0 Hz/dc to 14 GHz, Single-Pole, Four-Throw MEMS Switch with Integrated Driver

ADGM1304

FEATURES

- Fully operational down to 0 Hz/dc
- On resistance: 2.9 Ω (maximum)
- Off leakage: 0.5 nA (maximum)
- -3 dB bandwidth
  - 11 GHz (typical) for RF1, RF4
  - 14 GHz (typical) for RF2, RF3
- RF performance characteristics
  - Insertion loss: 0.26 dB (typical) at 2.5 GHz
  - Isolation: 24 dB (typical) at 2.5 GHz
  - IIP3: 69 dBm (typical)
  - RF power: 36 dBm (maximum)
- Actuation lifetime: 1 billion cycles (minimum)
  - Hermetically sealed switch contacts
  - On switching time: 75 µs (maximum)
- Integrated driver removes the need for an external driver
  - Supply voltage: 3.0 V to 3.6 V
  - CMOS/LVTTL compatible
  - Parallel and SPI interface
  - Independently controllable switches
- Switch is in an open state with no power supply present
- Requirement to avoid floating nodes on all RFx pins (see the Floating Node section)
- 24-lead, 5 mm × 4 mm × 0.95 mm, LFCSP
- Operating temperature range: 0°C to 85°C

APPLICATIONS

- Relay replacements
- Automatic test equipment: RF/high speed digital and mixed signals
- Load and probe boards: RF/high speed digital and mixed signals
- RF test instrumentation
- Reconfigurable filters and attenuators
- High performance RF switching

GENERAL DESCRIPTION

The ADGM1304 is a wideband, single-pole, four-throw (SP4T) switch, fabricated using Analog Devices, Inc., microelectromechanical system (MEMS) switch technology. This technology enables a small form factor, wide RF bandwidth, highly linear, low insertion loss switch that is operational from 0 Hz/dc to 14 GHz, making the ADGM1304 an ideal solution for a wide range of RF and precision equipment switching needs.

An integrated driver chip generates a high voltage to electrostatically actuate a switch that can be controlled by a parallel interface and a serial peripheral interface (SPI). All four switches are independently controllable.

The device is packaged in a 24-lead, 5 mm × 4 mm × 0.95 mm, lead frame chip-scale package (LFCSP).

To ensure optimum operation of the ADGM1304, the Critical Operational Requirements section must be followed exactly.

The on resistance (Ron) performance of the ADGM1304 is affected by device to device variation, channel to channel variation, cycle actuations, settling time post turn on, bias voltage, and temperature changes.

COMPANION PRODUCTS

- Quad Parametric Measurement Unit (PMU): AD5522
- SP4T MEMS Switch: ADGM1004
- Low Noise, LDO Regulators: ADP7142, LT1962, LT3045-1
- Additional companion products on the ADGM1304 product page

</table>

1. Typical specifications tested at 25°C with V_{DD} = 3.3 V.
2. RFx is RF1, RF2, RF3, and RF4. INx is IN1, IN2, IN3, and IN4.
3. Typically, the on resistance over time drifts by −0.05 Ω per decade.
4. Maximum R_{ON} over time is R_{ON (max)} + ΔR_{ON (max)} = 2.65 Ω.
5. Maximum R_{ON} after 1 billion actuations is R_{ON (max)} + ΔR_{ON (max)} = 7.9 Ω.
6. Actuating the switch at 85°C and measuring R_{ON} at 25°C is the most severe condition for ADGM1304 R_{ON} drift over actuations.
7. Failure occurs when 50% of a sample lot fails. For more details, see the Cumulative On Switch Lifetime section.
8. Switch is settled after 75 µs. Do not apply RF power between 0 µs to 75 µs.
9. Disable the internal oscillator to eliminate feedthrough. When the internal oscillator and charge pump circuitry are disabled, the V_c pin (Pin 24) must be driven with 80 V dc (V_{CP EXT}) from an external voltage supply, as outlined in Table 5, required for MEMS switch actuation.
10. The spectrum analyzer setup is as follows: RBW = 200 Hz, video bandwidth (VBW) = 2 Hz, span = 100 kHz, input attenuator = 0 dB, the detector type is peak, and the maximum hold is off. The fundamental feedthrough noise or harmonic thereof (whichever is higher) is tested.
11. For more details, see the Low Power Mode section.
12. For more details, see the Internal Oscillator Feedthrough Mitigation section.
TIMING CHARACTERISTICS

$V_{DD} = 3.0\, \text{V to 3.6\, \text{V}},\ AGND = 0\, \text{V},\ RFGND = 0\, \text{V},$ all specifications $T_{\text{MIN}}$ to $T_{\text{MAX}} = 0^\circ \text{C to 85}\, ^\circ \text{C}$, unless otherwise noted.

