

Quad IEEE 802.3af Power over Ethernet Controller with Integrated Detection

FEATURES

- Controls Four Independent –48V Powered Ethernet Ports
- Each Port Includes:
 - IEEE 802[®].3af Compliant PD Detection and Classification
 - Output Current Limit with Foldback
 - Short-Circuit Protection with Fast Gate Pull-Down
 - PD Disconnect Using DC Sensing
 - Power Good Indication
- Operates Autonomously or by I²C™ Control
- 4-Bit Programmable Digital Address Allows Control of Up to 64 Ports
- Programmable $\overline{\text{INT}}$ Pin Eliminates Software Polling
- Current and Duty Cycle Limits Protect External FETs
- Available in a 36-Pin SSOP Package

APPLICATIONS

- IEEE 802.3af Compliant Endpoint and Midspan Power Sources
- IP Phone Systems
- DTE Power Distribution

DESCRIPTION

The LTC[®]4258 is a quad –48V Hot Swap™ controller designed for use in IEEE 802.3af compliant Power Sourcing Equipment (PSE). It consists of four independent ports, each with output current limit, short-circuit protection, complete Powered Device (PD) detection and classification capability, and programmable PD disconnect using DC sensing. Used with power MOSFETs and passives as in Figure 1, the LTC4258 can implement a complete IEEE 802.3af-compliant PSE.

The LTC4258 can operate autonomously or be controlled by an I²C serial interface. Up to 16 LTC4258s may coexist on the same data bus, allowing up to 64 powered Ethernet ports to be controlled with only two digital lines. Fault conditions are optionally signaled with the $\overline{\text{INT}}$ pin to eliminate software polling.

External power MOSFETs, current sense resistors and diodes allow easy scaling of current and power dissipation levels and provide protection against voltage and current spikes and ESD events.

The LTC4258 is available in a 36-pin SSOP package.

Linear Technology also provides solutions for 802.3af PD applications with the LTC4257, LTC4257-1, and LTC4267.

TYPICAL APPLICATION

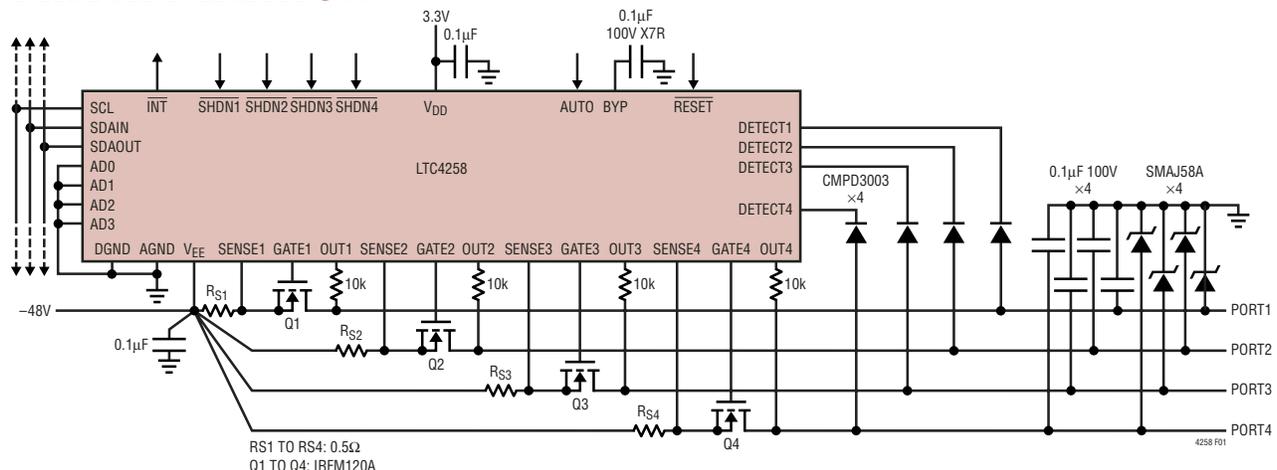

Figure 1. Complete 4-Port Powered Ethernet Power Source

ABSOLUTE MAXIMUM RATINGS

(Note 1)

Supply Voltages

V_{DD} to DGND -0.3V to 5V

V_{EE} to AGND 0.3V to -70V

DGND to AGND (Note 2) ±0.3V

Digital Pins

SCL, SDAIN, SDAOUT, INT, AUTO, RESET

SHDN_n, AD_n DGND - 0.3V to DGND + 5V

Analog Pins

GATE_n (Note 3) V_{EE} - 0.3V to V_{EE} + 12V

DETECT_n DGND - 21V to DGND + 0.3V

SENSE_n V_{EE} - 0.3V to V_{EE} + 1V

OUT_n V_{EE} - 70V to V_{EE} + 70V

BYP Current ±0.1mA

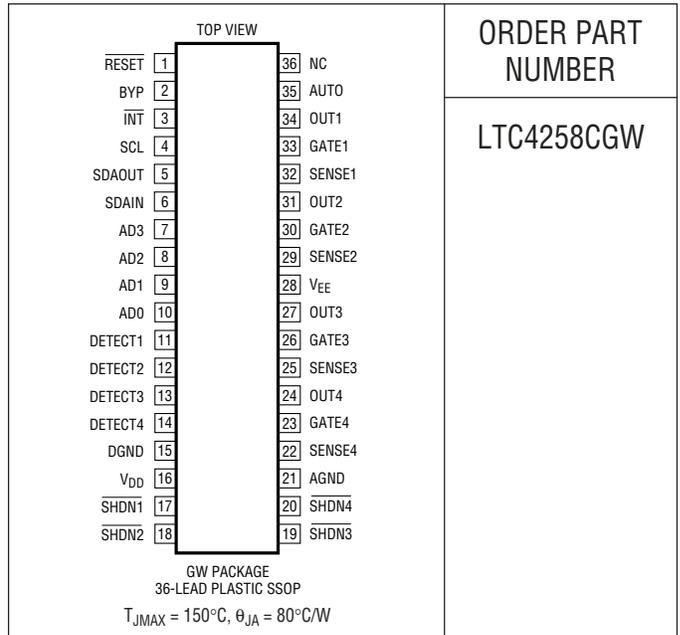

Operating Ambient Temperature Range 0°C to 70°C

Junction Temperature (Note 4) 150°C

Storage Temperature Range -65°C to 150°C

Lead Temperature (Soldering, 10 sec) 300°C

PACKAGE/ORDER INFORMATION

ORDER PART NUMBER

LTC4258CGW

Order Options Tape and Reel: Add #TR

Lead Free: Add #PBF Lead Free Tape and Reel: Add #TRPBF

Lead Free Part Marking: <http://www.linear.com/leadfree/>

Consult LTC Marketing for parts specified with wider operating temperature ranges.

ELECTRICAL CHARACTERISTICS

The ● denotes the specifications which apply over the full operating temperature range, otherwise specifications are at T_A = 25°C. AGND = DGND = 0V, V_{DD} = 3.3V, V_{EE} = -48V unless otherwise noted (Note 5).

| SYMBOL | PARAMETER | CONDITIONS | MIN | TYP | MAX | UNITS |

Note 1: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

Note 2: DGND and AGND should be tied together in normal operation.

Note 3: An internal clamp limits the GATE pins to a minimum of 12V above V_{EE} . Driving this pin beyond the clamp may damage the part.

Note 4: This IC includes overtemperature protection that is intended to protect the device during momentary overload conditions. Junction temperature will exceed 125°C when overtemperature protection is active. Continuous operation above the specified maximum operating junction temperature may impair device reliability.

Note 5: All currents into device pins are positive; all currents out of device

pins are negative. All voltages are referenced to ground (AGND and DGND) unless otherwise specified.

Note 6: The LTC4258 is designed to maintain a port voltage of -46.6V to -57V . The V_{EE} supply voltage range accounts for the drop across the MOSFET and sense resistor.

Note 7: The LTC4258 implements overload current detection per IEEE 802.3af. The minimum overload current (I_{CUT}) is dependent on port voltage; $I_{\text{CUT_MIN}} = 15.4\text{W}/V_{\text{PORT_MIN}}$. An IEEE compliant system using the LTC4258 should maintain port voltage above -46.6V .

Note 8: V_{EE} supply current while classifying a short is measured indirectly by measuring the $\text{DETECT}n$ pin current while classifying a short.

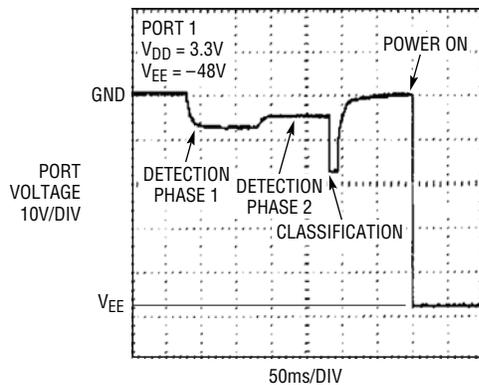

Note 9: Guaranteed by design, not subject to test.

Note 10: Values measured at V_{ILD} and V_{IHD} .

Note 11: If fault occurs during an I²C transaction, the $\overline{\text{INT}}$ pin will not be pulled down until a stop condition is present on the I²C bus.

PIN FUNCTIONS

RESET (Pin 1): Chip Reset, Active Low. When the $\overline{\text{RESET}}$ pin is low, the LTC4258 is held inactive with all ports off and all internal registers reset to their power-up states. When $\overline{\text{RESET}}$ is pulled high, the LTC4258 begins normal operation. $\overline{\text{RESET}}$ can be connected to an external capacitor or RC network to provide a power turn-on delay. Internal filtering of the $\overline{\text{RESET}}$ pin prevents glitches less than $1\mu\text{s}$ wide from resetting the LTC4258. Pull $\overline{\text{RESET}}$ high with $\leq 10\text{k}$ or tie to V_{DD} .

BYP (Pin 2): Bypass Output. The BYP pin is used to connect the internally generated -20V supply to an external $0.1\mu\text{F}$ bypass capacitor. Use a 100V rated $0.1\mu\text{F}$, X7R capacitor. Do not connect the BYP pin to any other external circuitry.

INT (Pin 3): Interrupt Output, Open Drain. $\overline{\text{INT}}$ will pull low when any one of several events occur in the LTC4258. It will return to a high impedance state when bits 6 or 7 are set in the Reset PB register (1Ah). The $\overline{\text{INT}}$ signal can be used to generate an interrupt to the host processor, eliminating the need for continuous software polling. Individual $\overline{\text{INT}}$ events can be disabled using the Int Mask register (01h). See Register Functions and Applications Information for more information. The INT pin is only updated between I²C transactions.

SCL (Pin 4): Serial Clock Input. High impedance clock input for the I²C serial interface bus. The SCL pin should be connected directly to the I²C SCL bus line.

SDAOUT (Pin 5): Serial Data Output, Open Drain Data Output for the I²C Serial Interface Bus. The LTC4258 uses two pins to implement the bidirectional SDA function to simplify optoisolation of the I²C bus. To implement a standard bidirectional SDA pin, tie SDAOUT and SDAIN together. See Applications Information for more information.

SDAIN (Pin 6): Serial Data Input. High impedance data input for the I²C serial interface bus. The LTC4258 uses two pins to implement the bidirectional SDA function to simplify optoisolation of the I²C bus. To implement a standard bidirectional SDA pin, tie SDAOUT and SDAIN together. See Applications Information for more information.

