FEATURES

- $V_{IN}$ and $V_{OUT}$ Limited Only by External Components
- Adjustable Slope Compensation
- Internal Soft-Start
- Constant Frequency 200kHz Operation
- $\pm 1.5\%$ Reference Accuracy
- Current Mode Operation for Excellent Line and Load Transient Response
- No Minimum Load Requirement
- Low Quiescent Current: 240μA
- Low Profile (1mm) SOT-23 Package

APPLICATIONS

- Telecom Power Supplies
- 42V and 12V Automotive Power Supplies
- Auxiliary/Housekeeping Power Supplies
- Power Over Ethernet

DESCRIPTION

The LTC®3803 is a constant frequency current mode flyback controller optimized for driving N-channel MOSFETs in high input voltage applications. Constant frequency operation is maintained down to very light loads, resulting in less low frequency noise generation over a wide range of load currents. Slope compensation can be programmed with an external resistor.

The LTC3803 provides $\pm 1.5\%$ output voltage accuracy and consumes only 240μA of quiescent current. Ground-referenced current sensing allows LTC3803-based converters to accept input supplies beyond the LTC3803’s absolute maximum $V_{CC}$. A micropower hysteretic start-up feature allows efficient operation at high input voltages. For simplicity, the LTC3803 can also be powered from a high $V_{IN}$ through a resistor, due to its internal shunt regulator. An internal undervoltage lockout shuts down the LTC3803 when the input voltage is too low to provide sufficient gate drive to the external MOSFET.

The LTC3803 is available in a low profile (1mm) 6-lead SOT-23 (ThinSOT™) package.

TYPICAL APPLICATION

5V Output Nonisolated Telecom Housekeeping Power Supply

Efficiency vs Load Current

$V_{IN} = 36V$
$V_{IN} = 48V$
$V_{IN} = 60V$
$V_{IN} = 72V$

ELECTRICAL CHARACTERISTICS

Note 1: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

Note 2: The LTC3803 is tested under pulsed load conditions such that $T_J = T_A$. The LTC3803E is guaranteed to meet specifications from 0°C to 85°C junction temperature. Specifications over the −40°C to 125°C operating junction temperature range are assured by design, characterization and correlation with statistical process controls. The LTC3803I is guaranteed to meet performance specifications over the −40°C to 125°C operating junction temperature range, the LTC3803H is guaranteed to meet performance specifications over the −40°C to 150°C operating junction temperature range and the LTC3803MP is tested and guaranteed over the full −55°C to 150°C operating junction temperature range. High junction temperatures degrade operating lifetimes; operating lifetime is derated for junction temperatures greater than 125°C. Note that the maximum ambient temperature consistent with these specifications is determined by specific operating conditions in conjunction with board layout, the rated package thermal impedance and other environmental factors.

Note 3: $T_J$ is calculated from the ambient temperature $T_A$ and power dissipation $P_D$ according to the following formula:

$$T_J = T_A + (P_D • 230°C/W).$$

Note 4: Dynamic supply current is higher due to the gate charge being delivered at the switching frequency.

Note 5: The LTC3803 is tested in a feedback loop that servos $V_{FB}$ to the output of the error amplifier while maintaining $I_{TH}/RUN$ at the midpoint of the current limit range.

Note 6: Peak current sense voltage is reduced dependent on duty cycle and an optional external resistor in series with the SENSE pin ($R_{SL}$). For details, refer to the programmable slope compensation feature in the Applications Information section.

Note 7: Guaranteed by design.

**PIN FUNCTIONS**

**ITH/RUN (Pin 1):** This pin performs two functions. It serves as the error amplifier compensation point as well as the run/shutdown control input. Nominal voltage range is 0.7V to 1.9V. Forcing this pin below the shutdown threshold ($V_{ITH/SHDN}$) causes the LTC3803 to shut down. In shutdown mode, the NGATE pin is held low.

**GND (Pin 2):** Ground Pin.

**VFB (Pin 3):** Receives the feedback voltage from an external resistive divider across the output.

**SENSE (Pin 4):** This pin performs two functions. It monitors switch current by reading the voltage across an external current sense resistor to ground. It also injects a current ramp that develops slope compensation voltage across an optional external programming resistor.

