FEATURES

- Allows Multiple Slaves with the Same Address to Coexist on the Same Bus
- Resistor Configurable Address Translation
- No Software Programming Required
- Compatible with SMBus, I²C and I²C Fast Mode
- Pass-Through Mode Allows General Call Addressing
- ±4kV HBM ESD Ruggedness
- Level Translation for 2.5V, 3.3V and 5V Buses
- Stuck Bus Timeout
- Prevents SDA and SCL Corruption During Live Board Insertion and Removal
- Support Bus Hot Swap
- 10-Lead MSOP and DFN 3mm × 3mm Packages

APPLICATIONS

- I²C, SMBus Address Expansion
- Address Translation
- Servers
- Telecom

DESCRIPTION

The LTC®4316 enables the hardwired address of one or more I²C or SMBus slave devices to be translated to a different address. This allows slaves with the same hardwired address to coexist on the same bus. Only discrete resistors are needed to select the new address and no software programming is required. Up to 127 different address translations are available.

The LTC4316 incorporates a pass-through mode which disables the address translation and allows general call addressing by the master. The LTC4316 is designed to automatically recover from abnormal bus conditions like bus stuck low or premature STOP bits.

**Note 1:** Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

**Note 2:** All currents into pins are positive and all voltages are referenced to GND unless otherwise indicated.

**Note 3:** Guaranteed by design and not tested.
For more information www.linear.com/LTC4316
TYPICAL PERFORMANCE CHARACTERISTICS  \( T_A = 25^\circ C, \ V_{CC} = 3.3V \) unless otherwise noted.

**PIN FUNCTIONS**

**XORL:** Translator XOR Lower Nibble Configuration Input. The DC voltage at this pin configures the lower 4-bit nibble of the address translation byte. Tie the pin to an external resistive divider connected between \( V_{CC} \) and GND to set the desired DC voltage.

**XORH:** Translator XOR Upper Nibble Configuration Input. The DC voltage at this pin configures the upper 3-bit nibble of the address translation byte. Tie the pin to an external resistive divider connected between \( V_{CC} \) and GND to set the desired DC voltage. Connect this pin to \( V_{CC} \) to activate pass-through mode. See Application Information section for more details.

**ENABLE:** Enable Input. If ENABLE pin is low, the address translation is disabled, SDAIN is disconnected from SDAOUT, and SCLIN is disconnected from SCLOUT. A low to high transition on ENABLE restarts the configuration of the address translation byte and also enables the address translation. Connect to \( V_{CC} \) if unused.

**Exposed Pad (DFN Package Only):** Exposed pad may be left open or connected to device GND.

**GND:** Device Ground.

**READY:** Ready Status Output. This is an open drain output to indicate that the device is ready for address translation. The pin releases high when the LTC4316 has completed configuration of the address translation byte. SDAIN is connected to SDAOUT and SCLIN is connected to SCLOUT. Connect a pull-up resistor, typically 10k, from this pin to the bus pull-up supply. Leave open or tie to GND if unused.

**SCLIN:** Input Bus Clock Input and Output. Connect this pin to the SCL line on the master side. An external pull-up resistor or current source is required.

**SCLOUT:** Output Bus Clock Input and Output. Connect this pin to the SCL line on the slave side. An external pull-up resistor or current source is required.

**SDAIN:** Input Bus Data Input and Output. Connect this pin to the SDA line on the master side. An external pull-up resistor or current source is required.

**SDAOUT:** Output Bus Data Input and Output. Connect this pin to the SDA line on the slave side. An external pull-up resistor or current source is required.

**VCC:** Power Supply Input (2.25V to 5.5V). If the supply voltages for the input and output buses are different, connect this pin to the lower supply. If the input and output supplies have the same nominal value and with tolerance less than or equal to \( \pm 10\% \), connect \( V_{CC} \) to either supply. Bypass with at least 0.1\( \mu F \) to GND.
The LTC4316 is an I²C/SMBus address translator. It bridges two segments of an I²C bus, reading incoming addresses on the master side and retransmitting them to the slave side with the 7-bit I²C addresses translated in real time. This allows multiple I²C devices with the same address to be connected to the same bus without interference.