AD3 (Pin 7): Address Bit 3. Tie the address pins high or low to set the I²C serial address to which the LTC4258 responds. This address will be $(010A_3A_2A_1A_0)_b$. Pull AD3 high or low with $\leq 10\text{k}$ or tie to V_{DD} or DGND.

AD2 (Pin 8): Address Bit 2. See AD3.

AD1 (Pin 9): Address Bit 1. See AD3.

AD0 (Pin 10): Address Bit 0. See AD3.

PIN FUNCTIONS

DETECT1 (Pin 11): Detect Sense, Port 1. The LTC4258 Powered Device (PD) detection and classification hardware monitors port 1 with this pin. Connect DETECT1 to the output port via a low leakage diode (see Figure 1). If the port is unused, the DETECT1 pin can be tied to AGND or allowed to float.

DETECT2 (Pin 12): Detection Sense, Port 2. See DETECT1.

DETECT3 (Pin 13): Detection Sense, Port 3. See DETECT1.

DETECT4 (Pin 14): Detection Sense, Port 4. See DETECT1.

DGND (Pin 15): Digital Ground. DGND should be connected to the return from the 3.3V supply. DGND and AGND should be tied together.

V_{DD} (Pin 16): Logic Power Supply. Connect to a 3.3V power supply relative to DGND. V_{DD} must be bypassed to DGND near the LTC4258 with at least a 0.1 μ F capacitor.

SHDN1 (Pin 17): Shutdown Port 1, Active Low. When pulled low, SHDN1 shuts down port 1, regardless of the state of the internal registers. Pulling SHDN1 low is equivalent to setting the Reset Port 1 bit in the Reset Pushbutton register (1Ah). Internal filtering of the SHDN1 pin prevents glitches less than 1 μ s wide from resetting the LTC4258. Pull SHDN1 high with $\leq 10k$ or tie to V_{DD}.

SHDN2 (Pin 18): Shutdown Port 2, Active Low. See SHDN1.

SHDN3 (Pin 19): Shutdown Port 3, Active Low. See SHDN1.

SHDN4 (Pin 20): Shutdown Port 4, Active Low. See SHDN1.

AGND (Pin 21): Analog Ground. AGND should be connected to the return from the $-48V$ supply. AGND and DGND should be tied together.

SENSE4 (Pin 22): Port 4 Current Sense Input. SENSE4 monitors the external MOSFET current via a 0.5 Ω sense resistor between SENSE4 and V_{EE}. Whenever the voltage across the sense resistor exceeds the overcurrent detection threshold V_{CUT}, the current limit fault timer counts up. If the voltage across the sense resistor reaches the current limit threshold V_{LIM} (typically 25mV/50mA higher), the GATE4 pin voltage is lowered to maintain constant current in the external MOSFET. See Applications Information for further details. If the port is unused, the SENSE4 pin must be tied to V_{EE}.

GATE4 (Pin 23): Port 4 Gate Drive. GATE4 should be connected to the gate of the external MOSFET for port 4. When the MOSFET is turned on, a 50 μ A pull-up current source is connected to the pin. The gate voltage is clamped to 13V (typ) above V_{EE}. During a current limit condition, the voltage at GATE4 will be reduced to maintain constant current through the external MOSFET. If the fault timer expires, GATE4 is pulled down with 50 μ A, turning the MOSFET off and recording a t_{CUT} or t_{START} event. If the port is unused, float the GATE4 pin or tie it to V_{EE}.

OUT4 (Pin 24): Port 4 Output Voltage Monitor. OUT4 should be connected to the output port through a 10k series resistor. A current limit foldback circuit limits the power dissipation in the external MOSFET by reducing the current limit threshold when the port voltage is within 18V of AGND. The port 4 Power Good bit is set when the voltage from OUT4 to V_{EE} drops below 2V (typ). A 2.5M Ω resistor is connected internally from OUT4 to AGND. If the port is unused, the OUT4 pin can be tied to AGND or allowed to float.

SENSE3 (Pin 25): Port 3 Current Sense Input. See SENSE4.

GATE3 (Pin 26): Port 3 Gate Drive. See GATE4.

OUT3 (Pin 27): Port 3 Output Voltage Monitor. See OUT4.

V_{EE} (Pin 28): $-48V$ Supply Input. Connect to a $-48V$ to $-57V$ supply, relative to AGND.

SENSE2 (Pin 29): Port 2 Current Sense Input. See SENSE4.

GATE2 (Pin 30): Port 2 Gate Drive. See GATE4.

OUT2 (Pin 31): Port 2 Output Voltage Monitor. See OUT4.

SENSE1 (Pin 32): Port 1 Current Sense Input. See SENSE4.

GATE1 (Pin 33): Port 1 Gate Drive. See GATE 4.

OUT1 (Pin 34): Port 1 Output Voltage Monitor. See OUT4.

AUTO (Pin 35): Auto Mode Input. Auto mode allows the LTC4258 to detect and power up a PD even if there is no host controller present on the I²C bus. The voltage of the AUTO pin determines the state of the internal registers when the LTC4258 is reset or comes out of V_{DD} UVLO (see the Register map in Table 1). The states of these register bits can subsequently be changed via the I²C interface. The real-time state of the AUTO pin is read at bit 0 in the Pin Status register (11h). Pull AUTO high or low with $\leq 10k$ or tie to V_{DD} or DGND.

NC (Pin 36): No Internal Connection.

REGISTER FUNCTIONS

Interrupt Registers

Interrupt (Address 00h): Interrupt Register, Read Only. A transition to logical 1 of any bit in this register will assert the $\overline{\text{INT}}$ pin (Pin 3) if the corresponding bit in the Int Mask register is set. Each bit is the logical OR of the corresponding bits in the Event registers. The Interrupt register is Read Only and its bits cannot be cleared directly. To clear a bit in the Interrupt register, clear the corresponding bits in the appropriate Status or Event registers or set bit 7 in the Reset Pushbutton register (1Ah).

Int Mask (Address 01h): Interrupt Mask, Read/Write. A logic 1 in any bit of the Int Mask register allows the corresponding Interrupt register bit to assert the $\overline{\text{INT}}$ pin if it is set. A logic 0 in any bit of the Int Mask register prevents the corresponding Interrupt bit from affecting the $\overline{\text{INT}}$ pin. The actual Interrupt register bits are unaffected by the state of the Int Mask register.

Event Registers

Power Event (Address 02h): Power Event Register, Read Only. The lower four bits in this register indicate that the corresponding port Power Enable status bit has changed; the logical OR of these four bits appears in the Interrupt register as the Pwr Enable Event bit. The upper four bits indicate that the corresponding port Power Good status bit has changed; the logical OR of these four bits appears in the Interrupt register as the Pwr Good Event bit. The Power Event bits latch high and will remain high until cleared by reading from address 03h.

Power Event CoR (Address 03h): Power Event Register, Clear on Read. Read this address to clear the Power Event register. Address 03h returns the same data as address 02h and reading address 03h clears all bits at both addresses.

Detect Event (Address 04h): Detect Event Register, Read Only. The lower four bits in this register indicate that at least one detection cycle for the corresponding port has completed; the logical OR of these four bits appears in the Interrupt register as the Detect Complete bit. The upper four bits indicate that at least one classification cycle for the corresponding port has completed; the logical OR of these four bits appears in the Interrupt register as the Class Complete bit. In Manual mode, this register indicates that the requested detection/classification cycle has completed and

the LTC4258 is awaiting further instructions. In Semiauto or Auto modes, these bits indicate that the Detect Status and Class Status bits in the Port Status registers are valid. The Detect Event bits latch high and will remain high until cleared by reading from address 05h.

Detect Event CoR (Address 05h): Detect Event Register, Clear on Read. Read this address to clear the Detect Event register. Address 05h returns the same data as address 04h, and reading address 05h clears all bits at both addresses.

Fault Event (Address 06h): Fault Event Register, Read Only. The lower four bits in this register indicate that a t_{CUT} fault has occurred at the corresponding port; the logical OR of these four bits appears in the Interrupt register as the t_{CUT} Fault bit. The upper four bits indicate that a Disconnect event has occurred at the corresponding port; the logical OR of these four bits appears in the Interrupt register as the Disconnect bit. The Fault Event bits latch high and will remain high until cleared by reading from address 07h.

Fault Event CoR (Address 07h): Fault Event Register, Clear on Read. Read this address to clear the Fault Event register. Address 07h returns the same data as address 06h and reading address 07h clears all bits at both addresses.

t_{START} Event (Address 08h): t_{START} Event Register, Read Only. The lower four bits in this register indicate that a t_{START} fault has occurred at the corresponding port; the logical OR of these four bits appears in the Interrupt register as the t_{START} Fault bit. The t_{START} Event bits latch high and will remain high until cleared by reading from address 09h. The upper four bits in this register are reserved and will always read as 0.

t_{START} Event CoR (Address 09h): t_{START} Event Register, Clear on Read. Read this address to clear the Fault Event register. Address 09h returns the same data as address 08h and reading address 09h clears all bits at both addresses.

Supply Event (Address 0Ah): Supply Event Register, Read Only. Bit 4 indicates that V_{EE} has dropped below the V_{EE} UVLO level (typically -28V). Bit 5 signals that the V_{DD} supply has dropped below the V_{DD} UVLO threshold. Bit 7 indicates that the LTC4258 die temperature has exceeded its thermal shutdown limit (see Note 4 under Electrical Characteristics). The logical OR of bits 4, 5 and 7 appears in the Interrupt register as the Supply Fault bit. The remaining bits in

REGISTER FUNCTIONS

the register are reserved and will always read as 0. The Supply Event bits latch high and will remain high until cleared by reading from address 0Bh.

Supply Event CoR (Address 0Bh): Supply Event Register, Clear on Read. Read this address to clear the Fault Event register. Address 0Bh returns the same data as address 0Ah, and reading address 0Bh clears all bits at both addresses.

Status Registers

Port 1 Status (Address 0Ch): Port 1 Status Register, Read Only. This register reports the most recent detection and classification results for port 1. Bits 0-2 report the status of the most recent detection attempt at the port and bits 4-6 report the status of the most recent classification attempt at the port. If power is on, these bits report the detection/classification status present just before power was turned on. If power is turned off at the port for any reason, all bits in this register will be cleared. See Table 1 for detection and classification status bit encoding.

Port 2 Status (Address 0Dh): Port 2 Status Register, Read Only. See Port 1 Status.

Port 3 Status (Address 0Eh): Port 3 Status Register, Read Only. See Port 1 Status.

Port 4 Status (Address 0Fh): Port 4 Status Register, Read Only. See Port 1 Status.

Power Status (Address 10h): Power Status Register, Read Only. The lower four bits in this register report the switch on/off state for the corresponding ports. The upper four bits (the power good bits) indicate that the drop across the power switch and sense resistor for the corresponding ports is less than 2V (typ) and power start-up is complete. The power good bits are latched high and are only cleared when a port is turned off or the LTC4258 is reset.

Pin Status (Address 11h): External Pin Status, Read Only. This register reports the real time status of the AUTO (Pin 35) and AD0-AD3 (Pins 7-10) digital input pins. The logic state of the AUTO pin appears at bit 0 and the AD0-AD3 pins at bits 2-5. The remaining bits are reserved and will read as 0. AUTO affects the initial states of some of the LTC4258 configuration registers at start-up but has no effect after start-up and can be used as a general purpose input if desired, as long as it is guaranteed to be in the appropriate state at start-up.

