FEATURES

Ultracompact solution
- Small 2 mm × 1.5 mm 12-ball WLCSP package
- Tiny, low profile 2.2 μH power inductor
- LED current source for local LED grounding and low EMI
- Synchronous 2 MHz PWM boost converter, no external diode

High efficiency: 88% peak
- Reduces high levels of input battery current during flash
- Limits battery current drain in torch mode

I²C programmable
- Currents up to 400 mA in flash mode for two LEDs
- Currents up to 500 mA in flash mode for one LED with 5% accuracy
- Currents up to 160 mA in torch mode with 10% accuracy
- Peak inductor current limit
- Flash timer

Control
- I²C-compatible control registers
- External STROBE pin
- External direct TORCH pin
- TX_MASK input to prevent high input battery current levels

Safety
- Thermal overload protection
- Flash timeout
- Inductor fault detection
- Output overvoltage
- Short circuit protection
- Soft start reduces inrush input current

APPLICATIONS

Camera-enabled cellular phones and smart phones
Digital still cameras, camcorders, and PDAs

GENERAL DESCRIPTION

The ADP1655 is a very compact, highly efficient, dual white LED flash driver for high resolution camera phones, which improves picture and video quality in low light environments. The device integrates a 2 MHz synchronous inductive boost converter, an I²C-compatible interface and a 500 mA current source. The high switching frequency enables the use of a tiny, low profile 2.2 μH power inductor, and the current source permits LED cathode grounding for thermally enhanced, low EMI and compact layouts.

The efficiency is high over the entire battery voltage range to maximize the input power to LED power conversion and minimize battery current draw during flash events. In addition, a Tx-mask input permits the flash LED current to reduce quickly and, therefore, the battery current reduces quickly, during a GSM power amplifier current burst.

The I²C-compatible interface enables the programmability of timers, currents, and status bit readback for operation monitoring and safety control.

The ADP1655 comes in a compact 12-ball 0.5 mm pitch WLCSP package and is specified over the full −40°C to +125°C junction temperature range.

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

THERMAL DATA

The ADP1655 may be damaged if the junction temperature limits are exceeded. Monitoring TA does not guarantee that TJ is within the specified temperature limits. In applications with high power dissipation and poor thermal resistance, the maximum TA may have to be derated. In applications with moderate power dissipation and low PCB thermal resistance, the maximum TA can exceed the maximum limit as long as the TJ is within specification limits. TJ of the device is dependent on the TA, the power dissipation (PD) of the device, and the junction-to-ambient thermal resistance ($\theta_{JA}$) of the package. Maximum TJ is calculated from the TA and PD using the following formula:

$$TJ = TA + (PD \times \theta_{JA})$$

THERMAL RESISTANCE

$\theta_{JA}$ of the package is based on modeling and calculation using a 4-layer board. $\theta_{JA}$ is highly dependent on the application and board layout. In applications where high maximum power dissipation exists, attention to thermal board design is required. The value of $\theta_{JA}$ may vary, depending on PCB material, layout, and environmental conditions. The specified value of $\theta_{JA}$ is based on a 4-layer, 4 in × 3 in, 2 1/2 oz copper board, per JEDEC standards. For more information, see the AN-617 Application Note, MicroCSP™ Wafer Level Chip Scale Package.

$\theta_{JA}$ is specified for a device mounted on a JEDEC 2S2P PCB.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

THEORY OF OPERATION

The ADP1655 is a high power, white LED driver ideal for driving white LEDs for use as a camera flash. The ADP1655 includes a boost converter and a current regulator suitable for powering one or two high power, white LEDs.

The ADP1655 responds to a 2-pin control interface that can operate in two separate pin-selectable modes: tying the I2C/EN pin high enables the I2C interface; tying the I2C/EN pin low enables a 2-bit logic interface.

WHITE LED DRIVER

The ADP1655 drives a synchronous boost converter to power one or two series-connected, high power LEDs. The white LED driver regulates the high power LED current for accurate brightness control. The ADP1655 uses an integrated PFET current regulator.