The translated addresses are configured with external resistors, and no extra software is required. An ENABLE pin allows bus segments to be enabled and disabled, and the LTC4316 allows hot swapping isolated bus segments together.
OPERATION

Figure 1 shows an I²C master connected to the input bus of the LTC4316 (SCLIN and SDAIN). The slave devices requiring address translation are connected to the output bus of the LTC4316 (SCLOUT and SDAOUT). Any other slave devices that do not require address translation are placed together with the master on the input bus of the LTC4316. Two switches (N1 and N2) inside the LTC4316 connect the input bus to the output bus. N1 connects SCLIN to SCLOUT while N2 connects SDAIN to SDAOUT. In most conditions, N1 and N2 stay on so that the input and output buses are connected.

Translation starts when the master issues a START bit (SDAIN goes low while SCLIN is high). The LTC4316 turns off N2 to disconnect SDAIN from SDAOUT. As the master sends the address byte, the LTC4316 translates the incoming address at the SDAIN pin to a new address at the SDAOUT pin by XORing each incoming bit with a user-configurable translation byte, one bit at a time. N3 turns on and off to send out the new address to the SDAOUT pin. Once all 7 bits of the address are processed, the LTC4316 turns on N2 again to reconnect SDAIN to SDAOUT. The master then transmits the R/W bit directly to the slave. If the new, translated address on SDAOUT matches the slave’s address, the slave pulls SDAOUT low to acknowledge (ACK bit). N2 remains on and the rest of the data bytes are transmitted unmodified between the master and slave. The address translation process restarts when the master issues a new START bit.

Figure 2 shows typical waveforms for the circuit on the front page. In this example, the master transmits address 0x34 while the slave is configured to respond to address 0x36. The resistive dividers at the XORL and XORH pins are configured to generate an address translation byte of 0x02.

Note that in this example, the 8-bit hexadecimal address format (with R/W=0) is used. 7-bit addresses are also commonly found in I²C device documentation. Make sure to use the correct format when calculating the address translation byte. Table 1 shows examples of both formats.

Figure 1. Basic Functions of the LTC4316

Figure 2. Basic Address Translation Waveforms
**LTC4316**

**Operation**

**Setting the Translation Byte**

When the LTC4316 is first powered up or any time a rising edge is detected on the ENABLE pin, the LTC4316 reads the voltages at XORH and XORL pins to determine the 7-bit translation byte. These voltages are referenced to VCC so a resistive divider at each of these pins is the most convenient way to set the voltages. The required translation byte can be determined by taking the bitwise XOR of the slave’s original address and the desired input address.

The voltages at the XORH and XORL pins configure the translation byte. The XORL voltage configures the lower 4 translation bits (excluding the R/W bit), while the XORH voltage configures the upper 3 translation bits. Tables 2 and 3 show the recommended resistive divider values. RLT and RLB are the top and bottom resistors connected to XORL, while RHT and RHB are the top and bottom resistors connected to XORH (Figure 5). Use 1% tolerance resistors for RLT, RLB, RHT and RHB.

**System Configurations**

There are several ways that individual slaves or banks of slaves can be connected to an LTC4316. In Figure 3, each slave is paired with an LTC4316. This configuration allows for maximum flexibility in allocating the bus addresses. Both read and write operations and all protocols supported by the LTC4316 are allowed. Figure 4 shows two slaves with different hardwired addresses translated to two different addresses using a single LTC4316 and a common translation byte. A program is available to help the user visualize an I²C bus with the LTC4316; this program can be found in the following link:

For more information [www.linear.com/LTC4316](http://www.linear.com/LTC4316)
For more information www.linear.com/LTC4316
OPERATION

N1, N2 and N3 are off, the READY pin is pulled low and the quiescent current drops to 350μA.

Precharge and Hot Swap

When the LTC4316 is first powered on, switches N1 and N2 are initially off. This allows a LTC4316 and its connected slaves to be hot swapped onto an active \( \text{I}^2\text{C} \) bus. Internal precharge circuitry initially sets the bus lines to 1V through a 200k resistor, minimizing disturbance to an active bus when the LTC4316 is connected. The LTC4316 keeps N1 and N2 off until ENABLE goes high, the XORL/XORH pins are read, and both sides of the \( \text{I}^2\text{C} \) bus are idle (indicated either by a STOP bit or all bus pins high for longer than 120μs). Once these conditions are met, N1 and N2 turn on, and the READY pin goes high to indicate that the LTC4316 is ready to start address translation.