Configuration Registers

Operating Mode (Address 12h): Operating Mode Configuration, Read/Write. This register contains the mode bits for each of the four ports in the LTC4258. See Table 1 for mode bit encoding. At power-up, all bits in this register will be set to the logic state of the AUTO pin (Pin 35). See Operating Modes in the Applications Information section.

Disconnect Enable (Address 13h): Disconnect Enable Register, Read/Write. The lower four bits of this register enable or disable DC disconnect detection circuitry at the corresponding port. If the DC Discon Enable bit is set the port circuitry will turn off power if the current draw at the port falls below I_{MIN} for more than t_{DIS} . I_{MIN} is equal to V_{MIN}/R_S , where R_S is the sense resistor and should be 0.5Ω for IEEE 802.3af compliance. If the bit is clear the port will not remove power due to low current.

Detect/Class Enable (Address 14h): Detection and Classification Enable, Read/Write. The lower four bits of this register enable the detection circuitry at the corresponding port if that port is in Auto or Semiauto mode. The upper four bits enable the classification circuitry at the corresponding port if that port is in Auto or Semiauto mode. In manual mode, setting a bit in this register will cause the LTC4258 to perform one classification or detection cycle on the corresponding port. Writing to the Detect/Class Restart PB (18h) has the same effect without disturbing the Detect/Class Enable bits for other ports.

Timing Config (Address 16h): Global Timing Configuration, Read/Write. Bits 0-1 program t_{DIS} , the time duration before a port is automatically tuned off after the PD is removed. Bits 2-3 program t_{CUT} , the time during which a port's current can exceed I_{CUT} without it being turned off. If the current is still above I_{CUT} after t_{CUT} , the LTC4258 will indicate a t_{CUT} fault and turn the port off. Bits 4-5 program t_{START} , the time duration before an overcurrent condition during port power-on is considered a t_{START} fault and the port is turned off. Note that using the t_{CUT} and t_{START} times other than the default is not compliant with IEEE 802.3af and may double or quadruple the energy dissipated by the external MOSFETs during fault conditions. Bits 6-7 are reserved and should be read/written as 0. See Electrical Characteristics for timer bit encoding. Also see the Applications Information for descriptions of t_{START} , t_{CUT} and DC disconnect timing.

REGISTER FUNCTIONS

Misc Config (Address 17h): Miscellaneous Configuration, Read/Write. Setting bit 7 enables the $\overline{\text{INT}}$ pin. If this bit is reset, the LTC4258 will not pull down the $\overline{\text{INT}}$ pin in any condition nor will it respond to the Alert Response Address. This bit is set by default.

Pushbutton Registers

Note Regarding Pushbutton Registers: “Pushbutton” registers are specialized registers that trigger an event when a 1 is written to a bit; writing a 0 to a bit will do nothing. Unlike a standard read/write register, where setting a single bit involves reading the register to determine its status, setting the appropriate bit in software and writing back the entire register, a pushbutton register allows a single bit to be written without knowing or affecting the status of the other bits in the register. Pushbutton registers are write-only and will return 00h if read.

Det/Class Restart PB (Address 18h): Detection/Classification Restart Pushbutton Register, Write Only. Writing a 1 to any bit in this register will start or restart a single detection or classification cycle at the corresponding port in Manual mode. It can also be used to set the corresponding bits in the Detect/Class Enable register (address 14h) for ports in auto or semiauto mode. The lower 4 bits affect detection on each port while the upper 4 bits affect classification.

Power Enable PB (Address 19h): Power Enable Pushbutton Register, Write Only. The lower four bits of this register set the Power Enable bit in the corresponding Port Status register; the upper four bits clear the corresponding Power Enable bit. Setting or clearing the Power Enable bits via this

register will turn on or off the power in any mode except shutdown, regardless of the state of detection or classification. Note that t_{ICUT} , t_{START} and disconnect events (if enabled) will still turn off power if they occur.

The Power Enable bit cannot be set if the port has turned off due to a t_{ICUT} or t_{START} fault and the t_{ICUT} timer has not yet counted back to zero. See Applications Information for more information on t_{ICUT} timing.

Clearing the Power Enable bits with this register also clears the detect and fault event bits, the Port Status register, and the Detection and Classification Enable bits for the affected port(s).

Reset PB (Address 1Ah): Reset Pushbutton, Write Only. Bits 0-3 reset the corresponding port by clearing the power enable bit, the detect and fault event bits, the status register and the detection and classification enable bits for that port. Bit 4 returns the entire LTC4258 to the power-on reset state; all ports are turned off, the AUTO pin is reread and all registers are returned to their power-on defaults, except $V_{\text{DD UVLO}}$, which remains cleared. Bit 5 is reserved; setting it has no effect. Setting bit 6 releases the Interrupt pin if it is asserted without affecting the Event registers or the Interrupt register. When the $\overline{\text{INT}}$ pin is released in this way, the condition causing the LTC4258 to pull the $\overline{\text{INT}}$ pin down must be removed before the LTC4258 will be able to pull $\overline{\text{INT}}$ down again. This can be done by reading and clearing the event registers or by writing a 1 into bit 7 of this register. Setting bit 7 releases the Interrupt pin, clears all the Event registers and clears all the bits in the Interrupt register.

APPLICATIONS INFORMATION

OVERVIEW

Over the years, twisted-pair Ethernet has become the most commonly used method for local area networking. The IEEE 802.3 group, the originator of the Ethernet standard, has defined an extension to the standard, known as 802.3af, which allows DC power to be delivered simultaneously over the same cable used for data communication. This promises a whole new class of Ethernet devices, including IP telephones, wireless access points, and PDA charging stations, which do not require additional AC wiring or external power transformers, a.k.a. “wall warts.” With about 13W of power available, small data devices can be powered by their Ethernet connections, free from AC wall outlets. Sophisticated detection and power monitoring techniques prevent damage to legacy data-only devices, while still supplying power to newer, Ethernet-powered devices over the twisted-pair cable.

A device that supplies power is called Power Sourcing Equipment (PSE); a device that draws power from the wire is called a Powered Device (PD). A PSE is typically an Ethernet switch, router, hub, or other network switching

equipment that is commonly found in the wiring closets where cables converge. PDs can take many forms: digital IP telephones, wireless network access points, PDA or notebook computer docking stations, cell phone chargers, and HVAC thermostats are examples of devices that can draw power from the network.

A PSE is required to provide a nominal 48V DC between either the signal pairs or the spare pairs (but not both) as shown in Figure 10. The power is applied as a voltage between two of the pairs, typically by powering the center-taps of the isolation transformers used to couple the differential data signals to the wire. Since Ethernet data is transformer coupled at both ends and is sent differentially, a voltage difference between the transmit pairs and the receive pairs does not affect the data. A 10base-T/100base-TX Ethernet connection only uses 2 of the 4 pairs in the cable. The unused or spare pairs can be powered directly, as shown in Figure 10, without affecting the data. However, 1000base-T uses all 4 pairs and power must be connected to the transformer center taps for compatibility.

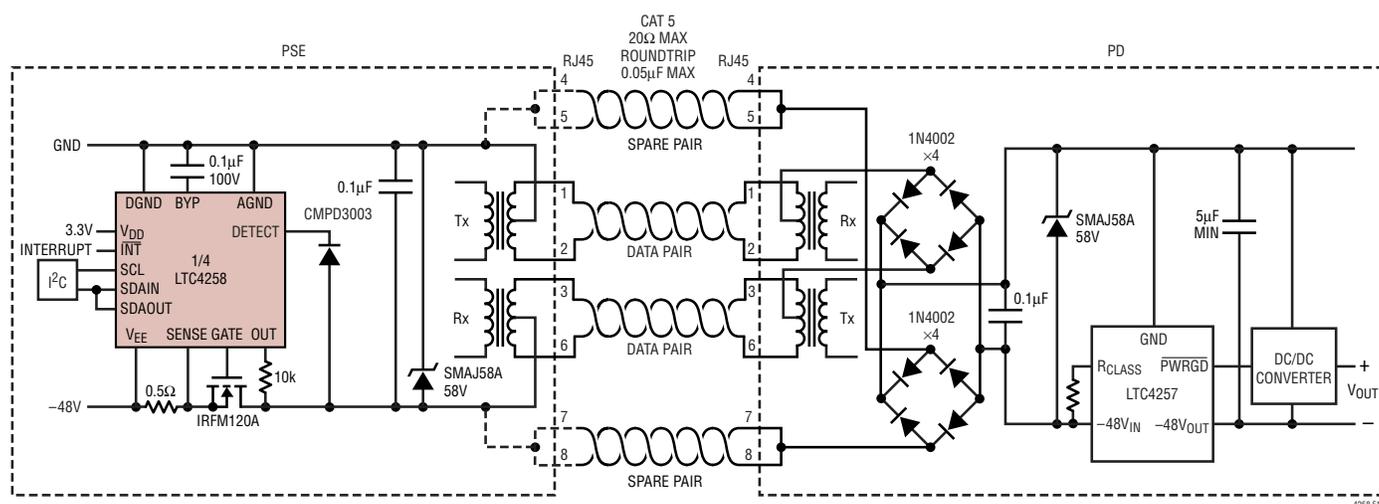

Figure 10. PoE System Diagram

APPLICATIONS INFORMATION

The LTC4258 provides a complete solution for detection and powering of PD devices in an IEEE 802.3af compliant system. The LTC4258 consists of four independent ports, each with the ability to detect, classify, and provide isolated -48V power to a PD device connected to it. The LTC4258 senses removal of a PD with IEEE 802.3af compliant DC method and turns off -48V power when the PD is removed. An internal control circuit takes care of system configuration and timing, and uses an I²C interface to communicate with the host system.

OPERATING MODES

Each LTC4258 port can operate in one of four modes: Manual, Semiauto, Auto or Shutdown. The operating mode for a port is set by the appropriate bits in the Operating Mode register. The LTC4258 will power up with all ports in Shutdown mode if the external AUTO pin is tied low; if AUTO is high, all ports will wake up in Auto mode. The operating mode can be changed at any time via the I²C interface, regardless of the state of the AUTO pin.

- In Manual mode, a port will wait for instructions from the host system before taking any action. It will run single detection or classification cycles when commanded, and will report results in the Port Status registers. When the host system decides it is time to turn on or off power to a port, it can do so by setting the appropriate Power On/Off bits in the Power Enable PB register regardless of the current status of detection or classification.
- In Semiauto mode, the port will repeatedly attempt to detect and classify a PD device attached to the link. It will report this information in its Port Status register, and wait for the host system to set the appropriate Power On bit in the Power Enable PB register before applying power to the port.
- In Auto mode, the port will detect and classify a PD device connected to it, then immediately turn on the power if detection was successful regardless of the result of classification.
- In Shutdown mode, the port is disabled and will not detect or power a PD. Also, the detect and fault event bits, status bits and enable bits for the port are reset to zero.

Regardless of which mode it is in, the LTC4258 will remove power automatically from any port that generates a t_{START} or t_{ICUT} overcurrent fault event (see t_{ICUT} Timing and t_{START} Timing sections). It will also automatically remove power from any port that generates a disconnect event if the appropriate Disconnect Enable bit is set in the Disconnect Enable register. The host controller may also remove power at any time by setting the appropriate Power Off bit in the Power Enable PB register.

