The LT®3751 is a high input voltage capable flyback controller designed to rapidly charge a large capacitor to a user-adjustable high target voltage set by the transformer turns ratio and three external resistors. Optionally, a feedback pin can be used to provide a low noise high voltage regulated output.

The LT3751 has an integrated rail-to-rail MOSFET gate driver that allows for efficient operation down to 4.75V. A low 106mV differential current sense threshold voltage accurately limits the peak switch current. Added protection is provided via user-selectable overvoltage and undervoltage lockouts for both VCC and VTRANS. A typical application can charge a 1000µF capacitor to 500V in less than one second.

The CHARGE pin is used to initiate a new charge cycle and provides ON/OFF control. The DONE pin indicates when the capacitor has reached its programmed value and the part has stopped charging. The FAULT pin indicates when the LT3751 has shut down due to either VCC or VTRANS voltage exceeding the user-programmed supply tolerances.

The LT3751 is a high input voltage capable flyback controller designed to rapidly charge a large capacitor to a user-adjustable high target voltage set by the transformer turns ratio and three external resistors. **Note 1:** Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

**Note 2:** The LT3751E is guaranteed to meet performance specifications from 0°C to 125°C junction temperature. Specifications over the −40°C to 125°C operating junction temperature range are assured by design characterization and correlation with statistical process controls. The LT3751I is guaranteed over the full −40°C to 125°C operating junction temperature range.

**Note 3:** A 60V internal clamp is connected to $RV_{TRANS}$, $RDCM$, $RV_{OUT}$, UVLO1, UVLO2, OVLO1 and OVLO2. Resistors should be used such that the pin currents do not exceed the Absolute Maximum Ratings.

**Note 4:** Currents will increase as pin voltages are taken higher than the internal clamp voltage.

**Note 5:** Refer to Block Diagram for $V_{TRANS}$ and $V_{DRAIN}$ definitions.

**Note 6:** Low noise regulation of the output voltage requires a resistive voltage divider from output voltage to FB pin. FB pin should not be grounded in this configuration. Refer to the Typical Application diagram for proper FB pin configuration.

**Note 7:** The feedback pin has built-in hysteresis that defines the boundary between charge-only mode and low noise regulation mode.

**Note 8:** LVGATE should be used in parallel with HVGATE when $V_{CC}$ is less than or equal to 8V (LVGATE active). When not in use, LVGATE should be tied to $V_{CC}$ (LVGATE inactive).

**Note 9:** Do not apply a positive or negative voltage or current source to HV GATE, otherwise permanent damage may occur.

**TYPICAL PERFORMANCE CHARACTERISTICS**

**PIN FUNCTIONS (TSSOP/QFN)**

**RV\textsubscript{TRANS} (Pin 1/Pin 19):** Transformer Supply Sense Pin. Connect a resistor between the RV\textsubscript{TRANS} pin and the V\textsubscript{TRANS} supply. Refer to Table 2 for proper sizing of the RV\textsubscript{TRANS} resistor. The minimum operation voltage for V\textsubscript{TRANS} is 4.75V.

**UVLO1 (Pin 2/Pin 20):** V\textsubscript{TRANS} Undervoltage Lockout Pin. Senses when V\textsubscript{TRANS} drops below:

\[
V_{UVLO1} = 1.225 + 50\mu A \cdot R_{UVLO1}
\]

and trips the FAULT latch low, disabling switching. After V\textsubscript{TRANS} rises above V\textsubscript{UVLO1}, toggling the CHARGE pin reactivates switching.

**OVLO1 (Pin 3/Pin 1):** V\textsubscript{TRANS} Overvoltage Lockout Pin. Senses when V\textsubscript{TRANS} rises above:

\[
V_{OVLO1} = 1.225 + 50\mu A \cdot R_{OVLO1}
\]

and trips the FAULT latch low, disabling switching. After V\textsubscript{TRANS} drops below V\textsubscript{OVLO1}, toggling the CHARGE pin reactivates switching.

**UVLO2 (Pin 4/Pin 2):** V\textsubscript{CC} Undervoltage Lockout Pin. Senses when V\textsubscript{CC} drops below:

\[
V_{UVLO2} = 1.225 + 50\mu A \cdot R_{UVLO2}
\]

and trips the FAULT latch low, disabling switching. After V\textsubscript{CC} rises above V\textsubscript{UVLO2}, toggling the CHARGE pin reactivates switching.

**OVLO2 (Pin 5/Pin 3):** V\textsubscript{CC} Overvoltage Lockout Pin. Senses when V\textsubscript{CC} rises above:

\[
V_{OVLO2} = 1.225 + 50\mu A \cdot R_{OVLO2}
\]

and trips the FAULT latch low, disabling switching. After V\textsubscript{CC} drops below V\textsubscript{OVLO2}, toggling the CHARGE pin reactivates switching.

**FAULT (Pin 6/Pin 4):** Open Collector Indicating Pin. When either V\textsubscript{TRANS} or V\textsubscript{CC} exceeds the user-selected voltage range, or an internal UVLO condition occurs, a transistor turns on. The part will stop switching. This pin needs a proper pull-up resistor or current source.

