output Pin. The charge pump output, OUTCP, serves as the 3.3V LDO’s input supply.

**PG3 (Pin 7):** Power Good Open Drain Logic Output. Goes high impedance when OUT3 is near its final operating voltage. PG3 is intended to be pulled up to a low voltage supply (such as OUT3, OUT5 or OUTCP) with an external resistor.

**PG5 (Pin 8):** Power Good Open Drain Logic Output. Goes high impedance when OUT5 is near its final operating voltage. PG5 is intended to be pulled up to a low voltage supply (such as OUT3, OUT5 or OUTCP) with an external resistor.

**RST (Pin 9):** Reset Open Drain Logic Output. The RST pin is low impedance to GND during the reset period, and goes high impedance during the watchdog period. RST is intended to be pulled up to low voltage supply (such as OUT3, OUT5, or OUTCP) with an external resistor.

**WT (Pin 10):** Watchdog Timer Control Pin. Attach an external capacitor (CWT) to GND to set the watchdog upper boundary timeout. Tie WT to OUTCP to generate a timeout of about 1.6s. Tie WT and WDI to GND to disable the watchdog timer.

**RT (Pin 11):** Reset Timeout Control Pin. Attach an external capacitor (CRT) to GND to set the reset timeout period, RT can be left open to minimize the reset timeout. Tie RT to OUTCP to generate a reset timeout of about 200ms.

**RSTI (Pin 12):** Reset Logic Comparator Input Pin. The RSTI input is compared to a 1.2V (typical) threshold voltage. If RSTI is below the threshold voltage the LTC3256 will enter the reset state and drive the RST pin low. Once RSTI rises above the threshold voltage, the reset timer is started and the RST pin is held low until the reset period times out.

**WDI (Pin 13):** Watchdog Logic Input Pin. Application circuitry must toggle the logic state of this pin such that falling edges occur at a rate faster than the watchdog upper boundary time but slower than the watchdog lower boundary time. If these conditions are not met, RST will be asserted low. Tie WT and WDI to GND to disable the watchdog timer. Do not float this pin.

**VIN (Pin 14):** Power Input Pin. Input voltage for both charge pump and IC control circuitry.

**EN3 (Pin 15):** Logic input pin which enables the 3.3V LDO when high and disables it when low. Bringing EN3 high causes the charge pump to enable if it isn’t already on. The LDO powers up once the charge pump output, OUTCP, rises above 97.5% of its regulation value (typical). The EN3 pin has a 1µA (typical) pull down current to ground and can tolerate 38V inputs.

**EN5 (Pin 16):** Logic Input Pin. Enables or disables the 5V output, OUT5. Bringing EN5 high causes the charge pump to enable if it isn’t already on. When the charge pump output rises above 97.5% of its regulation value (typical), a fault protected internal power switch connects OUTCP to OUT5, delivering power to any OUT5 load. A soft-start circuit limits any inrush current through the switch to help avoid glitching the charge pump output. If the input voltage falls below 10V (typical) and the charge pump regulates to a voltage lower than 5V, OUT5 receives its power directly from a VIN-powered 1:1 mode regulator. The EN5 pin has a 1µA (typical) pull down current to ground and can tolerate 38V inputs.

**GND (Exposed Pad):** Ground. The exposed package pad is ground and must be soldered to the PC board ground plane for proper functionality and for rated thermal performance.
TIMING DIAGRAM

Reset Timing

Watchdog Timing

For more information www.linear.com/LTC3256
The LTC3256 is an inductorless wide input range step-down DC/DC converter that produces 5V and 3.3V regulated outputs with a total output current of 350mA. It uses a step-down charge pump with automatic 2:1/1:1 mode switching as a pre-regulator for the 5V and 3.3V outputs. This optimizes system efficiency and minimizes thermal problems due to excess power dissipation. In typical 12V automotive systems, the LTC3256 reduces power dissipation by a full 2W at maximum load relative to a dual LDO solution.