**VCC (Pin 5):** Supply Pin. Must be closely decoupled to GND (Pin 2).

**NGATE (Pin 6):** Gate Drive for the External N-Channel MOSFET. This pin swings from 0V to $V_{CC}$.

---

**BLOCK DIAGRAM**

![Block Diagram of LTC3803](image-url)
**OPERATION**

The LTC3803 is a constant frequency current mode controller for flyback and DC/DC boost converter applications in a tiny ThinSOT package. The LTC3803 is designed so that none of its pins need to come in contact with the input or output voltages of the power supply circuit of which it is a part, allowing the conversion of voltages well beyond the LTC3803’s absolute maximum ratings.

**Main Control Loop**

Due to space limitations, the basics of current mode DC/DC conversion will not be discussed here; instead, the reader is referred to the detailed treatment in Application Note 19, or in texts such as Abraham Pressman’s *Switching Power Supply Design*.

Please refer to the Block Diagram and the Typical Application on the front page of this data sheet. An external resistive voltage divider presents a fraction of the output voltage to the $V_{FB}$ pin. The divider must be designed so that when the output is at the desired voltage, the $V_{FB}$ pin voltage will equal the 800mV from the internal reference. If the load current increases, the output voltage will decrease slightly, causing the $V_{FB}$ pin voltage to fall below 800mV. The error amplifier responds by feeding current into the $I_{TH/RUN}$ pin. If the load current decreases, the $V_{FB}$ voltage will rise above 800mV and the error amplifier will sink current away from the $I_{TH/RUN}$ pin.

The voltage at the $I_{TH/RUN}$ pin commands the pulse-width modulator formed by the oscillator, current comparator and RS latch. Specifically, the voltage at the $I_{TH/RUN}$ pin sets the current comparator’s trip threshold. The current comparator monitors the voltage across a current sense resistor in series with the source terminal of the external MOSFET. The LTC3803 turns on the external power MOSFET when the internal free-running 200kHz oscillator sets the RS latch. It turns off the MOSFET when the current comparator resets the latch or when 80% duty cycle is reached, whichever happens first. In this way, the peak current levels through the flyback transformer’s primary and secondary are controlled by the $I_{TH/RUN}$ voltage.

Since the $I_{TH/RUN}$ voltage is increased by the error amplifier whenever the output voltage is below nominal, and decreased whenever output voltage exceeds nominal, the voltage regulation loop is closed. For example, whenever the load current increases, output voltage will decrease slightly, and sensing this, the error amplifier raises the $I_{TH/RUN}$ voltage by sourcing current into the $I_{TH/RUN}$ pin, raising the current comparator threshold, thus increasing the peak currents through the transformer primary and secondary. This delivers more current to the load, bringing the output voltage back up.

The $I_{TH/RUN}$ pin serves as the compensation point for the control loop. Typically, an external series RC network is connected from $I_{TH/RUN}$ to ground and is chosen for optimal response to load and line transients. The impedance of this RC network converts the output current of the error amplifier to the $I_{TH/RUN}$ voltage which sets the current comparator threshold and commands considerable influence over the dynamics of the voltage regulation loop.

**Start-Up/Shutdown**

The LTC3803 has two shutdown mechanisms to disable and enable operation: an undervoltage lockout on the $V_{CC}$ supply pin voltage, and a forced shutdown whenever external circuitry drives the $I_{TH/RUN}$ pin low. The LTC3803 transitions into and out of shutdown according to the state diagram (Figure 1).

![Figure 1. Start-Up/Shutdown State Diagram](image-url)
OPERATION

The undervoltage lockout (UVLO) mechanism prevents the LTC3803 from trying to drive a MOSFET with insufficient $V_{GS}$. The voltage at the $V_{CC}$ pin must exceed $V_{\text{TURNON}}$ (nominally 8.7V) at least momentarily to enable LTC3803 operation. The $V_{CC}$ voltage is then allowed to fall to $V_{\text{TURNOFF}}$ (nominally 5.7V) before undervoltage lockout disables the LTC3803. This wide UVLO hysteresis range supports the use of a bias winding on the flyback transformer to power the LTC3803—see the section Powering the LTC3803.