1 Clamp overvoltages at INx pin by internal diodes. Limit the current to the maximum ratings given.
2 This rating is with respect to the switch in the on position with no RF signal applied.
3 This rating is with respect to the switch in the off position.
4 Take proper precautions during handling, as detailed in the Handling Precautions section.
5 A safe automated handling and assembly process is achieved at this rating level by implementing industry-standard ESD controls.
6 If the device is dropped during handling, do not use the device.

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

Only one absolute maximum rating can be applied at any one time.

#### THERMAL RESISTANCE

Thermal performance is directly linked to printed circuit board (PCB) design and operating environment. Careful attention to PCB thermal design is required.

$\theta_{JA}$ is the junction to ambient thermal resistance.

$\theta_{JC}$ is the junction to case thermal resistance.

#### Table 4. Thermal Resistance

</table>

1 See JEDEC standard JESD51-2 for additional information on optimizing the thermal impedance (PCB with 3 x 3 vias).

#### ESD CAUTION

**ESD (electrostatic discharge) sensitive device.** Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

TERMINOLOGY

Insertion Loss (IL)
IL is the amount of signal attenuation between the input and output ports of the switch when the switch is in the on state. IL is expressed in decibels. Ensure that insertion loss is as small as possible for maximum power transfer.

An example calculation of insertion loss based on the setup in Figure 37 is as follows:

\[ IL = -20 \log_{10} |S_{RF2RFC}| \]

where \( S_{RF2RFC} \) is the transmission coefficient measured from RF2 to RFC with RF2 in the on position.

All unused switches are in the off position and terminated in a purely resistive load of 50 Ω.

Isolation (ISO)
ISO is the amount of signal attenuation between the input and output ports of the switch when the switch is in the off state. ISO is expressed in decibels. Ensure that isolation is as large as possible.

An example calculation of isolation based on the setup in Figure 38 is as follows:

\[ ISO = -20 \log_{10} |S_{RFCRF1}| \]

where \( S_{RFCRF1} \) is the transmission coefficient measured from RFC to RF1 with RF1 in the off position.

All unused switches are in the off position and terminated in a purely resistive load of 50 Ω.

Crosstalk (CTK)
CTK is a measure of unwanted signals coupled through from one channel to another because of parasitic capacitance. CTK is expressed in decibels.

An example calculation of crosstalk based on the setup in Figure 39 is as follows:

\[ CTK = -20 \log_{10} |S_{RF1RF2}| \]

where \( S_{RF1RF2} \) is the transmission coefficient measured from RF1 to RF2 with RF1 in the off position and RF2 in the on position.

All unused switches are in the off position and terminated in a purely resistive load of 50 Ω.

Return Loss (RL)
RL is the magnitude of the reflection coefficient (expressed in decibels), and the amount of reflected signal relative to the incident signal.

An example calculation of return loss based on the setup in Figure 37 is as follows:

\[ RL = -20 \log_{10} |S_{11}| \]

where \( S_{11} \) is the reflection coefficient of the port under test.

Third-Order Intermodulation Intercept (IIP3)
IIP3 is the intersection point of the fundamental output power (\( P_{\text{OUT}} \)) vs. input power (\( P_{\text{IN}} \)) extrapolated line and the third-order intermodulation products extrapolated line of a two-tone test. IIP3 is a figure of merit that characterizes the switch linearity.

Second-Order Intermodulation Intercept (IIP2)
IIP2 is the intersection point of the fundamental \( P_{\text{OUT}} \) vs. \( P_{\text{IN}} \) extrapolated line and the second-order intermodulation products extrapolated line of a two-tone test. IIP2 is a figure of merit that characterizes the switch linearity.

Second Harmonic (HD2)
HD2 is the amplitude of the second harmonic, where, for a signal whose fundamental frequency is \( f \), the second harmonic has a frequency \( 2f \). This measurement is a single tone test, expressed with reference to the carrier signal (dBc).