Each regulated output may be independently enabled to provide maximum flexibility. Enabling either of the regulator outputs will first turn on the step-down charge pump. Once the charge pump nears its regulation point, the enabled outputs will turn on in a controlled, soft-started manner.

The charge pump typically produces a regulated 5.05V output but allows this output to drop as needed in order to stay in 2:1 mode and maximize overall efficiency whenever $V_{IN}$ falls below ~10.1V. If $V_{IN}$ falls near the low end of its operating range, the charge pump automatically enters 1:1 mode as required to keep the 3.3V LDO in regulation. Whenever the charge pump output drops below 5V, the regulated 5V output will automatically be supplied using a simple gated switch regulator powered from $V_{IN}$.

### 2:1 Step-Down Charge Pump Operation ($V_{IN} > \sim 10.1V$)

The increased efficiency and reduced power dissipation advantages of the LTC3256 arise from the use of a 2:1 step-down charge pump to perform the bulk of the voltage step-down from $V_{IN}$ to 5V and 3.3V. An ideal 2:1 charge-pump has the property that its input current is exactly half its output current (See Figure 1). In real-world charge pumps like the LTC3256, input current slightly exceeds half the output current due to additional current needed for biasing and for driving power switches.
APPLICATIONS INFORMATION

Under typical conditions ($V_{IN} > 10.1V$), the LTC3256 operates in 2:1 mode and both the 5V output and 3.3V LDO are powered directly from the charge pump output (see Figure 3).

![Figure 3. Power Connections for Typical 12V $V_{IN}$ Operation](image)

The overall efficiency and power dissipation under typical 2:1 step-down conditions can be approximated with the equations below.

**Total LTC3256 efficiency when $V_{IN} > ~10.1V$:**

$$\eta \equiv \frac{5V \cdot I_{OUT5} + 3.3V \cdot I_{OUT3}}{V_{IN} \left( \frac{I_{OUT5}}{2} + \frac{I_{OUT3}}{2} \right)}$$

**Total LTC3256 power dissipation when $V_{IN} > ~10.1V$:**

$$P_D \equiv \left( \frac{V_{IN}}{2} - 5V \right) \cdot I_{OUT5} + \left( \frac{V_{IN}}{2} - 3.3V \right) \cdot I_{OUT3}$$

**2:1 Step-Down Charge Pump Operation ($-7.2V < V_{IN} < -10.1V$)**

In this operating region, the charge pump regulates slightly below $V_{IN}/2$ in order to remain in 2:1 mode and maximize overall $V_{IN}$ to 3.3V conversion efficiency. Figure 4 shows typical charge pump step-down mode and output voltage as a function of $V_{IN}$.

![Figure 4. Typical Charge Pump Output Voltage and Mode vs $V_{IN}$](image)

If OUT5 is enabled and the charge pump output falls below 5V, OUT5 is disconnected from the charge pump output and a separate internal $V_{IN}$-powered 1:1 step-down mode regulator is used to regulate 5V at the OUT5 pin. Refer to the Simplified Block Diagram. The 3.3V LDO remains powered by the 2:1 charge pump output.

Overall efficiency and power dissipation in this operating region can be approximated by the equations below.

**Total LTC3256 efficiency when $-7.2V < V_{IN} < -10.1V$:**

$$\eta \equiv \frac{5V \cdot I_{OUT5} + 3.3V \cdot I_{OUT3}}{V_{IN} \left( I_{OUT5} + \frac{I_{OUT3}}{2} \right)}$$

**Total LTC3256 power dissipation when $-7.2V < V_{IN} < -10.1V$:**

$$P_D \equiv (V_{IN} - 5V) \cdot I_{OUT5} + \left( \frac{V_{IN}}{2} - 3.3V \right) \cdot I_{OUT3}$$
1:1 Step-Down Charge Pump Operation (V\textsubscript{IN} < ~7.2V)

At the low end of the V\textsubscript{IN} operating range, the minimum charge pump regulation point is typically V\textsubscript{OUT CP} = 3.6V, with the charge pump automatically switching to 1:1 mode as needed to maintain regulation. Under 1:1 mode conditions, both the 5V and 3.3V outputs are powered directly from V\textsubscript{IN} with no improvement in efficiency over a dual LDO solution. The overall efficiency and power dissipation in 1:1 step-down mode can be approximated by the equations below.

