FEATURES
Drives 4 LEDs from a 2.6 V to 5.5 V (Li-ion) input supply
1×/1.5×/2× fractional charge pump to maximize power efficiency
0.3% typical LED current matching
Up to 88% power efficiency over Li-Ion range
Powers main and sub display LEDs with individual shutdown
Package footprint only 9 mm² (3 mm × 3 mm)
Package height only 0.75 mm
Low power shutdown mode
Shutdown function
Soft start limiting in-rush current

APPLICATIONS
Cellular phones with main and sub displays
White LED backlighting
Camera flash/strobes and movie light applications
Micro TFT color displays
DSC
PDAs

GENERAL DESCRIPTION
The ADM8843 uses charge pump technology to provide the power to drive up to four LEDs. The LEDs are used for backlighting a color LCD display that has regulated constant current for uniform brightness intensity. The main display can use up to three LEDs, and the sub display uses one LED. The CTRL1 and CTRL2 digital input control pins control the shutdown operation and the brightness of the main and sub displays.

To maximize power efficiency, the charge pump can operate in 1×, 1.5×, or 2× mode. The charge pump automatically switches among 1×/1.5×/2× modes, based on the input voltage, to maintain sufficient drive for the LED anodes at the highest power efficiency.

Improved brightness matching of the LEDs is achieved by a feedback pin that senses individual LED current with a typical matching accuracy of 0.3%.

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

THERMAL RESISTANCE

Thermal resistance values specified in Table 3 are simulated based on JEDEC specifications, unless specified otherwise, and must be used in compliance with JESD51-12.

Table 3. Thermal Resistance

1 For $\theta_{JC}$, 100 µm thermal interface material is used. Thermal interface material is assumed to have 3.6 W/mK.
2 Using enhanced heat removal (printed circuit board (PCB), heat sink, and airflow) techniques improves thermal resistance values.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

THEORY OF OPERATION

The ADM8843 charge pump driver for LCD white LED backlights implements a multiple-gain charge pump (1×, 1.5×, 2×) to maintain the correct voltage on the anodes of the LEDs over a 2.6 V to 5.5 V (Li-Ion) input supply voltage. The charge pump automatically switches among 1×/1.5×/2× modes, based on the input voltage, to maintain sufficient drive for the LED anodes, with \( V_{CC} \) input voltages as low as 2.6 V. It also includes regulation of the charge pump output voltage for supply voltages up to 5.5 V.

The ADM8843’s four LEDs are arranged into two groups, main and sub. The main display can have up to three LEDs (FB1 to FB3), and the sub display has one LED (FB4) (see Figure 18). The CTRL1 and CTRL2 digital input control pins control the shutdown operation and the brightness of the main and sub displays (see Table 5).

</tbody>
</table>

An external resistor, \( R_{SET} \), is connected between the \( I_{SET} \) pin and GND. This resistor sets up a reference current, \( I_{SET} \), which is internally gained up by 120 within the ADM8843 to produce \( I_{LED} \) currents of up to 20 mA/LED (\( I_{LED} = I_{SET} \times 120 \) and \( I_{SET} = 1.18 \) V/\( R_{SET} \)). The ADM8843 uses four separate current sinks to sense each LED current individually with a typical matching performance of 0.3%. This current matching performance ensures uniform brightness across a color display.

The ADM8843 lets the user control the brightness of the white LEDs with a digital PWM signal applied to CTRL1 and/or CTRL2. The duty cycle of the applied PWM signal determines the brightness of the main and/or sub display backlight white LEDs. The ADM8843 also allows the brightness of the white LEDs to be controlled using a dc voltage (see Figure 17). Soft start circuitry limits the in-rush current flow at power-up. The ADM8843 is fabricated using CMOS technology for minimal power consumption and is packaged in a 16-lead lead frame chip scale package.

![Figure 17. PWM Brightness Control Using a DC Voltage Applied to VBRIGHT](image)

![Figure 18. Functional Block Diagram](image)
AUTOMATIC GAIN CONTROL

The automatic gain control block controls the operation of the charge pump by selecting the appropriate gain for the charge pump. Doing so maintains sufficient drive for the LED anodes at the highest power efficiency over a 2.6 V to 5.5 V input supply range. The charge pump switching thresholds are described in Table 6.

BRIGHTNESS CONTROL WITH A DIGITAL PWM SIGNAL

PWM brightness control provides the widest brightness control method by pulsing the white LEDs on and off using one or both digital input control pins, CTRL1 and CTRL2. PWM brightness control also removes any chromaticity shifts associated with changing the white LED current, because the LEDs operate at either zero current or full current (set by RSET).