Third Harmonic (HD3)
HD3 is the amplitude of the third harmonic, where, for a signal whose fundamental frequency is \( f \), the third harmonic has a frequency \( 3f \). This measurement is a single tone test, expressed with reference to the carrier signal (dBc).

RF Power Rating
The RF power rating is the maximum level of RF power that passes through the switch without degradation to the switch lifetime when it is in the on state.

On Switching Time (\( t_{\text{ON}} \))
\( t_{\text{ON}} \) is the time it takes for the switch to turn on. It is measured from 50% of the control signal (\( I_{\text{N}} \)) to 90% of the on level. No power is applied through the switch during this test (cold switched). The switch is terminated into a 50 Ω load.

Off Switching Time (\( t_{\text{OFF}} \))
\( t_{\text{OFF}} \) is the time it takes for the switch to turn off. It is measured from 50% of the control signal (\( I_{\text{N}} \)) to 10% of the on level. No power is applied through the switch during this test (cold switched). The switch is terminated into a 50 Ω load.

Actuation Frequency
The actuation frequency refers to the speed at which the ADGM1304 can be switched on and off. It is dependent on both settling times and on to off switching times.

Wake-Up Time
The wake-up time is a measure of the time required for the voltage on \( V_{\text{CP}} \) to reach the typical voltage of 80 V after the device exits sleep mode.

Video Feedthrough
Video feedthrough is a measure of the spurious signals present at the RF ports of the switch when the control voltage is switched from high to low or from low to high without an RF signal present.
**Internal Oscillator Frequency**
The internal oscillator frequency is the value of the on-board oscillator that drives the gate control chip of the ADGM1304.

**Internal Oscillator Feedthrough**
The internal oscillator feedthrough is the amount of internal oscillator signal that feeds through to the RF pins of the switch. This signal appears as a noise spur on the RFx pin and RFC pin of the switch at the oscillator operating frequency and oscillator harmonics.

**On Resistance (R_{on})**
$R_{on}$ is the resistance of a switch in the closed (on) state measured between the package pins. Measure on resistance in 4-wire mode to eliminate any cabling or PCB series resistances.

**On Resistance Drift**
On resistance drift is the change in the on resistance of the switch over the specified criteria in Table 1.

**Continuously on Lifetime**
The continuously on lifetime measures how long the switch is left in a continuously on state. If the switch is left in the on position for an extended period, it affects the turn off mechanism of the device.

**Actuation Lifetime**
Actuation lifetime is the number of consecutive open to close to open cycles that can complete without the on resistance exceeding a specified limit and no occurrence of failures to open (FTO) or failures to close (FTC).

**Cold Switching**
Cold switching operates the switch in a mode so that no voltage differential exists between source and drain when the switch is closed or no current is flowing from source to drain when the switch opens. All switches have longer lives when cold switched.

**Hot Switching**
Hot switching is operating the switch in a mode where a voltage differential exists between source and drain when the switch is closed and/or current is flowing from RFx channel to RFC channel when the switch is opened. Hot switching results in a reduced switch life, depending on the magnitude of the open circuit voltage between the source and the drain.

**Input High Voltage (V_{INH})**
$V_{INH}$ is the minimum input voltage for Logic 1.

**Input Low Voltage (V_{INL})**
$V_{INL}$ is the maximum input voltage for Logic 0.

**Input Current (I_{INL}, I_{INH})**
$I_{INL}$ and $I_{INH}$ are the low and high input currents of the digital inputs.

**Output High Voltage (V_{OH})**
$V_{OH}$ is the minimum output voltage for Logic 1.

**Output Low Voltage (V_{OL})**
$V_{OL}$ is the maximum output voltage for Logic 0.

**Low Power Mode Current (I_{DD EXT VCP})**
$I_{DD EXT VCP}$ is the amount of supply current used by the gate driver circuitry when the internal oscillator and the charge pump circuitry are turned off by setting the EXTD_EN pin high.

**External Drive Current (I_{CP EXT VCP})**
$I_{CP EXT VCP}$ is the amount of current used by the ADGM1304 from the external 80 V power supply when the internal oscillator and charge pump circuitry are turned off by setting the EXTD_EN pin high.
THEORY OF OPERATION

The ADGM1304 is an SP4T switch fabricated using Analog Devices MEMS switch technology. This technology enables high power, low loss, low distortion GHz switches for use in demanding RF applications.