Power-On RESET

At turn-on or any time the LTC4258 is reset (either by pulling the RESET pin low or writing to the global Reset All bit), all the ports turn off and all internal registers go to a predefined state, shown in Table 1.

Several of the registers assume different states based on the state of the AUTO pin at reset. The default states with AUTO high allow the LTC4258 to detect and power up a PD in Automatic mode, even if nothing is connected to the I²C interface.

SIGNATURE DETECTION

The IEEE defines a specific pair-to-pair PD signature resistance that identifies a device that can accept Power over Ethernet in accordance with the 802.3af specification. When the port voltage is below 10V, an 802.3af compliant PD will have a 25k signature resistance. Figure 11 illustrates the relationship between the PD signature resistance (white box from 23.75k to 26.25k) and required resistance ranges the PSE must accept (white box) and reject (gray boxes). According to the 802.3af specification, the PSE may or may not accept resistances in the two ranges of 15k to 19k and 26.5k to 33k. Note that the black box in Figure 11 represents the 150 Ω pair-to-pair termination used in legacy 802.3 devices like a computer's network interface card (NIC) that cannot accept power.

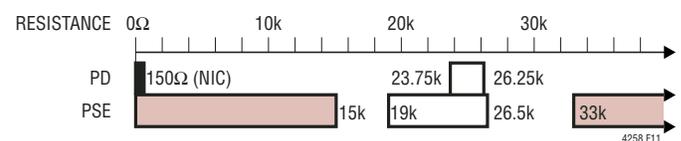

Figure 11. IEEE 802.3af Signature Resistance Ranges

APPLICATIONS INFORMATION

The LTC4258 checks for the signature resistance by forcing two test currents on the port (via the DETECT n pins) in sequence and measuring the resulting voltages. It then subtracts the two V-I points to determine the resistive slope while removing voltage offset caused by any series diodes or current offset caused by leakage at the port (see Figure 12). The LTC4258 will typically accept any PD resistance between 17k and 29k as a valid PD and report Detect Good (100 binary) in the Detect Status bits (bits 2 through 0) of the corresponding Port Status register. Values outside this range, including open and short circuits, are also reported in the Detect Status bits. Refer to Table 1 for a complete decoding of the Detect Status bits.

The first test point is taken by forcing a test current into the port, waiting a short time to allow the line to settle and measuring the resulting voltage. This result is stored and the second current is applied to the port, allowed to settle and the voltage measured. Each point takes about 100ms to measure, and an entire detection cycle takes 230ms (max).

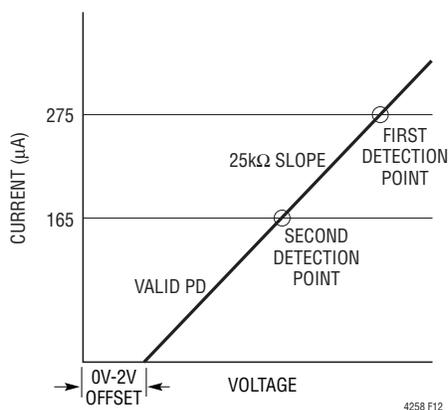

Figure 12. PD Detection

The LTC4258 will not report Detect Good if the PD has more than 5µF in parallel with its signature resistor.

The port's operating mode controls if and when the LTC4258 runs a detection cycle. In manual mode, the port will sit idle until a Restart Detection (register 18h) command is received. It will then run a complete 200ms detection cycle on the selected port, report the results in the Detect Status bits in the corresponding Port Status register and return to idle until another command is received. In Semiauto mode, the LTC4258 autonomously tests valid PDs connected to the ports but it will not apply power until instructed to do so by the host controller. It repeatedly queries the port every 320ms and updates the Detect Status bits at the end of each cycle. If a Detect Good is reported, it will advance to the classification phase and report that result in the Port Status register. Until instructed to do otherwise, the LTC4258 will continue to repeat detection on the port. Behavior in Auto mode is similar to Semiauto; however, after a Detect Good is reported, the LTC4258 performs the classification phase and then powers up the port without further intervention.

The signature detection circuitry is disabled when the port is in Shutdown mode, powered up or the corresponding Detect Enable bit is cleared.

CLASSIFICATION

A PD has the option of presenting a “classification signature” to the PSE to indicate how much power it will draw when powered up. This signature consists of a specific constant current draw when the PSE port voltage is between 15.5V and 20.5V, with the current level indicating the power class to which the PD belongs. Per the IEEE 802.3af specification, the LTC4258 identifies the five classes of PD listed in Table 2. During classification, the LTC4258 controls and

Table 2. IEEE 802.3af Powered Device Classes

| IEEE 802.3af CLASS | CLASSIFICATION CURRENT AT PSE | MAXIMUM PD POWER | MINIMUM PSE OUTPUT POWER | CLASS DESCRIPTION |
|--------------------|-------------------------------|------------------|--------------------------|---|
| 0 | 0mA to 5mA | 12.95W | 15.4W | PD Does Not Implement Classification, Unknown Power |
| 1 | 8mA to 13mA | 3.84W | 4W | Low Power PD |
| 2 | 16mA to 21mA | 6.49W | 7W | Medium Power PD |
| 3 | 25mA to 31mA | 12.95W | 15.4W | High or Full Power PD |
| 4 | 35mA to 45mA | 12.95W | 15.4W | Reserved, Power as Class 0 |

APPLICATIONS INFORMATION

measures the port voltage through the DETECT n pin. Note that class 4 is presently specified by the IEEE as reserved for future use. Figure 13 shows a PD load line, starting with the shallow slope of the 25k signature resistor below 10V, then drawing the classification current (in this case, class 3) between 14.5V and 20.5V. The LTC4258's load line for classification is also shown in Figure 13. It has low impedance until current limit is reached at 55mA (min).

The LTC4258 will classify a port immediately after a successful detection cycle in Semiauto or Auto modes, or when commanded to in Manual mode. It measures the PD classification signature current by applying 18V (typ) to the port and measuring the resulting current. It reports the detected class in the Class Status bits in the corresponding Port Status register. Note that in Auto mode, the port will power up regardless of which class is detected.

The classification circuitry is disabled when the port is in Shutdown mode, powered up, or the corresponding Class Enable bit is cleared.

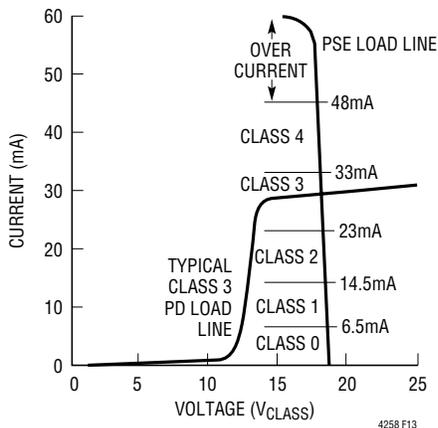

Figure 13. PD Classification

POWER CONTROL

The primary function of the LTC4258 is to control the delivery of power to the PSE port. It does this by controlling the gate drive voltage of an external power MOSFET while monitoring the current via a sense resistor and the output voltage at the OUT pin. This circuitry serves to couple the raw isolated -48V input supply to the port in a controlled manner that satisfies the PD's power needs while minimizing disturbances on the -48V backplane.

Gate Currents

Once the decision has been made to turn on power to a port, the LTC4258 uses a $50\mu\text{A}$ current source to pull up on the GATE pin. Under normal power-up circumstances, the MOSFET gate will charge up rapidly to V_T (the MOSFET threshold voltage), the MOSFET current will rise quickly to the current limit level and the GATE pin will be servoed to maintain the proper I_{INRUSH} charging current. When output charging is complete, the MOSFET current will fall and the GATE pin will be allowed to continue rising to fully enhance the MOSFET and minimize its on resistance. The final V_{GS} is nominally 13V . When a port is turned off, a $50\mu\text{A}$ current source pulls down on the GATE pin, turning the MOSFET off in a controlled manner.

No External Capacitors

No external capacitors are required on the GATE pins for active current limit stability, lowering part count and cost. This also allows the fastest possible turn-off under severe overcurrent conditions, providing maximum safety and protection for the MOSFETs, load devices and board traces. Connecting capacitors to the external MOSFET gates can adversely affect the LTC4258's ability to respond to a shorted port.

Inrush Control

The 802.3af standard lists two separate maximum current limits, I_{LIM} and I_{INRUSH} . Because they have identical values, the LTC4258 implements both as a single current limit using V_{LIM} (described below). Their functions are differentiated through the use of t_{ICUT} and t_{START} , respectively (see t_{ICUT} Timing and t_{START} Timing sections). To maintain consistency with the standard, the I_{INRUSH} term is used when referring to an initial t_{START} power-up event.

When the LTC4258 turns on a port, it turns on the MOSFET by pulling up on the gate. The LTC4258 is designed to power up the port in current limit, limiting the inrush current to I_{INRUSH} .

The port voltage will quickly rise to the point where the PD reaches its input turn-on threshold and begins to draw current to charge its bypass capacitance, slowing the rate of port voltage increase.

APPLICATIONS INFORMATION

Dual-Level Current Limit

A PD is permitted to draw up to 15.4W continuously and up to 400mA for 50ms. The LTC4258 has two corresponding current limit thresholds, I_{CUT} (375mA typ) and I_{LIM} (425mA typ). These are given by the equations:

$$I_{CUT} = V_{CUT}/R_S, I_{LIM} = V_{LIM}/R_S$$

R_S is the sense resistor and should be 0.5Ω for IEEE 802.3af compliance. While the LTC4258 allows the port current to exceed I_{CUT} for a limited time period (see t_{CUT} timing below), it does not allow the current to exceed I_{LIM} . The current limit circuit monitors the port current by monitoring the voltage across the sense resistor and reduces the MOSFET gate voltage as needed to keep the current at or below I_{LIM} . When the current drops below I_{LIM} , the gate voltage is restored to the full value to keep the MOSFET resistance to a minimum.

t_{CUT} Timing

Whenever more than $I_{CUT} = V_{CUT}/R_S$ flows through a port, the port's sense voltage is above V_{CUT} and the t_{CUT} timer counts up. If the sense voltage is still above V_{CUT} when the t_{CUT} timer expires, the LTC4258 will turn off the power to the port immediately and set the appropriate t_{CUT} Fault bit in register 06h/07h. The t_{CUT} timer duration can be programmed via register 16h, bits 3 and 2 (Table 1).

The t_{CUT} timer is an up/down counter that is designed to protect the external MOSFET from thermal stress caused by repeatedly operating in current limit. The counter counts up whenever the current is above I_{CUT} and counts down at 1/16th the rate when it is not. The counter will bottom out at zero to prevent underflow. Full count indicates that the t_{CUT} timer has expired and the port will be turned off.

This count up/count down behavior implements duty cycle protection, preventing intermittent current limit faults from causing cumulative thermal stress in the MOSFET. If the port enters current limit but then exits before the timer expires, the count will decrease slowly, giving the I_{CUT} timer the ability to turn off sooner in the case of a repetitive fault. If the overcurrent duty cycle is less than 6.3% the t_{CUT} timer will be fully reset.

If the t_{CUT} timer expires and causes the port to shut off, the timer will continue to run, counting down at the slow 1/16th rate and preventing the port from being repowered until the count returns to zero. This protects the MOSFET from damage due to a faulty PD that may still have a valid signature, or from errant software that repeatedly writes to the Power On bit.