For more information visit www.linear.com/LT3751
PIN FUNCTIONS

DONE (Pin 7/ Pin 5): Open Collector Indication Pin. When the target output voltage (charge mode) is reached or the FAULT pin goes low, a transistor turns on. This pin needs a proper pull-up resistor or current source.

CHARGE (Pin 8/Pin 6): Charge Pin. Initiates a new charge cycle (charge mode) or enables the part (regulation mode) when driven higher than 1.5V. Bring this pin below 0.3V to discontinue charging and put the part into shutdown. Turn-on ramp rates should be between 10ns to 10ms. CHARGE pin should not be directly ramped with VCC or LT3751 may not properly initialize.

CLAMP (Pin 9/Pin 7): Internal Clamp Voltage Selection Pin. Tie this pin to VCC to activate the internal 5.6V gate driver clamp. Tie this pin to ground to activate the internal 10.5V gate driver clamp.

FB (Pin 10/Pin 8): Feedback Regulation Pin. Use this pin to achieve low noise voltage regulation. FB is internally regulated to 1.22V when a resistive divider is tied from this pin to the output. FB pin should not float. Tie FB pin to either a resistor divider or ground.

CSN (Pin 11/Pin 9): Negative Current Sense Pin. Senses external NMOS source current. Connect to local RSENSE ground connection for proper Kelvin sensing. The current limit is set by 106mV/RSENSE.

CSP (Pin 12/Pin 10): Positive Current Sense Pin. Senses NMOS source current. Connect the NMOS source terminal and the current sense resistor to this pin. The current limit is fixed at 106mV/RSENSE in charge mode. The current limit can be reduced to a minimum 11mV/RSENSE in regulation mode.

VCC (Pin 13/Pin 11): Input Supply Pin. Must be locally bypassed with high grade (X5R or better) ceramic capacitor. The minimum operating voltage for VCC is 4.75V.

LVGATE (Pin 14/Pin 12): Low Voltage Gate Pin. Connect the NMOS gate terminal to this pin when operating VCC below 8V. The internal gate driver will drive the voltage to the VCC rail. When operating VCC higher than 8V, tie this pin directly to VCC.

HVGATE (Pin 15/Pin 13): High Voltage Gate Pin. Connect NMOS gate terminal to this pin for all VCC operating voltages. Internal gate driver will drive the voltage to within VCC – 2V during each switch cycle.

RBG (Pin 16/Pin 14): Bias Generation Pin. Generates a bias current set by 0.98V/RBG. Select RBG to achieve desired resistance for RDCM, RVOUT, and RVTRANS.

NC (Pins 17, 19/Pins 15, 18): No Connection.

RVOUT (Pin 18/Pin 16): Output Voltage Sense Pin. Develops a current proportional to the output capacitor voltage. Connect a resistor between this pin and the drain of NMOS such that:

\[ V_{OUT} = 0.98 \cdot N \left( \frac{R_{OUT}}{R_{BG}} \right) - V_{DIODE} \]

when RVOUT is set equal to RVTRANS; otherwise:

\[ V_{OUT} = N \left[ 0.98 \cdot \frac{R_{OUT}}{R_{BG}} + V_{TRANS} \left( \frac{R_{OUT}}{R_{TRANS}} - 1 \right) \right] - V_{DIODE} \]

where VDIODE = forward voltage drop of diode D1 (refer to the Block Diagram).

RDCM (Pin 20/Pin 17): Discontinuous Mode Sense Pin. Senses when the external NMOS drain is equal to 20µA • RDCM + VTRANS and initiates the next switch cycle. Place a resistor equal to 0.45 times the resistor on the RVTRANS pin between this pin and VDRAIN.

GND (Pin 21/Pin 21): Ground. Tie directly to local ground plane.
BLOCK DIAGRAM

For more information www.linear.com/LT3751
The LT3751 can be used as either a fast, efficient high voltage capacitor charger controller or as a high voltage, low noise voltage regulator. The FB pin voltage determines one of the three primary modes: charge mode, low noise regulation, or no-load operation (see Figure 1).

**CHARGE MODE**

When the FB pin voltage is below 1.16V, the LT3751 acts as a rapid capacitor charger. The charging operation has four basic states for charge mode steady-state operation (see Figure 2).

1. **Start-Up**

The first switching cycle is initiated approximately 2µs after the CHARGE pin is raised high. During this phase, the start-up one-shot enables the master latch turning on the external NMOS and beginning the first switching cycle. After start-up, the master latch will remain in the switching-enable state until the target output voltage is reached or a fault condition occurs.

The LT3751 utilizes circuitry to protect against transformer primary current entering a runaway condition and remains in start-up mode until the DCM comparator has enough headroom. Refer to the Start-Up Protection section for more detail.

2. **Primary-Side Charging**

When the NMOS switch latch is set, and depending on the use of LVGATE, the gate driver rapidly charges the gate pin to \( V_{CC} - 2V \) in high voltage applications or directly to \( V_{CC} \) in low voltage applications (refer to the Application

**OPERATION**

Information section for proper use of LVGATE). With the gate driver output high, the external NMOS turns on, forcing \( V_{\text{TRANS}} - V_{\text{DS(ON)}} \) across the primary winding. Consequently, current in the primary coil rises linearly at a rate \((V_{\text{TRANS}} - V_{\text{DS(ON)}})/L_{\text{PRI}} \). The input voltage is mirrored on the secondary winding \(-N \cdot (V_{\text{TRANS}} - V_{\text{DS(ON)}})\) which reverse-biases the diode and prevents current flow in the secondary winding. Thus, energy is stored in the core of the transformer.