Figure 48 shows a stylized cross section graphic of the switch with dimensions. The switch is an electrostatically actuated cantilever beam connected in a 3-terminal configuration. Functionally, the switch is analogous to a field effect transistor (FET), and the terminals can be used as a source, gate, and drain.

![Figure 48. Cross Section of the MEMS Switch Design Showing the Cantilever Switch Beam (Not to Scale)](image)

When a dc actuation voltage is applied between the gate electrode and the source (the switch beam), an electrostatic force is generated, which attracts the beam toward the substrate. A separate on-board charge pump IC generates the bias voltage, and 80 V is used for actuation.

When the bias voltage between the gate and the source exceeds the threshold voltage of the switch, $V_{TH}$, the contacts on the beam touch the drain, which completes the circuit between the source and the drain and turns the switch on. When the bias voltage is removed (0 V on the gate electrode), the beam acts as a spring to generate a sufficient restoring force to open the connection between the source and the drain, break the circuit, and turn the switch off.

Figure 49 shows the SP4T MEMS switch and controller die within the LFCSP. Some of the LFCSP plastic molding material is removed to allow the MEMS switch die (right) and controller die (left) with associated wire bonds to be visible. The silicon hermetically sealed cap covering the switch die is the black rectangle on the right. Hermetically sealing the switches improves the reliability and lifetime of the switches by keeping them in a controlled atmosphere. The switch contacts do not suffer from dry switching or low power switching lifetime degradation.

![Figure 49. ADGM1304 LFCSP Package with Molding Compound Partially Removed to Show MEMS Switch Die (Right), Controller Die (Left), and Associated Wire Bonds](image)

PARALLEL DIGITAL INTERFACE

The ADGM1304 is controlled via a parallel interface. Standard CMOS/LVTTL signals applied through this interface control the actuation and release of all the switch channels of the ADGM1304. Applied gate signals are boosted to give the required voltages needed to actuate the MEMS switches.

Setting the PIN/SP1 pin low enables the parallel digital interface in 4-wire SP4T mode. In parallel mode, Pin 1 to Pin 4 (IN1 to IN4) control the switching functions of the ADGM1304. When a Logic 1 is applied to one of these pins, the gate of the corresponding switch is activated and the switch turns on. Conversely, when a Logic 0 is applied to one of these pins, the switch turns off. Note that it is possible to connect more than one RFx input to RFC at a time. Table 6 is the truth table for the ADGM1304.

Rev. H | Page 23 of 34
SPI DIGITAL INTERFACE

The ADGM1304 can be controlled via an SPI digital interface when Pin 6 (PIN/SPI) is high. The SPI is compatible with SPI Mode 0 (clock polarity (CPOL) = 0, clock phase (CPHA) = 0) and Mode 3 (CPOL = 1, CPHA = 1) and it operates with SCLK frequencies up to 10 MHz. When the SPI is active, the default mode is addressable, in which, the device registers are accessed by a 16-bit SPI command that is bound by the state of the \( \overline{CS} \) pin. The ADGM1304 can also operate in daisy-chain mode.

The SPI interface pins of the ADGM1304 are \( \overline{CS} \), SCLK, SDI, and SDO. Hold \( \overline{CS} \) low when using the SPI interface. The data on SDI is captured on the rising edge of SCLK and data is propagated out on SDO on the falling edge of SCLK. SDO has push-pull output driver architecture that does not require pull-up resistors.

Addressable Mode

Addressable mode is the default mode for the ADGM1304 on power up. A single SPI frame in addressable mode is bounded by a \( \overline{CS} \) falling edge and the succeeding \( \overline{CS} \) rising edge. It comprises 16 SCLK cycles. The timing diagram for addressable mode, in SPI Mode 0, is shown in Figure 51.

The first SDI bit indicates if the SPI command is a read or write command. The next seven bits determine the target register address. The remaining eight bits provide the data to the addressed register. The last eight bits are ignored during a read command, during which time the SDO propagates out the data contained in the addressed register.

In Mode 0, during any SPI command, SDO sends out eight alignment bits on the \( \overline{CS} \) falling edge and the first seven SCLK falling edges (in Mode 3, the first SCLK falling edge is ignored as shown in Figure 51). The alignment bits observed at SDO are 0x25.

The target register address of an SPI command is determined on the eighth SCLK rising edge. Data from the target register propagates out on the SDO pin from the eighth to the 15th SCLK falling edge during SPI reads. A register write occurs on the 16th SCLK rising edge during SPI writes.