The port will not re-power until after the t_{CUT} counter returns to zero. In manual and semiauto modes the power enable command must be received after the t_{CUT} counter reaches zero. In auto mode the LTC4258 must complete a valid detection cycle after the t_{CUT} counter reaches zero.

t_{START} Timing

To distinguish between normal turn-on current limit behavior and current limit faults which occur after power-up is complete, the LTC4258 starts a timer (the t_{START} timer) whenever a power-up sequence begins.

The t_{START} timer serves three functions. First and foremost, it allows the user to specify a different current limit timeout (t_{START} instead of t_{CUT}) during turn-on (current limit duty cycle protection remains functional). Second, the DC disconnect timer is disabled during this period and can only begin counting up after the t_{START} timer has expired. Together, these two features let the PD draw the maximum current I_{INRUSH} to charge its input capacitance, boot up and begin drawing power without triggering a t_{START} fault. Finally, if the device is in current limit for the entire t_{START} period, a t_{START} fault will be generated instead of a t_{CUT} fault. This can be useful for tracking down the cause of a current fault.

As long as the PD draws less than I_{CUT} at the end of t_{START} and begins drawing the minimum current within t_{DIS} after t_{START} expires (if DC disconnect is enabled), no faults will be indicated.

The t_{START} timer also implements the duty cycle protection described under t_{CUT} timing and its duration can be programmed via register 16h, bits 5 and 4 (Table 1).

APPLICATIONS INFORMATION

Foldback

Foldback is designed to limit power dissipation in the MOSFET during power-up and momentary short-circuit conditions. At low port output voltages, the voltage across the MOSFET is high, and power dissipation will be large if significant current is flowing. Foldback monitors the port output voltage and reduces the V_{LIM} current limit level linearly from its full value (212.5mV typ) at a port voltage of 18V to approximately 1/7th of the full value (30mV typ) at a port voltage of 0V. With 0.5 Ω sense resistors, this limits the short-circuit current to 60mA (typ) instead of the full 425mA (typ) current limit. When the LTC4258 is in foldback, the t_{ICUT} timer is active.

Short-Circuit Protection

If a port is suddenly shorted out, the MOSFET power dissipation can rise to very high levels, jeopardizing the MOSFET even before the normal current limit circuit can respond. A separate short-circuit current limit circuit watches for significant overcurrent events ($V_{SENSE} > 275\text{mV}$, $> 550\text{mA}$ with a 0.5 Ω sense resistor) and pulls the GATE pin down immediately if such an event occurs, shutting off the MOSFET in less than 1 μs (with no external capacitor on GATE). Approximately 100 μs later, GATE is allowed to rise back up and the normal current limit circuit will take over, allowing I_{LIM} current to flow and causing the t_{ICUT} timer to count up. During a short circuit, I_{LIM} will be reduced by the foldback feature to 1/7th of the nominal value.

Figures 14 and 15 show the LTC4258 controlling port current during short circuits. In Figure 14, the MOSFET is turned off 0.5 μs after the port is shorted with 1 Ω . The spike in port voltage and current at the moment the MOSFET turns off is the response of inductance in the system, such as the magnetics and the Ethernet cable; see Surge Suppressors and Circuit Protection for further details. The 0.1 μF port bypass cap (see Figure 1) provides some port current for 0.25 μs after the MOSFET is off. In Figure 15, the LTC4258 quickly turns the port off and the

spike above ground is again due to inductance. It then ramps the MOSFET gate up, similar to applying power after a PD is detected, bringing the port into a controlled 425mA (typ) I_{LIM} current limit. When the short is removed, the port current no longer needs to be limited and LTC4258 ramps up its GATE pin to fully enhance the MOSFET. Short-circuit protection quickly stops excessive current and limits the energy delivered to a short or faulty PD. Yet the LTC4258 only stops current briefly, so momentary faults typically do not cause the PD to lose power and PDs receive at least 50ms of 400mA to 450mA peak current as required by the 802.3af standard.

APPLICATIONS INFORMATION

Choosing External MOSFETs

Power delivery to the ports is regulated with external power MOSFETs. These MOSFETs are controlled as previously described to meet the IEEE 802.3af specification. Under normal operation, once the port is powered and the PD's bypass capacitor is charged to the port voltage, the external MOSFET dissipates very little power. This suggests that a small MOSFET is adequate for the job. Unfortunately, other requirements of the IEEE 802.3af mandate a MOSFET capable of dissipating significant power. When the port is being powered up, the port voltage must reach 30V or more before the PD turns on. The port voltage can then drop to 0V as the PD's bypass capacitor is charged. According to the IEEE, the PD can directly connect a 180 μ F capacitor to the port and the PSE must charge that capacitor with a current limit of 400mA to 450mA for at least 50ms.

An even more extreme example is a noncompliant PD that provides the proper signature during detection but then behaves like a low valued resistor, say 50 Ω , in parallel with a 1 μ F capacitor. When the PSE has charged this noncompliant PD up to 20V, the 50 Ω resistor will draw 400mA (the minimum IEEE prescribed I_{LIM} current limit) keeping the port voltage at 20V for the remainder of t_{START} . The external MOSFET sees 24V to 37V V_{DS} at 400mA to 450mA, dissipating 9.6W to 16.7W for 60ms (typ).

The LTC4258 implements foldback to reduce the current limit when the MOSFET V_{DS} is high; see the Foldback section. Without foldback, the MOSFET could see as much as 25.7W for 60ms (typ) when powering a shorted or a noncompliant PD with only a few ohms of resistance. With foldback, the MOSFET sees a maximum of 18W for the duration of t_{START} .

The LTC4258's duty cycle protection enforces 15 times longer off time than on time, preventing successive attempts to power a defective PD from damaging the MOSFET. System software can enforce even longer wait times. When the LTC4258 is operated in semiauto or manual mode—described in more detail under Operating Modes—

it will not power on a port until commanded to do so by the host controller. By keeping track of t_{START} and t_{CUT} faults, the host controller can delay turning on the port again after one of these faults even if the LTC4258 reports a Detect Good. In this way the host controller implements a MOSFET cooling off period which may be programmed to protect smaller MOSFETs from repeated thermal cycling. The LTC4258 has built-in duty cycle protection for t_{CUT} and t_{START} (see t_{CUT} Timing and t_{START} Timing sections) that is sufficient to protect the MOSFETs shown in Figure 1.

Before designing a MOSFET into your system, carefully compare its safe operating area (SOA) with the worst case conditions (like powering up a defective PD) the device will face. Using transient suppressors, polyfuses and extended wait times after disconnecting a PD are effective strategies to reduce the extremes applied to the external MOSFETs.

Surge Suppressors and Circuit Protection

IEEE 802.3af Power over Ethernet is a challenging Hot Swap application because it must survive the (probably unintentional) abuse of everyone in the building. While hot swapping boards in a networking or telecom card cage is done by a trained technician or network administrator, anyone in the building can plug a device into the network. Moreover, in a card cage the physical domain being powered is confined to the card cage. With Power over Ethernet, the PSE supplies power to devices up to 100 meters away. Ethernet cables could potentially be cut, shorted together, and so on by all kinds of events from a contractor cutting into walls to someone carelessly sticking a screwdriver where it doesn't belong. Consequently, the Power over Ethernet power source (PSE) must be designed to handle these events.

The most dramatic of these is shorting a powered port. What the PSE sees depends on how much CAT-5 cable is between it and the short. If the short occurs on the far end of a long cable, the cable inductance will prevent the

APPLICATIONS INFORMATION

current in the cable from increasing too quickly and the LTC4258's built-in short-circuit protection will take control of the situation and turn off the port. Some energy is stored in the cable, but the transient suppressor on the port clamps the port voltage when the cable inductance causes the voltage to fly back after the MOSFET is turned off. Because the cable only had 600mA or so going through it, an SMAJ58A or equivalent device can easily control the port voltage during flyback. With no cable connected at all, a powered port shorted at the PSE's RJ-45 connector can reach high current levels before the port is shut down. There is no cable inductance to store energy so once the port is shut down the situation is under control.

A short—hence low inductance—piece of CAT-5 will not limit the rapid increase of current when the port is shorted. Even though the LTC4258 short-circuit shutdown is fast, the cable may have many amps flowing through it before the MOSFET can be turned off. Due to the high current, this short piece of cable flies back with significant energy behind it and must be controlled by the transient suppressor. Choosing a surge suppressor that will not develop more than a few volts of forward voltage while passing more than 10A is important. A positive port voltage may forward bias the detect diode (D_{DETn}), bringing the LTC4258's DETECT n pin positive as well and engaging the DETECT n clamps. This will generally not damage the LTC4258 but extreme cases can cause the LTC4258 to reset. When it resets, the LTC4258 signals an interrupt, alerting the host controller which can then return the LTC4258 to normal operating mode.

A substantial transient surge suppressor can typically protect the LTC4258 and the rest of the PSE from these faults. Placing a polyfuse between the RJ-45 connector and the LTC4258 and its associated circuitry can provide additional protection. To meet safety requirements, place the polyfuse in the ground leg of the PSE's output.

DC DISCONNECT

DC disconnect monitors the sense resistor voltage whenever the power is on to make sure that the PD is drawing the minimum specified current. The disconnect timer counts up whenever port current is below 7.5mA (typ). If the t_{DIS} timer runs out, the corresponding port will be turned off and the disconnect bit in the fault register will be set. If the undercurrent condition goes away before the t_{DIS} timer runs out, the timer will reset. The timer will start counting from the beginning if the undercurrent condition occurs again. The undercurrent circuit includes a glitch filter to filter out noise.

The DC disconnect feature can be disabled by clearing the corresponding DC Discon Enable bits in the Disconnect register (13h). The t_{DIS} timer duration can be programmed by bits 1 and 0 of register 16h.

The LTC4258 implements a variety of current sense and limit thresholds to control current flowing through the port. Figure 16 is a graphical representation of these thresholds and the action the LTC4258 takes when current crosses the thresholds.

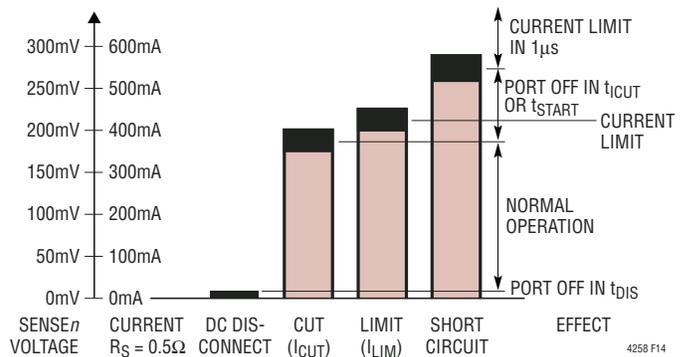

Figure 16. LTC4258 Current Sense and Limits

APPLICATIONS INFORMATION

SERIAL DIGITAL INTERFACE

The LTC4258 communicates with a host (master) using the standard 2-wire interface as described in the SMBus Specification Version 2.0 (available at <http://smbus.org>). The SMBus is an extension of the I²C bus, and the LTC4258 is also compatible with the I²C bus standard. The Timing Diagrams (Figures 5 through 9) show the timing relationship of the signals on the bus. The two bus lines, SDA and SCL, must be high when the bus is not in use. External pull-up resistors or current sources, such as the LTC1694 SMBus accelerator, are required on these lines. If the SDA and SCL pull-ups are absent, not connected to the same positive supply as the LTC4258's V_{DD} pin, or are not activated when the power is applied to the LTC4258, it is possible for the LTC4258 to see a START condition on the I²C bus. The interrupt pin ($\overline{\text{INT}}$) is only updated between I²C transactions. Therefore if the LTC4258 sees a START condition when it powers up because the SCL and SDA lines were left floating, it will not assert an interrupt (pull $\overline{\text{INT}}$ low) until it sees a STOP condition on the bus. In a typical application the I²C bus will immediately have traffic and the LTC4258 will see a STOP so soon after power up that this momentary condition will go unnoticed.