3. Secondary Energy Transfer

When current limit is reached, the current limit comparator resets the NMOS switch latch and the device enters the third phase of operation, secondary energy transfer. The energy stored in the transformer core forward-biases the diode and current flows into the output capacitor. During this time, the output voltage (neglecting the diode drop) is reflected back to the primary coil. If the target output voltage is reached, the \( V_{\text{OUT}} \) comparator resets the master latch and the DONE pin goes low. Otherwise, the device enters the next phase of operation.

4. Discontinuous Mode Detection

During secondary energy transfer to the output capacitor, \((V_{\text{OUT}} + V_{\text{DIODE}})/N\) will appear across the primary winding. A transformer with no energy cannot support a DC voltage, so the voltage across the primary will decay to zero. In other words, the drain of the NMOS will ring down from \( V_{\text{TRANS}} + (V_{\text{OUT}} + V_{\text{DIODE}})/N \) to \( V_{\text{TRANS}} \). When the drain voltage falls to \( V_{\text{TRANS}} + 20 \mu\text{A} \cdot R_{\text{DCM}} \), the DCM comparator sets the NMOS switch latch and a new switch cycle begins. Steps 2-4 continue until the target output voltage is reached.

**Start-Up Protection**

The LT3751 at start-up, when the output voltage is very low (or shorted), usually does not have enough \( V_{\text{DRain}} \) node voltage to trip the DCM comparator. The part in start-up mode uses the internal 26kHz clock and an auxiliary current comparator. Figure 3 shows a simplified block diagram of the start-up circuitry.

![Figure 3. Start-Up Protection Circuitry](image)

Toggling the CHARGE pin always generates a start-up one-shot to turn on the external switch, initiating the charging process. After the start-up one-shot, the LT3751 waits for either the DCM comparator to generate a one-shot or the output of the start-up protection circuitry going high, whichever comes first. If the switch drain node, \( V_{\text{DRain}} \), is below the DCM comparator threshold (see Entering Normal Boundary Mode), the DCM comparator will never fire and the start-up circuitry is dominant.

![Figure 4. DCM Comparator Thresholds](image)
OPERATION

At very low output voltages, the boundary-mode switching cycle period increases significantly such that the energy stored in the transformer core is not depleted before the next clock cycle. In this situation, the clock may initiate another switching cycle before the secondary winding current reaches zero and cause the LT3751 to enter continuous-mode conduction. Normally, this is not a problem; however, if the secondary energy transfer time is much longer than the CLK period, significant primary current overshoot can occur. This is due to the non-zero starting point of the primary current when the switch turns on and the finite speed of the current comparator.

The LT3751 startup circuitry adds an auxiliary current comparator with a trip level 50% higher than the nominal trip level. Every time the auxiliary current comparator trips, the required clock count between switching cycles is incremented by one. This allows more time for secondary energy transfer.

Counter 1 in Figure 3 is set to its maximum count when the first DCM comparator one-shot is generated. If no DCM one-shot is initiated in normal boundary-mode operation during a maximum count of approximately 500µs, the LT3751 re-enters start-up mode and the count is returned to zero.

Note that Counter 1 is initialized to zero at start-up. Thus, the output of the startup circuitry will go high after one clock cycle. Counter 2 is reset when the gate driver goes high. This repeats until either the auxiliary current comparator increments the required clock count or until V_DRAIN is high enough to sustain normal operation described in steps 2 through 4 in the previous section.

Entering Normal Boundary Mode

The LT3751 has two DCM comparator thresholds that are dependent on what mode the part is in, either start-up mode or normal boundary-mode, and the state of the mode latch. For boundary-mode switching, the LT3751 requires the DCM sense voltage (V_DRAIN) to exceed V_TRANS by the ΔDCM comparator threshold, ΔV_DRAIN:

\[ \Delta V_{\text{DRAIN}} = (40\mu A + I_{\text{OFFSET}}) \cdot R_{\text{DCM}} - 40\mu A \cdot R_{\text{TRANS}} \]

where I_OFFSET is mode dependent. The DCM one-shot signal is negative edge triggered by the switch node, V_DRAIN, and indicates that the energy in the secondary winding has depleted. For this to happen, V_DRAIN must exceed V_TRANS + ΔV_DR over prior to its negative edge; otherwise, the DCM comparator will not generate a one-shot to initiate the next switching cycle. The part would remain stuck in this state indefinitely; however, the LT3751 uses the start-up protection circuitry to jumpstart switching if the DCM comparator does not generate a one-shot after a maximum time-out of 500µs.