When the white LED is turned on, the step-up converter output voltage slew is limited to prevent excessive battery current while charging the output capacitor. The output voltage of the boost converter is sensed at VOUT. If the output voltage exceeds the 9.5 V (typical) limit, the white LED driver turns off and indicates that a fault condition has occurred through the system registers. This feature prevents damage due to an overvoltage if the white LED string fails with an open-circuit condition.

Setting the LED regulation currents depends on the 2-pin control interface used.

ASSIST LIGHT AND TORCH MODES

The ADP1655 features a programmable assist light mode that provides continuous LED current. The STROBE pin or the 2-bit logic interface can be used to transition from assist light mode directly to flash mode. The TORCH pin provides an alternative means of accessing a continuous LED current mode of operation. Both assist light and torch modes deliver the same current, which is programmable via the I2C-compatible interface.

![Figure 28. Detailed Block Diagram](image-url)
2-BIT LOGIC INTERFACE MODE (I2C/EN = 0)

In 2-bit logic interface mode, the two control pins, EN1 and EN2, select whether the part is disabled or operating in assist light mode or flash mode, as outlined in Table 6. Additionally, the TORCH pin selects torch mode.

Figure 29 illustrates state transitions of 2-bit logic mode controlled by digital inputs EN1, EN2, TORCH, and TX_MASK.

When the ADP1655 is in flash mode, the TX_MASK pin can be used to reduce the battery load. The device remains in flash mode, but the LED driver output current is reduced to the assist light level.

I2C INTERFACE MODE (I2C/EN = 1)

The ADP1655 includes an I2C-compatible serial interface for control of the LED current, as well as for a readback of system status registers. The I2C chip address is 0x60 in write mode and 0x61 in read mode.

<sup>1</sup> Torch mode has to be enabled from Register 0x04.
<sup>2</sup> The output current value depends on the register settings.

Registers values are reset to the default values when VIN supply falls below the undervoltage (UVLO) level.

Figure 30 illustrates the I2C write sequence to a single register. The subaddress content selects which of the five ADP1655 registers is written to first. The ADP1655 sends an acknowledgement to the master after the 8-bit data byte has been written. The ADP1655 increments the subaddress automatically and starts receiving a data byte to the following register until the master sends an I2C stop as shown in Figure 31. Figure 32 shows the I2C read sequence of a single register. ADP1655 sends the data from the register denoted by the subaddress and increments the subaddress automatically, sending data from the next register until the master sends an I2C stop condition as shown in Figure 33.

State transitions between standby, assist light, flash, and external torch modes are described in the State Transitions section and Figure 34.

The register definitions are shown in the I2C Register Map section. The lowest bit number (0) represents the least significant bit, and the highest bit number (7) represents the most significant bit.

STATE TRANITIONS

When the ADP1655 is in flash mode, the TX_MASK pin can be used to reduce the battery load. The device remains in flash mode, but the LED driver output current is reduced to the assist light level. In Figure 34, if the flash was triggered by the strobe pin in level-sensitive mode, a timeout triggers a timeout fault, as defined in the Safety Features section.

SAFETY FEATURES

For critical system conditions, such as output overvoltage, flash timeout, LED output short circuit, and overtemperature conditions, the ADP1655 has built-in safety mechanisms. If one of the fault conditions occurs, the device shuts down and a corresponding flag is set in the fault information register (Register 0x05). In I2C interface mode, the system baseband processor can read the fault information register through the I2C interface to determine the nature of the fault condition and, consequently, the fault flag is cleared. The device is disabled until the fault information register is cleared.

In 2-bit logic interface mode, the I2C register readback is not available. To clear a fault, set EN1, EN2, and TORCH low.

OVERVOLTAGE FAULT

The ADP1655 contains a comparator at the VOUT pin that monitors the voltage between VOUT and SGND. If the voltage exceeds 9.5 V (typical), the ADP1655 shuts down. In I2C mode, Bit 7 in the fault information register is read back as high. The ADP1655 is disabled until the fault is cleared, ensuring protection against an open circuit.