Pass-Through Mode

If the master wants to communicate with the slave using the general call address, it can temporarily disable address translation by pulling XORH high. This disables address translation and keeps N1 and N2 on regardless of the activity on the buses. Any translation that may be in progress is stopped immediately when XORH goes high.

Extra Transitions on SDAOUT

In an \( \text{I}^2\text{C} \)/SMBus system, the master changes the state of the SDA line when SCL is low. The LTC4316 also advances the address translation byte shift register when the SCLIN is low. The translation byte transitions occur approximately 100ns after the falling edge of SCLIN. If the SDAIN transitions sent by the master do not coincide exactly with the LTC4316 address translation bit transitions, an extra transition on SDAOUT may appear (Figure 7). These extra SDA transitions are like glitches similar to those occurring during normal Acknowledge bit transitions and do not pose problems in the system because devices on the bus latch SDA data only when SCL is high.

Level Translation and Supply Voltage Matching

The LTC4316 can operate with different supply voltages on the input and output bus, and it will level shift the voltages on the SCLIN, SDAIN, SClOUT, and SDAOUT pins to match the supply voltage at each side. \( V_{\text{CC}} \) must be powered from the lower of the two supply voltages for level shifting to operate correctly. For example, if the input bus is powered by a 5V supply and the output bus is powered by a 3.3V supply, the LTC4316 \( V_{\text{CC}} \) pin must be connected to the 3.3V supply as shown in Figure 8.

Extra START and STOP Bits

During normal operation, an \( \text{I}^2\text{C} \) master should not issue a START or STOP bit within a data byte. \( \text{I}^2\text{C} \) slave behavior when such a command is received can be unpredictable. The LTC4316 will recover automatically when an unexpected START or STOP is received during the address byte; however, depending on the state of the translating bits,
OPERATION

it may convert START bits to STOP bits and vice versa, causing unexpected slave behavior.

If an START bit is received during the address byte when the active translating bit is a 1, the slave device will see a STOP bit. This will typically reset the slave and cause it to miss the remainder of the transmission. If the START bit is received while the active translating bit is a 0, the START passes through the LTC4316 unchanged. The slave will react in the same way it would if the LTC4316 was not present, and will typically reset when the master next issues a STOP bit. In both cases, the LTC4316 automatically resets at the next STOP bit and the next message will be transmitted normally.

If an STOP bit is received during the address byte, the LTC4316 will abort the address translation and ensure that a STOP bit is issued at SDAOUT to reset the slave. If the active translating bit is a 0 when the STOP arrives, it is not modified, and the slave will see the STOP and typically reset. If the active translating bit is a 1 when the STOP arrives, the slave device will see a START bit. This might leave the slave in an indeterminate state, so the LTC4316 briefly disconnects the slave from the master, adds a short delay, and then generates a STOP bit at the SDAOUT pin (Figure 9). It then reconnects the busses and waits for a START bit to begin the next transmission. Again, in both cases, the LTC4316 automatically resets and the next message will be transmitted normally.

Stuck Bus Timeout

During the address translation, if SCLIN stays low or high for more than 30ms without any transitions, the LTC4316 will abort the address translation and reconnect SDAIN to SDAOUT. It will then wait for a START bit to start a new address translation. This prevents any bus stuck low/high conditions from permanently disconnecting SDAIN from SDAOUT.

Supported Protocols

The LTC4316 is designed to support most I^2C and SMBus message protocols. The only exceptions are protocols that use pre-assigned addresses on the slave side of the bus.

Supported I^2C and SMBus Protocols

- Send/Receive Byte
- Write Byte/Word
- Read Byte/Word
- Process Call
- Block Write/Read
- Block Write-Block Read Process Call
- Extended Read and Write Commands
- General Call (I^2C only)
- Start Byte (I^2C only)
- PMBus (without PEC)

Unsupported I^2C Protocols

- 10-Bit Addressing
- Device ID
- Ultra Fast-Mode I^2C Bus Protocol

Unsupported SMBus Protocols

- SMBus Host Notify
- Address Resolution Protocol (ARP)
- Parity Error Code (PEC)
- Alert Response Address (ARA)
- PMBus (with PEC)