Isolating the Serial Digital Interface

IEEE 802.3af requires that network segments be electrically isolated from the chassis ground of each network interface device. However, the network segments are not required to be isolated from each other provided that the segments are connected to devices residing within a single building on a single power distribution system.

For simple devices such as small powered Ethernet switches, the requirement can be met by using an isolated power supply to power the entire device. This implementation can only be used if the device has no electrically conducting ports other than twisted-pair Ethernet. In this case, the SDAIN and SDAOUT pins of the LTC4258 can be connected together to act as a standard I²C/SMBus SDA pin.

If the device is part of a larger system, contains serial ports, or must be referenced to protective ground for some other reason, the Power over Ethernet subsystem

including the LTC4258s must be electrically isolated from the rest of the system. The LTC4258 includes separate pins (SDAIN and SDAOUT) for the input and output functions of the bidirectional data line. This eases the use of optocouplers to isolate the data path between the LTC4258s and the system controller. Figure 17 shows one possible implementation of an isolated interface. The SDAOUT pin of the LTC4258 is designed to drive the inputs of an optocoupler directly, but a standard I²C device typically cannot. U1 is used to buffer I²C signals into the optocouplers from the system controller side. Schmitt triggers must be used to prevent extra edges on transitions of SDA and SCL.

Bus Addresses and Protocols

The LTC4258 is a read-write slave device. The master can communicate with the LTC4258 using the Write Byte, Read Byte and Receive Byte protocols. The LTC4258's primary serial bus address is (010A₃A₂A₁A₀)b, as designated by pins AD3-AD0. All LTC4258s also respond to the address (0110000)b, allowing the host to write the same command into all of the LTC4258s on a bus in a single transaction. If the LTC4258 is asserting (pulling low) the $\overline{\text{INT}}$ pin, it will also acknowledge the Alert Response Address (0001100)b using the receive byte protocol.

The START and STOP Conditions

When the bus is idle, both SCL and SDA must be high. A bus master (typically the host controller) signals the beginning of communication with a slave device (like the LTC4258) by transmitting a START condition. A START condition is generated by transitioning SDA from high to low while SCL is high. A REPEATED START condition is functionally the same as a START condition, but used to extend the protocol for a change in data transmission direction. A STOP condition is not used to set up a REPEATED START condition, for this would clear any data already latched in. When the master has finished communicating with the slave, it issues a STOP condition. A STOP condition is generated by transitioning SDA from low to high while SCL is high. The bus is then free for communication with another SMBus or I²C device.

APPLICATIONS INFORMATION

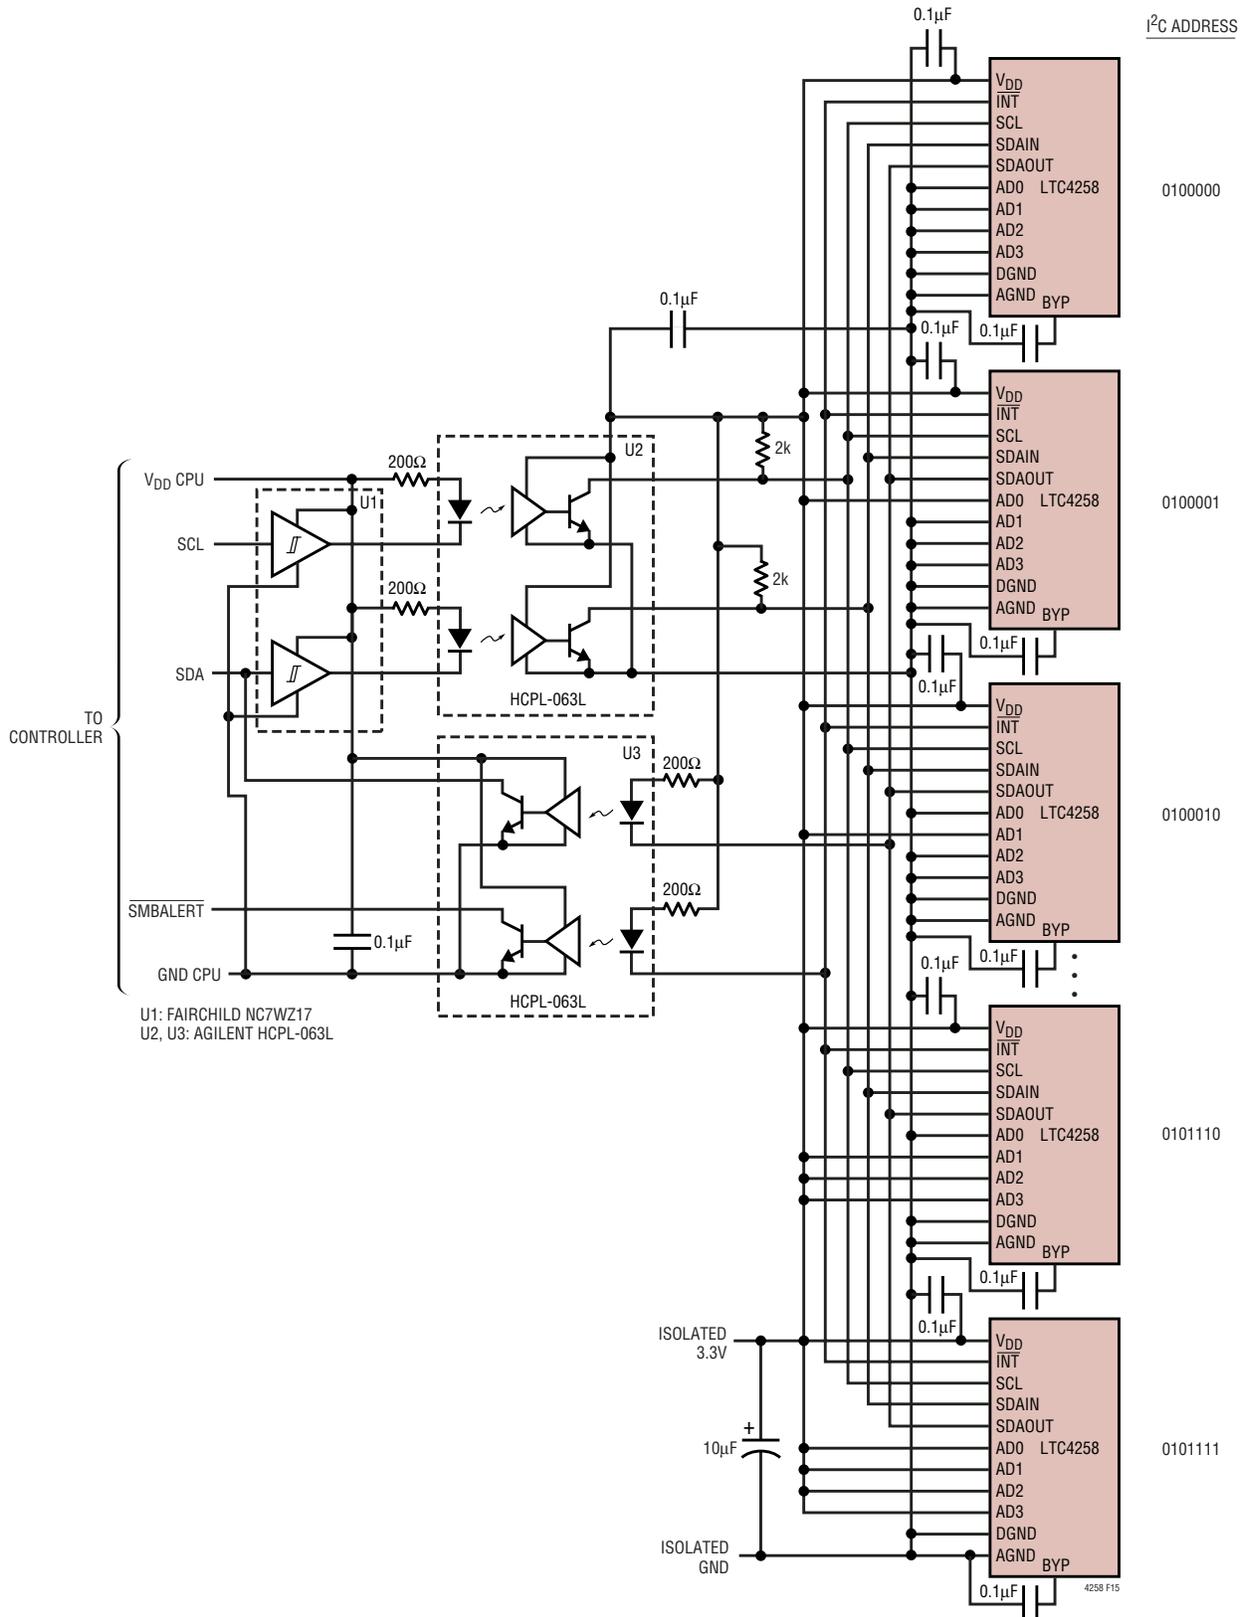

Figure 17. Optoisulating the I²C Bus

APPLICATIONS INFORMATION

Acknowledge

The Acknowledge signal is used for handshaking between the master and the slave. An Acknowledge (active LOW) generated by the slave lets the master know that the latest byte of information was received. The corresponding SCL clock pulse is always generated by the master. The master releases the SDA line (HIGH) during the Acknowledge clock pulse. The slave must pull down the SDA line during the Acknowledge clock pulse so that it remains a stable LOW during the HIGH period of this clock pulse. When the master is reading from a slave device, it is the master's responsibility to acknowledge receipt of the data byte in the bit that follows unless the transaction is complete. In that case the master will decline to acknowledge and issue the STOP condition to terminate the communication.

Write Byte Protocol

The master initiates communication to the LTC4258 with a START condition and a 7-bit bus address followed by the Write Bit (Wr) = 0. If the LTC4258 recognizes its own address, it acknowledges and the master delivers the command byte, signifying to which internal LTC4258 register the master wishes to write. The LTC4258 acknowledges and latches the lower five bits of the command byte into its Register Address register. Only the lower five bits of the command byte are checked by the LTC4258; the upper three bits are ignored. The master then delivers the data byte. The LTC4258 acknowledges once more and latches the data into the appropriate control register. Finally, the master terminates the communication with a STOP condition. Upon reception of the STOP condition, the Register Address register is cleared (see Figure 6).

Read Byte Protocol

The master initiates communication from the LTC4258 with a START condition and the same 7-bit bus address followed by the Write Bit (Wr) = 0. If the LTC4258 recognizes its own address, it acknowledges and the master delivers the command byte, signifying which internal LTC4258 register it wishes to read from. The LTC4258 acknowledges and latches the lower five bits of the command byte into its Register Address register. At this time the master sends a REPEATED START condition and the same 7-bit bus address followed by the Read Bit

(Rd) = 1. The LTC4258 acknowledges and sends the contents of the requested register. Finally, the master declines to acknowledge and terminates communication with a STOP condition. Upon reception of the STOP condition, the Register Address register is cleared (see Figure 7).