The digital PWM signal applied with a frequency of 100 Hz to 200 kHz turns the current control sinks on and off using CTRL1 and/or CTRL2. The average current through the LEDs changes with the PWM signal duty cycle. If the PWM frequency is much less than 100 Hz, flicker may be seen in the LEDs. For the ADM8843, zero duty cycle turns off the LEDs, and a 50% duty cycle results in an average LED current, $I_{LED}$, that is half the programmed LED current. For example, if RSET is set to program 20 mA/LED, a 50% duty cycle results in an average $I_{LED}$ of 10 mA/LED, which is half the programmed LED current.

Applying a digital PWM signal to one or both digital input control pins, CTRL1 and CTRL2, adjusts the brightness of the sub and/or main displays. The ADM8843's four white LEDs are organized into two groups, main display (FB1 to FB3) and sub display (FB4); refer to the Theory of Operation section.

The brightness of the ADM8843's main and sub displays can be controlled together or separately. This is achieved by applying a digital PWM signal to both the CTRL1 and CTRL2 pins. The duty cycle of the applied digital PWM signal determines the brightness of the main and sub displays together. Varying the duty cycle of the applied PWM signal varies the brightness of the main and sub displays from 0% to 100%.

By holding CTRL1 low and applying a digital PWM signal to CTRL2, the sub display is turned off and the main display is turned on. Then the brightness of the main display is determined by the duty cycle of the applied digital PWM signal.

By applying a digital PWM signal to CTRL1 and holding CTRL2 low, the sub display is turned on and the main display is turned off. Then the brightness of the sub display is determined by the duty cycle of the applied digital PWM signal.

By applying a digital PWM signal to CTRL1 and holding CTRL2 high, the sub display is turned on and the main display is turned on. Then the brightness of the sub display is determined by the duty cycle of the applied digital PWM signal. The brightness of the main display is set to the maximum (maximum is set by RSET).

By holding CTRL1 high and applying a digital PWM signal to CTRL2, the sub and main displays are turned on. Then the brightness of the main display is determined by the duty cycle of the applied digital PWM signal. The brightness of the sub display is set to the maximum (maximum is set by RSET).

When CTRL1 and CTRL2 are low, the LED current control sinks shutdown. Shutdown of the charge pump is delayed by 15 ms. This timeout period, $t_{CP}$, allows the ADM8843 to determine if a digital PWM signal is present on CTRL1 and CTRL2, or if the user has selected a full chip shutdown (see Figure 20).

If digital PWM brightness control of the LEDs is not required, a constant Logic Level 1 (VCC) or Logic Level 0 (GND) must be applied.

The four white LED in the ADM8843 are arranged into two groups, sub and main. It is possible to configure the four LEDs as in Table 7. Refer also to Figure 20.

¹ Sub display on means the display is on with the maximum brightness set by the RSET resistor. CTRL1 = 1 means a constant logic level (VCC) is applied to CTRL1.
² Main display off means only the main display is off. CTRL2 = 0 means a constant logic level (GND) is applied to CTRL2.
³ Main display on means the display is on with the maximum brightness set by the RSET resistor. CTRL2 = 1 means a constant logic level (VCC) is applied to CTRL2.
⁴ Sub display off means only the sub display LEDs is off. CTRL1 = 0 means a constant logic level (GND) is applied to CTRL1.
⁵ PWM means a digital PWM signal is applied to the CTRL1 and/or the CTRL2 pin with a frequency from 100 Hz to 200 kHz.

---

### Figure 20. Application Timing

![Application Timing Diagram](image-url)
LED BRIGHTNESS CONTROL USING A PWM SIGNAL APPLIED TO \( V_{PWM} \)

Adding two external resistors and a capacitor, as shown in Figure 21, can also be used for PWM brightness control. This PWM brightness control method can be used instead of CTRL1 and/or CTRL2 digital PWM brightness control. With this configuration, CTRL1 and CTRL2 digital logic pins can control shutdown of the white LEDs, and \( V_{PWM} \) can control the brightness of all the white LEDs. This is done by applying a high frequency PWM signal (amplitude 0 V to 2.5 V) to drive an R-C-R filter on the ISET pin of the ADM8843. A 0% PWM duty cycle corresponds to 20 mA/LED, and a 100% PWM duty cycle corresponds to 0 mA/LED. At PWM frequencies above 5 kHz, C5 may be reduced (see Figure 21). The amplitude of the PWM signal must only be 0 V and 2.5 V to result in 20 mA flowing in each LED.

\[
I_{LED} = \frac{I_{SET} - \text{Voltage}}{R_{SET} \times 2R} \times 120 \times \frac{(1 - \text{Duty Cycle})}{R_{SET} + 2R}
\]

where:

- \( R = 15 \, \text{k}\Omega \)
- \( V_{SET} = \text{voltage at ISET pin (1.18 V)} \)

The equation for ILED is

\[
I_{LED} = 120 \times I_{SET}
\]

LED BRIGHTNESS CONTROL USING A DC VOLTAGE APPLIED TO \( V_{BRIGHT} \)

By adding one resistor, as shown in Figure 17, this configuration can also be used for brightness control of the white LEDs by using a dc voltage applied to the \( V_{BRIGHT} \) node. Figure 22 shows an application example of LED brightness control using a dc voltage with an amplitude of 0 V to 2.5 V applied to \( V_{BRIGHT} \).