The $I_{\text{TH/RUN}}$ pin can be driven below $V_{\text{ITHSHDN}}$ (nominally 0.28V) to force the LTC3803 into shutdown. An internal 0.3μA current source always tries to pull this pin towards $V_{CC}$. When the $I_{\text{TH/RUN}}$ pin voltage is allowed to exceed $V_{\text{ITHSHDN}}$, and $V_{CC}$ exceeds $V_{\text{TURNON}}$, the LTC3803 begins to operate and an internal clamp immediately pulls the $I_{\text{TH/RUN}}$ pin up to about 0.7V. In operation, the $I_{\text{TH/RUN}}$ pin voltage will vary from roughly 0.7V to 1.9V to represent current comparator thresholds from zero to maximum.

Internal Soft-Start

An internal soft-start feature is enabled whenever the LTC3803 comes out of shutdown. Specifically, the $I_{\text{TH/RUN}}$ voltage is clamped and is prevented from reaching maximum until roughly 1.4ms has passed. This allows the input and output currents of LTC3803-based power supplies to rise in a smooth and controlled manner on start-up.

Powering the LTC3803

In the simplest case, the LTC3803 can be powered from a high voltage supply through a resistor. A built-in shunt regulator from the $V_{CC}$ pin to GND will draw as much current as needed through this resistor to regulate the $V_{CC}$ voltage to around 9.5V as long as the $V_{CC}$ pin is not forced to sink more than 25mA. This shunt regulator is always active, even when the LTC3803 is in shutdown, since it serves the vital function of protecting the $V_{CC}$ pin from seeing too much voltage.

For higher efficiency or for wide $V_{IN}$ range applications, flyback controllers are typically powered through a separate bias winding on the flyback transformer. The LTC3803 has the wide UVLO hysteresis and small $V_{CC}$ supply current draw that is needed to support such bootstrapped hysteretic start-up schemes.

The $V_{CC}$ pin must be bypassed to ground immediately adjacent to the IC pins with a minimum of a 10μF ceramic or tantalum capacitor. Proper supply bypassing is necessary to supply the high transient currents required by the MOSFET gate driver.

Adjustable Slope Compensation

The LTC3803 injects a 5μA peak current ramp out through its SENSE pin which can be used for slope compensation in designs that require it. This current ramp is approximately linear and begins at zero current at 6% duty cycle, reaching peak current at 80% duty cycle. Additional details are provided in the Applications Information section.
APPLICATIONS INFORMATION

Many LTC3803 application circuits can be derived from the topology shown in Figure 2.

The LTC3803 itself imposes no limits on allowed power output, input voltage $V_{IN}$ or desired regulated output voltage $V_{OUT}$; these are all determined by the ratings on the external power components. The key factors are: Q1’s maximum drain-source voltage ($BV_{DSS}$), on-resistance ($R_{DS(ON)}$) and maximum drain current, T1’s saturation flux level and winding insulation breakdown voltages, $C_{IN}$ and $C_{OUT}$’s maximum working voltage, ESR, and maximum ripple current ratings, and D1 and $R_{SENSE}$’s power ratings.

TRANSFORMER DESIGN CONSIDERATIONS

Transformer specification and design is perhaps the most critical part of applying the LTC3803 successfully. In addition to the usual list of caveats dealing with high frequency power transformer design, the following should prove useful.

Turns Ratios

Due to the use of the external feedback resistor divider ratio to set output voltage, the user has relative freedom in selecting transformer turns ratio to suit a given application. Simple ratios of small integers, e.g., 1:1, 2:1, 3:2, etc. can be employed which yield more freedom in setting total turns and mutual inductance. Simple integer turns ratios also facilitate the use of “off-the-shelf” configurable transformers such as the Coiltronics VERSA-PAC™ series in applications with high input to output voltage ratios. For example, if a 6-winding VERSA-PAC is used with three windings in series on the primary and three windings in parallel on the secondary, a 3:1 turns ratio will be achieved.