Figure 4 shows a typical V_DRAIN node waveform with a test circuit voltage clamp applied to the output. V_TH1 is the start-up threshold and is set internally by forcing I_OFFSET to 40µA. Once the first DCM one-shot is initiated, the mode latch is set to boundary-mode. The mode latch then sets the clock count to maximum (500µs) and lowers the DCM comparator threshold to V_TH2 (I_OFFSET = 20µA). This provides needed hysteresis between start-up mode and boundary-mode operation.

LOW NOISE REGULATION

Low noise voltage regulation can be achieved by adding a resistive divider from the output node to the LT3751 FB pin. At start-up (FB pin below 1.16V), the LT3751 enters the charge mode to rapidly charge the output capacitor. Once the FB pin is within the threshold range of 1.16V to 1.34V, the part enters into low noise regulation. The switching methodology in regulation mimics that used in the capacitor charging mode, but with the addition of peak current and duty cycle control techniques. Figure 5 shows the steady state operation for both regulation techniques. Figure 6 shows how both techniques are combined to provide stable, low noise operation over a wide load and supply range.

During heavy load conditions, the LT3751 sets the peak primary current to its maximum value, 106mV/R_SENSE and sets the maximum duty cycle to approximately 95%. This allows for maximum power delivery. At very light loads, the opposite occurs, and the LT3751 reduces the peak primary current to approximately one tenth its maximum value while modulating the duty cycle below 10%. The LT3751 controls moderate loads with a combination of peak current mode control and duty cycle control.
**Figure 5. Modes of Operation (Steady State)**

**Figure 6. Regulation Technique**
**OPERATION**

**Periodic Refresh**

When the LT3751 enters regulation, the internal circuitry deactivates switching when the internal one-shot clock is high. The clock operates at a 1/20th duty cycle with a minimum blank time of 1.5µs. This reset pulse is timed to drastically reduce switching frequency content within the audio spectrum and is active during all loading conditions. Each reset pulse guarantees at least one energy cycle. A minimum load is required to prevent the LT3751 from entering no-load operation.

**Heavy Load Operation**

The LT3751 enters peak current mode control at higher output load conditions. The control loop maximizes the number of switch cycles between each reset pulse. Since the control scheme operates in boundary mode, the resonant boundary-mode period changes with varying peak primary current:

$$\text{Period} = I_{PK} \cdot L_{PRI} \cdot \left[ \frac{1}{V_{\text{TRANS}}} + \frac{N}{V_{\text{OUT}}} \right]$$

and the power output is proportional to the peak primary current:

$$P_{\text{OUT}} = \frac{1}{2} \cdot I_{PK} \cdot \left[ \frac{1}{V_{\text{TRANS}}} + \frac{N}{V_{\text{OUT}}} \right].$$

Noise becomes an issue at very low load currents. The LT3751 remedies this problem by setting the lower peak current limit to one tenth the maximum level and begins to employ duty-cycle control.

**Light Load Operation**

The LT3751 uses duty cycle control to drastically reduce audible noise in both the transformer (mechanical) and the ceramic capacitors (piezoelectric effects). Internal control circuitry forces a one-shot condition at a periodic rate greater than 20kHz and out of the audio spectrum. The regulation loop then determines the number of pulses that are required to maintain the correct output voltage. Figure 5 shows the use of duty-cycle control.

**No-Load Operation**

The LT3751 can remain in low noise regulation at very low loading conditions. Below a certain load current threshold (Light Load Operation), the output voltage would continue to increase and a runaway condition could occur. This is due to the periodic one-shot forced by the periodic refresh circuitry. By design, the LT3751 has built-in overvoltage protection associated with the FB pin.

When the FB pin voltage exceeds 1.34V (±20mV), the LT3751 enters no-load operation. No-load operation does not reset with the one-shot clock. Instead, the pulse train is completely load-dependent. These bursts are asynchronous and can contain long periods of inactivity. This allows regulation at a no-load condition but with the increase of audible noise and voltage ripple. Note that when operating with no-load, the output voltage will increase 10% above the nominal output voltage.
APPLICATIONS INFORMATION

The LT3751 charger controller can be optimized for either capacitor charging only or low noise regulation applications. Several equations are provided to aid in the design process.

Safety Warning
Large capacitors charged to high voltage can deliver a lethal amount of energy if handled improperly. It is particularly important to observe appropriate safety measures when designing the LT3751 into applications. First, create a discharge circuit that allows the designer to safely discharge the output capacitor. Second, adequately space high voltage nodes from adjacent traces to satisfy printed circuit board voltage breakdown requirements.

Selecting Operating Mode
Tie the FB pin to GND to operate the LT3751 as a capacitor charger. In this mode, the LT3751 charges the output at peak primary current in boundary mode operation. This constitutes maximum power delivery and yields the fastest charge times. Power delivery is halted once the output reaches the desired output voltage set by the RVOUT and RBG pins.

Select a resistor divider from the FB pin to VOUT and GND to operate the LT3751 as a low noise voltage regulator (refer to Low Noise regulation section for proper design procedures). The LT3751 operates as a voltage regulator using both peak current and duty cycle modulation to vary output current during different loading conditions.

Selecting Component Parameters
Most designs start with the initial selection of VTRANS, VOUT, COUT, and either charge time, tCHARGE, (capacitor charger) or POUT,MAX (regulator). These design inputs are then used to select the transformer ratio, N, the peak primary current, IPK, and the primary inductance, LPRI. Figure 7 can be used as a rough guide for maximum power output for a given VTRANS and IPK.