OUTPUT CAPACITOR FAULT

If no output capacitor is present at the VOUT pin when the ADP1655 is enabled for a flash, torch, or assist light event, the part shuts down and Bit 7 in the fault information register is read back as high. The ADP1655 is disabled until the fault is cleared. The output capacitor detection scheme does not cause the VOUT pin to rise above the overvoltage threshold even though the overvoltage flag (Bit 7) in the fault information register (Register 5) is set. The overvoltage and output capacitor fault flags share a single register bit to reduce the required number of registers.

TIMEOUT FAULT

If the 2-bit logic interface is used, the maximum duration for flash being enabled (EN1/EN2 = 1) is preset to 850 ms. If EN1 and EN2 remain high for longer than 850 ms, ADP1655 is disabled until the fault is cleared (EN1, EN2, and TORCH low). In I2C mode, if strobe mode is enabled (Register 0x04, Bit 2), strobe is set to level sensitive mode (Register 0x04, Bit 5), and if strobe remains high for longer than 850 ms, the timeout fault bit, Register 0x05, Bit 4), is read back as high. The ADP1655 is disabled until the fault is cleared.

OVERTEMPERATURE FAULT

If the junction temperature of the ADP1655 rises above 150°C, a thermal protection circuit shuts down the device. In I2C mode, Bit 5 of the fault information register is read back as high. The ADP1655 is disabled until the fault is cleared.

SHORT-CIRCUIT FAULT

The LED_OUT pin features short-circuit protection that disables the ADP1655 if it detects a short circuit to ground at the LED_OUT pin. The ADP1655 monitors the LED voltage when the LED driver is enabled. If the LED_OUT pin remains below the short-circuit detection threshold during startup, a short circuit is detected. Bit 6 of the fault information register is read back as high. The ADP1655 is disabled until the fault is cleared.

CURRENT LIMIT

The internal switch limits battery current by ensuring that the peak inductor current does not exceed the programmed limit (current limit is set by Bit 6 and Bit 7 in the output mode register, Register 0x04). If the peak inductor current exceeds the limit, the part shuts down and Bit 1 of the fault information register is read back as high. The ADP1655 is disabled until the fault is cleared.

AMOUNT OF LED DETECTION

The ADP1655 is able to detect the amount of LED connected in series between the LED_OUT pin and the PGND potential. In I2C mode, the detection is enabled with Bit 3 in the output mode register. The part uses an 80 mA LED driver current setting to detect the LED forward voltage (Vf) with a voltage comparator at the start of a flash, torch, or assist light event. If the detected forward voltage is higher than 4.3 V (typical), Bit 3 of the fault information register is read back as high.

INPUT UNDERVOLTAGE

The ADP1655 includes an input undervoltage lockout circuit. If the battery voltage drops below the 2.4 V (typical) input UVLO threshold, the ADP1655 shuts down. In this case, information in all registers is lost, and when power is reapplied, a power-on reset circuit resets the registers to their default conditions.
Selecting the Inductor

The ADP1655 boost converter increases the battery voltage to allow driving of one or two LEDs, whose combined voltage drop is higher than the battery voltage plus the current source headroom voltage. This allows the converter to regulate the LED current over the entire battery voltage range and with a wide variation of LED forward voltage.

The inductor saturation current should be greater than the sum of the dc input current and half the inductor ripple current. A reduction in the effective inductance due to saturation increases the inductor current ripple. Suggested inductors are shown in Table 15.

</tbody>
</table>

Selecting the Input Capacitor

The ADP1655 requires an input bypass capacitor to supply transient currents while maintaining constant input and output voltages. The input capacitor carries the input ripple current, allowing the input power source to supply only the dc current. Use an input capacitor with a sufficient ripple current rating to handle the inductor ripple. Increased input capacitance reduces the amplitude of the switching frequency ripple on the battery. Because of the dc bias characteristics of ceramic capacitors, a 0603, 6.3 V X5R/X7R, 10 μF ceramic capacitor is preferable.

Higher value input capacitors help to reduce the input voltage ripple and improve transient response. Maximum input capacitor current is calculated using the following equation:

\[ I_{\text{CIN}} \geq I_{\text{LOAD(MAX)}} \sqrt{\frac{V_{\text{OUT}}(V_{\text{IN}} - V_{\text{OUT}})}{V_{\text{IN}}}} \]

To minimize supply noise, place the input capacitor as close to the VIN pin of the ADP1655 as possible. As with the output capacitor, a low ESR capacitor is suggested. A list of suggested input capacitors is shown in Table 16.