---

**Figure 50. Addressable Mode Timing Diagram (Mode 0)**

**Figure 51. Addressable Mode Timing Diagram (Mode 3)**
**Daisy-Chain Mode**

The connection of several ADGM1304 devices in a daisy-chain configuration is possible. All devices share the same CS and SCLK lines while the SDO pin of one device forms a connection to the SDI pin of the next device, creating a shift register. In daisy-chain mode, the SDO signal is an 8-cycle delayed version of the SDI signal (see Figure 53).

The ADGM1304 can only enter daisy-chain mode from addressable mode by sending the 16-bit SPI command, 0x2500. See Figure 53 for an example of this command. When the ADGM1304 receives this command, the SDO pin of the devices sends out the same command because the alignment bits at the SDO pin are 0x25. This command allows multiple daisy-chained devices to enter daisy-chain mode in a single SPI frame. A hardware reset is required to exit daisy-chain mode.

For the timing diagram of a typical daisy-chain SPI frame, see Figure 54. When the CS pin goes high, Device 1 writes Command 0 to Bits[7:0] to the SWITCH_DATA register. Device 2 writes Command 1 to Bits[7:0] to the switches, and so on. The SPI block uses the last eight bits received through the SDI pin to update the switches. After entering daisy-chain mode, the first eight bits sent out by the SDO pin are 0x00. When CS goes high, the internal shift register value does not reset back to 0. An SCLK rising edge reads in data on the SDI pin while data is propagated out of the SDO pin on an SCLK falling edge. The expected number of SCLK cycles are a multiple of eight before the CS pin goes high. When this is not the case, the SPI interface sends the last eight bits received to the SWITCH_DATA register.
Hardware Reset
The digital portion of the ADGM1304 goes through an initialization phase during VDD power up. To hardware reset the ADGM1304, power cycle the VDD input. After power-up or a hardware reset, ensure there is a minimum of 10 µs before any SPI command is issued. Ensure that VDD does not drop out during the 10 µs initialization phase because it may result in incorrect operation of the ADGM1304.

Internal Error Status
When an internal error is detected in the device, the internal error is flagged by the INTERNAL_ERROR bits (Bits[7:6]) of the SWITCH_DATA register (Register 0x20), as shown in Table 10. An internal error results from an error in the configuration of the device at power up.

INTERNAL OSCILLATOR FEEDTHROUGH
The ADGM1304 has an internal oscillator running at a nominal 10 MHz. This oscillator drives the charge pump circuitry that provides the actuation voltage for each of the switch gate electrodes. Although this oscillator is very low power, the 10 MHz signal is coupled to the switch and can be considered a noise spur on the switch channels. The magnitude of this feedthrough noise spur is specified in Table 1 and is typically −123 dBm or −146 dBm/Hz when one switch is on. When all four switches are simultaneously on, the feedthrough goes up to −120 dBm. VDD level and temperature changes affect the frequency of the noise spur. For the maximum and minimum frequency range over temperature and voltage supply range, see Table 1.

INTERNAL OSCILLATOR FEEDTHROUGH MITIGATION
In normal operation, the 80 V actuation voltage is supplied by the driver IC. Setting the EXTD_EN pin (Pin 7) low enables the built-in 10 MHz oscillator. This setting enables the charge pump circuitry to generate the 80 V required for MEMS switch actuation. The internal oscillator is a source of noise which couples through to the RF ports. The magnitude of this feedthrough noise spur is specified in Table 1 and is typically −123 dBm or −146 dBm/Hz when one switch is on. The internal oscillator feedthrough can be eliminated by setting the EXTD_EN pin high, which disables the internal oscillator and charge pump circuitry. When the internal oscillator and charge pump circuitry is disabled, the VCP pin (Pin 24) must be driven with 80 V dc (VCPEXT) from an external voltage supply, as outlined in Table 5, required for MEMS switch actuation. The switch can still be controlled via the digital logic interface pins or via SPI interface pins.

LOW POWER MODE
Setting the EXTD_EN pin high shuts down the internal oscillator. The ADGM1304 enters low power quiescent state, drawing only 50 µA maximum supply current. When the internal oscillator and charge pump circuitry is disabled, the VCP pin (Pin 24) must be driven with 80 V dc (VCPEXT) from an external voltage supply, as outlined in Table 5, required for MEMS switch actuation. The switch can still be controlled via the digital logic interface pins or via SPI interface.