Total LTC3256 efficiency when V\textsubscript{IN} < ~7.2V:

\[
\eta \approx \frac{5V \cdot I\textsubscript{OUT5} + 3.3V \cdot I\textsubscript{OUT3}}{V\textsubscript{IN} \cdot (I\textsubscript{OUT5} + I\textsubscript{OUT3})}
\]

Total LTC3256 power dissipation when V\textsubscript{IN} < ~7.2V:

\[
P\textsubscript{D} \approx (V\textsubscript{IN} - 5V) \cdot I\textsubscript{OUT5} + (V\textsubscript{IN} - 3.3V) \cdot I\textsubscript{OUT3}
\]

Referring to Figure 2, in 1:1 mode, charge pump switches C and D remain off, and switches A and B are pulsed on and off together to transfer charge directly from V\textsubscript{IN} to OUTCP.

V\textsubscript{IN} Bypass Capacitor Selection

The total amount and type of capacitance necessary for input bypassing is very dependent on the impedance of the input power source as well as existing bypassing already on the V\textsubscript{IN} node. For optimal input noise and ripple reduction, it is recommended that a low ESR ceramic capacitor be used for V\textsubscript{IN} bypassing. Low ESR will reduce the voltage steps caused by changing input current, while the absolute capacitor value will determine the level of ripple. An electrolytic or tantalum capacitor may be used in parallel with the ceramic capacitor on V\textsubscript{IN} to increase the total capacitance, but due to the higher ESR, it is not recommended that an electrolytic or tantalum capacitor be used alone for input bypassing. The LTC3256 will operate with capacitors less than 10μF, but depending on the source impedance, input noise can feed through to the output causing degraded performance. For best performance, 10μF or greater total capacitance is suggested for V\textsubscript{IN} bypassing.

Flying Capacitor Selection

The flying capacitor should always be a ceramic type. Polarized capacitors such as tantalum or aluminum electrolytics are not recommended. The flying capacitor controls the strength of the charge pump. In order to achieve the rated output current, it is necessary for the flying capacitor to have at least 0.4μF of capacitance over operating temperature at 5.05V (see Ceramic Capacitor Selection Guidelines). The voltage rating of the ceramic capacitor should be 6V or greater.

Ceramic Capacitor Selection Guidelines

Capacitors of different materials lose their capacitance with higher temperature and voltage at different rates. For example, a ceramic capacitor made of X5R or X7R material will retain most of its capacitance from -40°C to 85°C, whereas a Z5U or Y5V style capacitor will lose considerable capacitance over that range (60% to 80% loss typical). Z5U and Y5V capacitors may also have a very strong voltage coefficient, causing them to lose an additional 60% or more of their capacitance when the rated voltage is applied. Therefore, when comparing different capacitors, it is often more appropriate to compare the amount of achievable capacitance for a given case size rather than discussing the specified capacitance value. For example, over rated voltage and temperature conditions, a 4.7μF, 10V, Y5V ceramic capacitor in an 0805 case may not provide any more capacitance than a 1μF, 10V, X5R or X7R available in the same 0805 case. In fact, over bias and temperature range, the 1μF, 10V, X5R or X7R will provide more capacitance than the 4.7μF, 10V, Y5V. The capacitor manufacturer’s data sheet should be consulted to determine what value of capacitor is needed to ensure minimum capacitance values are met over operating temperature and bias voltage. Table 1 is a list of ceramic capacitor manufacturers in alphabetical order:
3.3V LDO Operation (OUT3)

The 3.3V LDO post-regulates the charge pump output to produce a lower noise output than is typically available from switching regulators, and supports a load of up to 250mA. To ensure stability, the LDO output should be bypassed to ground with at least a 10µF X7R ceramic capacitor.