Selecting Transformer Turns Ratio
The transformer ratio, N, should be selected based on the input and output voltages. Smaller N values equate to faster charge times and larger available output power. Note that drastically reducing N below the VOUT/VTRANS ratio will increase the flyback voltage on the drain of the NMOS and increase the current through the output diode. The ratio, N, should not be drastically increased either, due to the increased capacitance, N^2 • CSEC, reflected to the primary. A good choice is to select N equal to VOUT/VTRANS:

\[ N \leq \frac{V_{OUT}}{V_{TRANS}} \]

Choosing Capacitor Charger IPK
When operating the LT3751 as capacitor charger, choose IPK based on the required capacitor charge time, tCHARGE, and the initial design inputs.

\[ I_{PK} = \frac{(2 \cdot N \cdot V_{TRANS} + V_{OUT}) \cdot C_{OUT} \cdot V_{OUT}}{Efficiency \cdot V_{TRANS} \cdot (t_{CHARGE} - t_d)} \]

The converter efficiency varies over the output voltage range. The IPK equation is based on the average efficiency over the entire charging period. Several factors can cause the charge time to increase. Efficiency is the most dominant factor and is mainly affected by the transformer winding resistance, core losses, leakage inductance, and transistor RDS. Most applications have overall efficiencies above 70%.
APPLICATIONS INFORMATION

The total propagation delay, \( t_d \), is the second most dominant factor that affects efficiency and is the summation of gate driver on-off propagation delays and the discharge time associated with the secondary winding capacitance. There are two effective methods to reduce the total propagation delay. First, reduce the total capacitance on the secondary winding, most notably the diode capacitance. Second, reduce the total required NMOS gate charge. Figure 8 shows the effect of large secondary capacitance.

The energy stored in the secondary winding capacitance is \( \frac{1}{2} \cdot C_{SEC} \cdot V_{OUT}^2 \). This energy is reflected to the primary when the diode stops forward conduction. If the reflected capacitance is greater than the total NMOS drain capacitance, the drain of the NMOS power switch goes negative and its intrinsic body diode conducts. It takes some time for this energy to be dissipated and thus adds to the total propagation delay.

Choosing Regulator Maximum \( I_{PK} \)

The \( I_{PK} \) parameter in regulation mode is calculated based on the desired maximum output power instead of charge time like that in a capacitor charger application.

\[
I_{PK} = 2 \cdot \frac{P_{OUT(AVG)}}{\text{Efficiency}} \left( \frac{1}{V_{TRANS}} + \frac{N}{V_{OUT}} \right)
\]

Note that the LT3751 regulation scheme varies the peak current based on the output load current. The maximum \( I_{PK} \) is only reached during charge mode or during heavy load conditions where output power is maximized.

Transformer Design

The transformer’s primary inductance, \( L_{PRI} \), is determined by the desired \( V_{OUT} \) and previously calculated \( N \) and \( I_{PK} \) parameters. Use the following equation to select \( L_{PRI} \):

\[
L_{PRI} = \frac{3 \mu s \cdot V_{OUT}}{I_{PK} \cdot N}
\]

The previous equation guarantees that the \( V_{OUT} \) comparator has enough time to sense the flyback waveform and trip the DONE pin latch. Operating \( V_{OUT} \) significantly higher than that used to calculate \( L_{PRI} \) could result in a runaway condition and overcharge the output capacitor.

The \( L_{PRI} \) equation is adequate for most regulator applications. Note that if both \( I_{PK} \) and \( N \) are increased significantly for a given \( V_{TRANS} \) and \( V_{OUT} \), the maximum \( I_{PK} \) will not be reached within the refresh clock period. This will result in a lower than expected maximum output power. To prevent this from occurring, maintain the condition in the following equation.

\[
L_{PRI} < \frac{38 \mu s}{I_{PK} \cdot \left( \frac{1}{V_{TRANS}} + \frac{N}{V_{OUT}} \right)}
\]

The upper constraint on \( L_{PRI} \) can be reduced by increasing \( V_{TRANS} \) and starting the design process over. The best regulation occurs when operating the boundary-mode frequency above 100kHz (refer to Operation section for boundary-mode definition).

Figure 9 defines the maximum boundary-mode switching frequency when operating at a desired output power level and is normalized to \( L_{PRI}/P_{OUT} \) (\( \mu H/Watt \)). The relationship of output power, boundary-mode frequency, \( I_{PK} \), and primary inductance can be used as a guide throughout the design process.

*Transformer has three secondaries where the ratio is designated as PRI:SEC1:SEC2:SEC3

RV_{TRANS}, RV_{OUT} and R_{DCM} Selection

RV_{TRANS} sets the common-mode reference voltage for both the DCM comparator and V_{OUT} comparator. Select RV_{TRANS} from Table 2 based on the transformer supply voltage range, V_{TRANS}, and the maximum trip voltage, ΔV_{DRAIN} (V_{DRAIN} - V_{TRANS}).