TYPICAL OPERATING CIRCUIT
Figure 55 shows the typical operating circuit for the ADGM1304 as used in the EVAL-ADGM1304SDZ. A 47 pF (100 V rated) external capacitor is required on the VCP pin as a holding capacitor for the 80 V gate drive voltage. The VDD pin is connected to a 3.3 V supply. However, VDD can operate from 3.0 V to 3.6 V. RFGND is separated from AGND internally in the device.

It is recommended to connect RFGND to AGND using one large pad on the PCB to short together EP1 and EP2. Figure 55 shows the ADGM1304 configured to use the internal oscillator as the reference to the driver IC control circuit. Alternatively, set Pin 7 (EXTD_EN) high and apply 80 V dc directly to Pin 24 to disable the internal oscillator and eliminate all oscillator feedthrough. The switches can then be controlled normally via the logic control interface (Pin 1 to Pin 4) or via the SPI interface.

To avoid any floating nodes, connect a 10 MΩ shunt resistor to RFGND on all RFx pins (RF1 to RF4, and RFC), as shown in Figure 55. See the Floating Node section for more information. An example of a 10 MΩ resistor that can be used with the MEMS switch is the Multicomp MCRE000262. The MCRE000262 is tested with the switch and has very small (negligible) impact on the RF performance of the MEMS switch.
*10MΩ RESISTORS ARE REQUIRED TO AVOID ANY FLOATING NODES.
FOR MORE INFORMATION, REFER TO THE APPLICATIONS INFORMATION SECTION

Figure 55. Typical Operating Circuit in Parallel Digital Interface Mode
APPLICATIONS INFORMATION

POWER SUPPLY RAILS

It is recommended that a 0.1 µF decoupling capacitor be added to the power supply port of the ADGM1304.

The ADGM1304 can operate with unipolar supplies between 3.0 V and 3.6 V.

The device is fully specified at a 3.3 V analog supply voltage.

POWER SUPPLY RECOMMENDATIONS

Analog Devices has a wide range of power management products to meet the requirements of most high performance signal chains.

An example of a unipolar power solution for the ADGM1304 is shown in Figure 56. The ADP7142 is a low dropout linear regulator that operates from 2.7 V to 40 V and is ideal for regulation of high performance analog and mixed-signal circuits operating from 39 V down to 1.2 V rails. The ADP7142 has 11 µV rms output noise independent of the output voltage. The ADP7142 can be used to power the supply rail for the ADGM1304, a microcontroller, and/or other devices in the signal chain.

If low noise performance at the power supply is required, the ADP7142 can be replaced by the LT1962 or the LT3045-1.

SWITCHABLE RF ATTENUATOR

It is common to see RF attenuator networks used in RF instrumentation equipment such as vector network analyzers, spectrum analyzers, and signal generators. Routing RF signals through an attenuator enables the equipment to accept higher power signals and increase the dynamic range of the instrument. In RF attenuation applications like the vector network analyzers, spectrum analyzers, and signal generators, maintaining the bandwidth of the signal after it passes through the network is critical. Any degradation of the signal reduces the performance of the equipment. Therefore, the RF characteristics of the switches used for routing are integral to the quality of an attenuator network.

The ADGM1304 MEMS switch is suited for use as a switchable RF attenuator due to its low flat insertion loss, very wide RF bandwidth, and high reliability. The ADGM1304, as an SP4T switch, also provides added flexibility. Figure 57 shows an example attenuation network configuration using two ADGM1304 switches and three different attenuators. The fourth channel of the switches is used as a nonattenuated route.

![Figure 56. Unipolar Power Solution](image)

If low noise performance at the power supply is required, the ADP7142 can be replaced by the LT1962 or the LT3045-1.

RECONFIGURABLE RF FILTER

A reconfigurable RF filter is advantageous in many RF front-end applications. A reconfigurable RF filter provides more saved space. As space becomes more constrained in applications, it is useful to have the option of using an economical reconfigurable RF filter instead of individual frequency dependent filters.

The ADGM1304 has low flat insertion loss, very wide RF bandwidth, low parasitic, low capacitance, and high linearity, and as such, is needed to turn on the lump components (capacitor and inductor). As such, the MEMS switch is suited for reconfigurable filter application.