Drive the EN3 pin high or low to turn the LDO on or off, respectively. When turning on the LDO, the LTC3256 checks whether the charge pump output (OUTCP) is on, enabling the charge pump automatically if needed.

3.3V LDO Fault Protection

The 3.3V LDO output is current limited to 350mA (typical) to protect against overloads and short circuits. In addition, to reduce power dissipation during an output fault condition, foldback circuitry reduces the LDO current limit to 116mA (typical) for VOUT3 < 0.9V (typical).

To avoid startup issues due to the foldback feature, it is recommended that heavy loads on OUT3 be held off during LDO startup until the PG3 pin goes Hi-Z to indicate that the LDO has completed power up.

5V Output Operation (OUT5)

Bringing EN5 high enables the 5V output at the OUT5 pin. When the 5V output is enabled, the LTC3256 checks whether the charge pump output (OUTCP) is on, enabling the charge pump automatically if needed.

As shown in the Block Diagram, two on-board regulators can drive the 5V output: the 2:1 charge pump and the VIN-powered gated-switch regulator. Regulator selection is automatic. The LTC3256 prefers the 2:1 charge pump whenever possible due to its increased efficiency, but transitions automatically to the VIN-powered gated-switch regulator as needed to maintain regulation depending on line and load conditions.

To reduce 5V output noise and ripple, it is suggested that a low ESR (equivalent series resistance < 0.1Ω) ceramic capacitor (10µF or greater) be used for OUT5 bypass. Tantalum or aluminum electrolytic capacitors can be used in parallel with a ceramic capacitor to increase the total capacitance but should not be used alone because of their high ESR.

5V Output from 2:1 Charge Pump via Fault-Protected PMOS Switch

If at least 5V (typical) is present at OUTCP when EN5 is brought high, the LTC3256 connects OUT5 to OUTCP via an internal PMOS power switch. Soft-start circuitry controls the PMOS turn-on rate to limit in-rush current draw from OUTCP. See Figure 5.

Upon a hard short circuit to ground, OUT5's foldback cir-
cuitry limits current to 85mA (typical). This limit remains in effect for \( V_{OUT5} < 0.8 \text{V} \) (typical). To avoid startup issues due to this foldback feature, heavy loads on OUT5 should be held off during OUT5 startup until PG5 goes Hi-Z.

The LTC3256 has current limit circuitry to protect against overcurrent faults beyond hard shorts to ground.

**Reset Generation (RSTI input, RST output)**

The LTC3256 pulls the \( \text{RST} \) open-drain output low whenever RSTI is below threshold (typically 1.2V) or OUTCP is not in regulation. RST remains asserted low for a reset timeout period \((t_{RST})\) once RSTI goes above the threshold and OUTCP is in regulation. Requiring that OUTCP is in regulation ensures that at least one of the outputs (OUT5 or OUT3) is enabled before the reset timeout period starts. RST deasserts by going high impedance at the end of the reset timeout period.

The reset timeout can be configured to use an internal timer without external components, or an adjustable timer programmed by connecting an external capacitor from the RT pin to GND. Glitch filtering ensures reliable reset operation without false triggering.

During initial power up, the RST output asserts low while \( V_{IN} \) is below the \( V_{IN} \) undervoltage lockout threshold. The state of OUTCP and RSTI have no effect on RST while \( V_{IN} \) is below the undervoltage lockout threshold. The reset timeout period cannot start until \( V_{IN} \) exceeds the undervoltage lockout threshold.

**Selecting the Reset Timing Capacitor**

The reset timeout period can be set to a fixed internal timer or programmed with a capacitor in order to accommodate a variety of applications. Connecting a capacitor, \( C_{RT} \), between the RT pin and GND sets the reset timeout period, \( t_{RST} \). The following formula approximates the value of capacitor needed for a particular timeout:

\[
C_{RT} = (t_{RST} - 0.75\text{ms}) \cdot \frac{67\text{pF}}{\text{ms}}
\]

For example, using a standard capacitor value of 2.2nF would give a 32ms reset timeout period.