Turns ratio can be chosen on the basis of desired duty cycle. However, remember that the input supply voltage plus the secondary-to-primary referred version of the flyback pulse (including leakage spike) must not exceed the allowed external MOSFET breakdown rating.

Leakage Inductance

Transformer leakage inductance (on either the primary or secondary) causes a voltage spike to occur after the output switch (Q1) turn-off. This is increasingly prominent at higher load currents, where more stored energy must be dissipated. In some cases a “snubber” circuit will be required to avoid overvoltage breakdown at the MOSFET’s drain node. Application Note 19 is a good reference on snubber design.

A bifilar or similar winding technique is a good way to minimize troublesome leakage inductances. However, remember that this will limit the primary-to-secondary breakdown voltage, so bifilar winding is not always practical.

SELECTING FEEDBACK RESISTOR DIVIDER VALUES

The regulated output voltage is determined by the resistor divider across $V_{OUT}$ (R1 and R2 in Figure 2). The ratio of R2 to R1 needed to produce a desired $V_{OUT}$ can be calculated:

$$R2 = \frac{V_{OUT} - 0.8V}{0.8V} \cdot R1$$

Choose resistance values for R1 and R2 to be as large as possible in order to minimize any efficiency loss due to the static current drawn from $V_{OUT}$, but just small enough so that when $V_{OUT}$ is in regulation, the error caused by the nonzero input current to the VFB pin is less than 1%. A good rule of thumb is to choose R1 to be 80k or less.
APPLICATIONS INFORMATION

CURRENT SENSE RESISTOR CONSIDERATIONS

The external current sense resistor (R\textsubscript{SENSE} in Figure 2) allows the user to optimize the current limit behavior for the particular application. As the current sense resistor is varied from several ohms down to tens of milliohms, peak switch current goes from a fraction of an ampere to several amperes. Care must be taken to ensure proper circuit operation, especially with small current sense resistor values.

For example, a peak switch current of 5A requires a sense resistor of 0.020Ω. Note that the instantaneous peak power in the sense resistor is 0.5W and it must be rated accordingly. The LTC3803 has only a single sense line to this resistor. Therefore, any parasitic resistance in the ground side connection of the sense resistor will increase its apparent value. In the case of a 0.020Ω sense resistor, one milliohm of parasitic resistance will cause a 5% reduction in peak switch current. So the resistance of printed circuit copper traces and vias cannot necessarily be ignored.

PROGRAMMABLE SLOPE COMPENSATION

The LTC3803 injects a ramping current through its SENSE pin into an external slope compensation resistor (R\textsubscript{SL} in Figure 2). This current ramp starts at zero right after the NGATE pin has been high for the LTC3803’s minimum duty cycle of 6%. The current rises linearly towards a peak of 5μA at the maximum duty cycle of 80%, shutting off once the NGATE pin goes low. A series resistor (R\textsubscript{SL}) connecting the SENSE pin to the current sense resistor (R\textsubscript{SENSE}) thus develops a ramping voltage drop. From the perspective of the SENSE pin, this ramping voltage adds to the voltage across the sense resistor, effectively reducing the current comparator threshold in proportion to duty cycle. This stabilizes the control loop against subharmonic oscillation. The amount of reduction in the current comparator threshold (ΔV\textsubscript{SENSE}) can be calculated using the following equation:

\[
\Delta V\textsubscript{SENSE} = \frac{\text{Duty Cycle} - 6\%}{74\%} \times 5\mu A \times R\textsubscript{SL}
\]

Note: LTC3803 enforces 6% < Duty Cycle < 80%.

A good starting value for R\textsubscript{SL} is 5.9k, which gives a 30mV drop in current comparator threshold at 80% duty cycle. Designs not needing slope compensation may replace R\textsubscript{SL} with a short circuit.