In applications such as wireless communications or mobile radios, the number of bands and modes constantly increases. A reconfigurable RF filter allows more bands and modes to be covered using the same components.

Figure 58 shows an example of a reconfigurable band-pass filter. The topology shown is of a generalized two section, inductively coupled, single-ended band-pass filter that is nominally centered on 400 MHz (ultrahigh frequency (UHF) band). The MEMS switches are positioned in series with each of the shunt inductors.
Different functions of the switches include or omit a shunt inductor from the circuit. Changing the shunt inductor value affects the bandwidth and center frequency of the filter. Using inductance values from 15 nH to 30 nH significantly alters the bandwidth and center frequency, allowing the filter to dynamically configure to operate in the UHF band or very high frequency (VHF) band while preserving the 50 Ω match on the input and output ports. The low $R_{ON}$ value and large bandwidth of the MEMS switch makes it an ideal choice for dynamic configuration. The low $R_{ON}$ reduces the negative effect a series resistance has on the quality of the shunt inductor. The large bandwidth enables higher frequency band-pass filters.

CRITICAL OPERATIONAL REQUIREMENTS

SYSTEM ERROR CONSIDERATIONS DUE TO ON-RESISTANCE DRIFT

The $R_{\text{ON}}$ performance of the ADGM1304 is affected by device to device variation, channel to channel variation, cycle actuations, settling time post turn on, bias voltage, and temperature changes (see Figure 6 to Figure 12 and Figure 60).

In a 50 Ω system, the on-resistance drift over switch actuations ($\Delta R_{\text{ON}}$) can introduce system inaccuracy. Figure 59 shows the ADGM1304 connected with the load in a 50 Ω system, where $R_S$ is the source impedance. To calculate the system error caused by the ADGM1304 on-resistance drift, use the following equation:

$$\text{System Error} \% = \frac{\Delta R}{R_{\text{LOAD}}}$$

where:

$\Delta R$ is the ADGM1304 on-resistance drift.

$R_{\text{LOAD}}$ is the load impedance.

The ADGM1304 on-resistance drift also affects insertion loss, which must be considered when using the device. To calculate the on-resistance impact on insertion loss, use the following equation:

$$\text{Insertion Loss} = 10 \log \left(1 + \frac{\Delta R}{R_{\text{LOAD}}} \right)$$

Figure 59. 50 Ω System Representation Where the ADGM1304 Is Connected with the Load

Table 8. System Error and Insertion Loss Error Due to ADGM1304 $R_{\text{ON}}$ Drift

</tr>
<tr>
<td>5</td>
<td>10</td>
<td>0.41</td>
</tr>
</tbody>
</table>

The on-resistance drift over time specification is $-0.25 \Omega$ measured after 100 ms, as shown in Figure 8 to Figure 10. According to the plots, the on-resistance drift over time is $-0.12 \Omega$ after 100 ms. The on resistance of the ADGM1304 typically drifts by $-0.05 \Omega$ per decade. For example, after 100 ms, the on resistance drifts $-0.12 \Omega$. After 1 sec, the on resistance drifts $-0.17 \Omega$, and after 10 sec, it drifts $-0.22 \Omega$. Therefore, after 1000 sec, the on resistance is expected to drift by $-0.32 \Omega$.

ON-RESISTANCE SHIFT DUE TO TEMPERATURE SHOCK POST ACTUATIONS

When the switch is actuated multiple times at one temperature, and if there is a sudden shift in this temperature, a large shift is shown in the switch $R_{\text{ON}}$. Figure 60 shows the absolute $R_{\text{ON}}$ performance of the population of devices over actuation lifetime. Figure 60 shows how the absolute $R_{\text{ON}}$ of the device drifts over actuation lifetime. During this measurement, the switch is actuated at 85°C and the switch $R_{\text{ON}}$ is measured at 25°C. Actuating the switch at 85°C and measuring $R_{\text{ON}}$ at 25°C is the most severe condition for the ADGM1304 $R_{\text{ON}}$ drift over actuations.

Figure 60. Population vs. Absolute $R_{\text{ON}}$, Switch Actuated at 85°C and $R_{\text{ON}}$ Measured at 25°C

HOT SWITCHING

Hot switching is caused by cycling the switch on or off with a signal applied to the switch. The presence of the applied signal during switching cycle damages the switch contacts. Hot switching damage is dependent on the current or the voltage levels. Hot switching causes a significant reduction in the cycle lifetime of the switch, as shown in Table 1, Figure 13, and Figure 14.