Figure 6 shows the desired reset timeout period as a function of the value of the timer capacitor. Leaving RT open with no external capacitor generates a reset timeout of approximately 0.75ms. Shorting RT to OUTCP generates a reset timeout of approximately 0.2s.

**Figure 6. Reset Timeout Period vs RT Pin Capacitance**

**RST Output Characteristics**

\( \text{RST} \) is an open-drain pin and thus requires an external pull-up resistor to the logic supply. \( \text{RST} \) is typically pulled up to OUT5, OUT3, or OUTCP, but can be pulled up to any other supply voltage providing the voltage limits of the pin are observed.

**Watchdog Timer (WDI input, RST output)**

The LTC3256 includes a windowed watchdog function that can continuously monitor the application’s logic or microprocessor and issue automatic resets to aid recovery from unintended lockups or crashes. With the RSTI input held above threshold, the application must periodically toggle the logic state of the watchdog input (WDI pin) in order to clear the watchdog timer. Specifically, successive
APPLICATIONS INFORMATION

falling edges on the WDI pin must be spaced by more than the watchdog lower boundary but less than the watchdog upper boundary. As long as this condition holds, RST remains high impedance.

If a falling edge arrives before the watchdog lower boundary, or if the watchdog timer reaches the upper boundary without seeing a falling edge on WDI, the watchdog timer enters its reset state and asserts RST low for the reset timeout period. Once the reset timeout completes, RST is released to go high and the watchdog timer starts again.

During power-up, the watchdog timer remains cleared while RST is asserted low. As soon as the reset timer times out, RST goes high and the watchdog timer is started.

Setting the Watchdog Reset Time

The watchdog upper boundary (t_{WDU}) and lower boundary (t_{WDL}) are not observable outside the part, only the watchdog reset time (t_{WDR}) of the part is observable via the RST pin. The watchdog upper boundary (t_{WDU}) occurs one watchdog clock cycle before the watchdog reset time (t_{WDR}). The internal watchdog reset time consists of 8193 clock cycles, so the internal watchdog upper boundary time is essentially the same as the internal watchdog reset time. Conversely the external watchdog reset time consists of only 129 clock cycles, so the external watchdog upper boundary should be more accurately calculated as:

\[ t_{WDU(EXT)} = t_{WDR(EXT)} \cdot \frac{128}{129} \]

The external watchdog lower boundary (t_{WDL(EXT)}) occurs five clock cycles into the watchdog reset time (t_{WDR(EXT)}). Thus the external watchdog lower boundary can be calculated from the external watchdog reset time as:

\[ t_{WDL(EXT)} = t_{WDR(EXT)} \cdot \frac{5}{129} \]

The internal watchdog lower boundary can be calculated from the internal watchdog reset time by the following:

\[ t_{WDL(INT)} = \frac{t_{WDR(INT)}}{32} \]

The watchdog reset time is adjustable and can be optimized for software execution. The watchdog reset time is adjusted by connecting a capacitor, C_{WT}, between the WT and GND pins. Given a desired watchdog reset time t_{WDR}, the capacitor value is approximately:

\[ C_{WT} = (t_{WDR} - 3.8\text{ms}) \cdot \frac{8.8\text{nF}}{s} \]

For example, using a standard capacitor value of 0.047μF would give a 5.3s watchdog reset time. Shorting WT to BIAS generates a timeout of approximately 1.6s. Connecting WT to GND disables the watchdog function.

Power Good Output Operation (PG3, PG5 Outputs)

A built-in dual supply monitor indicates which of the OUT3 and OUT5 voltages are in regulation. The monitor detects both overvoltage and undervoltage faults, reporting Power Good status via the PG3 and PG5 open-drain outputs. These will be referred to as the PGx pins in the description below.

