FEATURES
Gain: 24 dB typical
Output power for 1 dB compression: 28 dBm typical
Saturated output power: 29 dBm typical
Output third-order intercept: 34 dBm typical
Input return loss: 18 dB typical
Output return loss: 10 dB typical
DC supply: 4 V at 800 mA
No external matching required
Die size: 2.999 mm × 3.999 mm × 0.05 mm

APPLICATIONS
E-band communication systems
High capacity wireless backhaul radio systems
Test and measurement

GENERAL DESCRIPTION
The ADMV7710 is an integrated, E-band, gallium arsenide (GaAs), pseudomorphic, high electron mobility tranfer (pHEMT), mono-lithic microwave integrated circuit (MMIC), medium power amplifier with an on-chip, temperature compensated power detector that operates from 71 GHz to 76 GHz. The ADMV7710 provides 24 dB of gain, 28 dBm of output power at 1 dB compression, and 29 dBm of saturated output power at 20% power added efficiency from a 4 V power supply. The ADMV7710 exhibits excellent linearity and is optimized for E-band communications and high capacity, wireless backhaul radio systems. The amplifier configuration and high gain make the device an excellent candidate for last stage signal amplification before the antenna. All data is taken with the chip in a 50 Ω test fixture connected via a 3 mil wide × 0.5 mil thick × 7 mil long ribbon on each port. The ADMV7710 is available in a 40-pad bare die (CHIP) and operates over the −55°C to +85°C temperature range.

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

THERMAL RESISTANCE

Thermal performance is directly linked to printed circuit board (PCB) design and operating environment. Careful attention to PCB thermal design is required.

θjc is the junction to case (or die to package) thermal resistance.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

THEORY OF OPERATION

The circuit architecture of the ADMV7710 power amplifier is shown in Figure 46. The ADMV7710 uses four cascaded gain stages to form an amplifier with a combined gain of 24 dB and a saturated output power (P_{SAT}) of 29 dBm. At the output of the last stage, a coupler taps off a small portion of the output signal. The coupled signal is presented to an on-chip diode detector for external monitoring of the output power. A matched reference diode is included to correct detector temperature dependencies. See the application circuit shown in Figure 47 for further details on biasing the different blocks and using the detector features.

![Figure 46. Power Amplifier Circuit Architecture](image-url)
APPLICATIONS INFORMATION

A typical application circuit for the ADMV7710 is shown in Figure 47. Combine the supply lines as shown in the application circuit schematic to minimize the external component count and to simplify power supply routing.

The ADMV7710 uses several amplifier, detector, and attenuator stages. All stages use depletion mode pHEMT transistors. It is important to use the following power-up bias sequence to avoid transistor damage:

1. Apply a −2 V bias to the VGG1A to VGG4A and VGG1B to VGG4B pads.

2. Apply 4 V to the VDD1A to VDD1B and VDD4B to VDD4B pads.

3. Adjust VGG1A to VGG4A and VGG1B to VGG4B between −2 V and 0 V to achieve a total amplifier drain current of 800 mA.

To power down the ADMV7710, follow the reverse procedure. For additional guidance on general bias sequencing, see the MMIC Amplifier Biasing Procedure application note.

Figure 47. Typical Application Circuit
Figure 48. Assembly Diagram
MOUNTING AND BONDING TECHNIQUES FOR MILLIMETERWAVE GaAs MMICS

Attach the die directly to the ground plane eutectically or with conductive epoxy.

To bring RF to and from the chip, use 50 Ω microstrip transmission lines on 0.127 mm (5 mil) thick alumina thin film substrates (see Figure 49).

![Figure 49. Routing RF Signals](image)

To minimize bond wire length, place microstrip substrates as close to the die as possible. Typical die to substrate spacing is 0.076 mm to 0.152 mm (3 mil to 6 mil).

HANDLING PRECAUTIONS

To avoid permanent damage, adhere to the following precautions.

**Storage**

All bare die ship in either waffle or gel-based ESD protective containers, sealed in an ESD protective bag. After opening the sealed ESD protective bag, all die must be stored in a dry nitrogen environment.

**Cleanliness**

Handle the chips in a clean environment. Never use liquid cleaning systems to clean the chip.

**Static Sensitivity**

Follow ESD precautions to protect against ESD strikes.

**Transients**

Suppress instrument and bias supply transients while bias is applied. To minimize inductive pickup, use shielded signal and bias cables.

**General Handling**

Handle the chip on the edges only using a vacuum collet or with a sharp pair of bent tweezers. Because the surface of the chip has fragile air bridges, never touch the surface of the chip with a vacuum collet, tweezers, or fingers.

**MOUNTING**

The chip is back metallized and can be die mounted with gold/tin (AuSn) eutectic preforms or with electrically conductive epoxy. The mounting surface must be clean and flat.

**Eutectic Die Attach**

It is best to use an 80% Au/20% Sn preform with a work surface temperature of 255°C and a tool temperature of 265°C. When hot 90% nitrogen/10% hydrogen gas is applied, maintain tool tip temperature at 290°C. Do not expose the chip to a temperature greater than 320°C for more than 20 sec. No more than 3 sec of scrubbing is required for attachment.

**Epoxy Die Attach**

ATROX 800HT1V is recommended for die attachment. Apply a minimum amount of epoxy to the mounting surface so that a thin epoxy fillet is observed around the perimeter of the chip after placing it into position. Cure the epoxy per the schedule provided by the manufacturer.

**WIRE BONDING**

RF bonds made with 3 mil × 0.5 mil gold ribbon are recommended for the RF ports. These bonds must be thermosonically bonded with a force of 40 g to 60 g. DC bonds of 1 mil (0.025 mm) diameter, thermosonically bonded, are recommended. Create ball bonds with a force of 40 g to 50 g and wedge bonds with a force of 18 g to 22 g. Create all bonds with a nominal stage temperature of 150°C. Apply a minimum amount of ultrasonic energy to achieve reliable bonds. Keep all bonds as short as possible, less than 12 mil (0.31 mm).
