**Introduction**

Generating an output voltage that is always above or below the input voltage range can easily be handled by conventional boost or buck regulators, respectively. However, when the output voltage is *within* the input voltage range, as in many Li-Ion battery powered applications requiring a 3V or 3.3V output, conventional designs fall short, suffering variously from low efficiency, complex magnetics, polarity inversion and circuit complexity. The LTC3785 buck-boost controller facilitates a simple, efficient, low parts-count, single-converter solution that is easy to implement and does not have any of the drawbacks associated with conventional circuits.

**3.3V, 3A Converter Operates from 2.7V–10V Source**

Figure 1 shows a synchronous, 4-switch, buck-boost design that provides a 3.3V, 3A output from a 2.7V–10V input—perfect for a Li-Ion and/or loosely regulated wall adapter input. The controller provides short-circuit protection, offering a choice of burp-mode or latch-off operation for severe overload faults. Other features include soft-start, overvoltage protection (OVP) and a 2.7V–10V output range.

The circuit produces seamless operation throughout the input voltage range, operating as a synchronous buck converter, synchronous boost converter, or a combination of the two through the transition region. At input voltages well above the output, the converter operates in buck mode. Switches Q1A and Q1B commutate the input voltage, and Q2A stays

inrush currents while charging the output caps during startup, as well as minimizing voltage overshoot when starting into light loads.

For those applications requiring a power good output on the third channel, the LTC3545-1 version of the part substitutes a PGOOD3 output in place of the MODE/SYNC pin. The option of an external clock is not available on this version, and the part enters Burst Mode operation at light load currents.

![Diagram](image)

**Figure 5.** At low load currents, Burst Mode operation improves efficiency without degrading output voltage ripple.

---

**Minimal Channel Crosstalk**

A potential problem with multiple output regulators is the interaction between channels when one of the channels undergoes a load transient. Figure 4 shows the response on channels 2 and 3 to a 0mA to 500mA load step on channel 1. Channels 2 and 3 are each loaded at 400mA. In each case, the crosstalk is on the order of 1mV to 2mV.

---

**High Efficiency with Low Ripple**

At low load currents, the LTC3545 operates in either pulse-skipping mode or Burst Mode operation depending on the state of the MODE/SYNC pin. Though pulse-skipping mode exhibits lower output ripple, the ripple in Burst Mode operation is still quite low while maintaining the added advantage of better efficiency at the lightest loads. The Burst Mode operation and Burst Mode efficiency are shown in Figures 5 and 6.

---

**Conclusion**

The LTC3545 is a unique part with tremendous flexibility. It greatly simplifies system and board design where multiple voltage supply rails are needed without sacrificing the features and performance found in individual regulators. The LTC3545 is ideally suited for battery powered applications where multiple or isolated voltage rails are required and board space is at a premium.

**LTC3785, continued from page 34**

The LTC3785 buck-boost controller overcomes the deficiencies of traditional designs with a smooth-transition, 4-switch, single-IC solution. It is elegant in its simplicity, high in efficiency and requires only a small number of inexpensive external components. The LTC3785 is available in a small 4mm × 4mm QFN package as well as a 28-lead SSOP.