Receive Byte Protocol

Since the LTC4258 clears the Register Address register on each STOP condition, the interrupt register (register 0) may be read with the Receive Byte Protocol as well as with the Read Byte Protocol. In this protocol, the master initiates communication with the LTC4258 with a START condition and a 7-bit bus address followed by the Read Bit (Rd) = 1. The LTC4258 acknowledges and sends the contents of the interrupt register. The master then declines to acknowledge and terminates communication with a STOP condition (see Figure 8).

Alert Response Address and the \overline{INT} Pin

In a system where several LTC4258s share a common \overline{INT} line, the master can use the Alert Response Address (ARA) to determine which LTC4258 initiated the interrupt.

The master initiates the ARA procedure with a START condition and the 7-bit ARA bus address (0001100)_b followed by the Read Bit (Rd) = 1. If an LTC4258 is asserting the \overline{INT} pin, it acknowledges and sends its 7-bit bus address (010A₃A₂A₁A₀)_b and a 1 (see Figure 9). While it is sending its address, it monitors the SDA_{IN} pin to see if another device is sending an address at the same time using standard I²C bus arbitration. If the LTC4258 is sending a 1 and reads a 0 on the SDA_{IN} pin on the rising edge of SCL, it assumes another device with a lower address is sending and the LTC4258 immediately aborts its transfer and waits for the next ARA cycle to try again. If transfer is successfully completed, the LTC4258 will stop pulling down the \overline{INT} pin. When the \overline{INT} pin is released in this way or if a 1 is written into the Clear Interrupt pin bit (bit 6 of register 1Ah), the condition causing the LTC4258 to pull the \overline{INT} pin down must be removed before the LTC4258 will be able to pull \overline{INT} down again. This can be done by reading and clearing the event registers or by writing a 1 into the Clear All Interrupts bit (bit 7 of register

APPLICATIONS INFORMATION

1Ah). The state of the $\overline{\text{INT}}$ pin can only change between I²C transactions, so an interrupt is cleared or new interrupts are generated after a transaction completes and before new I²C bus communication commences. Periodic polling of the alert response address can be used instead of the $\overline{\text{INT}}$ pin if desired. If any device acknowledges the alert response address, then the $\overline{\text{INT}}$ line, if connected, would have been low.

System Software Strategy

Control of the LTC4258 hinges on one decision, the LTC4258's operating mode. The three choices are described under Operating Modes. In Auto mode the LTC4258 can operate autonomously without direction from a host controller. Because LTC4258s running in Auto mode will power every valid PD connected to them, the PSE must have 15.4W/port available. To reduce the power requirements of the -48V supply, PSE systems can track power usage, only turning on ports when sufficient power is available. The IEEE describes this as a power allocation algorithm and places two limitations: the PSE shall not power a PD unless it can supply the guaranteed power for that PD's class (see Table 2) and power allocation may not be based solely on a history of each PD's power consumption. In order for a PSE to implement power allocation, the PSE's processor/controller must control whether ports are powered—the LTC4258 cannot be allowed to operate in Auto mode. Semiauto mode fits the bill as the LTC4258 automatically detects and classifies PDs, then makes this information available to the host controller, which decides to apply power or not. Operating the LTC4258 in Manual mode also lets the controller decide whether to power the ports but the controller must also control detection and classification. If the host controller operates near the limit of its computing resources, it may not be able to guide a Manual mode LTC4258 through detect, classification and port turn-on in less than the IEEE mandated maximum of 950ms.

In a typical PSE, the LTC4258s will operate in Semiauto mode as this allows the controller to decide to power a port without unduly burdening the controller. With an interrupt mask of F4h, the LTC4258 will signal to the host after it has successfully detected and classified a PD, at

which point the host can decide whether enough power is available and command the LTC4258 to turn that port on. Similarly, the LTC4258 will generate interrupts when a port's power is turned off. By reading the LTC4258's interrupt register, the host can determine if a port was turned off due to overcurrent (t_{START} or t_{CUT} faults) or because the PD was removed (Disconnect event). The host then updates the amount of available power to reflect the power no longer consumed by the disconnected PD. Setting the MSB of the interrupt mask causes the LTC4258 to communicate fault conditions caused by failures within the PSE, so the host does not need to poll to check that the LTC4258s are operating properly. This interrupt driven system architecture provides the controller with the final say on powering ports at the same time, minimizing the controller's computation requirements because interrupts are only generated when a PD is detected or on a fault condition.

The LTC4258 can also be used to power older powered Ethernet devices that are not 802.3af compliant and may be detected with other methods. Although the LTC4258 does not implement these older detection methods automatically, if software or external circuitry can detect the noncompliant devices, the host controller may command the LTC4258 to power the port, bypassing IEEE compliant detection and classification and sending power to the noncompliant device.

LOGIC LEVEL SUPPLY

In addition to the 48V used to source power to each port, a logic level supply is required to power the digital portion of the LTC4258. To simplify design and meet voltage isolation requirements, the logic level supply can be generated from the isolated -48V supply. Figure 18 shows an example method using an LTC3803 to control a -48V to 3.3V current mode supply. This boost converter topology uses the LTC3803 current mode controller and a current mirror which reflects the 3.3V output voltage to the -48V rail, improving the regulation tolerance over the more traditional large resistor voltage divider. This approach achieves high accuracy with a transformerless design.

APPLICATIONS INFORMATION

IEEE 802.3af COMPLIANCE AND EXTERNAL COMPONENT SELECTION

The LTC4258 is designed to control power delivery in IEEE 802.3af compliant Power Sourcing Equipment (PSE). Because proper operation of the LTC4258 may depend on external signals and power sources, like the -48V supply (V_{EE}), external components such as the sense resistors (R_S), and possibly software running on an external micro-processor, using the LTC4258 in a PSE does not guarantee 802.3af compliance. Using an LTC4258 does get you most of the way there. This section discusses the rest of the elements that go along with the LTC4258 to make an 802.3af complaint PSE. Each paragraph below addresses a component which is critical for PSE compliance as well as possible pitfalls that can cause a PSE to be noncompliant. For further assistance please contact Linear Technology's Applications department.

Sense Resistors

The LTC4258 is designed to use a 0.5Ω sense resistor, R_S , to monitor the current through each port. The value of the sense resistor has been minimized in order to reduce power loss and as a consequence, the voltage which the

LTC4258 must measure is small. Each port may be drawing up to 450mA with this current flowing through the sense resistor and associated circuit board traces. To prevent parasitic resistance on the circuit board from obscuring the voltage drop across the sense resistor, the LTC4258 must Kelvin sense the resistor voltage. One way to achieve Kelvin sensing is "star grounding," shown pictorially in Figure 1. Another option is to use a -48V power plane to connect the sense resistor and the LTC4258 V_{EE} pin. Either of these strategies will prevent voltages developed across parasitic circuit board resistances from affecting the LTC4258 current measurement accuracy. The precision of the sense resistor directly affects the measurement of the IEEE parameters I_{INRUSH} , I_{LIM} , I_{CUT} and I_{MIN} . Therefore, to maintain IEEE compliance, use a resistor with 0.5% or better accuracy.

Power MOSFETs

The LTC4258 controls power MOSFETs in order to regulate current flow through the Ethernet ports. Under certain conditions these MOSFETs have to dissipate significant power. See the Choosing External MOSFETs section for a detailed discussion of the requirements these devices must meet.

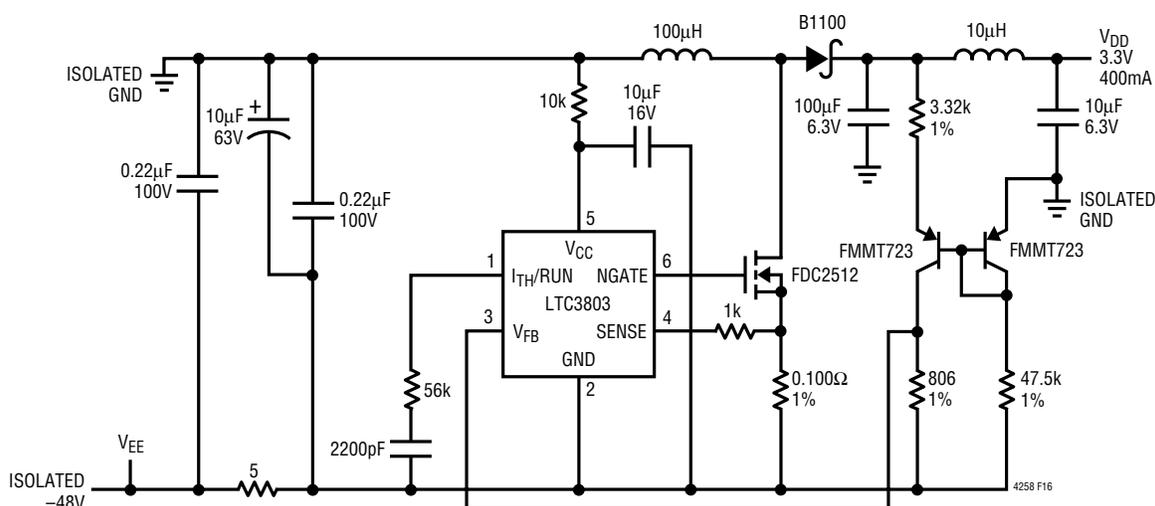

Figure 18. -48V to 3.3V Boost Converter

APPLICATIONS INFORMATION

Common Mode Chokes

Both nonpowered and powered Ethernet connections achieve best performance (for data transfer, power transfer and EMI) when a common mode choke is used on each port. In the name of cost reduction, some designs share a common mode choke between two adjacent ports. Even for nonpowered Ethernet, sharing a choke is not recommended. With two ports passing through the choke, it cannot limit the common mode current of either port. Instead, the choke only controls the sum of both ports' common mode current. Because cabling from the ports generally connects to different devices up to 200m apart, a current loop can form. In such a loop, common mode current flows in one port and out the other, and the choke will not prevent this because the sum of the currents is zero. Another way to view this interaction between the paired ports is that the choke acts as a transformer coupling the ports' common modes together. In nonpowered Ethernet, common mode current results from nonidealities like ground loops; it is not part of normal operation. However, Power over Ethernet sends power and hence significant current through the ports; common mode current is a byproduct of normal operation. As described in the Choosing External MOSFETs section and under the Power Supplies heading below, large transients can occur when a port's power is turned on or off. When a powered port is shorted (see Surge Suppressors and Circuit Protection), a port's common mode current may be excessive. Sharing a common mode choke between two ports couples start-up, disconnect and fault transients from one port to the other. The end result can range from momentary noncompliance with 802.3af to intermittent behavior and even to excessive voltages that may damage circuitry (in both the PSE and PD) connected to the ports.

Detect Pin Diodes

During detection and classification, the LTC4258 senses the port voltage through the detect diodes D_{DET} . Excessive voltage drop across D_{DET} will corrupt the LTC4258's detect and classification results. Select a diode for D_{DET} that will have less than 0.7V of forward drop at 0.4mA and less than 0.9V of forward drop at 50mA.