Figure 61 shows the hot switching condition when the switch is turned on with a 1 V signal present at the switch terminal during switching.

NOTES
1. THE PRESENCE OF THE APPLIED SIGNAL DURING SWITCHING CYCLE DAMAGES THE SWITCH CONTACTS.
Figure 62 shows the hot switching condition when the switch is turned off with 10 mA passing through the switch during switching.

**FLOATING NODE**

The ADGM1304 has no internal impedance to ground, and charges can develop on the switch terminals, leading to unreliable switch behavior. To mitigate this behavior, provide a discharge path to all switch nodes. Figure 63 to Figure 66 show examples of cases to avoid where floating nodes can occur when using the switch. Conditions to avoid include the following:

- Leaving the RFx pins open circuit (see Figure 63).
- Connecting a series capacitor directly to the switch (see Figure 64).
- Connecting the RFx pin of two switches together directly or connecting the RFC pin to the RFx pin (see Figure 65 and Figure 66).

Provide a discharge path to the switch nodes to avoid floating nodes. In a typical application, a 50 Ω termination connected to the switch provides this path. Driving switch nodes with a device of adequate impedance (<10 MΩ) provides a discharge path. If there is no discharge path in the application circuit, add a 10 MΩ shunt resistor or inductor on the source RFx pin of the MEMS switch to provide the discharge path. Note that the shunt resistors introduce leakage. Figure 67 shows an example of a configuration providing a discharge path.

Avoid connecting shunt capacitors directly to the switch. A capacitor can store a charge and potentially lead to hot switching events when the switch opens or closes if there are no alternative discharge paths. These events affect the cycle lifetime of the switch.
CUMULATIVE ON SWITCH LIFETIME

Leaving the switch in an on state for a long period affects the lifetime of the switch because of mechanical degradation effects. These effects can result in the switch failing to turn off. Figure 70 shows a failure rate at 50°C where the mean time to failure is 7.2 years (2628 days), resulting in 50% of the sample lot failing at this point.

![Figure 70. Cumulative On Switch Lifetime at 50°C, VDD = 3.3 V, Sample Size = 31 Devices](image)

Temperatures above 50°C further reduce the switch lifetime. The cumulative on switch lifetime specification is also duty cycle dependent. If the user operates the MEMS switch with a duty cycle of less than 50%, the lifetime of the MEMS switch improves.

HANDLING PRECAUTIONS

**ESD Precautions**

All RFx pins of the ADGM1304 pass the following ESD limits:

- 100 V, Class 0 HBM, ANSI/ESDA/JEDEC JS-001-2010
- 500 V, Class C2 FICDM, JEDEC JESD22_C101E

All the RFx pins are rated to 500 V FICDM, making the device safe for automated handling and assembly process. Standard ESD precautions should be taken during manufacturing.

100 V HBM rating of ADGM1304 is susceptible to ESD surge due to human body contact. ESD protection should be added if human body contact is expected.

**Electrical Overstress (EOS) Precautions**

The ADGM1304 is susceptible to EOS. Therefore, take the following precautions:

- The ADGM1304 is an ESD sensitive device. Ensure to take all normal handling precautions, including working only on static dissipative surfaces, wearing wrist straps or other ESD control devices, and storing unused devices in conductive foam.

- Avoid running measurement instruments, such as digital multimeters (DMMs), in autorange modes. Some instruments generate large transient compliance voltages when switching between ranges.

- Use the highest practical DMM range setting (the lowest resolution) for resistance measurements to minimize compliance voltages, particularly during switching.

- Discharge coaxial cables before connecting directly to the switch. Note that coaxial cables can store charge and lead to EOS when directly connected to the switch.

- Avoid connecting large capacitive terminations directly to the switch, as shown in Figure 71. A shunt capacitor can store a charge that potentially leads to hot switching events when the switch opens or closes, affecting the lifetime of the switch.

![Figure 71. Avoid Having a Large Capacitor Directly Connected to the MEMS Switch](image)

**Mechanical Shock Precautions**

The ADGM1304 passes Group D mechanical shocks tests, as detailed in Table 3 in the Absolute Maximum Ratings section. These tests validate the robustness of the device to typical mechanical shocks.

Do not use the device if dropped. To reduce excessive mechanical shock and ESD events, avoid handling of loose devices, as shown in Figure 72.