If the LTC3256 is shut down (EN3 and EN5 both low) or in undervoltage lockout, both PGx pins are pulled low. Otherwise, behavior is as follows:

If the OUTx pin voltage is greater than the overvoltage threshold or less than the undervoltage threshold, the corresponding PGx pin will pull low. PGx becomes high impedance when the OUTx pin voltage is between the overvoltage and undervoltage thresholds. Hysteresis is built into the overvoltage and undervoltage comparators to ensure PGx holds it’s state when in regulation.
A pull-up resistor can be inserted between PGx and a valid logic supply (i.e. OUTCP, OUT5 or OUT3) to signal a power good condition. The use of a large value pull-up resistor on PGx and a capacitor placed between PGx and GND can be used to delay the Power Good signal if desired.

1.1V Reference Output (REFOUT Output)

An internal bandgap voltage reference determines the regulation voltages at OUT3 and OUT5. A buffered version of this voltage reference appears at the REFOUT pin when the LTC3256 is enabled. The output has a typical impedance of 2k and can source but not sink current. To maximize supply rejection, REFOUT should be bypassed with a 0.1μF ceramic capacitor.

Thermal Management/Thermal Shutdown

The on chip power dissipation in the LTC3256 will cause the junction to ambient temperature to rise at rate of 40°C/W or more. To reduce the maximum junction temperature, a good thermal connection to the PC board is recommended.

Connecting the die paddle (Pin 17) with multiple vias to a large ground plane under the device can reduce the thermal resistance of the package and PC board considerably. Poor board layout and failure to connect the die paddle (Pin 17) to a large ground plane can result in thermal junction to ambient impedance well in excess of 40°C/W. See Linear Technology’s Application Notes for thermally Enhanced Leaded packages.

Because of the wide input operating range it is possible to exceed the specified operating junction temperature and even reach thermal shutdown (175°C typ).

The LTC3256 can operate up to 95°C at full load (IOUT3 = 250mA, IOUT5 = 100mA) with VIN < 15V. Above 95°C, or with input voltages greater than 15V, it is the responsibility of the user to calculate worst-case power dissipation to make sure the LTC3256’s specified operating junction temperature is not exceeded for extended periods of time.

Refer to the power dissipation equations provided earlier for calculating power dissipation (PD) in the different modes of operation.

For example, if it is determined that the maximum power dissipation (PD) is 1.2W under normal operation, then the junction to ambient temperature rise will be:

\[
\text{Junction to Ambient} = 1.2W \times 40^\circ\text{C/W} = 48^\circ\text{C}
\]

Thus, the ambient temperature under this condition cannot exceed 102°C if the junction temperature is to remain below 150°C and if the ambient temperature exceeds about 127°C the device will cycle in and out of the thermal shutdown.
PACKAGING DESCRIPTION

Please refer to http://www.linear.com/product/LTC3256#packaging for the most recent package drawings.

MSE Package
16-Lead Plastic MSOP, Exposed Die Pad
(Reference LTC DWG # 05-08-1667 Rev F)

NOTE:
1. DIMENSIONS IN MILLIMETER/(INCH)
2. DRAWING NOT TO SCALE
3. DIMENSION DOES NOT INCLUDE MOLD FLASH, PROTRUSIONS OR GATE BURRS. MOLD FLASH, PROTRUSIONS OR GATE BURRS SHALL NOT EXCEED 0.152mm (.006") PER SIDE
4. DIMENSION DOES NOT INCLUDE INTERLEAD FLASH OR PROTRUSIONS.
INTERLEAD FLASH OR PROTRUSIONS SHALL NOT EXCEED 0.152mm (.006") PER SIDE
5. LEAD COPLANARITY (BOTTOM OF LEADS AFTER FORMING) SHALL BE 0.102mm (.004") MAX
6. EXPOSED PAD DIMENSION DOES INCLUDE MOLD FLASH. MOLD FLASH ON E-PAD SHALL NOT EXCEED 0.254mm (.010") PER SIDE.