Power Supplies

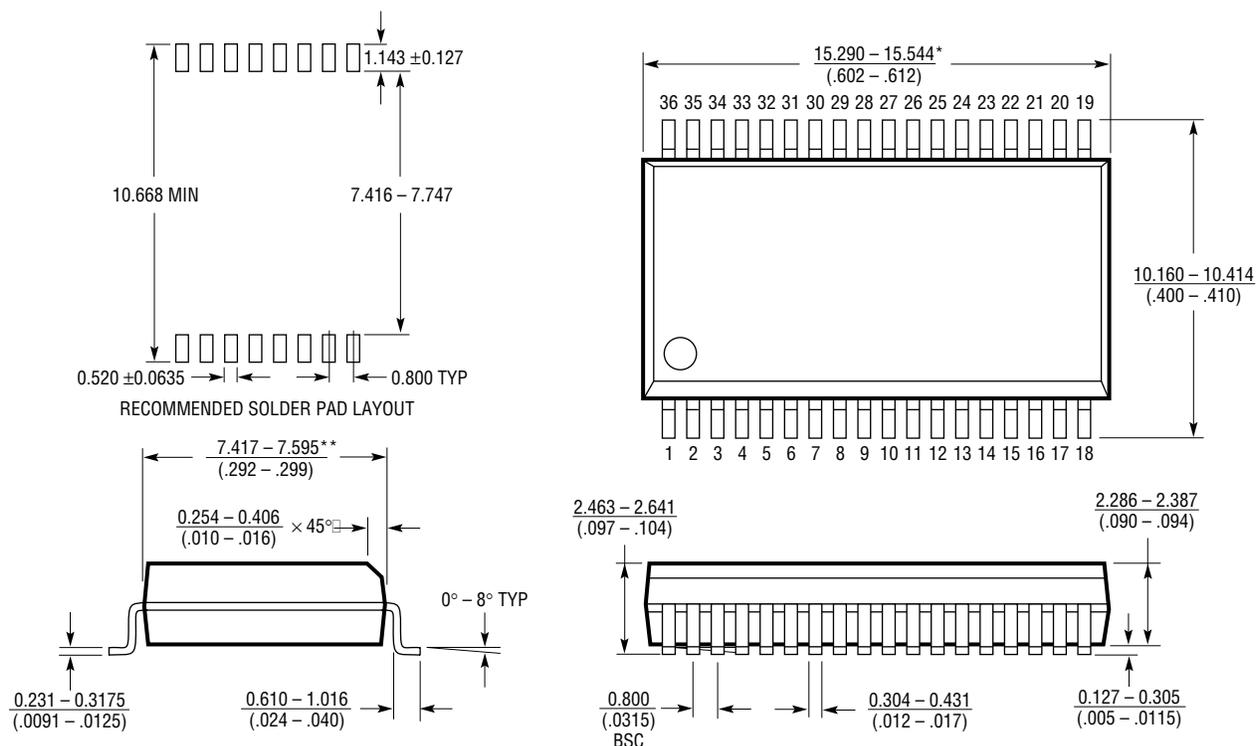

The LTC4258 must be supplied with 3.3V (V_{DD}) and $-48V$ (V_{EE}). Poor regulation on either of these supplies can lead to noncompliance. The IEEE requires a PSE output voltage between 44V and 57V. When the LTC4258 begins powering an Ethernet port, it controls the current through the port to minimize disturbances on V_{EE} . However, if the V_{EE} supply is underdamped or otherwise unstable, its voltage could go outside of the IEEE specified limits, causing all ports in the PSE to be noncompliant. This scenario can be even worse when a PD is unplugged because the current can drop immediately to zero. In both cases the port voltage must always stay between $-44V$ and $-57V$. In addition, the 802.3af specification places specific ripple, noise and load regulation requirements on the PSE. Among other things, disturbances on either V_{DD} or V_{EE} can adversely affect detection and classification sensing. Proper bypassing and stability of the V_{DD} and V_{EE} supplies is important.

Another problem that can affect the V_{EE} supply is insufficient power, leading to the supply voltage drooping out of the specified range. The 802.3af specification states that if a PSE powers a PD it must be able to provide the maximum power level requested by the PD based on the PD's classification. The specification does allow a PSE to choose not to power a port because the PD requires more power than the PSE has left to deliver. If a PSE is built with a V_{EE} supply capable of less than $15.4W \cdot (\text{number of PSE's Ethernet ports})$, it must implement a power allocation algorithm that prevents ports from being powered when there is insufficient power. Because the specification also requires the PSE to supply 400mA at up to a 5% duty cycle, the V_{EE} supply capability should be at least a few percent more than the maximum total power the PSE will supply to PDs. Finally, the LTC4258s draw current from V_{EE} . If the V_{DD} supply is generated from V_{EE} , that power divided by the switcher efficiency must also be added to the V_{EE} supply's capability.

Fast V_{EE} transients can damage the LTC4258. Limit the V_{EE} slew rate to $50mV/\mu s$. In most applications, existing V_{EE} bypass capacitors will cause the V_{EE} supply to slew much slower than $50mV/\mu s$.

PACKAGE DESCRIPTION

GW Package 36-Lead Plastic SSOP (Wide .300 Inch) (Reference LTC DWG # 05-08-1642)

NOTE:

1. CONTROLLING DIMENSION: MILLIMETERS
2. DIMENSIONS ARE IN $\frac{\text{MILLIMETERS}}{\text{(INCHES)}}$

*DIMENSION DOES NOT INCLUDE MOLD FLASH. MOLD FLASH SHALL NOT EXCEED 0.152mm (0.006") PER SIDE

**DIMENSION DOES NOT INCLUDE INTERLEAD FLASH. INTERLEAD FLASH SHALL NOT EXCEED 0.254mm (0.010") PER SIDE

GW36 SSOP 0502

TYPICAL APPLICATION

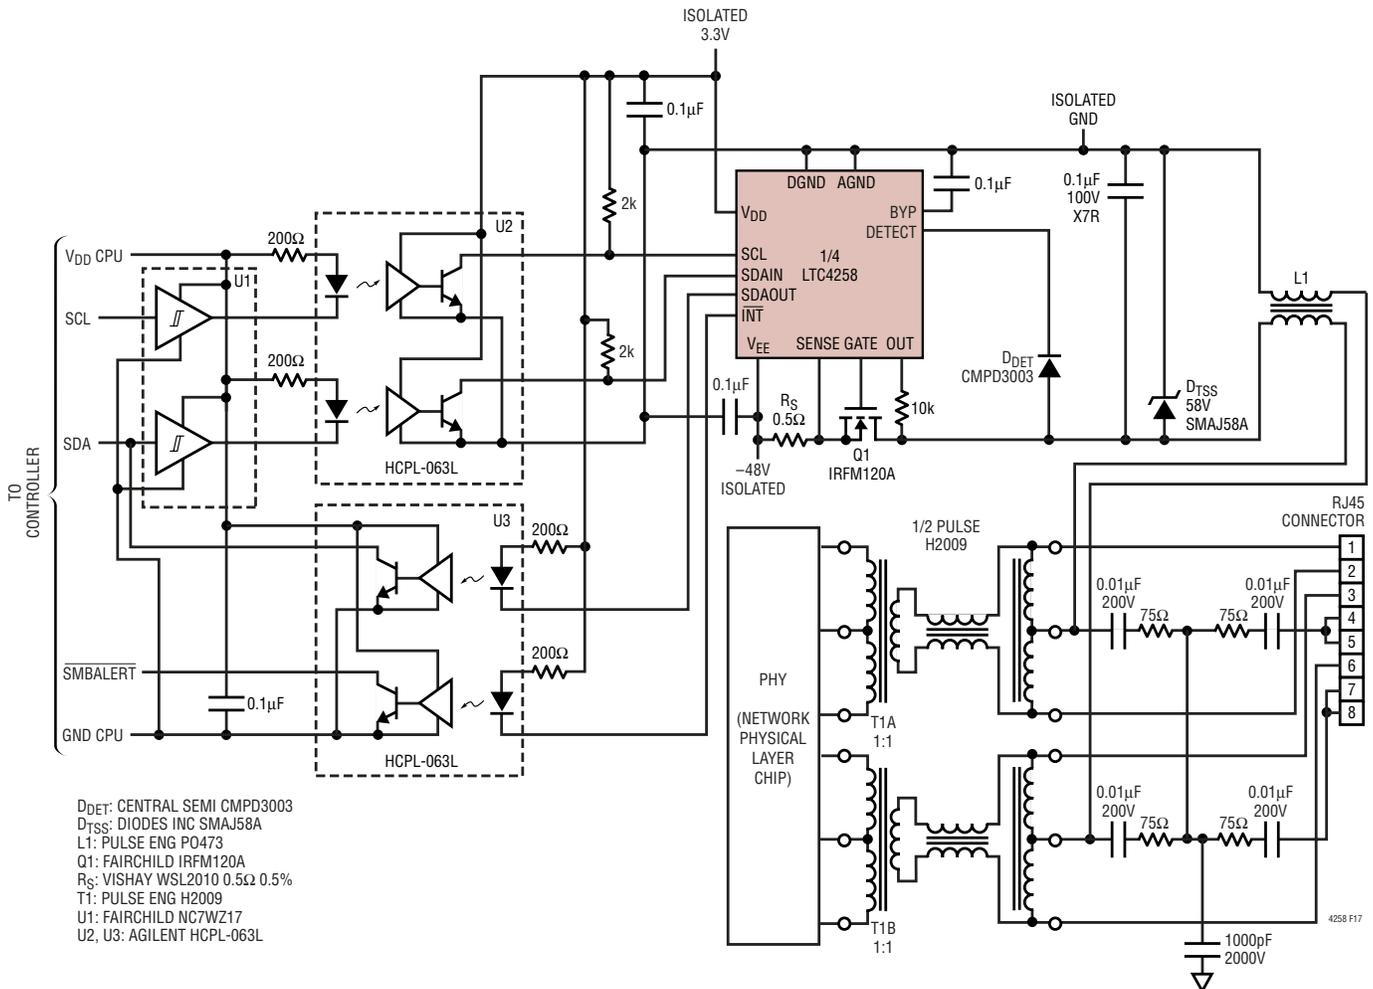

Figure 19. One Complete Isolated Powered Ethernet Port

RELATED PARTS

| PART NUMBER | DESCRIPTION | COMMENTS |
|-------------|--|---|
| LT1619 | Low Voltage Current Mode PWM Controller | -48V to 3.3V at 300mA, MSOP Package |
| LTC1694 | SMBus/I ² C Accelerator | Improved I ² C Rise Time, Ensures Data Integrity |
| LTC3803 | Current Mode Flyback DC/DC Controller in ThinSOT | 200kHz Constant Frequency, Adjustable Slope Compensation, Optimized for High Input Voltage Applications |
| LTC4255 | Quad Network Power Controller | Non-IEEE 802.3af Compliant Current Levels |
| LTC4257 | IEEE 802.3af PD Interface Controller | 100V 400mA Internal Switch, Programmable Classification |
| LTC4257-1 | IEEE 802.3af PD Interface Controller | 100V 400mA Internal Switch, Dual Current Limit |
| LTC4259A-1 | Quad IEEE 802.3af Power Over Ethernet Controller | With AC Disconnect |
| LTC4267 | IEEE802.3af PD Interface with Integrated Switching Regulator | 100V, 400mA UVLO Switch, Dual Inrush Current, Programmable Classification |