INTERNAL WIDE HYSTERESIS UNDervoltage LOCKOUT

The LTC3803 is designed to implement DC/DC converters operating from input voltages of typically 48V or more. The standard operating topology employs a third transformer winding (L\textsubscript{BIAS} in Figure 2) on the primary side that provides power for the LTC3803 via its V\textsubscript{CC} pin. However, this arrangement is not inherently self-starting. Start-up is affected by the use of an external “trickle-charge” resistor (R\textsubscript{START} in Figure 2) and the presence of an internal wide hysteresis undervoltage lockout circuit that monitors V\textsubscript{CC} pin voltage. Operation is as follows:

“Trickle charge” resistor R\textsubscript{START} is connected to V\textsubscript{IN} and supplies a small current, typically on the order of 100μA to 120μA, to charge CV\textsubscript{CC}. After some time, the voltage on CV\textsubscript{CC} reaches the V\textsubscript{CC} turn-on threshold. The LTC3803 then turns on abruptly and draws its normal supply current. The NGATE pin begins switching and the external MOSFET (Q1) begins to deliver power. The voltage on CV\textsubscript{CC} begins to decline as the LTC3803 draws its normal supply current, which exceeds that delivered by R\textsubscript{START}. After some time, typically tens of milliseconds, the output voltage approaches its desired value. By this time, the third transformer winding is providing virtually all the supply current required by the LTC3803.

One potential design pitfall is undersizing the value of capacitor CV\textsubscript{CC}. In this case, the normal supply current drawn by the LTC3803 will discharge CV\textsubscript{CC} too rapidly; before the third winding drive becomes effective, the V\textsubscript{CC} turn-off threshold will be reached. The LTC3803 turns off,
and the VCC node begins to charge via RSTART back up to the VCC turn-on threshold. Depending on the particular situation, this may result in either several on-off cycles before proper operation is reached or permanent relaxation oscillation at the VCC node.

Component selection is as follows:

Resistor RSTART should be made small enough to yield a worst-case minimum charging current greater than the maximum rated LTC3803 start-up current, to ensure there is enough current to charge CVCC to the VCC turn-on threshold. It should be made large enough to yield a worst-case maximum charging current less than the minimum rated LTC3803 supply current, so that in operation, most of the LTC3803’s supply current is delivered through the third winding. This results in the highest possible efficiency.

Capacitor CVCC should then be made large enough to avoid the relaxation oscillation behavior described above. This is complicated to determine theoretically as it depends on the particulars of the secondary circuit and load behavior. Empirical testing is recommended.

The third transformer winding should be designed so that its output voltage, after accounting for the D2’s forward voltage drop, exceeds the maximum VCC turn-off threshold. Also, the third winding’s nominal output voltage should be at least 0.5V below the minimum rated VCC clamp voltage to avoid running up against the LTC3803’s VCC shunt regulator, needlessly wasting power.

**VCC SHUNT REGULATOR**

In applications including a third transformer winding, the internal VCC shunt regulator serves to protect the LTC3803 from overvoltage transients as the third winding is powering up.

In applications where a third transformer winding is undesirable or unavailable, the shunt regulator allows the LTC3803 to be powered through a single dropping resistor from VIN to VCC, in conjunction with a bypass capacitor, CVCC, that closely decouples VCC to GND (see Figure 3). This simplicity comes at the expense of reduced efficiency due to the static power dissipation in the RVCC dropping resistor.

**EXTERNAL PREREGULATOR**

The circuit in Figure 4 shows a third way to power the LTC3803. An external series preregulator consisting of series pass transistor Q1, Zener diode D1, and bias resistor RB brings VCC to at least 7.6V nominal, well above the maximum rated VCC turn-off threshold. Resistor RSTART momentarily charges the VCC node up to the VCC turn-on threshold, enabling the LTC3803.

PACKAGE DESCRIPTION

S6 Package
6-Lead Plastic TSOT-23
(Reference LTC DWG # 05-08-1636)

RECOMMENDED SOLDER PAD LAYOUT
PER IPC CALCULATOR

NOTE:
1. DIMENSIONS ARE IN MILLIMETERS
2. DRAWING NOT TO SCALE
3. DIMENSIONS ARE INCLUSIVE OF PLATING
4. DIMENSIONS ARE EXCLUSIVE OF MOLD FLASH AND METAL BURR
5. MOLD FLASH SHALL NOT EXCEED 0.254mm
6. JEDEC PACKAGE REFERENCE IS MO-193