The RV_{TRANS} pin is connected to an internal 40µA current source. Pin current increases as the pin voltage is taken higher than the internal 60V Zener clamp. The LT3751 can operate from V_{TRANS} greater than the 60V internal Zener clamps by limiting the RV_{TRANS} pin current to 250µA. Operating V_{TRANS} above 200V requires the use of resistor dividers. Two applications are presented that operate

APPLICATIONS INFORMATION

with V\textsubscript{TRANS} between 100V and 400V (refer to Typical Applications section). Consult applications engineering for applications with V\textsubscript{TRANS} operating above 400V.

RV\textsubscript{OUT} is required for capacitor charger applications but may be removed for regulator applications. Note that the V\textsubscript{OUT} comparator can be used as secondary protection for regulator applications. If the V\textsubscript{OUT} comparator is used for protection, design V\textsubscript{OUT,TRIP} 15% to 20% higher than the regulation voltage. Tie the RV\textsubscript{OUT} pin to ground when RV\textsubscript{OUT} resistor is removed.

R\textsubscript{DCM} needs to be properly sized in relation to RV\textsubscript{TRANS}. Improper selection of R\textsubscript{DCM} can lead to undesired switching operation at low output voltages. Use Table 2 to size R\textsubscript{DCM}.

Parasitic capacitance on RV\textsubscript{TRANS}, RV\textsubscript{OUT}, and R\textsubscript{DCM} should be minimized. Capacitances on these nodes slow down the response times of the V\textsubscript{OUT} and DCM comparators. Keep the distance between the resistor and pin short. It is recommended to remove all ground and power planes underneath these pins and their respective components (refer to the recommended board layout at the end of this section).

R\textsubscript{BG} Selection

R\textsubscript{BG} sets the trip current (0.98/R\textsubscript{BG}) and is directly related to the selection of RV\textsubscript{OUT}. The best accuracy is achieved with a trip current between 100µA and 2mA. Choosing RV\textsubscript{OUT} from Table 2 meets this criterion. Use the following equation to size R\textsubscript{BG} (V\textsubscript{TRANS} ≤ 80V):

\[ R_{\text{BG}} = 0.98 \times N \times \frac{R_{\text{OUT}}}{V_{\text{OUT,TRIP}} + V_{\text{DIODE}}} \]

Tie R\textsubscript{BG} pin to ground when not using the V\textsubscript{OUT} comparator. Consult applications engineering for calculating R\textsubscript{BG} when operating V\textsubscript{TRANS} above 80V.

NMOS Switch Selection

Choose an external NMOS power switch with minimal gate charge and on-resistance that satisfies current limit and voltage break-down requirements. The gate is nominally driven to V\textsubscript{CC} – 2V during each charge cycle. Ensure that this does not exceed the maximum gate to source voltage rating of the NMOS but enhances the channel enough to minimize the on-resistance.

Similarly, the maximum drain-source voltage rating of the NMOS must exceed V\textsubscript{TRANS} + V\textsubscript{OUT}/N or the magnitude of the leakage inductance spike, whichever is greater. The maximum instantaneous drain current rating must exceed selected current limit. Because the switching period decreases with output voltage, the average current though the NMOS is greatest when the output is nearly charged and is given by:

\[ I_{\text{AVG,M}} = \frac{I_{\text{PK}} \times V_{\text{OUT}(PK)}}{2(V_{\text{OUT}(PK)} + N \times V_{\text{TRANS}})} \]

See Table 3 for recommended external NMOS transistors.

Gate Driver Operation

The LT3751 gate driver has an internal, selectable 10.5V or 5.6V clamp with up to 2A current capability (using LVGATE). For 10.5V operation, tie CLAMP pin to ground, and for 5.6V operation, tie the CLAMP pin to the VCC pin. Choose a clamp voltage that does not exceed the NMOS manufacturer’s maximum VGS ratings. The 5.6V clamp can also be used to reduce LT3751 power dissipation and increase efficiency when using logic-level FETs. The typical gate driver overshoot voltage is 0.5V above the clamp voltage.

The LT3751’s gate driver also incorporates a PMOS pull-up device via the LVGATE pin. The PMOS pull-up driver should only be used for VCC applications of 8V or below. Operating LVGATE with VCC above 8V will cause permanent damage to the part. LVGATE is active when tied to HVGATE and allows rail-to-rail gate driver operation. This is especially useful for low VCC applications, allowing better NMOS drive capability. It also provides the fastest rise times, given the larger 2A current capability verses 1.5A when using only HVGATE.

Output Diode Selection

The output diode(s) are selected based on the maximum repetitive reverse voltage (VRRM) and the average forward current (I_F(AV)). The output diode’s VRRM should exceed VOUT + N • VTRANS. The output diode’s I_F(AV) should exceed IPK/2N, the average short-circuit current.

The average diode current is also a function of the output voltage.

\[ I_{AVG} = \frac{I_{PK} \cdot V_{TRANS}}{2 \cdot (V_{OUT} + N \cdot V_{TRANS})} \]

The highest average diode current occurs at low output voltages and decreases as the output voltage increases. Reverse recovery time, reverse bias leakage and junction capacitance should also be considered. All affect the overall charging efficiency. Excessive diode reverse recovery times can cause appreciable discharging of the output capacitor, thereby increasing charge time. Choose a diode with a reverse recovery time of less than 100ns. Diode leakage current under high reverse bias bleeds the output capacitor of charge and increases charge time. Choose a diode that has minimal reverse bias leakage current. Diode junction capacitance is reflected back to the primary, and energy is lost during the NMOS intrinsic diode conduction. Choose a diode with minimal junction capacitance. Table 4 recommends several output diodes for various output voltages that have adequate reverse recovery times.