The equation for \( I_{LED} \) is

\[
I_{LED} = \left( \frac{1}{R_{SET}} + \frac{1}{R} \right) \left( V_{SET} \right) - \left( \frac{1}{R} \right) \left( V_{BRIGHT} \right)
\]

where:

- \( V_{SET} = \text{voltage at ISET pin (1.18 V)} \)

Figure 22. PWM Brightness Control Application Diagram Using a DC Voltage Applied to \( V_{BRIGHT} \)
APPLICATIONS

LAYOUT CONSIDERATIONS AND NOISE

Because of the ADM8843’s switching behavior, PCB trace layout is an important consideration. To ensure optimum performance, a ground plane should be used, and all capacitors (C1, C2, C3, C4) must be located with minimal track lengths to the pins of the ADM8843.

WHITE LED SHORTING

If an LED is shorted, the ADM8843 continues to drive the remaining LEDs with I_LED per LED (I_LED = I_SET × 120 mA). This is because the ADM8843 uses four internal current sinks to produce the LED current. If an LED is shorted, the ADM8843 continues to sink (I_SET × 120 mA).

DRIVING FOUR LEDS IN THE MAIN DISPLAY ONLY

The ADM8843 can be operated with four LEDs in the main display only (see Figure 23). With this configuration, CTRL1 and CTRL2 are used together to control the main display shutdown operation and brightness control.

DRIVING FEWER THAN FOUR LEDS

The ADM8843 can be operated with fewer than four LEDs in parallel by simply leaving the unused FBx pins floating or by connecting them to GND. For example, Figure 24 shows three LEDs being powered by the ADM8843.

Figure 23. Driving Four White LEDs

Figure 24. Driving Three White LEDs

Figure 25. Typical Application Diagram
USING SMALLER CAPACITOR VALUES

The ADM8843 can be operated with the smaller capacitor values described here to reduce capacitor footprint sizes.

Option 1
Input and output ripple plots for 1× and 1.5× modes of operation are shown with C1, C2 = 0.22 μF; C3 = 0.47 μF; and C4 = 1 μF.

Option 2
Input and output ripple plots for 1× and 1.5× modes of operation are shown with C1, C2 = 0.22 μF; C3 = 0.47 μF; and C4 = 4.7 μF.
**POWER EFFICIENCY**

The ADM8843 power efficiency (η) equations are as follows:

\[
\eta = \frac{P_{OUT}}{P_{IN}}
\]

\[
P_{IN} = ((V_{CC} \times I_{LOAD} \times Gain) + (I_Q \times V_{CC}))
\]

\[
P_{OUT} = 4 \times (V_F \times I_{LED})
\]

where:

- \(I_Q\) is the quiescent current of the ADM8843, 2.6 mA.
- \(V_F\) is the LED forward voltage.
- \(Gain\) is the charge pump mode (1×, 1.5×, 2×).

**Example 1**

The ADM8843 driving four white LED with 20 mA/LED at \(V_{CC} = 3.4\) V (1.5× mode), LED \(V_F = 4.5\) V.

\[
P_{IN} = ((V_{CC} \times I_{LOAD} \times Gain) + (V_{CC} \times I_Q))
\]

\[
P_{IN} = ((3.4 \times 80\ mA \times 1.5) + (3.4 \times 2.6\ mA))
\]

\[
P_{IN} = ((0.408) + (0.00884))
\]

\[
P_{IN} = 0.41684
\]

\[
P_{OUT} = 4(V_F \times I_{LED})
\]

\[
P_{OUT} = 4(4.5\ V \times 20\ mA)
\]

\[
P_{OUT} = 0.36
\]

\[
\eta = \frac{P_{OUT}}{P_{IN}}
\]

\[
\eta = 0.36/0.41684
\]

\[
\eta = 87\%
\]

**Example 2**

The ADM8843 driving four white LED with 20 mA/LED at \(V_{CC} = 3.4\) (1.5× mode), LED \(V_F = 3.6\) V.

\[
P_{IN} = ((V_{CC} \times I_{LOAD} \times Gain) + (V_{CC} \times I_Q))
\]

\[
P_{IN} = ((3.4 \times 80\ mA \times 1.5) + (3.4 \times 2.6\ mA))
\]

\[
P_{IN} = ((0.408) + (0.00884))
\]

\[
P_{IN} = 0.41684
\]

\[
P_{OUT} = 4(V_F \times I_{LED})
\]

\[
P_{OUT} = 4(3.6\ V \times 20\ mA)
\]

\[
P_{OUT} = 0.288
\]

\[
\eta = \frac{P_{OUT}}{P_{IN}}
\]

\[
\eta = 0.288/0.41684
\]

\[
\eta = 70\%
\]