Table 16. Suggested Input Capacitors

<td>10 μF, 6.3 V</td>
<td>JMK107BJ106MA</td>
</tr>
</tbody>
</table>

Selecting the Output Capacitor

The output capacitor maintains the output voltage and supplies the LED current during NFET power switch on period. It also stabilizes the loop. A 10.0 μF, 16 V X5R/X7R ceramic capacitor is suggested.

Note that dc bias characterization data is available from capacitor manufacturers and should be taken into account when selecting input and output capacitors. 16 V capacitors are recommended for most two-LED designs. Designs with 1 mm height restrictions can also use 0603 case size, 16 V capacitors in parallel. A list of suggested output capacitors is shown in Table 17.

</tr>
</tbody>
</table>

Higher output capacitor values reduce the output voltage ripple and improve load transient response. When choosing this value, it is also important to account for the loss of capacitance due to output voltage dc bias.

Ceramic capacitors are manufactured with a variety of dielectrics, each with different behavior over temperature and applied voltage. Capacitors must have a dielectric that ensures the minimum capacitance over the necessary temperature range and dc bias conditions. X5R or X7R dielectrics with a voltage rating of 10.0 V or 16 V are suggested for best performance. Y5V and Z5U dielectrics are not suggested for use with any dc-to-dc converter because of their poor temperature and dc bias characteristics.
The worst-case capacitance accounting for capacitor variation over temperature, component tolerance, and voltage is calculated using the following equation:

\[ C_{\text{EFF}} = C_{\text{OUT}} \times (1 - \text{TEMPCO}) \times (1 - \text{TOL}) \]

where:
- \( C_{\text{EFF}} \) is the effective capacitance at the operating voltage.
- \( \text{TEMPCO} \) is the worst-case capacitor temperature coefficient.
- \( \text{TOL} \) is the worst-case component tolerance.

In this example, \( \text{TEMPCO} \) over \(-40^\circ\text{C}\) to \(+85^\circ\text{C}\) is assumed to be 15% for an X5R dielectric, \( \text{TOL} \) is assumed to be 10%, and \( C_{\text{OUT}} \) is 9.528 \( \mu \text{F} \) at 1.8 V, as shown in Figure 35.

Substituting these values in the equation yields

\[ C_{\text{EFF}} = 9.528 \, \mu \text{F} \times (1 - 0.15) \times (1 - 0.1) = 7.288 \, \mu \text{F} \]

To guarantee the performance of the ADP1655, it is imperative that the effects of dc bias, temperature, and tolerances on the behavior of the capacitors be evaluated for each application. The peak-to-peak output voltage ripple for the selected output capacitor and inductor values is calculated using the following equation:

\[ V_{\text{RIPPLE}} = \frac{V_{\text{IN}}}{(2\pi f_{\text{SW}}) \times 2 \times L \times C_{\text{OUT}}} = \frac{I_{\text{RIPPLE}}}{8 \times f_{\text{SW}} \times C_{\text{OUT}}} \]

Capacitors with lower equivalent series resistance (ESR) are preferred to guarantee low output voltage ripple, as shown in the following equation:

\[ \text{ESR}_{\text{OUT}} \leq \frac{V_{\text{RIPPLE}}}{I_{\text{RIPPLE}}} \]

The effective capacitance needed for stability, which includes temperature and dc bias effects, is 4 \( \mu \text{F} \).
PCB LAYOUT

Poor layout can affect performance, causing electromagnetic interference (EMI) and electromagnetic compatibility (EMC) problems, ground bounce, and voltage losses. Poor layout can also affect regulation and stability. A good layout is implemented using the following rules and shown in Figure 36:

- Place the inductor, input capacitor, and output capacitor close to the IC using short tracks. These components carry high switching frequencies and large tracks act as antennas.
- Route the output voltage path away from the inductor and SW node to minimize noise and magnetic interference.
- Maximize the size of ground metal on the component side to help with thermal dissipation.
- Use a ground plane with several vias connecting to the component side ground to further reduce noise interference on sensitive circuit nodes.