Setting Current Limit

Placing a sense resistor from the positive sense pin, CSP, to the negative sense pin, CSN, sets the maximum peak switch current. The maximum current limit is nominally 106mV/RSENSE. The power rating of the current sense resistor must exceed:

\[ P_{RSENSE} \geq \frac{I_{PK}^2 \cdot R_{SENSE}}{3} \left( \frac{V_{OUT(PK)}}{V_{OUT(PK)} + N \cdot V_{TRANS}} \right) \]
**APPLICATIONS INFORMATION**

Additionally, there is approximately a 180ns propagation delay from the time that peak current limit is detected to when the gate transitions to the low state. This delay increases the peak current limit by \( \frac{V_{\text{TRANS}}}{180\text{ns}} \) \( \frac{L_{\text{PRI}}}{L_{\text{PRIMARY}}} \).

Sense resistor inductance \( L_{\text{RSENSE}} \) is another source of current limit error. \( L_{\text{RSENSE}} \) creates an input offset voltage \( V_{\text{OS}} \) to the current comparator and causes the current comparator to trip early. \( V_{\text{OS}} \) can be calculated as:

\[
V_{\text{OS}} = V_{\text{TRANS}} \left( \frac{L_{\text{RSENSE}}}{L_{\text{PRIMARY}}} \right)
\]

The change in current limit becomes \( V_{\text{OS}}/R_{\text{SENSE}} \). The error is more significant for applications using large \( \frac{\text{di}}{\text{dt}} \) ratios in the transformer primary. It is recommended to use very low inductance (<2nH) sense resistors. Several resistors can be placed in parallel to help reduce the inductance.

Care should also be taken in placement of the sense lines. The negative return line, CSN, must be a dedicated trace to the low side resistor terminal. Haphazardly routing the CSN connection to the ground plane can cause inaccurate current limit and can also cause an undesirable discontinuous charging profile.

**DONE and FAULT Pin Design**

Both the **DONE** and **FAULT** pins require proper pull-up resistors or current sources. Limit pin current to 1mA into either of these pins. 100k\( \Omega \) pull-up resistors are recommended for most applications. Both the **DONE** and **FAULT** pins are latched in the low output state. Resetting either latch requires the **CHARGE** pin to be toggled. A fault condition will also cause the **DONE** pin to go low. A third, non-latching condition occurs during startup when the **CHARGE** pin is driven high. During this start-up condition, both the **DONE** and **FAULT** pins will go low for several micro seconds. This indicates the internal rails are still ramping to their proper levels. External RC filters may be added to both indication pins to remove start-up indication. Time constants for the RC filter should be between 5\( \mu \)s to 20\( \mu \)s.

**Under/Overvoltage Lockout**

The LT3751 provides user-programmable under and overvoltage lockouts for both \( V_{\text{CC}} \) and \( V_{\text{TRANS}} \). Use the equations in the Pin Functions section for proper selection of resistor values. When under/overvoltage lockout comparators are tripped, the master latch is disabled, power delivery is halted, and the **FAULT** pin goes low.

Adequate supply bulk capacitors should be used to reduce power supply voltage ripple that could cause false tripping during normal switching operation. Additional filtering may be required due to the high input impedance of the under/overvoltage lockout pins to prevent false tripping. Individual capacitors ranging from 100pF to 1nF may be placed between each of the UVLO1, UVLO2, OVLO1 and OVLO2 pins and ground. Disable the undervoltage lockouts by directly connecting the UVLO1 and UVLO2 pins to VCC. Disable the overvoltage lockouts by directly connecting the OVLO1 and OVLO2 pins to ground.

The LT3751 provides internal Zener clamping diodes to protect itself in shutdown when \( V_{\text{TRANS}} \) is operated above 55V. Supply voltages should only be applied to UVLO1, UVLO2, OVLO1 and OVLO2 with series resistance such that the Absolute Maximum pin currents are not exceeded. Pin current can be calculated using:

\[
I_{\text{PIN}} = \frac{V_{\text{APPLIED}} - 55V}{R_{\text{SERIES}}}
\]

Note that in shutdown, \( R_{\text{TRANS}} \), \( R_{\text{OUT}} \), \( R_{\text{DCM}} \), UVLO1, UVLO2, OVLO1 and OVLO2 currents increase significantly when operating \( V_{\text{TRANS}} \) above the Zener clamp voltages and are inversely proportional to the external series pin resistances.

**NMOS Snubber Design**

The transformer leakage inductance causes a parasitic voltage spike on the drain of the power NMOS switch during the turn-off transition. Transformer leakage inductance effects become more apparent at high peak primary currents. The worst-case magnitude of the voltage spike is determined by the energy stored in the leakage inductance and the total capacitance on the \( V_{\text{DRAIN}} \) node.
APPLICATIONS INFORMATION

\[ V_{D,\text{LEAK}} = \sqrt{L_{\text{LEAK}} \cdot I_{PK}^2 / C_{V,\text{DRAIN}}} \]

Two problems can arise from large \( V_{D,\text{LEAK}} \). First, the magnitude of the spike may require an NMOS with an unnecessarily high \( V_{(BR)\text{DSS}} \) which equates to a larger \( R_{DS(\text{ON})} \). Secondly, the \( V_{\text{DRAIN}} \) node will ring—possibly below ground—causing false tripping of the DCM comparator or damage to the NMOS switch (see Figure 11). Both issues can be remedied using a snubber. If leakage inductance causes issues, it is recommended to use a RC snubber in parallel with the primary winding, as shown in Figure 10. Size \( C_{\text{SNUB}} \) and \( R_{\text{SNUB}} \) based on the desired leakage spike voltage, known leakage inductance, and an RC time constant less than 1µs. Otherwise, the leakage voltage spike can cause false tripping of the \( V_{\text{OUT}} \) comparator and stop charging prematurely.

Figure 11 shows the effect of the RC snubber resulting in a lower voltage spike and faster settling time.

LOW NOISE REGULATION

The LT3751 has the option to provide a low noise regulated output voltage when using a resistive voltage divider from the output node to the FB pin. Refer to the Selecting Component Parameters section to design the transformer, NMOS power switch, output diode, and sense resistor. Use the following equations to select the feedback resistor values based on the power dissipation and desired output voltage:

\[ R_{FBH} = \frac{(V_{\text{OUT}} - 1.22)^2}{P_D} \]; Top Feedback Resistor

\[ R_{FBL} = \frac{1.22}{V_{\text{OUT}} - 1.22} \cdot R_{FBH} \]; Bottom Feedback Resistor

\( R_{FBH} \), depending on output voltage and type used, may require several smaller values placed in series. This will reduce the risk of arcing and damage to the feedback resistors. Consult the manufacturer’s rated voltage specification for safe operation of the feedback resistors.

The LT3751 has a minimum periodic refresh frequency limit of 23kHz. This drastically reduces switching frequency components in the audio spectrum. The LT3751 can operate with no-load, but the regulation scheme switches to no-load operation and audible noise and output voltage ripple increase. This can be avoided by operating with a minimum load current.

Minimum Load Current

Periodic refresh circuitry requires an average minimum load current to avoid entering no-load operation. Usually, the feedback resistors should be adequate to provide this minimum load current.

\[ I_{\text{LOAD(MIN)}} \geq \frac{L_{\text{PRI}} \cdot I_{PK} \cdot 23kHz}{100 \cdot V_{\text{OUT}}} \]

\( I_{PK} \) is the peak primary current at maximum power delivery. The LT3751 will enter no-load operation if the minimum load current is not met. No-load operation will prevent the application from entering a runaway condition; however, the output voltage will increase 10% over the nominal regulated voltage.
APPLICATIONS INFORMATION

Large Signal Stability

Large signal stability can be an issue when audible noise is a concern. Figure 12 shows that the problem originates from the one-shot clock and the output voltage ripple. The load must be constrained such that the output voltage ripple does not exceed the regulation range of the error amplifier within one clock period (approximately 6mV referred to the FB pin).

The output capacitance should be increased if oscillations occur or audible noise is present. Use Figure 13 to determine the maximum load for a given output capacitance to maintain low audible noise operation. A small capacitor can also be added from the FB pin to ground to lower the ripple injected into FB pin.

Figure 12. Voltage Ripple Stability Constraint

Small Signal Stability

The LT3751’s error amplifier is internally compensated to increase its operating range but requires the converter’s output node to be the dominant pole. Small signal stability constraints become more prevalent during heavy loading conditions where the dominant output pole moves to higher frequency and closer to the internal feedback poles and zeros. The feedback loop requires the output pole frequency to remain below 200Hz to guarantee small signal stability. This allows smaller RLOAD values than the large signal constraint. Thus, small signal issues should not arise if the large signal constraint is met.

Board Layout

The high voltage operation of the LT3751 demands careful attention to the board layout, observing the following points:

1. Minimize the area of the high voltage end of the secondary winding.
2. Provide sufficient spacing for all high voltage nodes (NMOS drain, VOUT and secondary winding of the transformer) in order to meet the breakdown voltage requirements.
3. Keep the electrical path formed by CVTRANS, the primary of T1, and the drain of the NMOS as short as possible. Increasing the length of this path effectively increases the leakage inductance of T1, potentially resulting in an overvoltage condition on the drain of the NMOS.
4. Reduce the total node capacitance on the RVOUT and RDCM pins by removing any ground or power planes underneath the RDCM and RVOUT pads and traces. Parasitic capacitance can cause unwanted behavior on these pins.
5. Thermal vias should be added underneath the Exposed Pad, Pin 21, to enhance the LT3751’s thermal performance. These vias should go directly to a large area of ground plane.
6. Isolated applications require galvanic separation of the output-side ground and primary-side ground. Adequate spacing between both ground planes is needed to meet voltage safety requirements.
